

## Addition of angular momenta:

# Rotations in space are implemented on QM systems by unitary transformations  $U(\mathbf{R}) = \exp(-i \theta \cdot \mathbf{J}/\hbar)$ , where  $J^i$  are the hermitian generators of rotation.

#  $J^i$  are also the angular momentum operators, and are conserved if the Hamiltonian is invariant under rotations.

# Rotation group structure implies  $[J^i, J^j] = i\hbar \epsilon^{ijk} J^k$ .

# representations: can simultaneously diagonalize  $J_z$  and  $J^2$ , since  $[J_z, J^2] = 0$ . We analyzed this last semester.

Call the eigenstates  $|jm\rangle$ ,

where  $J_z |jm\rangle = m |jm\rangle$ ,  $J^2 |jm\rangle = j(j+1) |jm\rangle$ , with  $\hbar=1$  from now on.

The possible values of  $j$  are

0, 1/2, 1, 3/2, 2, ... and the possible values of  $m$ , for a given  $j$ , are  $j, j-1, j-2, \dots, -j$ .

The representation with a given  $j$  is called the "**spin- $j$** " representation,

and it is  $2j+1$  dimensional.

These representations are **irreducible**, in the sense that there is no subspace that is invariant (mapped into itself) under all rotations.

We can see this from the fact that

$J_+ |jm\rangle = \sqrt{j(j+1) - m(m+1)} |j, m+1\rangle$  and  $J_- |jm\rangle = \sqrt{j(j+1) - m(m-1)} |j, m-1\rangle$ ,

where  $J_+ = J_x + i J_y$ ,  $J_- = J_x - i J_y$ ,

from which it is clear that by acting with rotations we move through all the states.

#example: 3d vectors  $V^i$  form the spin-1 rep. The tensor product of two of these is the rank two tensors like  $V^i W^j$ , or more generally,  $T^{ij}$ . These are not irreducible.

Rather the antisymmetric part is by itself irreducible, and three dimensional,

hence another spin-1 rep. The symmetric part is reducible into the part proportional to the Kronecker delta (trace) and the rest (symmetric trace-free part).

The trace part is the  $j=0$  rep, the symm tracefree part is  $j=2$

(since then  $2j+1=5$ =number of independent components of a symmetric tracefree tensor).

# example:  $1/2 \times 1/2 = 1 + 0$ , example:  $1 \times 1 = 2 + 1 + 0$  (this is equivalent to the example above).

# Note three different examples of spin-1 rep:

vector, antisymmetric tensor,  $|2p, m=-1, 0, 1\rangle$  states of H-atom.

I.e., the rep is the abstract structure. Many things can realize it.

# general scheme:  $j_1 \times j_2$  spanned by basis  $\{|j_1 m_1\rangle |j_2 m_2\rangle\}$ . Decomposes into irreducibles.

Find by starting with top  $J_z$  state and working down with lowering operator  $J_-$ .

When fill out a rep, go back and start with the next highest top  $J_z$  state, which is the other linear combination of the two second to two top  $J_z$  states.

This results in

$$j_1 \times j_2 = (j_1 + j_2) + (j_1 + j_2 - 1) + \dots + |j_1 - j_2|.$$

# The largest spin rep,  $j_1 + j_2$ , starts with top state equal to the product of the two top states  $|j_1 j_1\rangle |j_2 j_2\rangle$ .

To see that the smallest spin rep is  $|j_1 - j_2|$ , suppose first that  $j_1 \geq j_2$ .

The argument I gave in class, cleaned up a bit here, was that the largest degeneracy that occurs for fixed total  $m$  is  $2j_2+1$ , so there must be  $2j_2+1$  different irreps in the decomposition. Working our way down from the  $j_1+j_2$  rep the last one must therefore be the  $j_1-j_2$  rep. A (sort of) different argument goes as follows. Each state  $|j_1 m_1\rangle$  must occur in every rep, since acting with  $J_+$  and  $J_-$  will eventually introduce it. In particular,  $|j_1 j_1\rangle$  must occur. The smallest total  $m$  the state  $|j_1 j_1\rangle|j_2 m_2\rangle$  can have is if  $m_2$  is as small as possible,  $m_2=-j_2$ . In this case, the total  $m$  is  $j_1-j_2$ , hence the smallest rep we have is spin-  $(j_1-j_2)$ . If  $j_2>j_1$  then reverse the roles, and the smallest rep is spin- $(j_2-j_1)$ . In general, we have that the smallest is spin- $|j_1-j_2|$ . You can check that the total dimension  $(2j_1+1)(2j_2+1)$  is equal to the sum over integer steps from  $j = |j_1-j_2|$  to  $j_1+j_2$  of  $(2j+1)$ .

#  $|jm\rangle = \sum_{m_1, m_2} |m_1 m_2\rangle \langle m_1 m_2 | jm\rangle$ , sum on  $m_1, m_2$  with  $m=m_1+m_2$ .

Similarly,  $|m_1 m_2\rangle = \sum_j |jm\rangle \langle jm | m_1 m_2\rangle$ , where the sum is over  $j$  with  $m=m_1+m_2$  fixed.

The expansion coefficients are the **Clebsch-Gordan coefficients**. The construction above shows that they can always be taken to be real, so  $\langle m_1 m_2 | jm\rangle = \langle jm | m_1 m_2\rangle^* = \langle jm | m_1 m_2\rangle$ .

There is still an overall sign ambiguity of the CG coeffs, that is typically fixed by requiring that the coefficient of  $|m_1=j_1\rangle|m_2=j-j_1\rangle$  in the the expansion of the top state  $|jj\rangle$  of the spin- $j$  rep. is positive, i.e.  $\langle j_1, j-j_1 | jj\rangle$  is positive. (There is a typo in Baym in the fourth line after (15-40), where it reads  $m_1=j$  instead of  $m_1=j_1$ .)

# Baym works out the case of  $j \times 1/2$ . There is a typo in eqn (15-44), which should have  $m_2 = -/+1/2$ .)

# The CG coeffs can be computed by:

-brute force

-Mathematica: `ClebschGordan[{j1,m1},{j2,m2},{j,m}]` (**Note:** I mis-spelled it "Gordon" in class.)

-tables

-recursion relations

-a projection operator method

-amazingly enough, a CLOSED FORM formula has been found by Wigner for all the CG coeffs, which was given in a more symmetrical form by Racah. See (106.14) of Landau & Lifshitz.

It is so complicated as to be unusable.
