and therefore is in fact a group homomorphism. To verify this assertion, show that

$$\begin{aligned}M_{\alpha\beta}(v_1v_2) &= (1/2)\mathrm{tr}[(v_1v_2)^\dagger\sigma^\alpha v_1v_2\sigma^\beta)] = (1/2)\mathrm{tr}[(v_2)^\dagger(v_1)^\dagger\sigma^\alpha v_1v_2\sigma^\beta)]\\ &= (1/2)\sum_\gamma M(v_1)_{\alpha\gamma}\mathrm{tr}(v_2^\dagger\sigma^\gamma v_2\sigma^\beta) = \sum_\gamma M(v_1)_{\alpha\gamma}M(v_2)_{\gamma\beta} = [M(v_1)M(v_2)]_{\alpha\beta}.\end{aligned} \tag{8.2.41}$$

Check the chain of deductions

$$I = M(I) = M(v^\dagger v) = M(v^\dagger)M(v) = M^T(v)M(v) \tag{8.2.42}$$

to conclude that M is orthogonal and that

$$M^{-1}(v) = M(v^{-1}). \tag{8.2.43}$$

Argue, based on (2.35) and the topology (connectedness) of $SU(2)$, that, by continuity, M must have determinant $+1$, and therefore $M \in SO(3,\mathbb{R})$. [We will see below that $M(v)$ is a real matrix.] Thus, (2.34) provides a map from $SU(2)$ to $SO(3,\mathbb{R})$ and, in view of (2.37) and (2.40), this map is a two-to-one homomorphism.

Even more explicit results are possible: Suppose that v is parameterized as in (3.7.187). Then (2.31) and (2.32) can be rewritten in the form

$$\begin{aligned}\bar{K}^\alpha(\theta,\boldsymbol{n}) &= v(\theta,\boldsymbol{n})^\dagger K^\alpha v(\theta,\boldsymbol{n})\\ &= \exp(-\theta\boldsymbol{n}\cdot\boldsymbol{K})K^\alpha\exp(\theta\boldsymbol{n}\cdot\boldsymbol{K})\\ &= \sum_\beta M_{\alpha\beta}(\theta,\boldsymbol{n})K^\beta,\end{aligned} \tag{8.2.44}$$

and (2.35) takes the form

$$M(0,\boldsymbol{n}) = I. \tag{8.2.45}$$

Next we will find a differential equation for M. Show that differentiating the first and third terms in (2.44) yields the result

$$\begin{aligned}&\partial_\theta \bar{K}^\alpha(\theta, \boldsymbol{n}) = \partial_\theta[\exp(-\theta \boldsymbol{n}\cdot \boldsymbol{K})K^\alpha \exp(\theta \boldsymbol{n}\cdot \boldsymbol{K})]\\ &= \exp(-\theta \boldsymbol{n}\cdot \boldsymbol{K})\{K^\alpha, \boldsymbol{n}\cdot \boldsymbol{K}\}\exp(\theta \boldsymbol{n}\cdot \boldsymbol{K}).\end{aligned} \tag{8.2.46}$$

But, according to (3.7.183) and (3.7.201), there is the relation

$$\begin{aligned}&\{K^\alpha, \boldsymbol{n}\cdot \boldsymbol{K}\} = \{\boldsymbol{e_\alpha}\cdot \boldsymbol{K}, \boldsymbol{n}\cdot \boldsymbol{K}\} = (\boldsymbol{e}_\alpha \times \boldsymbol{n})\cdot \boldsymbol{K}\\ &= -(\boldsymbol{n}\times \boldsymbol{e}_\alpha)\cdot \boldsymbol{K} = -[(\boldsymbol{n}\cdot \boldsymbol{L})\boldsymbol{e}_\alpha]\cdot \boldsymbol{K}\end{aligned} \tag{8.2.47}$$

so that (2.46) can also be written in the form

$$\begin{aligned}&\partial_\theta \bar{K}^\alpha(\theta, \boldsymbol{n}) = -\exp(-\theta \boldsymbol{n}\cdot \boldsymbol{K})[(\boldsymbol{n}\cdot \boldsymbol{L})\boldsymbol{e}_\alpha]\cdot \boldsymbol{K}\exp(\theta \boldsymbol{n}\cdot \boldsymbol{K})\\ &= -\sum_\beta \exp(-\theta \boldsymbol{n}\cdot \boldsymbol{K})[(\boldsymbol{n}\cdot \boldsymbol{L})\boldsymbol{e}_\alpha]_\beta \boldsymbol{K}^\beta \exp(\theta \boldsymbol{n}\cdot \boldsymbol{K})\\ &= \sum_\beta (\boldsymbol{n}\cdot \boldsymbol{L})_{\alpha\beta}\exp(-\theta \boldsymbol{n}\cdot \boldsymbol{K})\boldsymbol{K}^\beta \exp(\theta \boldsymbol{n}\cdot \boldsymbol{K})\\ &= \sum_{\beta\gamma}(\boldsymbol{n}\cdot \boldsymbol{L})_{\alpha\beta}M_{\beta\gamma}(\theta, \boldsymbol{n})K^\gamma = \sum_\gamma [(\boldsymbol{n}\cdot \boldsymbol{L})M(\theta, \boldsymbol{n})]_{\alpha\gamma}K^\gamma.\end{aligned} \tag{8.2.48}$$

Verify, by working with components, that here we have used the antisymmetry of the L^α to correctly make the calculation

$$\begin{aligned}&-[(\boldsymbol{n}\cdot \boldsymbol{L})\boldsymbol{e}_\alpha]_\beta = -(\boldsymbol{e}_\beta, [\boldsymbol{n}\cdot \boldsymbol{L}]\boldsymbol{e}_\alpha)\\ &= -[\boldsymbol{n}\cdot \boldsymbol{L}]_{\beta\alpha} = [\boldsymbol{n}\cdot \boldsymbol{L}]_{\alpha\beta}.\end{aligned} \tag{8.2.49}$$

On the other hand, differentiating the first and last terms in (2.44) and changing summation indices yields the result

$$\partial_\theta \bar{K}^\alpha(\theta, \boldsymbol{n}) = \sum_\gamma [\partial_\theta M(\theta, \boldsymbol{n})]_{\alpha\gamma}K^\gamma. \tag{8.2.50}$$

By comparing (2.48) and (2.50) conclude that M satisfies the differential equation

$$\partial_\theta M(\theta, \boldsymbol{n}) = (\boldsymbol{n}\cdot \boldsymbol{L})M(\theta, \boldsymbol{n}). \tag{8.2.51}$$

Show that (2.51) with the initial condition (2.45) has the unique solution

$$M(\theta, \boldsymbol{n}) = \exp(\theta \boldsymbol{n}\cdot \boldsymbol{L}) = R(\theta, \boldsymbol{n}). \tag{8.2.52}$$

You have demonstrated that

$$\exp(-\theta \boldsymbol{n}\cdot \boldsymbol{K})K^\alpha \exp(\theta \boldsymbol{n}\cdot \boldsymbol{K}) = \sum_\beta R(\theta, \boldsymbol{n})_{\alpha\beta}K^\beta, \tag{8.2.53}$$

and (2.34) becomes

$$R_{\alpha\beta}(v) = (1/2)\mathrm{tr}(v^\dagger \sigma^\alpha v \sigma^\beta) \ \Leftrightarrow\ R[\exp(\theta \boldsymbol{n}\cdot \boldsymbol{K})] = \exp(\theta \boldsymbol{n}\cdot \boldsymbol{L}). \tag{8.2.54}$$

(Here the symbol $\Leftrightarrow$ is used to indicate logical implication in both directions.) Should a relation of the form (2.54) be surprising? Not from a group-theoretic perspective. The matrices v and $v^\dagger$ on the right side of (2.54) each carry a spin 1/2 representation of $SU(2)$. The matrix R on the left carries a spin 1 representation. We know that two spin 1/2 representations can be combined to produce a spin 1 representation, and evidently the Pauli matrices σ^α and σ^β on the right act as Clebsch-Gordan coefficients to pick out this representation.

To find further consequences of (2.53), multiply both sides by a_α and sum over α to get the result

$$\exp(-\theta \boldsymbol{n}\cdot\boldsymbol{K})(\sum_\alpha a_\alpha K^\alpha)\exp(\theta\boldsymbol{n}\cdot\boldsymbol{K}) = \sum_{\alpha\beta} R(\theta,\boldsymbol{n})_{\alpha\beta} a_\alpha K^\beta$$
$$= \sum_{\alpha\beta} R^T(\theta,\boldsymbol{n})_{\beta\alpha} a_\alpha K^\beta = \sum_{\alpha\beta} R^{-1}(\theta,\boldsymbol{n})_{\beta\alpha} a_\alpha K^\beta. \tag{8.2.55}$$

Verify that (2.55) can be written in the more compact form

$$\exp(-\theta \boldsymbol{n}\cdot\boldsymbol{K})(\boldsymbol{a}\cdot\boldsymbol{K})\exp(\theta\boldsymbol{n}\cdot\boldsymbol{K}) = \sum_{\alpha\beta} R^{-1}(\theta,\boldsymbol{n})_{\beta\alpha} a_\alpha K^\beta$$
$$= \sum_\beta [R^{-1}(\theta,\boldsymbol{n})\boldsymbol{a}]_\beta K^\beta = [R^{-1}(\theta,\boldsymbol{n})\boldsymbol{a}]\cdot\boldsymbol{K}. \tag{8.2.56}$$

Show, by making the replacement $\theta \to -\theta$, that there is also the general result

$$\exp(\theta \boldsymbol{n}\cdot\boldsymbol{K})(\boldsymbol{a}\cdot\boldsymbol{K})\exp(-\theta\boldsymbol{n}\cdot\boldsymbol{K}) = [R(\theta,\boldsymbol{n})\boldsymbol{a}]\cdot\boldsymbol{K}. \tag{8.2.57}$$

Note that, according to (3.7.200), the matrix R is produced/generated by exponentiating elements in the adjoint representation of $SU(2)$. Recall from Section 3.7.7 that the adjoint representation is defined completely in terms of the structure constants. It can be shown that the relations (2.56) and (2.57) hold for *any* set of matrices K^α that satisfy the commutation relations (3.7.173). See Section 8.1. Show, for example, that

$$\exp(-\psi L^j)L^k\exp(\psi L^j) = L^k\cos\psi - \{L^j,L^k\}\sin\psi \;\text{ for }\; j\neq k. \tag{8.2.58}$$

Verify the general result

$$R(\boldsymbol{a}\cdot\boldsymbol{L})R^{-1} = (R\boldsymbol{a})\cdot\boldsymbol{L}. \tag{8.2.59}$$

Suppose that $\boldsymbol{a}$ and $\boldsymbol{b}$ are any three-component vectors. As an application of (2.59), verify that

$$R(\boldsymbol{a}\times\boldsymbol{b}) = R(\boldsymbol{a}\cdot\boldsymbol{L})\boldsymbol{b} = R(\boldsymbol{a}\cdot\boldsymbol{L})R^{-1}R\boldsymbol{b} = [(R\boldsymbol{a})\cdot\boldsymbol{L}]R\boldsymbol{b} = (R\boldsymbol{a})\times(R\boldsymbol{b}), \tag{8.2.60}$$

as expected from the geometric definition of the cross product. Here we have also used (3.7.201). Suppose O is a 3×3 orthogonal matrix. Show that

$$\begin{aligned} O(\boldsymbol{a}\times\boldsymbol{b}) &= O(\boldsymbol{a}\cdot\boldsymbol{L})\boldsymbol{b} = O(\boldsymbol{a}\cdot\boldsymbol{L})O^{-1}O\boldsymbol{b} \\ &= \det(O)[(O\boldsymbol{a})\cdot\boldsymbol{L}]O\boldsymbol{b} = \det(O)[(O\boldsymbol{a})\times(O\boldsymbol{b})], \end{aligned} \tag{8.2.61}$$

on account of which $\boldsymbol{a} \times \boldsymbol{b}$ is called a *psuedo* vector if $\boldsymbol{a}$ and $\boldsymbol{b}$ are vectors.

Observe also that, according to (3.7.189) through (3.7.191), for fixed $\boldsymbol{n}$ we must have $\theta \in [0, 4\pi)$ to achieve a closed path in $SU(2)$; and, by (3.7.200), (3.7.203), and (3.7.204), in doing so an associated closed path in $SO(3,\mathbb{R})$ gets covered *twice*. Therefore, as already asserted, the homomorphism between $SU(2)$ and $SO(3,\mathbb{R})$ is two to one. For a further discussion of the topologies of $SU(2)$ and $SO(3,\mathbb{R})$, see Exercise 8.2.11.

Let us use the relation (2.54) to explore once again the relation between $su(2)$ and $so(3,\mathbb{R})$. This can be done by studying (2.54) for elements v near the identity. Suppose v is written in the form

$$v = \exp(\epsilon K) = I + \epsilon K + O(\epsilon^2) \tag{8.2.62}$$

where ϵ is small and $K \in su(2)$ is therefore any 2×2 traceless anti-Hermitian matrix. That is, following the terminology of Exercise 3.7.31, K can be written in the form

$$K = \boldsymbol{a} \cdot \boldsymbol{K} = \sum_{\gamma=1}^{3} a_\gamma K^\gamma = \sum_{\gamma=1}^{3} a_\gamma (-i/2)\sigma^\gamma \tag{8.2.63}$$

where $\boldsymbol{a}$ is a real vector. Then we have

$$v^\dagger = \exp(\epsilon K^\dagger) = I + \epsilon K^\dagger + O(\epsilon^2), \tag{8.2.64}$$

and (2.54) yields

$$\begin{aligned} R_{\alpha\beta}(v) &= (1/2)\mathrm{tr}[(I + \epsilon K^\dagger)\sigma^\alpha (I + \epsilon K)\sigma^\beta] + O(\epsilon^2) \\ &= (1/2)\mathrm{tr}(\sigma^\alpha \sigma^\beta) + (\epsilon/2)\mathrm{tr}(\sigma^\alpha K \sigma^\beta + K^\dagger \sigma^\alpha \sigma^\beta) + O(\epsilon^2) \\ &= \delta_{\alpha\beta} + \epsilon L_{\alpha\beta} + O(\epsilon^2) = [\exp(\epsilon L)]_{\alpha\beta} + O(\epsilon^2) \end{aligned} \tag{8.2.65}$$

where

$$L_{\alpha\beta}(K) = (1/2)\mathrm{tr}(\sigma^\alpha K \sigma^\beta + K^\dagger \sigma^\alpha \sigma^\beta). \tag{8.2.66}$$

Show, using the fact that K is anti-Hermitian and the properties of the trace operation and of the Pauli matrices (see Exercise 5.7.7), that (2.66) can also be written in the form

$$\begin{aligned} L_{\alpha\beta}(\boldsymbol{a} \cdot \boldsymbol{K}) &= L_{\alpha\beta}(K) = (1/2)\mathrm{tr}(\sigma^\alpha K \sigma^\beta + K^\dagger \sigma^\alpha \sigma^\beta) = (1/2)\mathrm{tr}(K \sigma^\beta \sigma^\alpha - K \sigma^\alpha \sigma^\beta) \\ &= (-1/2)(-i/2)\sum_{\gamma=1}^{3} a_\gamma \, \mathrm{tr}(\sigma^\gamma \{\sigma^\alpha, \sigma^\beta\}) = (-4i)(-1/2)(-i/2)\sum_{\gamma=1}^{3} a_\gamma (L^\gamma)_{\alpha\beta} \\ &= (\boldsymbol{a} \cdot \boldsymbol{L})_{\alpha\beta}. \end{aligned} \tag{8.2.67}$$

Thus, the relations (2.66) and (2.67) provide an explicit isomorphism between $su(2)$ and $so(3,\mathbb{R})$. Indeed, we have the relations

$$\{L(K), L(K'\} = L(\{K, K'\}) \text{ and, specifically, } \{L(K^\alpha), L(K^\beta)\} = L(\{K^\alpha, K^\beta\}). \tag{8.2.68}$$

8.2.11. The purpose of this exercise is to study the topology of $SU(2)$ and $SO(3,\mathbb{R})$. Consider all points in three-dimensional space of the form $\theta\boldsymbol{n}$ where $\boldsymbol{n}$ is an arbitrary unit vector and $0 \le \theta \le \theta_{\max}$. They evidently comprise the interior and surface of a ball in

3-dimensional space with radius $\theta_{\max}$. By looking at (3.7.203), show that the topology of $SO(3,\mathbb{R})$ is the same as that of the interior and surface of a ball of radius π with opposite pairs of points on the surface identified. By looking at (3.7.189), show that the topology of $SU(2)$ is the same as that of the interior and surface of a ball of radius 2π with all points on the surface identified.

The topology of $SU(2)$ can also be examined without use of the exponential function. Suppose v is any 2×2 matrix with complex entries written in the form

$$v = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}. \tag{8.2.69}$$

Now require that v be unitary. Show that the conditions

$$v^\dagger v = vv^\dagger = I \tag{8.2.70}$$

yield, among others, the relations

$$\delta = \bar{\alpha} \tag{8.2.71}$$

and

$$\gamma = -\bar{\beta} \tag{8.2.72}$$

so that v takes the form

$$v = \begin{pmatrix} \alpha & \beta \\ -\bar{\beta} & \bar{\alpha} \end{pmatrix}. \tag{8.2.73}$$

Next introduce the general parameterizations

$$\alpha = w_0 + iw_3 \tag{8.2.74}$$

and

$$\beta = w_2 + iw_1 \tag{8.2.75}$$

where all the w_j are real. Show that, in terms of these parameters, v takes the form

$$v = \begin{pmatrix} w_0 + iw_3 & w_2 + iw_1 \\ -w_2 + iw_1 & w_0 - iw_3 \end{pmatrix}. \tag{8.2.76}$$

Verify that v can also be written in the form

$$v = w_0\sigma^0 + i\sum_{j=1}^{3} w_j\sigma^j. \tag{8.2.77}$$

Lastly, show that requiring v to have determinant 1 yields the relation

$$\det(v) = \sum_{j=0}^{3} w_j^2 = 1, \tag{8.2.78}$$

and that this relation also guarantees that v as given by (2.76) or (2.77) is unitary.

Equation (2.78) is that for S^3, the 3-dimensional surface of a sphere in 4-dimensional space. Thus, $SU(2)$ has the topology of S^3.[2] This manifold is known to be *simply connected*, and therefore $SU(2)$ is simply connected. Simply connected means that any closed curve can be shrunk to a point. By contrast, $SO(3,\mathbb{R})$ is not simply connected. Consider the ball with radius π that parameterizes $SO(3,\mathbb{R})$. Let P be any path in the ball that stretches between antipodal points on the surface of the ball. Since antipodal points on the surface are to be identified, this path is a closed curve. Show that it cannot be shrunk to a point while remaining closed. A more detailed study shows that $SO(3,\mathbb{R})$ is doubly connected. Given a multiply connected manifold, there is a standard procedure in topology for constructing an associated singly-connected manifold. This singly-connected manifold is called the *covering* manifold of the original manifold. In the same spirit, $SU(2)$ is said to be the covering group of $SO(3,\mathbb{R})$.

It can be shown that all the $SO(n,\mathbb{R})$ for $n \geq 3$ are doubly connected. [We have already learned that $SO(2,\mathbb{R})$ is infinitely connected. See Section 5.9.1.] Consequently each has a two-fold covering group. These groups are called $Spin(n,\mathbb{R})$. For small n there are the redundancies $Spin(3,\mathbb{R}) = SU(2)$, $Spin(4,\mathbb{R}) = SU(2) \times SU(2)$, $Spin(5,\mathbb{R}) = USp(4)$, and $Spin(6,\mathbb{R}) = SU(4)$.

Let return to the case of $SO(3,\mathbb{R})$. Comparison of (5.10.22) and (2.78), and reference to Exercises 5.10.13 and 5.10.14, show that v is a unit quaternion matrix. For this reason, the quantities $w_0 \cdots w_3$ are sometimes called quaternion parameters. The quaternion parameterization of $SU(2)$ can be extended to a quaternion parameterization of $SO(3,\mathbb{R})$ with the aid of (2.54) and (2.77).[3] Show that doing so gives the result

$$R_{\alpha\beta}(w) = \delta_{\alpha\beta}(w_0^2 - \sum_{\gamma=1}^{3} w_\gamma^2) + 2w_\alpha w_\beta + 2w_0 \sum_{\gamma=1}^{3} \epsilon_{\alpha\beta\gamma} w_\gamma. \tag{8.2.79}$$

Students of dynamics or quantum mechanics may be familiar with the use of Euler angles to parameterize elements in both $SU(2)$ and $SO(3,\mathbb{R})$. For example, we may write

$$R(\phi,\theta,\psi) = \exp(\phi L^3)\exp(\theta L^2)\exp(\psi L^3). \tag{8.2.80}$$

See (3.7.195) and (3.7.208). However, when studying rigid-body dynamics, this is not always a good idea because the Euler angles ϕ and ψ are not uniquely defined when $\theta = 0$ and $\theta = \pi$. [Only the quantity $(\phi + \psi)$ plays a role when $\theta = 0$, and only the quantity $(\phi - \psi)$ plays a role when $\theta = \pi$.] That is, the quantities ϕ, θ, ψ do not provide good coordinate patches in the neighborhoods $\theta \simeq 0$ and $\theta \simeq \pi$. Correspondingly, the equations of motion for rigid-body motion in terms of Euler angles have singularities at these values of θ, and are therefore not well suited for numerical integration.[4] By contrast, the equations of motion are regular everywhere when quaternion parameters are employed. The only penalty to be paid for this advantage is that equations of motion must be integrated for four parameters

[2] Put another way, the manifold S^3 can be given a group structure, namely that of $SU(2)$. It can be shown that S^1 and S^3 are the only spheres that can be given a group structure.

[3] The so called *Cayley-Klein* parameters for specifying rotations are closely related to quaternion parameters. Also, sometimes quaternion parameters are called *Euler-Rodrigues* parameters.

[4] The associated problems encountered in numerical integration are sometimes referred to as *gimbal lock*. Google the words *Euler angle evil*.

instead of three. Moreover, the equations of motion preserve the relation (2.78), and the extent to which numerical integration preserves this relation can be used as a check on the accuracy of the procedure. For further discussion, see Section 11.1.

8.2.12. In Exercise 3.7.35 you verified that the Lie algebras $su(4)$ and $so(6,\mathbb{R})$ have the same dimension, namely dimension 15. The purpose of this exercise is to verify that $su(4)$ and $so(6,\mathbb{R})$ are in fact the same (equivalent) over the real field. Moreover, we will learn that there is a corresponding two-to-one homomorphism between the groups $SU(4)$ and $SO(6,\mathbb{R})$ just as there is a two-to-one homomorphism between the groups $SU(2)$ and $SO(3,\mathbb{R})$. See Exercises 3.7.31, 8.2.10, and 8.2.11.

We begin by exploiting a mathematical fact familiar from the relativistic treatment of electromagnetism. Let A be a general antisymmetric 4×4 matrix. It can be written in the form

$$A = \begin{pmatrix} 0 & -B_z & B_y & E_x/c \\ B_z & 0 & -B_x & E_y/c \\ -B_y & B_x & 0 & E_z/c \\ -E_x/c & -E_y/c & -E_z/c & 0 \end{pmatrix} \tag{8.2.81}$$

where the quantities E_α/c and B_α are arbitrary. See (1.6.56). Then we know from its use in relativistic electromagnetic theory that there is the *mathematical* identity

$$\det(A) = [(1/c)\boldsymbol{E}\cdot\boldsymbol{B}]^2. \tag{8.2.82}$$

See Exercise 1.6.17. At this point introduce variables $z_1, z_2, \cdots, z_6$ by the rules

$$E_z/c = iz_1 + z_2, \tag{8.2.83}$$

$$B_z = -iz_1 + z_2, \tag{8.2.84}$$

$$E_x/c = iz_3 + z_4, \tag{8.2.85}$$

$$B_x = -iz_3 + z_4, \tag{8.2.86}$$

$$E_y/c = iz_5 + z_6, \tag{8.2.87}$$

$$B_y = -iz_5 + z_6. \tag{8.2.88}$$

(While workable, this ordering may seem a little strange. It will be of use in Exercise 27.5.4.) Verify that in terms of these variables there is the relation

$$(1/c)\boldsymbol{E}\cdot\boldsymbol{B} = \sum_{\alpha=1}^{6} z_\alpha^2. \tag{8.2.89}$$

Let us write

$$A = A(z) = A(z_1 \cdots z_6) = \sum_{\alpha=1}^{6} z_\alpha A^\alpha \tag{8.2.90}$$

where the A^α are matrices to be determined. Show, using (2.82) and (2.89), that

$$\det(A) = \Big[\sum_{\alpha=1}^{6} z_\alpha^2\Big]^2. \tag{8.2.91}$$

Verify that

$$A(z) = \begin{pmatrix} 0 & iz_1 - z_2 & -iz_5 + z_6 & iz_3 + z_4 \\ -iz_1 + z_2 & 0 & iz_3 - z_4 & iz_5 + z_6 \\ iz_5 - z_6 & -iz_3 + z_4 & 0 & iz_1 + z_2 \\ -iz_3 - z_4 & -iz_5 - z_6 & -iz_1 - z_2 & 0 \end{pmatrix} \tag{8.2.92}$$

so that the A^α are given by the relations

$$A^1 = \begin{pmatrix} 0 & i & 0 & 0 \\ -i & 0 & -0 & 0 \\ 0 & 0 & 0 & i \\ 0 & 0 & -i & 0 \end{pmatrix} = -\begin{pmatrix} \sigma^2 & 0 \\ 0 & \sigma^2 \end{pmatrix}, \tag{8.2.93}$$

$$A^2 = \begin{pmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix} = i\begin{pmatrix} -\sigma^2 & 0 \\ 0 & \sigma^2 \end{pmatrix}, \tag{8.2.94}$$

$$A^3 = \begin{pmatrix} 0 & 0 & 0 & i \\ 0 & 0 & i & 0 \\ 0 & -i & 0 & 0 \\ -i & 0 & 0 & 0 \end{pmatrix} = i\begin{pmatrix} 0 & \sigma^1 \\ -\sigma^1 & 0 \end{pmatrix}, \tag{8.2.95}$$

$$A^4 = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix} = i\begin{pmatrix} 0 & \sigma^2 \\ \sigma^2 & 0 \end{pmatrix}, \tag{8.2.96}$$

$$A^5 = \begin{pmatrix} 0 & 0 & -i & 0 \\ 0 & 0 & 0 & i \\ i & 0 & 0 & 0 \\ 0 & -i & 0 & 0 \end{pmatrix} = i\begin{pmatrix} 0 & -\sigma^3 \\ \sigma^3 & 0 \end{pmatrix}, \tag{8.2.97}$$

$$A^6 = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix} = \begin{pmatrix} 0 & \sigma^0 \\ -\sigma^0 & 0 \end{pmatrix}. \tag{8.2.98}$$

Here use has been made of the Pauli matrices given by (5.7.3). Evidently, the A^α span the space of 4×4 antisymmetric matrices when working over the complex field.

Verify that the A^α have the properties

$$(A^\alpha)^T = -A^\alpha, \tag{8.2.99}$$

$$(A^\alpha)^\dagger = -(-1)^\alpha A^\alpha, \tag{8.2.100}$$

and that they obey the multiplication rules

$$A^\alpha (A^\alpha)^\dagger = (A^\alpha)^\dagger A^\alpha = I, \tag{8.2.101}$$

$$A^1A^2 = A^2A^1 = i\begin{pmatrix} \sigma^0 & 0 \\ 0 & -\sigma^0 \end{pmatrix}, \tag{8.2.102}$$

$$A^1A^3 = -A^3A^1 = -iA^5, \tag{8.2.103}$$

$$A^1A^4 = A^4A^1 = -i\begin{pmatrix} 0 & \sigma^0 \\ \sigma^0 & 0 \end{pmatrix}, \tag{8.2.104}$$

$$A^1A^5 = -A^5A^1 = iA^3, \tag{8.2.105}$$

$$A^1A^6 = A^6A^1 = \begin{pmatrix} 0 & -\sigma^2 \\ \sigma^2 & 0 \end{pmatrix}, \tag{8.2.106}$$

$$A^2A^3 = A^3A^2 = -i\begin{pmatrix} 0 & \sigma^3 \\ \sigma^3 & 0 \end{pmatrix}, \tag{8.2.107}$$

$$A^2A^4 = -A^4A^2 = A^6, \tag{8.2.108}$$

$$A^2A^5 = A^5A^2 = -i\begin{pmatrix} 0 & \sigma^1 \\ \sigma^1 & 0 \end{pmatrix}, \tag{8.2.109}$$

$$A^2A^6 = -A^6A^2 = -A^4, \tag{8.2.110}$$

$$A^3A^4 = A^4A^3 = i\begin{pmatrix} -\sigma^3 & 0 \\ 0 & \sigma^3 \end{pmatrix}, \tag{8.2.111}$$

$$A^3A^5 = -A^5A^3 = -iA^1, \tag{8.2.112}$$

$$A^3A^6 = A^6A^3 = -i\begin{pmatrix} \sigma^1 & 0 \\ 0 & \sigma^1 \end{pmatrix}, \tag{8.2.113}$$

$$A^4A^5 = A^5A^4 = i\begin{pmatrix} -\sigma^1 & 0 \\ 0 & \sigma^1 \end{pmatrix}, \tag{8.2.114}$$

$$A^4A^6 = -A^6A^4 = A^2, \tag{8.2.115}$$

$$A^5A^6 = A^6A^5 = i\begin{pmatrix} \sigma^3 & 0 \\ 0 & \sigma^3 \end{pmatrix}. \tag{8.2.116}$$

Verify, by looking at (2.102) through (2.116), that there is the rule

$$A^\alpha A^\beta = (-1)(-1)^{\alpha+\beta}A^\beta A^\alpha \text{ for } \alpha \neq \beta. \tag{8.2.117}$$

Show that combining (2.100) and (2.117) gives the relations

$$A^\alpha(A^\beta)^\dagger = -A^\beta(A^\alpha)^\dagger \text{ for } \alpha \neq \beta, \tag{8.2.118}$$

$$(A^\alpha)^\dagger A^\beta = -(A^\beta)^\dagger A^\alpha \text{ for } \alpha \neq \beta. \tag{8.2.119}$$

Show that combining (2.101), (2.118), and (2.119) gives the relations

$$A^\alpha(A^\beta)^\dagger + A^\beta(A^\alpha)^\dagger = (A^\alpha)^\dagger A^\beta + (A^\beta)^\dagger A^\alpha = 2\delta_{\alpha\beta}I. \tag{8.2.120}$$

Finally, verify that the right sides of (2.102) through (2.116) are traceless. Combine this fact with (2.101) to derive the result

$$\mathrm{tr}[A^\alpha(A^\beta)^\dagger] = 4\delta_{\alpha\beta}. \tag{8.2.121}$$

For the moment, let v be any 4×4 matrix. Use it to define quantities $\bar{A}^{\alpha}(v)$ by the rule

$$\bar{A}^{\alpha}(v) = v^T A^{\alpha} v. \tag{8.2.122}$$

Note the similarity of (2.122) to (2.31) except that † has been replaced by T. Verify that the $\bar{A}^{\alpha}(v)$ are antisymmetric for any choice of v. It follows, since the A^{α} form a basis for the set of 4×4 antisymmetric matrices, that there must be a relation of the form

$$\bar{A}^{\alpha}(v) = v^T A^{\alpha} v = \sum_{\beta} R_{\alpha\beta}(v) A^{\beta} \tag{8.2.123}$$

where $R(v)$ is a 6×6 matrix to be determined. Verify, in view of (2.121), that there is the explicit formula

$$R_{\alpha\beta}(v) = (1/4)\mathrm{tr}[v^T A^{\alpha} v (A^{\beta})^{\dagger}]. \tag{8.2.124}$$

Let us find some of the properties of $R(v)$. Verify that

$$R(I) = I, \tag{8.2.125}$$

$$R(-I) = I, \tag{8.2.126}$$

and, more generally,

$$R(-v) = R(v). \tag{8.2.127}$$

The rule (2.124) is also a homomorphism,

$$R(v_1 v_2) = R(v_1) R(v_2). \tag{8.2.128}$$

Check this assertion by verifying the computation

$$\begin{aligned} R_{\alpha\beta}(v_1 v_2) &= (1/4)\mathrm{tr}[(v_1 v_2)^T A^{\alpha} v_1 v_2 (A^{\beta})^{\dagger}] = (1/4)\mathrm{tr}[v_2^T v_1^T A^{\alpha} v_1 v_2 (A^{\beta})^{\dagger}] \\ &= (1/4)\sum_{\gamma} R(v_1)_{\alpha\gamma} \mathrm{tr}[v_2^T A^{\gamma} v_2 (A^{\beta})^{\dagger}] = \sum_{\gamma} R(v_1)_{\alpha\gamma} R(v_2)_{\gamma\beta} = [R(v_1)R(v_2)]_{\alpha\beta}. \end{aligned} \tag{8.2.129}$$

From (2.123) deduce the relation

$$v^T \Big[\sum_{\alpha} z_{\alpha} A^{\alpha}\Big] v = \sum_{\alpha} z_{\alpha} v^T A^{\alpha} v = \sum_{\beta} \Big[\sum_{\alpha} z_{\alpha} R_{\alpha\beta}(v)\Big] A^{\beta}. \tag{8.2.130}$$

Define variables $\hat{z}_{\beta}$ by writing

$$\hat{z}_{\beta} = \sum_{\alpha} z_{\alpha} R_{\alpha\beta}(v). \tag{8.2.131}$$

Show that (2.130) can be written more compactly in the form

$$v^T A(z) v = A(\hat{z}). \tag{8.2.132}$$

Take the determinant of both sides of (2.132). Show that doing so yields, in view of (2.91), the result

$$[\det(v)]^2 \Big[\sum_{\alpha} z_{\alpha}^2\Big]^2 = \Big[\sum_{\beta} \hat{z}_{\beta}^2\Big]^2. \tag{8.2.133}$$

Take the square roots of both sides of (2.133) to find the result

$$[\det(v)]\Big[\sum_{\alpha} z_{\alpha}^2\Big] = \Big[\sum_{\beta} \hat{z}_{\beta}^2\Big]. \tag{8.2.134}$$

In taking this square root there is, of course, a sign ambiguity. This ambiguity is overcome by employing (2.125) and imposing continuity. For a Pfaffian-based approach that avoids this ambiguity, see Exercise 8.2.13.

Next manipulate the ingredients on the right side of (2.134) to show that

$$\begin{aligned}\sum_{\beta} \hat{z}_{\beta}^2 &= \sum_{\beta}\Big[\sum_{\alpha} z_{\alpha}R_{\alpha\beta}\Big]\Big[\sum_{\gamma} z_{\gamma}R_{\gamma\beta}\Big] \\ &= \sum_{\alpha\beta\gamma} z_{\alpha}R_{\alpha\beta}z_{\gamma}R_{\gamma\beta} = \sum_{\alpha\beta\gamma} z_{\alpha}R_{\alpha\beta}(R^T)_{\beta\gamma}z_{\gamma} = \sum_{\alpha\gamma} z_{\alpha}(RR^T)_{\alpha\gamma}z_{\gamma}.\end{aligned} \tag{8.2.135}$$

It follows that there is the relation

$$\det(v)\sum_{\alpha} z_{\alpha}^2 = \sum_{\alpha\gamma} z_{\alpha}(RR^T)_{\alpha\gamma}z_{\gamma}. \tag{8.2.136}$$

Prove from (2.136) that

$$R(v)R^T(v) = \det(v)I. \tag{8.2.137}$$

Finally, assume that v has unit determinant. Then we find that

$$R(v)R^T(v) = I, \tag{8.2.138}$$

the matrix R is *orthogonal*. At this stage we have found that (2.124) provides a homomorphism of $SL(4,C)$ into $SO(6,C)$. Verify, as a sanity check, that both $SL(4,C)$ and $SO(6,C)$ have dimension 30.

Next assume that v is also unitary so that $v \in SU(4)$. Then deduce the chain of relations

$$I = R(I) = R(v^{\dagger}v) = R(v^{\dagger})R(v) \tag{8.2.139}$$

to conclude that

$$R^T(v) = R(v^{\dagger}). \tag{8.2.140}$$

Also, we claim that $R(v)$ is *real* if $v \in SU(4)$. Verify that taking the complex conjugate of both sides of (2.124) and employing the invariance of the trace under transposing and cyclic permutation gives (with a * denoting complex conjugation) the result

$$\begin{aligned}R_{\alpha\beta}^*(v) &= (1/4)\mathrm{tr}[v^{\dagger}(A^{\alpha})^* v^*(A^{\beta})^T] = (1/4)\mathrm{tr}[A^{\beta}v^{\dagger}(A^{\alpha})^{\dagger}v^*] \\ &= (1/4)\mathrm{tr}[v^*A^{\beta}v^{\dagger}(A^{\alpha})^{\dagger}] = (1/4)\mathrm{tr}[(v^{\dagger})^T A^{\beta}v^{\dagger}(A^{\alpha})^{\dagger}] \\ &= R_{\beta\alpha}(v^{\dagger}) = [R(v^{\dagger})]_{\beta\alpha} = [R^T(v)]_{\beta\alpha} = R_{\alpha\beta}(v).\end{aligned} \tag{8.2.141}$$

Thus the mapping (2.124) has the property that $R(v) \in SO(6,\mathbb{R})$ if $v \in SU(4)$. In view of (2.127) and (2.128), this mapping is a two-to-one homomorphism.

Finally, we remark that $SU(4)$ is known to be simply connected. It follows that $SO(6,\mathbb{R})$ cannot be simply connected. Indeed, $SO(6,\mathbb{R})$ is known to be doubly connected, and its covering group is $SU(4)$.

At this point one might wonder again about employing the T operation in (2.123) and (2.124) rather than † operation as was done in (2.34). The reason for this choice lies in the Clebsch-Gordan series for $SU(4)$. The lowest dimensional representations for $SU(4)$, those of dimension 4, are *not* self conjugate. Rather, there are two distinct representations which we may call 4 and $\bar{4}$. The Clebsch-Gordan series for the direct products of these two representations, and it is something like a direct product that is going on in (2.124), are

$$4 \times 4 = 6 + 10, \tag{8.2.142}$$

$$4 \times \bar{4} = 1 + 15. \tag{8.2.143}$$

Thus, only by avoiding complex conjugation do we have any hope of obtaining something of dimension 6, the dimension that is required for the lowest dimensional representation of $SO(6,\mathbb{R})$.

We still have to address the relation between the two Lie algebras $su(4)$ and $so(6,\mathbb{R})$. This can be done by studying (2.124) for elements v near the identity. Suppose v is written in the form

$$v = \exp(\epsilon K) = I + \epsilon K + O(\epsilon^2) \tag{8.2.144}$$

where ϵ is small and $K \in su(4)$ is therefore any 4×4 traceless anti-Hermitian matrix. Then we have

$$v^T = \exp(\epsilon K^T) = I + \epsilon K^T + O(\epsilon^2), \tag{8.2.145}$$

and (2.124) yields

$$\begin{aligned} R_{\alpha\beta}(v) &= (1/4)\mathrm{tr}[(I+\epsilon K^T)A^\alpha(I+\epsilon K)(A^\beta)^\dagger] + O(\epsilon^2) \\ &= (1/4)\mathrm{tr}[A^\alpha(A^\beta)^\dagger] + (\epsilon/4)\mathrm{tr}[A^\alpha K(A^\beta)^\dagger + K^T A^\alpha(A^\beta)^\dagger] + O(\epsilon^2) \\ &= \delta_{\alpha\beta} + \epsilon L_{\alpha\beta} + O(\epsilon^2) = [\exp(\epsilon L)]_{\alpha\beta} + O(\epsilon^2) \\ &\Leftrightarrow \quad R[\exp(\epsilon K)] = \exp(\epsilon L) + O(\epsilon^2) \end{aligned} \tag{8.2.146}$$

where

$$L_{\alpha\beta}(K) = (1/4)\mathrm{tr}[A^\alpha K(A^\beta)^\dagger + K^T A^\alpha (A^\beta)^\dagger] = (1/4)\mathrm{tr}[K(A^\beta)^\dagger A^\alpha + K^T A^\alpha (A^\beta)^\dagger]. \tag{8.2.147}$$

Here we have made use of the trace property (3.6.130).

We note that, from the homomorphism property (2.128) and the infinitesimal relation (2.146), it follows that there is also the global result

$$R[\exp(K)] = \exp(L). \tag{8.2.148}$$

To verify this claim, show that

$$\begin{aligned} R[\exp(K)] &= R\{[\exp(K/\ell)]^\ell\} = \{R[\exp(K/\ell)]\}^\ell \\ &= \{\exp(L/\ell) + O[(1/\ell)^2]\}^\ell \\ &= \{\exp(L/\ell)\}^\ell + \ell O[(1/\ell)^2] \\ &= \exp(L) + \ell O[(1/\ell)^2]. \end{aligned} \tag{8.2.149}$$

Now let $\ell \to \infty$ in (2.149) to obtain the global result (2.148).

Let us examine the properties of L. We already know that R is orthogonal and real, and therefore L must be antisymmetric and real. It is valuable to check that these results can also be verified directly from (2.147). Show from (2.101) and (2.147) that

$$L_{\alpha\alpha}(K) = (1/4)\mathrm{tr}[KI + K^T I] = (1/2)\,\mathrm{tr}(K) = 0 \tag{8.2.150}$$

because K must be traceless to be in $su(4)$. Next show using (2.18) and (2.19) that, for $\alpha \neq \beta$,

$$\begin{aligned} L_{\alpha\beta}(K) &= (1/4)\mathrm{tr}[K(A^\beta)^\dagger A^\alpha + K^T A^\alpha (A^\beta)^\dagger] \\ &= -(1/4)\mathrm{tr}[K(A^\alpha)^\dagger A^\beta + K^T A^\beta (A^\alpha)^\dagger] \\ &= -L_{\beta\alpha}(K). \end{aligned} \tag{8.2.151}$$

Taken together, (2.150) and (2.151) show that L is antisymmetric. Next work on showing that L is real. Let * denote the operation of complex conjugation. To show that L is real, verify the chain of deductions

$$\begin{aligned} [L_{\alpha\beta}(K)]^* &= (1/4)\{\mathrm{tr}[K(A^\beta)^\dagger A^\alpha + K^T A^\alpha (A^\beta)^\dagger]\}^* \\ &= (1/4)\,\mathrm{tr}[K^*(A^\beta)^T (A^\alpha)^* + K^\dagger (A^\alpha)^* (A^\beta)^T] \\ &= (1/4)\,\mathrm{tr}\{(K^\dagger)^T (A^\beta)^T (A^\alpha)^* + K^\dagger [(A^\alpha)^T]^\dagger (A^\beta)^T\} \\ &= -(1/4)\,\mathrm{tr}\{K^T A^\beta (A^\alpha)^\dagger + K(A^\alpha)^\dagger A^\beta\} \\ &= -L_{\beta\alpha}(K) = L_{\alpha\beta}(K). \end{aligned} \tag{8.2.152}$$

Here we have used (2.99) and the fact that K must be anti-Hermitian to be in $su(4)$,

$$K^\dagger = -K, \tag{8.2.153}$$

and the antisymmetry conditions (2.150) and (2.151).

It remains to be verified that $L(K)$ is a homomorphism (and potentially an isomorphism). Let $(K^1, K^2, \cdots, K^{15})$ be a set of basis elements for $su(4)$. Form *group commutator* elements v by the rule

$$v = \exp(\epsilon K^\alpha)\exp(\epsilon K^\beta)\exp(-\epsilon K^\alpha)\exp(-\epsilon K^\beta). \tag{8.2.154}$$

Recall Exercise 3.7.41. Show, using the BCH series (3.7.41), that

$$v = \exp(\epsilon^2\{K^\alpha, K^\beta\}) + O(\epsilon^3), \tag{8.2.155}$$

from which it follows, using (2.148), that

$$R(v) = \exp[\epsilon^2 L(\{K^\alpha, K^\beta\})] + O(\epsilon^3). \tag{8.2.156}$$

Show from (2.128), (2.148), and BCH that

$$\begin{aligned} R(v) &= R[\exp(\epsilon K^\alpha)]R[\exp(\epsilon K^\beta)]R[\exp(-\epsilon K^\alpha)]R[\exp(-\epsilon K^\beta)] \\ &= \exp[\epsilon L(K^\alpha)]\exp[\epsilon L(K^\beta)]\exp[-\epsilon L(K^\alpha)]\exp[-\epsilon L(K^\beta)] \\ &= \exp[\epsilon^2\{L(K^\alpha), L(K^\beta)\}] + O(\epsilon^3). \end{aligned} \tag{8.2.157}$$

By equating powers of ϵ in (2.156) and (2.157), show that

$$\{L(K^{\alpha}), L(K^{\beta})\} = L(\{K^{\alpha}, K^{\beta}\}). \tag{8.2.158}$$

Suppose the quantities $c^{\gamma}_{\alpha\beta}$ are structure constants for $su(4)$ so that

$$\{K^{\alpha}, K^{\beta}\} = \sum_{\gamma} c^{\gamma}_{\alpha\beta} K^{\gamma}. \tag{8.2.159}$$

Show from (2.158) and (2.159) that there is the relation

$$\{L(K^{\alpha}), L(K^{\beta})\} = \sum_{\gamma} c^{\gamma}_{\alpha\beta} L(K^{\gamma}), \tag{8.2.160}$$

thereby verifying that, for suitable basis choices, $su(4)$ and $so(6,\mathbb{R})$ have the same structure constants.

We still want to know what particular $K \in su(4)$ produces what $L \in so(6,\mathbb{R})$, and we want to verify that every $L \in so(6,\mathbb{R})$ arises from some $K \in su(4)$ so that (2.150) is, in fact, an isomorphism. We begin this task by looking at specific cases. Listed below are three typical elements in $su(4)$:

$$K^1 = \begin{pmatrix} 0 & i & 0 & 0 \\ i & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} = i \begin{pmatrix} \sigma^1 & 0 \\ 0 & 0 \end{pmatrix}, \tag{8.2.161}$$

$$K^2 = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} = i \begin{pmatrix} \sigma^2 & 0 \\ 0 & 0 \end{pmatrix}, \tag{8.2.162}$$

$$K^3 = \begin{pmatrix} i & 0 & 0 & 0 \\ 0 & -i & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} = i \begin{pmatrix} \sigma^3 & 0 \\ 0 & 0 \end{pmatrix}. \tag{8.2.163}$$

The matrix K^1 is symmetric, pure imaginary, and has zeroes on the diagonal, which makes it anti-Hermitian and traceless. There are 6 linearly independent matrices of this kind in $su(4)$. The matrix K^2 is antisymmetric and real, which makes it anti-Hermitian and traceless. There are also 6 linearly independent matrices of this kind in $su(4)$. The element K^3 is diagonal and pure imaginary, which makes it anti-Hermitian, and it is traceless. There are 3 linearly independent matrices of this kind in $su(4)$ for a total count of $6 + 6 + 3 = 15$, the dimension of $su(4)$. Show that the associated L matrices are given by the relations

$$L^1 = L(K^1) = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \end{pmatrix}, \tag{8.2.164}$$

$$L^2 = L(K^2) = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 \end{pmatrix}, \tag{8.2.165}$$

$$L^3 = L(K^3) = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & -1 & 0 \end{pmatrix}. \tag{8.2.166}$$

We see that the associated L matrices are real and antisymmetric, as expected. In particular, L^1 is a linear combination of generators for rotations in the 3,6 and 4,5 planes; L^2 is a linear combination of generators for rotations in the 3,5 and 4,6 planes; and L^3 is a linear combination of generators for rotations in the 3,4 and 5,6 planes. Verify that the two generators in each linear combination commute. Verify that

$$\{K^1, K^2\} = -2K^3, \text{ etc.} \tag{8.2.167}$$

so that the elements K^1 through K^3 form some kind of $su(2)$ [or $so(3, R)$] within $su(4)$. Verify, in accord with (2.158), the relations

$$\{L(K^1), L(K^2)\} = -2L(K^3) = L(\{K^1, K^2\}), \text{ etc.} \tag{8.2.168}$$

Suppose the remaining elements of $su(4)$ are also considered so that we are working with a complete set of basis elements $(K^1, K^2, \cdots, K^{15})$ for $su(4)$. Then presumably their associated matrices $L^\alpha = L(K^\alpha)$ form a basis for $so(6, \mathbb{R})$. In fact we know from general principles that this must be the case. These principles are described in Section 8.9, and applied to the problem at hand in Exercise 8.9.19.

8.2.13. Review Section 3.13.3 and Exercise 8.2.12. The purpose of this exercise is to derive various results of Execise 8.2.12 with the aid of Pfaffians. Let A be a general 4×4 antisymmetric matrix written in the form

$$A = \begin{pmatrix} 0 & a & b & c \\ -a & 0 & d & e \\ -b & -d & 0 & f \\ -c & -e & -f & 0 \end{pmatrix}. \tag{8.2.169}$$

Then the Pfaffian of A is given by the relation

$$\mathrm{Pf}(A) = af - be + dc. \tag{8.2.170}$$

Suppose A is given in the form (2.81). Show, for this parameterization, that

$$\mathrm{Pf}(A) = -(1/c)\boldsymbol{E} \cdot \boldsymbol{B}. \tag{8.2.171}$$

Use the Pfaffian property (3.13.65) to derive (2.82). Use the Pfaffian property (3.13.66) to derive the relation

$$[\det(v)]\Big[\sum_{\alpha} z_{\alpha}^{2}\Big] = \Big[\sum_{\beta} \hat{z}_{\beta}^{2}\Big], \tag{8.2.172}$$

which is a specific square root of the relation (2.133), and yields (2.134) directly without any ambiguity in sign.

8.2.14. Review Exercise 2.10 that studied the relation between $SU(2)$ and $SO(3,\mathbb{R})$. In particular, it derived the formula (2.54) that maps $SU(2)$ to $SO(3,\mathbb{R})$ thereby demonstrating that $SU(2)$ is the covering group for $SO(3,\mathbb{R})$. The purpose of this exercise is to find analogous results for the relation between $SL(2,\mathbb{C})$ and the Lorentz group.

Begin by setting up some notation and definitions for later use. Let σ^{α} for $\alpha = 1,2,3$ be the usual Pauli matrices and let σ^4 be the 2×2 identity matrix,

$$\sigma^4 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \tag{8.2.173}$$

Verify, in accord with Exercise 5.7.7, that there are the relations

$$\operatorname{tr} \sigma^{\alpha}\sigma^{\beta} = 2\delta^{\alpha\beta} \text{ for } \alpha,\beta = 1,2,3,4. \tag{8.2.174}$$

Let x^{μ} and y^{μ} be any two four-vectors. Make the definition

$$x \star y = \sum_{\mu=1}^{4} x^{\mu} y^{\mu}. \tag{8.2.175}$$

Note that (2.175) is just the ordinary Euclidean scalar product (x, y). By extension of notation, make the definition

$$x \star \sigma = \sum_{\mu=1}^{4} x^{\mu}\sigma^{\mu}. \tag{8.2.176}$$

Verify that $x \star \sigma$ is Hermitian if x is real, and anti-Hermitian if x is pure imaginary. Verify that

$$\operatorname{tr}(x \star \sigma) = 2x^4. \tag{8.2.177}$$

Verify that

$$\operatorname{tr}[(x \star \sigma)(y \star \sigma)] = 2(x \star y) \tag{8.2.178}$$

and, as a special case,

$$\operatorname{tr}[(x \star \sigma)^2] = 2(x \star x). \tag{8.2.179}$$

Show that $x \star \sigma$ has the explicit matrix form

$$x \star \sigma = \begin{pmatrix} x^4 + x^3 & x^1 - ix^2 \\ x^1 + ix^2 & x^4 - x^3 \end{pmatrix}. \tag{8.2.180}$$

Given a 2×2 matrix M, is there a four-vector x such that

$$M = x \star \sigma? \tag{8.2.181}$$

Any 2 × 2 matrix M can be written in the form

$$M = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \tag{8.2.182}$$

where the quantities a through d are arbitrary. Verify, upon examination of (2.180) and (2.182), that for (2.181) to hold it must be possible to satisfy the relations

$$x^4 + x^3 = a, \tag{8.2.183}$$

$$x^1 - ix^2 = b, \tag{8.2.184}$$

$$x^1 + ix^2 = c, \tag{8.2.185}$$

$$x^4 - x^3 = d. \tag{8.2.186}$$

Show that the equation set (2.183) through (2.186) has the unique solution

$$x^1 = (1/2)(b + c), \tag{8.2.187}$$

$$x^2 = (i/2)(b - c), \tag{8.2.188}$$

$$x^3 = (1/2)(a - d), \tag{8.2.189}$$

$$x^4 = (1/2)(a + d). \tag{8.2.190}$$

Consequently, for any M, there exists a unique x such that (2.181) holds. That is, the σ^α form a basis for the set of all 2 × 2 matrices. Show that x is given in terms of M by the relations

$$x^\mu = (1/2)\,\mathrm{tr}(\sigma^\mu M). \tag{8.2.191}$$

Show that x is real if M is Hermitian, and is pure imaginary if M is anti-Hermitian.

Finally, make the definition

$$x \cdot y = x^4 y^4 - \sum_{\mu=1}^{3} x^\mu y^\mu. \tag{8.2.192}$$

Note that (2.192) is the Lorentz inner/scalar product.

We are now ready to make yet another remarkable statement about the Pauli matrices: Verify from (2.180) by explicit calculation that there is the relation

$$\det(x \star \sigma) = x \cdot x. \tag{8.2.193}$$

How could we have guessed that at least something like (2.193) should hold? Review Exercise 3.7.17. According to (3.7.150), for any 2 × 2 matrix A, there is the relation

$$\det(A) = \{[\mathrm{tr}(A)]^2 - \mathrm{tr}(A^2)\}/2. \tag{8.2.194}$$

Make the substitution

$$A = x \star \sigma. \tag{8.2.195}$$

Verify from (2.177) and (2.179) that

$$[\mathrm{tr}(A)]^2 = 4(x^4)^2 \tag{8.2.196}$$

and

$$\mathrm{tr}(A^2) = 2(x \star x). \tag{8.2.197}$$

Show, therefore, that use of (2.194) yields the result

$$\det(x \star \sigma) = [4(x^4)^2 - 2(x \star x)]/2 = [2(x^4)^2 - 2\sum_{\mu=1}^{3}(x^u)^2]/2 = x \cdot x, \tag{8.2.198}$$

in agreement with (2.193).

With the definitions and results just developed now at hand, we are ready to further explore the connection between the Lorentz group and $SL(2,\mathbb{C})$. Let v be any element of $SL(2,\mathbb{C})$ so that

$$\det v = 1. \tag{8.2.199}$$

Verify that then $v^\dagger$ is also in $SL(2,\mathbb{C})$ so that

$$\det v^\dagger = 1. \tag{8.2.200}$$

Next let x be any real four-vector. Consider the matrix $v(x \star \sigma)v^\dagger$. It is evidently 2×2. Show that it is also Hermitian,

$$[v(x \star \sigma)v^\dagger]^\dagger = v(x \star \sigma)v^\dagger. \tag{8.2.201}$$

Since $v(x \star \sigma)v^\dagger$ is a 2×2 Hermitian matrix, there must be a real and unique four-vector $\hat{x}$ such that

$$\hat{x} \star \sigma = v(x \star \sigma)v^\dagger. \tag{8.2.202}$$

Show, by taking determinants of both sides of (2.202), that there is the relation

$$\hat{x} \cdot \hat{x} = x \cdot x. \tag{8.2.203}$$

It follows that $\hat{x}$ and x are related by a Lorentz transformation! Thus, for each element $v \in SL(2,\mathbb{C})$ there is a Lorentz transformation $\Lambda(v)$.

How might one have guessed that this should be the case? We know from Exercise 7.3.30 that the $v \in SL(2,\mathbb{C})$ carry the representation $\Gamma(0,1/2)$ and we might expect, as can be proved, that the $v^\dagger$ would carry the representation $\Gamma(1/2,0)$. Since the right side of (2.202) involves both v and $v^\dagger$ in a "multiplicative" way, we might expect that what we are doing in (2.202) would involve the representation $\Gamma(0,1/2) \times \Gamma(1/2,0)$. But for the Lorentz group it is easy to see that there is the Clebsch-Gordan result

$$\Gamma(0,1/2) \times \Gamma(1/2,0) = \Gamma(1/2,1/2). \tag{8.2.204}$$

And, according to Exercise 7.3.29, $\Gamma(1/2,1/2)$ is the representation carried by Lorentz transformation matrices Λ acting on four-vectors.

Your next task is to find the matrix elements of Λ as functions of v. Let us examine and manipulate the "contents" of $v(x \star \sigma)v^\dagger$, the right side of (2.202). Verify that

$$v(x \star \sigma)v^\dagger = v(\sum_\nu x^\nu \sigma^\nu)v^\dagger = \sum_\nu (v\sigma^\nu v^\dagger)x^\nu. \tag{8.2.205}$$

Show that the matrices $v\sigma^\nu v^\dagger$ are Hermitian,

$$(v\sigma^\nu v^\dagger)^\dagger = v\sigma^\nu v^\dagger. \tag{8.2.206}$$

Verify it follows that there are *real* coefficients, call them $\Lambda^{\xi\nu}(v)$, such that

$$v\sigma^\nu v^\dagger = \sum_{\xi=1}^{4} \Lambda^{\xi\nu}(v)\sigma^\xi. \tag{8.2.207}$$

Show that, correspondingly, there is the relation

$$\Lambda^{\mu\nu}(v) = (1/2)\,\mathrm{tr}(\sigma^\mu v\sigma^\nu v^\dagger). \tag{8.2.208}$$

We already know that Λ is a real matrix. Still, it would be good to reverify directly that Λ as given by (2.208) is real even though some of the matrices appearing on the right side of (2.208) may be complex. Show, using (3.6.129) and (3.6.130), that

$$\begin{aligned}[\Lambda^{\mu\nu}(v)]^* &= (1/2)\,\mathrm{tr}[(\sigma^\mu v\sigma^\nu v^\dagger)^\dagger] = (1/2)\,\mathrm{tr}[v\sigma^\nu v^\dagger\sigma^\mu] \\ &= (1/2)\,\mathrm{tr}[\sigma^\mu v\sigma^\nu v^\dagger] = \Lambda^{\mu\nu}(v). \end{aligned} \tag{8.2.209}$$

Now what can be said about the vector $\hat{x}$ and its relation to x? Verify, in view of (2.202), that the components of $\hat{x}$ are given by the relations

$$\hat{x}^\mu = (1/2)\,\mathrm{tr}[\sigma^\mu v(x \star \sigma)v^\dagger]. \tag{8.2.210}$$

Next use (2.205) to find that

$$(1/2)\,\mathrm{tr}[\sigma^\mu v(x \star \sigma)v^\dagger] = (1/2)\sum_\nu [\mathrm{tr}(\sigma^\mu v\sigma^\nu v^\dagger)]x^\nu. \tag{8.2.211}$$

Finally, upon combining (2.208), (2.210), and (2.211), show that

$$\hat{x}^\mu = \sum_\nu \Lambda^{\mu\nu}(v)x^\nu \text{ or, in matrix/vector form, } \hat{x} = \Lambda x. \tag{8.2.212}$$

We have learned, as anticipated by our notation, that the quantities $\Lambda^{\mu\nu}(v)$ defined by (2.208) are the entries of a Lorentz transformation matrix.

What can be said about group properties? Suppose, to begin, that v is the 2×2 identity matrix σ^4. Verify that in this case use of (2.208) gives the result

$$\Lambda^{\mu\nu}(\sigma^4) = (1/2)\,\mathrm{tr}[\sigma^\mu\sigma^4\sigma^\nu(\sigma^4)^\dagger] = (1/2)\,\mathrm{tr}[\sigma^\mu\sigma^\nu] = \delta^{\mu\nu}. \tag{8.2.213}$$

That is, the image of the identity element in $SL(2,\mathbb{C})$ is the identity matrix in the Lorentz group. Next suppose that v is of the product form

$$v = uw \tag{8.2.214}$$

where u and w are both elements of $SL(2,\mathbb{C})$. In this case verify that use of (2.208) gives the result

$$\Lambda^{\mu\nu}(uw) = (1/2)\,\mathrm{tr}[\sigma^\mu uw\sigma^\nu(uw)^\dagger] = (1/2)\,\mathrm{tr}[\sigma^\mu u(w\sigma^\nu w^\dagger)u^\dagger]. \tag{8.2.215}$$

But, in analogy to (2.207), verify that

$$w\sigma^\nu w^\dagger = \sum_{\xi=1}^{4}\Lambda^{\xi\nu}(w)\sigma^\xi. \tag{8.2.216}$$

Show that combining (2.215) and (2.216) gives the intermediate results

$$\Lambda^{\mu\nu}(uw) = (1/2)\,\mathrm{tr}[\sigma^\mu u(\sum_{\xi=1}^{4}\Lambda^{\xi\nu}(w)\sigma^\xi)u^\dagger] = \sum_{\xi=1}^{4}\Lambda^{\xi\nu}(w)(1/2)\,\mathrm{tr}[\sigma^\mu(u\sigma^\xi u^\dagger)]. \tag{8.2.217}$$

But, again in analogy to (2.207), verify that

$$u\sigma^\xi u^\dagger = \sum_{\rho=1}^{4}\Lambda^{\rho\xi}(u)\sigma^\rho. \tag{8.2.218}$$

Show that combining (2.217) and (2.218) gives the final result

$$\begin{aligned}\Lambda^{\mu\nu}(uw) &= \sum_{\xi=1}^{4}\Lambda^{\xi\nu}(w)(1/2)\,\mathrm{tr}[\sigma^\mu(u\sigma^\xi u^\dagger)]\\ &= \sum_{\xi=1}^{4}\Lambda^{\xi\nu}(w)(1/2)\,\mathrm{tr}[\sigma^\mu\sum_{\rho=1}^{4}\Lambda^{\rho\xi}(u)\sigma^\rho]\\ &= \sum_{\xi=1}^{4}\sum_{\rho=1}^{4}\Lambda^{\rho\xi}(u)\Lambda^{\xi\nu}(w)(1/2)\,\mathrm{tr}[\sigma^\mu\sigma^\rho]\\ &= \sum_{\xi=1}^{4}\sum_{\rho=1}^{4}\Lambda^{\rho\xi}(u)\Lambda^{\xi\nu}(w)\delta^{\mu\rho}\\ &= \sum_{\xi=1}^{4}\Lambda^{\mu\xi}(u)\Lambda^{\xi\nu}(w) \qquad (8.2.219)\end{aligned}$$

or, in index-free notation,

$$\Lambda(uw) = \Lambda(u)\Lambda(w). \tag{8.2.220}$$

Complete our group property study with two calculations: First set

$$w = \sigma^4 \tag{8.2.221}$$

in (2.220) and deduce that

$$\Lambda(\sigma^4) = I \tag{8.2.222}$$

in agreement with (2.213). Second, set

$$w = v^{-1} \tag{8.2.223}$$

in (2.220) and deduce that

$$\Lambda(v^{-1}) = [\Lambda(v)]^{-1}. \tag{8.2.224}$$

The relation (2.220) and those that follow from it show that Lorentz transformation matrices Λ provide a representation of $SL(2,\mathbb{C})$. That is, the map (2.208) that sends elements of $SL(2,\mathbb{C})$ into elements of the Lorentz group is a homomorphism. At this point it is important to observe, by inspection, that the map (2.208) has the two-to-one property

$$\Lambda(-v) = \Lambda(v). \tag{8.2.225}$$

Therefore (2.208) is not an isomorphism. As we will see, $SL(2,\mathbb{C})$ is the covering group of the Lorentz group.

In Exercises 7.7.27 and 7.7.30 it was shown that the Lorentz group and $SL(2,\mathbb{C})$ have identical Lie algebras and analogous polar decompositions. And in this exercise we have seen that (2.208) provides a two-to-one homomorphic relation between the Lorentz group and $SL(2,\mathbb{C})$. The remainder of this exercise explores how these results fit together.

Suppose, employing the polar decomposition (7.3.241), that v is written in the form

$$v = \exp(\lambda \boldsymbol{m}\cdot\hat{\boldsymbol{N}})\exp(\theta\boldsymbol{n}\cdot\hat{\boldsymbol{L}}). \tag{8.2.226}$$

Show that employing this factorization in (2.220) yields the result

$$\Lambda(v) = \Lambda[\exp(\lambda\boldsymbol{m}\cdot\hat{\boldsymbol{N}})]\Lambda[\exp(\theta\boldsymbol{n}\cdot\hat{\boldsymbol{L}})]. \tag{8.2.227}$$

Your next tasks will be to work out results for each factor on the right side of (2.227).

Begin Evaluation of Second Factor

Begin with the second factor. For it you will need to work out

$$\Lambda^{\mu\nu}(w) = (1/2)\,\mathrm{tr}(\sigma^\mu w\sigma^\nu w^\dagger) \tag{8.2.228}$$

with

$$w = \exp(\theta\boldsymbol{n}\cdot\hat{\boldsymbol{L}}) = \exp(\theta\boldsymbol{n}\cdot\boldsymbol{K}) = \exp[\theta(-i/2)\boldsymbol{n}\cdot\boldsymbol{\sigma}]. \tag{8.2.229}$$

See (7.3.232) through (7.3.234). Verify that in this case w is unitary.

The simplest matrix element to work out is Λ^{44}. Verify using (2.208) that

$$\Lambda^{44}(w) = (1/2)\,\mathrm{tr}(\sigma^4 w\sigma^4 w^\dagger) = (1/2)\,\mathrm{tr}(ww^\dagger) = (1/2)\,\mathrm{tr}(\sigma^4) = 1. \tag{8.2.230}$$

The next simplest cases are the $\Lambda^{\alpha 4}$ and $\Lambda^{4\alpha}$ with $\alpha = 1,2,3$. Verify that for these α

$$\Lambda^{\alpha 4}(w) = (1/2)\,\mathrm{tr}(\sigma^\alpha w\sigma^4 w^\dagger) = (1/2)\,\mathrm{tr}(\sigma^\alpha) = 0 \tag{8.2.231}$$

and

$$\Lambda^{4\alpha}(w) = (1/2)\,\mathrm{tr}(\sigma^4 w \sigma^\alpha w^\dagger) = (1/2)\,\mathrm{tr}(w^\dagger w \sigma^\alpha) = (1/2)\,\mathrm{tr}(\sigma^\alpha) = 0. \tag{8.2.232}$$

[Here, in writing (2.232), use has been made of the trace relation (3.6.130).] So it has now been established that $\Lambda(w)$ is of the form

$$\Lambda(w) = \begin{pmatrix} * & * & * & 0 \\ * & * & * & 0 \\ * & * & * & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{8.2.233}$$

To fill in the missing entries in (2.233) the simplest way at this point is to use what has already been accomplished in Exercises 3.7.31 and 2.10, which you should review. Note, again using (3.6.130), that (2.208) can be rewritten in the form

$$\Lambda^{\mu\nu}(v) = (1/2)\,\mathrm{tr}(v^\dagger \sigma^\mu v \sigma^\nu), \tag{8.2.234}$$

which has the same form as (2.54). Consequently, the missing entries are the elements of the 3×3 matrix given by (2.54). It follows, as expected, that for the w given by (2.229) $\Lambda(w)$ is given by the relation

$$\Lambda(w) = \exp(\theta \boldsymbol{n} \cdot \boldsymbol{L}) \tag{8.2.235}$$

or

$$\Lambda[\exp(\theta \boldsymbol{n} \cdot \hat{\boldsymbol{L}})] = \exp(\theta \boldsymbol{n} \cdot \boldsymbol{L}) \tag{8.2.236}$$

where the $\boldsymbol{L}$ are the matrices given by (7.3.177) through (7.3.179) and whose upper left 3×3 submatrices are the matrices given by (3.7.178) through (3.7.180).

As a sanity check of (2.236), consider the simple case where

$$\boldsymbol{n} = \boldsymbol{e}_3 \tag{8.2.237}$$

so that

$$w = \exp(\theta \boldsymbol{n} \cdot \hat{\boldsymbol{L}}) = \exp(\theta \hat{L}^3) = \exp[\theta(-i/2)\sigma^3]. \tag{8.2.238}$$

Verify that

$$w = \exp[\theta(-i/2)\sigma^3] = \exp(\theta K^3) = \begin{pmatrix} \exp(-i\theta/2) & 0 \\ 0 & \exp(i\theta/2) \end{pmatrix}. \tag{8.2.239}$$

See (3.7.171) and (3.7.194). Also, compare (2.236) with the analogous result (2.54). Show that for the w given by (2.235) and (2.236) there is the result

$$\Lambda(w) = \begin{pmatrix} \cos(\theta) & -\sin(\theta) & 0 & 0 \\ \sin(\theta) & \cos(\theta) & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} = \exp(\theta L^3) \tag{8.2.240}$$

with L^3 given by (7.3.179. See (3.7.207). Note that, according to (2.240), $\Lambda(w)$ is periodic in θ with period 2π,

$$\Lambda(w)|_{\theta+2\pi} = \Lambda(w)|_\theta. \tag{8.2.241}$$

But, according to (2.239), w is not; it has period 4π,

$$w|_{\theta+4\pi} = w|_{\theta}, \tag{8.2.242}$$

and

$$w|_{\theta+2\pi} = -w|_{\theta}. \tag{8.2.243}$$

Show that this result is consistent with (2.225). Show also that results completely analogous to (2.251) through (2.243) hold for any choice of the unit vector $\boldsymbol{n}$ and are consistent with (2.225).

The work of Exercise 2.10, which is what we have been using, involved the formation and solution of a differential equation. Another way to proceed, which is the same in essence, is to evaluate (2.229) and then (2.228) for small θ, and then build up to large values of θ by repeatedly using the group property (2.220). Let us explore this approach, which will turn out to be simpler.

Suppose, in view of (2.229), we work with a w and a $w^\dagger$ of the forms

$$w = \exp(\epsilon \boldsymbol{n} \cdot \hat{\boldsymbol{L}}) = \exp[\epsilon(-i/2)\boldsymbol{n} \cdot \boldsymbol{\sigma}] = I + \epsilon(-i/2)\boldsymbol{n} \cdot \boldsymbol{\sigma} + O(\epsilon^2), \tag{8.2.244}$$

$$w^\dagger = I + \epsilon(+i/2)\boldsymbol{n} \cdot \boldsymbol{\sigma} + O(\epsilon^2). \tag{8.2.245}$$

Show that employing this w and $w^\dagger$ pair in (2.228) gives the result

$$\begin{aligned}
\Lambda^{\mu\nu}(w) &= (1/2)\,\mathrm{tr}(\sigma^\mu w \sigma^\nu w^\dagger) \\
&= (1/2)\,\mathrm{tr}[\sigma^\mu(I + \epsilon(-i/2)\boldsymbol{n} \cdot \boldsymbol{\sigma})\sigma^\nu(I + \epsilon(+i/2)\boldsymbol{n} \cdot \boldsymbol{\sigma})] + O(\epsilon^2) \\
&= (1/2)\,\mathrm{tr}\{\sigma^\mu\sigma^\nu + \epsilon(-i/2)\sigma^\mu[(\boldsymbol{n} \cdot \boldsymbol{\sigma})\sigma^\nu - \sigma^\nu(\boldsymbol{n} \cdot \boldsymbol{\sigma})]\} + O(\epsilon^2) \\
&= \delta^{\mu\nu} + \epsilon(-i/4)\,\mathrm{tr}\{\sigma^\mu[(\boldsymbol{n} \cdot \boldsymbol{\sigma})\sigma^\nu - \sigma^\nu(\boldsymbol{n} \cdot \boldsymbol{\sigma})]\} + O(\epsilon^2).
\end{aligned} \tag{8.2.246}$$

Verify that

$$(\boldsymbol{n} \cdot \boldsymbol{\sigma})\sigma^\nu - \sigma^\nu(\boldsymbol{n} \cdot \boldsymbol{\sigma}) = \sum_{\xi=1}^{3} n_\xi\{\sigma^\xi, \sigma^\nu\}. \tag{8.2.247}$$

Make the definition

$$n_4 = 0 \tag{8.2.248}$$

so that (2.247) can also be written in the form

$$(\boldsymbol{n} \cdot \boldsymbol{\sigma})\sigma^\nu - \sigma^\nu(\boldsymbol{n} \cdot \boldsymbol{\sigma}) = \sum_{\xi=1}^{4} n_\xi\{\sigma^\xi, \sigma^\nu\}. \tag{8.2.249}$$

Pause to Develop Needed Mathematical Results

At this point we pause in our present calculations to define and develop the properties of a remarkable tensor that will be of subsequent use. Let $U^{\alpha\beta\gamma}$ be the tensor defined in terms of the Pauli matrices σ^1 through σ^4 by the rule

$$U^{\alpha\beta\gamma} = \mathrm{tr}[\sigma^\alpha(\sigma^\beta\sigma^\gamma - \sigma^\gamma\sigma^\beta)]. \tag{8.2.250}$$

Evidently U has the symmetry property

$$U^{\alpha\gamma\beta} = -U^{\alpha\beta\gamma}. \tag{8.2.251}$$

That is, U is antisymmetric under the interchange of its last two indices. Next verify, because of the trace relation (3.6.130), that

$$\begin{aligned} U^{\alpha\beta\gamma} &= \mathrm{tr}[\sigma^\alpha(\sigma^\beta\sigma^\gamma - \sigma^\gamma\sigma^\beta)] = \mathrm{tr}[\sigma^\alpha\sigma^\beta\sigma^\gamma - \sigma^\alpha\sigma^\gamma\sigma^\beta] \\ &= \mathrm{tr}[\sigma^\beta\sigma^\gamma\sigma^\alpha - \sigma^\gamma\sigma^\beta\sigma^\alpha] = \mathrm{tr}[\sigma^\beta\sigma^\gamma\sigma^\alpha - \sigma^\beta\sigma^\alpha\sigma^\gamma] \\ &= \mathrm{tr}[\sigma^\beta(\sigma^\gamma\sigma^\alpha - \sigma^\alpha\sigma^\gamma)] = -U^{\beta\alpha\gamma}. \end{aligned} \tag{8.2.252}$$

Thus, U is also antisymmetric under the interchange of its first two indices. Show that it follows from (2.251) and (2.252) that U is *completely* antisymmetric: That is, U changes sign under the interchange of any pair of indices.

To continue, define an antisymmetric tensor A with Pauli matrix entries by the rule

$$A^{\mu\nu} = \{\sigma^\mu, \sigma^\nu\}. \tag{8.2.253}$$

Show that

$$A = 2i \begin{pmatrix} 0 & \sigma^3 & -\sigma^2 & 0 \\ -\sigma^3 & 0 & \sigma^1 & 0 \\ \sigma^2 & -\sigma^1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{8.2.254}$$

Look at the matrices L^α for $\alpha = 1,2,3$ defined by (3.180) through (3.182). Also define a matrix L^4 by the rule

$$L^4 = \mathbf{0} \tag{8.2.255}$$

where $\mathbf{0}$ is the 4×4 matrix with all entries having value zero. Show that

$$A = -2i \sum_{\alpha=1}^{4} L^\alpha \sigma^\alpha. \tag{8.2.256}$$

Consequently there is the associated component relation

$$\{\sigma^\mu, \sigma^\nu\} = A^{\mu\nu} = -2i \sum_{\alpha=1}^{4} (L^\alpha)^{\mu\nu} \sigma^\alpha \tag{8.2.257}$$

from which it follows that

$$\mathrm{tr}[\sigma^\beta(\sigma^\mu\sigma^\nu - \sigma^\nu\sigma^\mu)] = \mathrm{tr}[\sigma^\beta\{\sigma^\mu, \sigma^\nu\}] = -2i \sum_{\alpha=1}^{4} (L^\alpha)^{\mu\nu}\, \mathrm{tr}(\sigma^\beta\sigma^\alpha) = -4i(L^\beta)^{\mu\nu}. \tag{8.2.258}$$

Finally, show that comparison of (2.249) and (2.257) gives the result

$$A^{\beta\mu\nu} = -4i(L^\beta)^{\mu\nu}. \tag{8.2.259}$$

With these definitions before us, show that

$$(\boldsymbol{n}\cdot\boldsymbol{\sigma})\sigma^\nu - \sigma^\nu(\boldsymbol{n}\cdot\boldsymbol{\sigma}) = \sum_{\xi=1}^{4} n_\xi\{\sigma^\xi,\sigma^\nu\} = \sum_{\xi=1}^{4} n_\xi A^{\xi\nu} = -2i\sum_{\xi=1}^{4}\sum_{\alpha=1}^{4} n_\xi (L^\alpha)^{\xi\nu}\sigma^\alpha. \quad (8.2.260)$$

Continue on to show that

$$\mathrm{tr}\{\sigma^\mu[(\boldsymbol{n}\cdot\boldsymbol{\sigma})\sigma^\nu - \sigma^\nu(\boldsymbol{n}\cdot\boldsymbol{\sigma})]\} = -2i\sum_{\xi=1}^{4}\sum_{\alpha=1}^{4} n_\xi (L^\alpha)^{\xi\nu}\,\mathrm{tr}(\sigma^\mu\sigma^\alpha) = -4i\sum_{\xi=1}^{4} n_\xi (L^\mu)^{\xi\nu}. \quad (8.2.261)$$

But, from the relation (2.259) and the symmetry properties of A, it follows that

$$(L^\mu)^{\xi\nu} = -(L^\xi)^{\mu\nu}. \quad (8.2.262)$$

Show, therefore, that (2.261) can be rewritten in the form

$$\mathrm{tr}\{\sigma^\mu[(\boldsymbol{n}\cdot\boldsymbol{\sigma})\sigma^\nu - \sigma^\nu(\boldsymbol{n}\cdot\boldsymbol{\sigma})]\} = -4i\sum_{\xi=1}^{4} n_\xi (L^\mu)^{\xi\nu} = 4i\sum_{\xi=1}^{4} n_\xi (L^\xi)^{\mu\nu} = 4i(\boldsymbol{n}\cdot\boldsymbol{L})^{\mu\nu}. \quad (8.2.263)$$

Resume and Complete Evaluation of Second Factor

Verify, as a result of these intervening calculations, that combining (2.246) and (2.263) yields the pleasingly simple result

$$\Lambda^{\mu\nu}(w) = \delta^{\mu\nu} + \epsilon(\boldsymbol{n}\cdot\boldsymbol{L})^{\mu\nu} + O(\epsilon^2) \quad (8.2.264)$$

or, in matrix form,

$$\Lambda(w) = I + \epsilon\boldsymbol{n}\cdot\boldsymbol{L} + O(\epsilon^2). \quad (8.2.265)$$

Show, using (2.244) and (2.265), that there is the relation

$$\Lambda[\exp(\epsilon\boldsymbol{n}\cdot\hat{\boldsymbol{L}})] = \exp(\epsilon\boldsymbol{n}\cdot\boldsymbol{L})] + O(\epsilon^2). \quad (8.2.266)$$

As promised, we now intend to use (2.266) and the group property (2.219) to work out results for finite values of θ. Let ℓ be a positive integer and set

$$\epsilon = \theta/\ell. \quad (8.2.267)$$

Show that

$$\begin{aligned}\Lambda[\exp(\theta\boldsymbol{n}\cdot\hat{\boldsymbol{L}})] &= \Lambda[\exp(\ell\epsilon\boldsymbol{n}\cdot\hat{\boldsymbol{L}})] = \{\Lambda[\exp(\epsilon\boldsymbol{n}\cdot\hat{\boldsymbol{L}})]\}^\ell \\ &= [\exp(\epsilon\boldsymbol{n}\cdot\boldsymbol{L}) + O(\epsilon^2)]^\ell = \{\exp(\epsilon\boldsymbol{n}\cdot\boldsymbol{L}) + O[(\theta/\ell)^2]\}^\ell \\ &= \exp(\ell\epsilon\boldsymbol{n}\cdot\boldsymbol{L}) + \ell O[(\theta/\ell)^2] = \exp(\theta\boldsymbol{n}\cdot\boldsymbol{L}) + O(\theta^2/\ell). \quad (8.2.268)\end{aligned}$$

Verify that taking the limit $\ell \to \infty$ in (2.268) yields the expected result

$$\Lambda[\exp(\theta\boldsymbol{n}\cdot\hat{\boldsymbol{L}})] = \exp(\theta\boldsymbol{n}\cdot\boldsymbol{L}). \quad (8.2.269)$$

Begin Evaluation of First Factor

What remains is to work out results for the first factor on the right side of (2.226). For it you will need to work out $\Lambda(u)$ with

$$u = \exp(\lambda \boldsymbol{m} \cdot \hat{\boldsymbol{N}}) = \exp[\lambda(1/2)\boldsymbol{m} \cdot \boldsymbol{\sigma}]. \tag{8.2.270}$$

See (7.3.235) through (7.3.237). Verify that u is the exponential of a Hermitian matrix and is therefore Hermitian and positive definite.[5] See Exercise 3.7.44. According to (2.208) what we now need to compute are the entries

$$\Lambda^{\mu\nu}(u) = (1/2)\,\mathrm{tr}(\sigma^{\mu} u \sigma^{\nu} u^{\dagger}) = (1/2)\,\mathrm{tr}(\sigma^{\mu} u \sigma^{\nu} u). \tag{8.2.271}$$

To proceed, we will adopt a strategy analogous to what we employed for the second factor. We will evaluate (2.266) for small λ and then build up to large values of λ by repeatedly using the group property (2.219).

Suppose, in view of (2.242), we work with a u of the form

$$u = \exp(\epsilon \boldsymbol{m} \cdot \hat{\boldsymbol{N}}) = \exp[\epsilon(1/2)\boldsymbol{m} \cdot \boldsymbol{\sigma}] = I + \epsilon(1/2)\boldsymbol{m} \cdot \boldsymbol{\sigma} + O(\epsilon^2). \tag{8.2.272}$$

Show that employing this u in (2.243) gives the result

$$\begin{aligned}\Lambda^{\mu\nu}(u) &= (1/2)\,\mathrm{tr}(\sigma^{\mu} u \sigma^{\nu} u)\\ &= (1/2)\,\mathrm{tr}[\sigma^{\mu}(I + \epsilon(1/2)\boldsymbol{m} \cdot \boldsymbol{\sigma})\sigma^{\nu}(I + \epsilon(1/2)\boldsymbol{m} \cdot \boldsymbol{\sigma})] + O(\epsilon^2)\\ &= (1/2)\,\mathrm{tr}\{\sigma^{\mu}\sigma^{\nu} + \epsilon(1/2)\sigma^{\mu}[(\boldsymbol{m} \cdot \boldsymbol{\sigma})\sigma^{\nu} + \sigma^{\nu}(\boldsymbol{m} \cdot \boldsymbol{\sigma})]\} + O(\epsilon^2)\\ &= \delta^{\mu\nu} + \epsilon(1/4)\,\mathrm{tr}\{\sigma^{\mu}[(\boldsymbol{m} \cdot \boldsymbol{\sigma})\sigma^{\nu} + \sigma^{\nu}(\boldsymbol{m} \cdot \boldsymbol{\sigma})]\} + O(\epsilon^2).\end{aligned} \tag{8.2.273}$$

Verify that

$$(\boldsymbol{m} \cdot \boldsymbol{\sigma})\sigma^{\nu} + \sigma^{\nu}(\boldsymbol{m} \cdot \boldsymbol{\sigma}) = \sum_{\xi=1}^{3} m_{\xi}\{\sigma^{\xi}, \sigma^{\nu}\}_{+}. \tag{8.2.274}$$

Make the definition

$$m_4 = 0 \tag{8.2.275}$$

so that (2.246) can also be written in the form

$$(\boldsymbol{m} \cdot \boldsymbol{\sigma})\sigma^{\nu} + \sigma^{\nu}(\boldsymbol{m} \cdot \boldsymbol{\sigma}) = \sum_{\xi=1}^{4} m_{\xi}\{\sigma^{\xi}, \sigma^{\nu}\}_{+}. \tag{8.2.276}$$

[5] Note that, unlike in the context of the second factor where we encounter both w and $-w$, in the context of the first factor we will not encounter both u and $-u$ because if u is positive definite, then $-u$ is not, and in the context of the first factor we only encounter the positive definite case.

Again Pause to Develop Needed Mathematical Results

At this point we pause in our present calculations to define and develop the properties of another remarkable tensor that will be of subsequent use. Let $V^{\alpha\beta\gamma}$ be the tensor defined in terms of the Pauli matrices σ^1 through σ^4 by the rule

$$V^{\alpha\beta\gamma} = \mathrm{tr}[\sigma^\alpha(\sigma^\beta\sigma^\gamma + \sigma^\gamma\sigma^\beta)]. \tag{8.2.277}$$

Evidently V has the symmetry property

$$V^{\alpha\gamma\beta} = V^{\alpha\beta\gamma}. \tag{8.2.278}$$

That is, V is symmetric under the interchange of its last two indices. Next verify, because of the trace relation (3.6.130), that

$$\begin{aligned} V^{\alpha\beta\gamma} &= \mathrm{tr}[\sigma^\alpha(\sigma^\beta\sigma^\gamma + \sigma^\gamma\sigma^\beta)] = \mathrm{tr}[\sigma^\alpha\sigma^\beta\sigma^\gamma + \sigma^\alpha\sigma^\gamma\sigma^\beta] \\ &= \mathrm{tr}[\sigma^\beta\sigma^\gamma\sigma^\alpha + \sigma^\gamma\sigma^\beta\sigma^\alpha] = \mathrm{tr}[\sigma^\beta\sigma^\gamma\sigma^\alpha + \sigma^\beta\sigma^\alpha\sigma^\gamma] \\ &= \mathrm{tr}[\sigma^\beta(\sigma^\gamma\sigma^\alpha + \sigma^\alpha\sigma^\gamma)] = V^{\beta\alpha\gamma}. \end{aligned} \tag{8.2.279}$$

Thus, V is also symmetric under the interchange of its first two indices. Show that it follows from (2.250) and (2.251) that V is *completely* symmetric: That is, V is unchanged under any permutation of its indices.

To continue, define a symmetric tensor S with Pauli matrix entries by the rule

$$S^{\mu\nu} = \{\sigma^\mu, \sigma^\nu\}_+. \tag{8.2.280}$$

Show that

$$S = 2\begin{pmatrix} \sigma^4 & 0 & 0 & \sigma^1 \\ 0 & \sigma^4 & 0 & \sigma^2 \\ 0 & 0 & \sigma^4 & \sigma^3 \\ \sigma^1 & \sigma^2 & \sigma^3 & \sigma^4 \end{pmatrix}. \tag{8.2.281}$$

Look at the matrices N^α for $\alpha = 1, 2, 3$ defined by (3.180) through (3.182). Also define a matrix N^4 by the rule

$$N^4 = I \tag{8.2.282}$$

where I is the 4×4 identity matrix. Show that

$$S = 2\sum_{\alpha=1}^{4} N^\alpha\sigma^\alpha. \tag{8.2.283}$$

Consequently there is the associated component relation

$$\{\sigma^\mu, \sigma^\nu\}_+ = S^{\mu\nu} = 2\sum_{\alpha=1}^{4}(N^\alpha)^{\mu\nu}\sigma^\alpha \tag{8.2.284}$$

from which it follows that

$$\mathrm{tr}[\sigma^\beta(\sigma^\mu\sigma^\nu + \sigma^\nu\sigma^\mu)] = \mathrm{tr}[\sigma^\beta\{\sigma^\mu, \sigma^\nu\}_+] = 2\sum_{\alpha=1}^{4}(N^\alpha)^{\mu\nu}\,\mathrm{tr}(\sigma^\beta\sigma^\alpha) = 4(N^\beta)^{\mu\nu}. \tag{8.2.285}$$

Finally, show that comparison of (2.249) and (2.257) gives the result

$$V^{\beta\mu\nu} = 4(N^{\beta})^{\mu\nu}. \tag{8.2.286}$$

With these definitions before us, show that

$$(\boldsymbol{m}\cdot\boldsymbol{\sigma})\sigma^{\nu} + \sigma^{\nu}(\boldsymbol{m}\cdot\boldsymbol{\sigma}) = \sum_{\xi=1}^{4} m_{\xi}\{\sigma^{\xi},\sigma^{\nu}\}_{+} = \sum_{\xi=1}^{4} m_{\xi}S^{\xi\nu} = 2\sum_{\xi=1}^{4}\sum_{\alpha=1}^{4} m_{\xi}(N^{\alpha})^{\xi\nu}\sigma^{\alpha}. \tag{8.2.287}$$

Continue on to show that

$$\mathrm{tr}\{\sigma^{\mu}[(\boldsymbol{m}\cdot\boldsymbol{\sigma})\sigma^{\nu} + \sigma^{\nu}(\boldsymbol{m}\cdot\boldsymbol{\sigma})]\} = 2\sum_{\xi=1}^{4}\sum_{\alpha=1}^{4} m_{\xi}(N^{\alpha})^{\xi\nu}\,\mathrm{tr}[\sigma^{\mu}\sigma^{\alpha}] = 4\sum_{\xi=1}^{4} m_{\xi}(N^{\mu})^{\xi\nu}. \tag{8.2.288}$$

But, from the relation (2.258) and the symmetry properties of V, it follows that

$$(N^{\mu})^{\xi\nu} = (N^{\xi})^{\mu\nu}. \tag{8.2.289}$$

Show, therefore, that (2.260) can be rewritten in the form

$$\mathrm{tr}\{\sigma^{\mu}[(\boldsymbol{m}\cdot\boldsymbol{\sigma})\sigma^{\nu}+\sigma^{\nu}(\boldsymbol{m}\cdot\boldsymbol{\sigma})]\} = 4\sum_{\xi=1}^{4} m_{\xi}(N^{\mu})^{\xi\nu} = 4\sum_{\xi=1}^{4} m_{\xi}(N^{\xi})^{\mu\nu} = 4(\boldsymbol{m}\cdot\boldsymbol{N})^{\mu\nu}. \tag{8.2.290}$$

Resume and Complete Evaluation of First Factor

Show, as a result of these intervening calculations, that combining (2.269) and (2.286) yields the pleasingly simple result

$$\Lambda^{\mu\nu}(u) = \delta^{\mu\nu} + \epsilon(\boldsymbol{m}\cdot\boldsymbol{N})^{\mu\nu} + O(\epsilon^2) \tag{8.2.291}$$

or, in matrix form,

$$\Lambda(u) = I + \epsilon\boldsymbol{m}\cdot\boldsymbol{N} + O(\epsilon^2). \tag{8.2.292}$$

[We remark that had we replaced the matrices in (7.3.235) through (7.3.327) by their negatives, which would not have affected the commutation rules (7.328) through (7.3.240), the + signs in (2.291) and (2.292) would have been replaced by − signs. This change would lead to unpleasant consequences in what follows.]

As promised, we now intend to use (2.292) and the group property (2.219) to work out results for finite values of λ. Review the steps (2.266) through (2.269) that led from (2.265) to (2.269). Demonstrate that analogous steps lead from (2.292) to the expected and desired relation

$$\Lambda[\exp(\lambda\boldsymbol{m}\cdot\hat{\boldsymbol{N}})] = \exp(\lambda\boldsymbol{m}\cdot\boldsymbol{N}). \tag{8.2.293}$$

What would have been the resulting relation had the + sign in (2.292) been a − sign?

Summary of Results

We began this exercise with the knowledge that the $SL(2,\mathbb{C})$ and Lorentz groups have the same Lie algebras and analogous polar decompositions. We therefore expect they are closely related. In this exercise we found that (2.208) provides a map that sends elements of $SL(2,\mathbb{C})$ into elements of the Lorentz group, and (2.219) showed that this map is a homomorphism. Subsequently application of this homomorphism to elements of $SL(2,\mathbb{C})$ written in polar form produced the factorization (2.226). The results for each factor were then found to be given by (2.269) and (2.293). Verify that combining (2.226), (2.269), and (2.293) produces the relation

$$\begin{aligned}\Lambda[\exp(\lambda\boldsymbol{m}\cdot\hat{\boldsymbol{N}})\exp(\theta\boldsymbol{n}\cdot\hat{\boldsymbol{L}})] &= \Lambda[\exp(\lambda\boldsymbol{m}\cdot\hat{\boldsymbol{N}})]\Lambda[\exp(\theta\boldsymbol{n}\cdot\hat{\boldsymbol{L}})] \\ &= \exp(\lambda\boldsymbol{m}\cdot\boldsymbol{N})\exp(\theta\boldsymbol{n}\cdot\boldsymbol{L}). \qquad (8.2.294)\end{aligned}$$

This relation shows that the map (2.208) has the property that every element in the Lorentz group has a preimage in $SL(2,\mathbb{C})$. From (2.224) it follows that every element of the Lorentz group has (at least) two distinct preimages in $SL(2,\mathbb{C})$. Therefore the map (2.208) is not an isomorphism. To be more precise, examination of (2.293) shows that the mapping between the first factors of $SL(2,\mathbb{C})$ and of the Lorentz group is one to one. And examination of the discussion associated with (2.232) shows that the relation between the second factors of $SL(2,\mathbb{C})$ and of the Lorentz group is two to one in complete analogy to the relation between $SU(2)$ and $SO(3,\mathbb{R})$. We conclude that the map between $SL(2,\mathbb{C})$. and the Lorentz group provided by (2.208) and (2.294) is two to one.

What can be said about the topologies of the two groups? Since the topology of $SL(2,\mathbb{C})$ is $E^3\times S^3$, and both factors are simply connected, $SL(2,\mathbb{C})$ can be shown to be simply connected. From (7.3.186) we see that the topology of the Lorentz group is $E^3\times SO(3,\mathbb{R})$. Since E^3 is simply connected and $SO(3,\mathbb{R})$ is doubly connected, the Lorentz group can be shown to be doubly connected. All these topological statements are consistent with the nature of the map between $SL(2,\mathbb{C})$ and the Lorentz group provided by (2.208) and (2.294). It follows that $SL(2,\mathbb{C})$ is the covering group of the Lorentz group.

8.2.15. Let $\boldsymbol{\phi}$ and $\boldsymbol{k}$ be two real three-component vectors. Use them to parameterize the $s\ell(2,\mathbb{C})$ element $\hat{S}$ defined by

$$\hat{S} = \boldsymbol{\phi}\cdot\hat{\boldsymbol{L}} + \boldsymbol{k}\cdot\hat{\boldsymbol{N}}. \qquad (8.2.295)$$

In turn, let v be the $SL(2,\mathbb{C})$ element defined by

$$v = \exp(\hat{S}). \qquad (8.2.296)$$

Prove that for the map (2.208) there is the relation

$$\Lambda(v) = \Lambda[\exp(\hat{S})] = \exp(\boldsymbol{\phi}\cdot\boldsymbol{L} + \boldsymbol{k}\cdot\boldsymbol{N}). \qquad (8.2.297)$$

Suggestion: First show that for small ϵ there is the result

$$\Lambda[\exp(\epsilon\hat{S})] = \exp[\epsilon(\boldsymbol{\phi}\cdot\boldsymbol{L} + \boldsymbol{k}\cdot\boldsymbol{N})] + O(\epsilon^2). \qquad (8.2.298)$$

This small ϵ result can be obtained by direct evaluation of (2.208) or, more easily, by use of (2.269), (2.293), and the BCH formula. Then use (2.298) and the homomorphism relation (2.219) to work out results for any finite value of ϵ including $\epsilon = 1$.

8.2.16. When can and when cannot an element in $SL(2,\mathbb{C})$ be written in single exponential form? And what can be said about the related question for the Lorentz group? Your task for this exercise is to answer these questions.

Begin with the case of $SL(2,\mathbb{C})$. Recall that any 2×2 matrix v can be diagonalized if its eigenvalues are distinct. That is, if the eigenvalues of v are distinct, it can be written in the form

$$v = ada^{-1} \tag{8.2.299}$$

where a is a nonsingular matrix, d is the diagonal matrix

$$d = \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix}, \tag{8.2.300}$$

and λ_1, λ_2 are its eigenvalues. Verify that in this case

$$\det(v) = \det(d) = \lambda_1\lambda_2. \tag{8.2.301}$$

Moreover,

$$\lambda_1\lambda_2 = 1 \tag{8.2.302}$$

if v is an element of $SL(2,\mathbb{C})$. Verify therefore that, in the $SL(2,\mathbb{C})$ and distinct eigenvalue case, d can be written in the form

$$d = \begin{pmatrix} \lambda & 0 \\ 0 & \lambda^{-1} \end{pmatrix} = \exp(\alpha\sigma^3) \tag{8.2.303}$$

where

$$\alpha = \log(\lambda). \tag{8.2.304}$$

Consequently, verify that any element of $SL(2,\mathbb{C})$ with distinct eigenvalues can be written in the forms

$$v = ada^{-1} = a[\exp(\alpha\sigma^3)]a^{-1} = \exp(\alpha a\sigma^3 a^{-1}). \tag{8.2.305}$$

Verify that the matrix $a\sigma^3a^{-1}$ is traceless, and therefore there is a three-component (possibly complex) vector $\boldsymbol{\beta}$ such that

$$\alpha a\sigma^3 a^{-1} = \boldsymbol{\beta}\cdot\boldsymbol{\sigma}. \tag{8.2.306}$$

Show that the net result of these deliberations is the relation

$$v = \exp(\boldsymbol{\beta}\cdot\boldsymbol{\sigma}), \tag{8.2.307}$$

which demonstrates that any element of $SL(2,\mathbb{C})$ with distinct eigenvalues can be written in single exponential form.

There remain the cases in which the eigenvalues of v are not distinct, in which cases because of (2.302) there are the eigenvalue possibilities $1, 1$ and $-1, -1$. Suppose that in these non distinct cases that v can nevertheless be diagonalized. Show that then there are the two possibilities

$$v = \sigma^4 = \exp(\mathbf{0}) \tag{8.2.308}$$

and

$$v = -\sigma^4 = \exp(i\pi\sigma^3). \tag{8.2.309}$$

Here, as before, $\mathbf{0}$ is the matrix with all zero entries. Evidently in both these cases v has again been written in single exponential form.

The last possibility for these non distinct cases is that v cannot be diagonalized. Verify that for this possibility there are only the cases

$$v = aj_{\pm}a^{-1} \tag{8.2.310}$$

where $j_{\pm}$ are the two *Jordan* normal form elements

$$j_{+} = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \tag{8.2.311}$$

and

$$j_{-} = \begin{pmatrix} -1 & 1 \\ 0 & -1 \end{pmatrix}. \tag{8.2.312}$$

Consider the case with eigenvalues $1, 1$ and the Jordan normal form j_{+} given by (2.311). Show that in this case

$$j_{+} = \exp[(1/2)(\sigma^1 + i\sigma^2)] \tag{8.2.313}$$

from which it follows that

$$v = \exp[(1/2)a(\sigma^1 + i\sigma^2)a^{-1}]. \tag{8.2.314}$$

Verify that the exponent appearing in (2.314) is in $s\ell(2, \mathbb{C})$. You have demonstrated that in the $1, 1$ eigenvalue case every such v in $SL(2, \mathbb{C})$ can be written in single exponential form with the exponent being an element in $s\ell(2, \mathbb{C})$.

The final remaining case is that with eigenvalues $-1, -1$ and the Jordan normal form j_{-} given by (2.312). From the work of Exercise 3.7.12, which you should review, we know that j_{-} cannot be written in single exponential form. Show it follows that all $SL(2, \mathbb{C})$ elements that have j_{-} as their Jordan normal form cannot be written in single exponential form.

The case of $SL(2, \mathbb{C})$ has been dispatched: All elements in $SL(2, \mathbb{C})$ can be written in single exponential form except those having j_{-} as their Jordan normal form.

We now turn to the case of the Lorentz group. According to Exercise 2.15 above, all the Lorentz group elements associated with the $SL(2, \mathbb{C})$ elements that can be written in single exponential form can also be written in single exponential form. What about the Lorentz group elements associated with the $SL(2, \mathbb{C})$ elements whose Jordan normal form is j_{-}? Let v_{-} be any such $SL(2, \mathbb{C})$ element. What we wish to determine is the nature of $\Lambda(v_{-})$. Show that if a v in $SL(2, \mathbb{C})$ cannot be written in single exponential form, then $-v$ can. In particular, show that $-j_{-}$ has Jordan normal form j_{+}. (Again see the work of Exercise 3.7.12.) Verify it follows that $-v_{-}$ can be written in single exponential form, and therefore $\Lambda(-v_{-})$ can also be written in single exponential form. But from (2.225) we know that

$$\Lambda(v_{-}) = \Lambda(-v_{-}). \tag{8.2.315}$$

Therefore $\Lambda(v_{-})$, which is the same as $\Lambda(-v_{-})$, can be written in single exponential form. Conclude that *all* Lorentz group elements can be written in single exponential form!

8.2.17. Review Exercise 7.3.30. It showed that the use of $s\ell(2,\mathbb{C})$ provides the $\Gamma(1/2,0)$ and $\Gamma(0,1/2)$ representations of the Lorentz group Lie algebra. Review Exercise 7.3.34 that constructed an isomorphism between $n \times n$ possibly complex matrices and $2n \times 2n$ real matrices. The purpose of this exercise and the next is to describe how the results of Exercises 7.3.30 and 7.3.34 may be used to characterize/determine the effect of Lorentz transformations on what we will call Dirac 4-*spinors*.

Recall the $SL(2,\mathbb{C})$ group elements $\hat{\Lambda}$ given by (7.3.246). They are 2×2 possibly complex matrices. According to Exercise 7.3.30 they carry the representation $\Gamma(0,1/2)$ of the Lorentz group. Make the Ansatz

$$k = \hat{\Lambda} \tag{8.2.316}$$

and use (7.3.375) to define associated *real* 4×4 matrices. For example, suppose

$$\hat{\Lambda} = \exp(\theta \hat{L}^3). \tag{8.2.317}$$

Verify that in this case

$$\hat{\Lambda} = \exp(\theta \hat{L}^3) = \begin{pmatrix} \exp(-i\theta/2) & 0 \\ 0 & \exp(i\theta/2) \end{pmatrix} = \tag{8.2.318}$$

$$\begin{pmatrix} \cos(\theta/2) & 0 \\ 0 & \cos(\theta/2) \end{pmatrix} + i \begin{pmatrix} -\sin(\theta/2) & 0 \\ 0 & \sin(\theta/2) \end{pmatrix}, \tag{8.2.319}$$

and

$$K(k) = K(\hat{\Lambda}) = K[\exp(\theta \hat{L}^3)] = \begin{pmatrix} \cos(\theta/2) & 0 & \sin(\theta/2) & 0 \\ 0 & \cos(\theta/2) & 0 & -\sin(\theta/2) \\ -\sin(\theta/2) & 0 & \cos(\theta/2) & 0 \\ 0 & \sin(\theta/2) & 0 & \cos(\theta/2) \end{pmatrix}. \tag{8.2.320}$$

Verify that when $\theta = 2\pi$ there are the results

$$\hat{\Lambda} = \exp(2\pi \hat{L}^3) = -I^{[2]} \tag{8.2.321}$$

and

$$K(\hat{\Lambda}) = K[\exp(2\pi \hat{L}^3)] = -I^{[4]}. \tag{8.2.322}$$

Since the $\hat{\Lambda}$ are 2×2 matrices, they act on two-dimensional objects/arrays. Since the $K(\hat{\Lambda})$ are 4×4 matrices, they act on four-dimensional objects/arrays. But the 2×2 and 4×4 matrix/group elements given by (2.321) and (2.322) and corresponding to the Lorentz transformation consisting of a $\theta = 2\pi$ rotation about the z axis are *not* identity matrices. It follows that the objects/arrays on which they act are *not* vectors.[6] Rather, they are 2-*spinors* and 4-*spinors*, respectively.[7] Also note that, by the constructions (7.3.246) and (7.3.375), all elements $K(\hat{\Lambda})$ are continuously connected to the identity matrix $I^{[4]}$. As further evidence

[6] By their transformation properties ye shall know them.

[7] Sometimes what we have called 4-spinors are called *bispinors*.

that the four-component arrays that we have called 4-spinors are not vectors, observe that, according to (7.3.167), $-I^{[4]}$ is not a Lorentz transformation in the identity component of the Lorentz group.

Let b be any of the possibly complex 2×2 $s\ell(2, \mathbb{C})$ basis elements (7.3.236) through (7.3.241) and consider the associated *real* 4×4 matrices $K(b)$. What representation of the Lorentz group Lie algebra is provided by the matrices $K(\hat{L}^j)$ and $K(\hat{N}^j)$? Verify, using (7.3.383), that

$$WK(b)W^{-1} = \begin{pmatrix} b & 0 \\ 0 & \bar{b} \end{pmatrix}. \tag{8.2.323}$$

We know from the work of Exercise 7.3.30 that the matrices b provide the $\Gamma(0, 1/2)$ representation of the Lorentz group Lie algebra. Momentarily we will demonstrate that the matrices $\bar{b}$ provide the $\Gamma(1/2, 0)$ representation of the Lorentz group Lie algebra. That is, for the case of $s\ell(2, \mathbb{C})$, complex conjugation is equivalent to the grave operation. It follows from (2.323) that the matrices $K(b)$ provide the direct sum

$$\Gamma(0, 1/2) \,\oplus\, \Gamma(1/2, 0) = \Gamma(0, 1/2) \,\oplus\, \bar{\Gamma}(0, 1/2) = \bar{\Gamma}(1/2, 0) \,\oplus\, \Gamma(1/2, 0) \tag{8.2.324}$$

representation of the Lorentz group Lie algebra.

Now work on the advertised demonstration: We already know that complex conjugation is the result of the breve operation and that this operation is a conjugacy operation. See (3.7.223). For present purposes what we need to show is that, in the case of $s\ell(2, \mathbb{C})$, the breve/bar operation and the grave operation are equivalent in the sense of (3.7.218). Verify that for the bar and grave operations there are the relations

$$(\bar{\hat{L}}^1, \bar{\hat{L}}^2, \bar{\hat{L}}^3, \bar{\hat{N}}^1, \bar{\hat{N}}^2, \bar{\hat{N}}^3) = (-\hat{L}^1, \hat{L}^2, -\hat{L}^3, \hat{N}^1, -\hat{N}^2, \hat{N}^3), \tag{8.2.325}$$

$$(\grave{\hat{L}}^1, \grave{\hat{L}}^2, \grave{\hat{L}}^3, \grave{\hat{N}}^1, \grave{\hat{N}}^2, \grave{\hat{N}}^3) = (\hat{L}^1, \hat{L}^2, \hat{L}^3, -\hat{N}^1, -\hat{N}^2, -\hat{N}^3). \tag{8.2.326}$$

See (7.3.248) and (7.3.249). We will next show is that the contents of the right sides of (2.325) and (2.326) are related by a similarity transformation. Recall the relation (3.7.234) which involved the matrix

$$J_2 = i\sigma^2 = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}. \tag{8.2.327}$$

Using the anticommutation relations (5.7.41) verify that

$$J_2 \sigma^1 J_2^{-1} = -\sigma^1, \tag{8.2.328}$$

$$J_2 \sigma^2 J_2^{-1} = \sigma^2, \tag{8.2.329}$$

$$J_2 \sigma^3 J_2^{-1} = -\sigma^3. \tag{8.2.330}$$

Show it follows from the definitions (7.3.236) through (7.3.241) and the results (2.328) through (3.230) that there are the similarity relations

$$J_2(-\hat{L}^1, \hat{L}^2, -\hat{L}^3, \hat{N}^1, -\hat{N}^2, \hat{N}^3)J_2^{-1} = (\hat{L}^1, \hat{L}^2, \hat{L}^3, -\hat{N}^1, -\hat{N}^2, -\hat{N}^3). \tag{8.2.331}$$

Thus the right sides of (2.325) and (2.326) are related by a similarity transformation, and therefore the left sides of (2.325) and (2.326) are related by a similarity transformation.

There is a second way of verifying that the matrices $K(\hat{L}^j)$ and $K(\hat{N}^j)$ provide a representation of $s\ell(2,\mathbb{C})$ that is equivalent to the direct sum (2.324). It essentially amounts to the previous argument, but appears to be more direct. Verify, using (7.3.236) through (7.3.241), that there are the *six* explicit results

$$K(\hat{L}^1) = (1/2)K(-i\sigma^1) = (1/2)\begin{pmatrix} \mathbf{0} & \sigma^1 \\ -\sigma^1 & \mathbf{0} \end{pmatrix}, \tag{8.2.332}$$

$$K(\hat{L}^2) = (1/2)K(-i\sigma^2) = (1/2)\begin{pmatrix} -i\sigma^2 & \mathbf{0} \\ \mathbf{0} & -i\sigma^2 \end{pmatrix}, \tag{8.2.333}$$

$$K(\hat{L}^3) = (1/2)K(-i\sigma^3) = (1/2)\begin{pmatrix} \mathbf{0} & \sigma^3 \\ -\sigma^3 & \mathbf{0} \end{pmatrix}, \tag{8.2.334}$$

$$K(\hat{N}^1) = (1/2)K(\sigma^1) = (1/2)\begin{pmatrix} \sigma^1 & \mathbf{0} \\ \mathbf{0} & \sigma^1 \end{pmatrix}, \tag{8.2.335}$$

$$K(\hat{N}^2) = (1/2)K(\sigma^2) = (1/2)\begin{pmatrix} \mathbf{0} & i\sigma^2 \\ -i\sigma^2 & \mathbf{0} \end{pmatrix}, \tag{8.2.336}$$

$$K(\hat{N}^3) = (1/2)K(\sigma^3) = (1/2)\begin{pmatrix} \sigma^3 & \mathbf{0} \\ \mathbf{0} & \sigma^3 \end{pmatrix}. \tag{8.2.337}$$

Next let V be the matrix defined by the rule

$$V = (1/\sqrt{2})\begin{pmatrix} I^{[2]} & iI^{[2]} \\ i\sigma^2 & \sigma^2 \end{pmatrix}. \tag{8.2.338}$$

Note that V involves $i\sigma^2$, which is J_2 in disguise, just as (2.331) involves J_2. Show that V is unitary so that

$$V^{-1} = V^\dagger = (1/\sqrt{2})\begin{pmatrix} I^{[2]} & -i\sigma^2 \\ -iI^{[2]} & \sigma^2 \end{pmatrix}. \tag{8.2.339}$$

Finally, by executing the indicated matrix multiplications, verify the six similarity relation results

$$VK(\hat{L}^1)V^{-1} = (-i/2)\begin{pmatrix} \sigma^1 & \mathbf{0} \\ \mathbf{0} & \sigma^1 \end{pmatrix}, \tag{8.2.340}$$

$$VK(\hat{L}^2)V^{-1} = (-i/2)\begin{pmatrix} \sigma^2 & \mathbf{0} \\ \mathbf{0} & \sigma^2 \end{pmatrix}, \tag{8.2.341}$$

$$VK(\hat{L}^3)V^{-1} = (-i/2)\begin{pmatrix} \sigma^3 & \mathbf{0} \\ \mathbf{0} & \sigma^3 \end{pmatrix}, \tag{8.2.342}$$

$$VK(\hat{N}^1)V^{-1} = (1/2)\begin{pmatrix} \sigma^1 & \mathbf{0} \\ \mathbf{0} & -\sigma^1 \end{pmatrix}, \tag{8.2.343}$$

$$VK(\hat{N}^2)V^{-1} = (1/2)\begin{pmatrix} \sigma^2 & \mathbf{0} \\ \mathbf{0} & -\sigma^2 \end{pmatrix}, \tag{8.2.344}$$

$$VK(\hat{N}^3)V^{-1} = (1/2)\begin{pmatrix} \sigma^3 & \mathbf{0} \\ \mathbf{0} & -\sigma^3 \end{pmatrix}. \tag{8.2.345}$$

In summary, there are the results

$$VK(\hat{L}^j)V^{-1} = \begin{pmatrix} \hat{L}^j & \mathbf{0} \\ \mathbf{0} & \grave{\hat{L}}^j \end{pmatrix} = \begin{pmatrix} \hat{L}^j & \mathbf{0} \\ \mathbf{0} & \hat{L}^j \end{pmatrix}, \tag{8.2.346}$$

$$VK(\hat{N}^j)V^{-1} = \begin{pmatrix} \hat{N}^j & \mathbf{0} \\ \mathbf{0} & \grave{\hat{N}}^j \end{pmatrix} = \begin{pmatrix} \hat{N}^j & \mathbf{0} \\ \mathbf{0} & -\hat{N}^j \end{pmatrix}. \tag{8.2.347}$$

Evidently the matrices on the right sides of (2.340) through (2.347) are block diagonal. Moreover, the upper blocks carry the representation $\Gamma(0, 1/2)$ of $s\ell(2, \mathbb{C})$ and the lower blocks carry the representation $\Gamma(1/2, 0)$. See Exercise 7.3.30. Thus the full matrices carry the representation

$$\Gamma(0, 1/2) \oplus \Gamma(1/2, 0). \tag{8.2.348}$$

.

8.2.18. This exercise is a continuation of the previous exercise and is devoted to sketching the relation of the $s\ell(2, \mathbb{C})$ representation provided by the real 4×4 matrices $K(\hat{L}^j)$ and $K(\hat{N}^j)$, see (7.3.385), to some of the mathematical machinery associated with some forms of the *Dirac* (1902-1984) equation.

Background

Discussion of the Dirac equation often begins with with the introduction of four 4×4 *gamma* matrices, denoted as γ^μ with $\mu = 1 \cdot \cdot 4$, which are required to satisfy the *anticommutation* rules

$$\{\gamma^\mu, \gamma^\nu\}_+ = \gamma^\mu\gamma^\nu + \gamma^\nu\gamma^\mu = 2g^{\mu\nu}I^{[4]}. \tag{8.2.349}$$

The relations (2.349) are sometimes called the *Dirac algebra*.[8] For our purposes it is convenient to take the γ^μ to be the matrices

$$\gamma^1 = \begin{pmatrix} \mathbf{0} & i\sigma^3 \\ i\sigma^3 & \mathbf{0} \end{pmatrix} = i \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \\ 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & -0 \end{pmatrix}, \tag{8.2.350}$$

$$\gamma^2 = \begin{pmatrix} iI^{[2]} & \mathbf{0} \\ \mathbf{0} & -iI^{[2]} \end{pmatrix} = i \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}, \tag{8.2.351}$$

$$\gamma^3 = \begin{pmatrix} \mathbf{0} & -i\sigma^1 \\ -i\sigma^1 & \mathbf{0} \end{pmatrix} = i \begin{pmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & -1 & 0 \\ 0 & -1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}, \tag{8.2.352}$$

[8] Dirac algebra is a particular case of *Clifford* (1845-1879) algebra.

$$\gamma^4 = \begin{pmatrix} \mathbf{0} & -\sigma^2 \\ -\sigma^2 & \mathbf{0} \end{pmatrix} = i \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}. \tag{8.2.353}$$

Verify that the γ^μ do indeed satisfy the Dirac algebra (2.349). Note that they are all *purely imaginary.* Representations of the Dirac algebra that are purely imaginary are called *Majorana* (1906-1938) representations. Thus the Ansätze (2.350) through (2.353) provide a Majorana representation.[9]

Verify that for this Majorana representation there are the results

$$(\gamma^\mu)^\dagger = -\gamma^\mu \text{ for } \mu = 1, 2, 3 \tag{8.2.354}$$

and

$$(\gamma^4)^\dagger = \gamma^4. \tag{8.2.355}$$

Verify that, in view of (2.349), the results (2.354) and (2.355) are equivalent to the relations

$$(\gamma^\mu)^\dagger = \gamma^4\gamma^\mu\gamma^4 \text{ for } \mu = 1 \cdot\cdot 4. \tag{8.2.356}$$

Finally, verify that γ^4 can be written in the form

$$\gamma^4 = i \begin{pmatrix} \mathbf{0} & J_2 \\ J_2 & \mathbf{0} \end{pmatrix}. \tag{8.2.357}$$

Definition and some Properties of γ^5

It is useful to define a fifth 4×4 gamma matrix γ^5 in terms of the γ^μ by the rule

$$\gamma^5 = i\gamma^1\gamma^2\gamma^3\gamma^4. \tag{8.2.358}$$

Verify that it too is purely imaginary in a Majorana representation.[10] Show that, for the above Majorana representation given by (2.350) through (2.353), there is the result

$$\gamma^5 = i \begin{pmatrix} \mathbf{0} & -I^{[2]} \\ I^{[2]} & \mathbf{0} \end{pmatrix} = -iJ \tag{8.2.359}$$

where here J denotes the 4×4 version of (3.1.1),

$$J = \begin{pmatrix} \mathbf{0} & I^{[2]} \\ -I^{[2]} & \mathbf{0} \end{pmatrix}. \tag{8.2.360}$$

It follows that γ^5 is antisymmetric in our Majorana representation,

$$(\gamma^5)^T = -\gamma^5. \tag{8.2.361}$$

[9] There are several possible Majorana representations. As trivial examples of how one Majorana representation may be converted into another, the γ^μ or any subset of the γ^μ may be multiplied by -1. Also, the γ^μ for $\mu = 1 \cdot 3$ may be permuted among each other. See, in addition, Exercise 2.21.

[10] The notation γ^5 can be misleading. Whereas we will see that in some contexts the contravariant index ν in γ^ν for $\nu = 1 \cdot\cdot 4$ can be lowered using $g_{\mu\nu}$, there is in the Dirac machinery no analogous operation for γ^5. Thus, in the Dirac machinery, the 5 in γ^5 is simply a label and not a contravariant index.

The matrix γ^5 defined by (2.358) has some other properties that follow from the Dirac algebra relations (2.349) and therefore hold in in any representation of the γ^μ. Verify from (2.349) and (2.358) that

$$\{\gamma^\mu, \gamma^5\}_+ = 0, \tag{8.2.362}$$

$$\{\gamma^\mu\gamma^\nu, \gamma^5\} = 0, \tag{8.2.363}$$

and

$$(\gamma^5)^2 = I^{[4]}. \tag{8.2.364}$$

Definition of the $\hat{\sigma}^{\mu\nu}$ and their Relation to the $K(\hat{L}^j)$ and $K(\hat{N}^j)$

Also, for $\mu, \nu = 1 \cdot\cdot 4$, define matrices $\hat{\sigma}^{\mu\nu}$ by the *commutators*

$$\hat{\sigma}^{\mu\nu} = (1/2)\{\gamma^\mu, \gamma^\nu\} \Rightarrow \hat{\sigma}^{\mu\nu} = \gamma^\mu\gamma^\nu \text{ for } \mu \neq \nu. \tag{8.2.365}$$

[Here, in writing the second relation in (2.365), we have used the Dirac algebra.] Note that, because the γ^μ are purely imaginary in a Majorana representation, the $\hat{\sigma}^{\mu\nu}$ are purely real.[11] We will soon see that the $\hat{\sigma}^{\mu\nu}$ are related to the Lorentz group Lie generator matrices $K(\hat{L}^j)$ and $K(\hat{N}^j)$ and, since these K matrices are real, we would like the $\hat{\sigma}^{\mu\nu}$ to be real. That is the reason for our use of a Majorana representation for the γ^μ; and indeed it will transpire that we have chosen a particular Majorana representation to make things work out neatly.

Verify that there are the *six* results

$$\hat{\sigma}^{12} = \gamma^1\gamma^2 = \begin{pmatrix} \mathbf{0} & \sigma^3 \\ -\sigma^3 & \mathbf{0} \end{pmatrix}, \tag{8.2.366}$$

$$\hat{\sigma}^{23} = \gamma^2\gamma^3 = \begin{pmatrix} \mathbf{0} & \sigma^1 \\ -\sigma^1 & \mathbf{0} \end{pmatrix}, \tag{8.2.367}$$

$$\hat{\sigma}^{31} = \gamma^3\gamma^1 = \begin{pmatrix} -i\sigma^2 & \mathbf{0} \\ \mathbf{0} & -i\sigma^2 \end{pmatrix}, \tag{8.2.368}$$

$$\hat{\sigma}^{41} = \gamma^4\gamma^1 = \begin{pmatrix} \sigma^1 & \mathbf{0} \\ \mathbf{0} & \sigma^1 \end{pmatrix}, \tag{8.2.369}$$

$$\hat{\sigma}^{42} = \gamma^4\gamma^2 = \begin{pmatrix} \mathbf{0} & i\sigma^2 \\ -i\sigma^2 & \mathbf{0} \end{pmatrix}, \tag{8.2.370}$$

$$\hat{\sigma}^{43} = \gamma^4\gamma^3 = \begin{pmatrix} \sigma^3 & \mathbf{0} \\ \mathbf{0} & \sigma^3 \end{pmatrix}, \tag{8.2.371}$$

and that all other $\hat{\sigma}^{\mu\nu}$ results can be obtained from the antisymmetry relation

$$\hat{\sigma}^{\mu\nu} = -\hat{\sigma}^{\nu\mu}. \tag{8.2.372}$$

[11] Observe also that we depart from the usual Dirac literature definition/notation $\sigma^{\mu\nu} = (i/2)\{\gamma^\mu, \gamma^\nu\}$ by omitting a factor of i and placing a hat $\hat{}$ on σ to indicate that a change of notation has occurred. As described in the end of Exercise 3.7.43, we do this to avoid introducing mathematically unnecessary factors of i.

For comparison, recall the *six* results (2.332) through (2.337). Verify from (7.3.236) through (7.3.241), (2.332) through (2.337), and (2.366) through (2.371) that there are the relations

$$(1/2)\hat{\sigma}^{12} = (1/2)K(-i\sigma^3) = K(\hat{L}^3), \tag{8.2.373}$$

$$(1/2)\hat{\sigma}^{23} = (1/2)K(-i\sigma^1) = K(\hat{L}^1), \tag{8.2.374}$$

$$(1/2)\hat{\sigma}^{31} = (1/2)K(-i\sigma^2) = K(\hat{L}^2), \tag{8.2.375}$$

$$(1/2)\hat{\sigma}^{41} = (1/2)K(\sigma^1) = K(\hat{N}^1), \tag{8.2.376}$$

$$(1/2)\hat{\sigma}^{42} = (1/2)K(\sigma^2) = K(\hat{N}^2), \tag{8.2.377}$$

$$(1/2)\hat{\sigma}^{43} = (1/2)K(\sigma^3) = K(\hat{N}^3). \tag{8.2.378}$$

We see that, when the Majorana representation (2.350) through (2.353) is employed for the γ^μ, the matrices $(1/2)\hat{\sigma}^{\mu\nu}$ are simply a relabeling of the matrices $K(\hat{L}^j)$ and $K(\hat{N}^j)$.

It follows that, at least in this case, the matrices $(1/2)\hat{\sigma}^{\mu\nu}$ satisfy the Lorentz group Lie algebra commutation rules. For example, verify using (2.373) through (2.375), (7.3.385), and (7.3.243) that there is the commutation rule

$$\{(1/2)\hat{\sigma}^{12}, (1/2)\hat{\sigma}^{23}\} = \{K(\hat{L}^3), K(\hat{L}^1)\} = K(\{\hat{L}^3, \hat{L}^1\}) = K(\hat{L}^2) = (1/2)\hat{\sigma}^{31}. \tag{8.2.379}$$

Actually, the same commutation rules for the matrices $(1/2)\hat{\sigma}^{\mu\nu}$ hold for any representation choice for the γ^μ, and are in fact a consequence of the Dirac algebra (2.349). Consider again, for example, the commutator $\{(1/2)\hat{\sigma}^{12}, (1/2)\hat{\sigma}^{23}\}$. Verify, using (2.349) and (2.365), that

$$\begin{gathered}\{(1/2)\hat{\sigma}^{12}, (1/2)\hat{\sigma}^{23}\} = (1/4)\{\gamma^1\gamma^2, \gamma^2\gamma^3\} = (1/4)(\gamma^1\gamma^2\gamma^2\gamma^3 - \gamma^2\gamma^3\gamma^1\gamma^2) = \\ (1/4)(-\gamma^1\gamma^3 - \gamma^3\gamma^1\gamma^2\gamma^2) = (1/4)(\gamma^3\gamma^1 + \gamma^3\gamma^1) = (1/2)\gamma^3\gamma^1 = (1/2)\hat{\sigma}^{31},\end{gathered} \tag{8.2.380}$$

as expected. The matrices $(1/2)\hat{\sigma}^{\mu\nu}$ depend on the choice of representation for the γ^μ, but their commutation rules do not.

Additional Notation

At his point it is useful to introduce additional notation. Since the γ^μ (for $\mu = 1 \cdots 5$) are purely imaginary in a Majorana representation, we may write them in the form

$$\gamma^\mu = i\gamma_r^\mu \tag{8.2.381}$$

where the γ_r^μ are purely *real*. For example, from (2.353) we see that

$$\gamma_r^4 = \begin{pmatrix} \mathbf{0} & J_2 \\ J_2 & \mathbf{0} \end{pmatrix}, \tag{8.2.382}$$

and from (2.359) we see that

$$\gamma_r^5 = -J. \tag{8.2.383}$$

Verify that both γ_r^4 and γ_r^5 are antisymmetric in our Majorana representation,

$$(\gamma_r^4)^T = -\gamma_r^4 \text{ and } (\gamma_r^5)^T = -\gamma_r^5. \tag{8.2.384}$$

Lorentz Invariance of γ^5

We are now prepared to further explore some properties of Dirac matrices and 4-spinors. The first step has to do with γ^5 and consists of verifying that it is invariant under the action the Lorentz group. That is, there is the result

$$\{K(k), \gamma^5\} = 0 \Leftrightarrow K^{-1}\gamma^5 K = \gamma^5 \tag{8.2.385}$$

where k is any element in $SL(2, \mathbb{C})$. We will arrive at this result by several steps.

Begin by verifying from (2.363) and (2.365) that

$$\{\gamma^5, \hat{\sigma}^{\mu\nu}\} = 0. \tag{8.2.386}$$

At this point review Exercise 7.3.30. Use (2.316) and (7.3.246) to write

$$k(\lambda, \boldsymbol{m}; \theta, \boldsymbol{n}) = \exp(\lambda \boldsymbol{m} \cdot \hat{\boldsymbol{N}}) \exp(\theta \boldsymbol{n} \cdot \hat{\boldsymbol{L}}). \tag{8.2.387}$$

Verify it follows from (7.3.378) and (7.3.386) that

$$\begin{aligned} K(k) &= K[\exp(\lambda \boldsymbol{m} \cdot \hat{\boldsymbol{N}}) \exp(\theta \boldsymbol{n} \cdot \hat{\boldsymbol{L}})] \\ &= K[\exp(\lambda \boldsymbol{m} \cdot \hat{\boldsymbol{N}})] K[\exp(\theta \boldsymbol{n} \cdot \hat{\boldsymbol{L}})] \\ &= \exp[K(\lambda \boldsymbol{m} \cdot \hat{\boldsymbol{N}})] \exp[K(\theta \boldsymbol{n} \cdot \hat{\boldsymbol{L}})]. \end{aligned} \tag{8.2.388}$$

As a further step, verify it follows from (2.373) through (2.378) and (2.386) that

$$\{K(\hat{L}^j), \gamma^5\} = 0 \tag{8.2.389}$$

and

$$\{K(\hat{N}^j), \gamma^5\} = 0. \tag{8.2.390}$$

Use these results to show that

$$\{\exp[K(\theta \boldsymbol{n} \cdot \hat{\boldsymbol{L}})], \gamma^5\} = 0 \tag{8.2.391}$$

and

$$\{\exp[K(\lambda \boldsymbol{m} \cdot \hat{\boldsymbol{N}})], \gamma^5\} = 0; \tag{8.2.392}$$

and therefore it follows from (2.388) that (2.385) holds. Note that, in view of (2.381), there is the equivalent *real* matrix relation

$$\{K(k), \gamma_r^5\} = 0. \tag{8.2.393}$$

Properties of γ_r^4

Next, in preparation for future use, let us study various properties of γ_r^4. You have already verified that it is antisymmetric. Recall (2.384). Verify that it also satisfies the relation

$$(\gamma_r^4)^2 = -I^{[4]}. \tag{8.2.394}$$

Verify from (2.381) that

$$(\gamma^\mu)^\dagger = -i(\gamma_r^\mu)^T. \tag{8.2.395}$$

Insert this result into (2.356) to obtain the result

$$-i(\gamma_r^\mu)^T = (i)^3\gamma_r^4\gamma_r^\mu\gamma_r^4 \Leftrightarrow (\gamma_r^\mu)^T = \gamma_r^4\gamma_r^\mu\gamma_r^4. \tag{8.2.396}$$

Finally employ (2.394) in (2.396) to obtain (for $\mu = 1 \cdot\cdot 4$) the result

$$(\gamma_r^\mu)^T = -(\gamma_r^4)^{-1}\gamma_r^\mu\gamma_r^4 = -\gamma_r^4\gamma_r^\mu(\gamma_r^4)^{-1}. \tag{8.2.397}$$

The matrix γ_r^4 has one further, and remarkable, property with regard to $SL(2,\mathbb{C})$/Lorentz transformations. Namely, suppose k is any element in $SL(2,\mathbb{C})$. Then there is the result

$$K^T(k)\gamma_r^4K(k) = \gamma_r^4. \tag{8.2.398}$$

We/you will also prove this result in steps.

Begin by verifying the following relations:

$$\hat{\sigma}^{\mu\nu} = \gamma^\mu\gamma^\nu = (i)^2\gamma_r^\mu\gamma_r^\nu = -\gamma_r^\mu\gamma_r^\nu, \tag{8.2.399}$$

$$\begin{aligned}&\gamma_r^4\hat{\sigma}^{\mu\nu}(\gamma_r^4)^{-1} = -\gamma_r^4\gamma_r^\mu\gamma_r^\nu(\gamma_r^4)^{-1} = -\gamma_r^4\gamma_r^\mu(\gamma_r^4)^{-1}\gamma_r^4\gamma\nu_r(\gamma_r^4)^{-1} = \\ &-(\gamma_r^\mu)^T(\gamma_r^\nu)^T = -(\gamma_r^\nu\gamma_r^\mu)^T = (\gamma_r^\mu\gamma_r^\nu)^T = -(\hat{\sigma}^{\mu\nu})^T,\end{aligned} \tag{8.2.400}$$

$$(\hat{\sigma}^{\mu\nu})^T = -\gamma_r^4\hat{\sigma}^{\mu\nu}(\gamma_r^4)^{-1}. \tag{8.2.401}$$

Recall that the $\hat{\sigma}^{\mu\nu}$ are proportional to the $K(\hat{N}^j)$ and the $K(\hat{L}^j)$. See (2.373) through (2.378). Show from (2.401) that

$$[K(\hat{N}^j)]^T = -\gamma_r^4K(\hat{N}^j)(\gamma_r^4)^{-1} \tag{8.2.402}$$

and

$$[K(\hat{L}^j)]^T = -\gamma_r^4K(\hat{L}^j)(\gamma_r^4)^{-1}. \tag{8.2.403}$$

Let us pause for a moment. Note that (2.402) and (2.403) can be rewritten in the form

$$-[K(\hat{N}^j)]^T = \gamma_r^4K(\hat{N}^j)(\gamma_r^4)^{-1} \tag{8.2.404}$$

and

$$-[K(\hat{L}^j)]^T = \gamma_r^4K(\hat{L}^j)(\gamma_r^4)^{-1}. \tag{8.2.405}$$

Observe that the left side of (2.404) is the result of applying the tilde conjugacy operation to $K(\hat{N}^j)$, and the left side of (2.405) is the result of applying the tilde conjugacy operation to $K(\hat{L}^j)$. Recall (3.7.129). Consequently, the relations (2.404) and (2.405) show that the representation of $s\ell(2,\mathbb{C})$ provided by the $K(\hat{N}^j)$ and the $K(\hat{L}^j)$ is *self conjugate* (for the tilde conjugacy relation) under the similarity transformation provided by γ_r^4.

Recall (7.3.377). Continue on to verify it follows from (2.402) and (2.403) that

$$[K(\lambda\boldsymbol{m}\cdot\hat{\boldsymbol{N}})]^T = -\gamma_r^4K(\lambda\boldsymbol{m}\cdot\hat{\boldsymbol{N}})(\gamma_r^4)^{-1} \tag{8.2.406}$$

and

$$[K(\theta\boldsymbol{n}\cdot\hat{\boldsymbol{L}})]^T = -\gamma_r^4K(\theta\boldsymbol{n}\cdot\hat{\boldsymbol{L}})(\gamma_r^4)^{-1}. \tag{8.2.407}$$

Using (2.387), (2.406), and (2.407) verify that

$$\begin{aligned}
&K^T(k) = \{\exp[K(\lambda\boldsymbol{m}\cdot\hat{\boldsymbol{N}})]\exp[K(\theta\boldsymbol{n}\cdot\hat{\boldsymbol{L}})]\}^T = \\
&\{\exp[K(\theta\boldsymbol{n}\cdot\hat{\boldsymbol{L}})]\}^T\{\exp[K(\lambda\boldsymbol{m}\cdot\hat{\boldsymbol{N}})]\}^T = \\
&\exp\{[K(\theta\boldsymbol{n}\cdot\hat{\boldsymbol{L}})]^T\}\exp\{[K(\lambda\boldsymbol{m}\cdot\hat{\boldsymbol{N}})]^T\} = \\
&\exp[-\gamma_r^4K(\theta\boldsymbol{n}\cdot\hat{\boldsymbol{L}})(\gamma_r^4)^{-1}]\exp[-\gamma_r^4K(\lambda\boldsymbol{m}\cdot\hat{\boldsymbol{N}})(\gamma_r^4)^{-1}] = \\
&\gamma_r^4\exp[-K(\theta\boldsymbol{n}\cdot\hat{\boldsymbol{L}})](\gamma_r^4)^{-1}\gamma_r^4\exp[-K(\lambda\boldsymbol{m}\cdot\hat{\boldsymbol{N}})](\gamma_r^4)^{-1} = \\
&\gamma_r^4\{\exp[K(\theta\boldsymbol{n}\cdot\hat{\boldsymbol{L}})]\}^{-1}\{\exp[K(\lambda\boldsymbol{m}\cdot\hat{\boldsymbol{N}})]\}^{-1}(\gamma_r^4)^{-1} = \\
&\gamma_r^4\{\exp[K(\lambda\boldsymbol{m}\cdot\hat{\boldsymbol{N}})]\exp[K(\theta\boldsymbol{n}\cdot\hat{\boldsymbol{L}})]\}^{-1}(\gamma_r^4)^{-1} = \\
&\gamma_r^4[K(k)]^{-1}(\gamma_r^4)^{-1},
\end{aligned} \tag{8.2.408}$$

from which it follows that

$$K^T(k)\gamma_r^4 = \gamma_r^4K^{-1}(k) \tag{8.2.409}$$

and therefore

$$K^T(k)\gamma_r^4K(k) = \gamma_r^4. \tag{8.2.410}$$

Show, using (2.384), that there is also the relation

$$K^T(k)(\gamma_r^4)^TK(k) = (\gamma_r^4)^T. \tag{8.2.411}$$

Note that (2.408), upon comparing its beginning and end, can be written as

$$K^T(k) = \gamma_r^4[K(k)]^{-1}(\gamma_r^4)^{-1}. \tag{8.2.412}$$

This relation shows that, when the Majorana matrices (2.350) through (2.353) are employed, the matrices $K^T(k)$ and $K^{-1}(k)$ are related by the similarity transformation provided by γ_r^4. Persuade yourself, upon reflection, that this group element relation is a consequence of the Lie algebraic self conjugacy relations (2.404) and (2.405).

The relation (2.411) has an important consequence. Let M be *any* 4×4 matrix. Verify that

$$[\gamma_r^4K]^TMK = K^T(\gamma_r^4)^TMK = K^T(\gamma_r^4)^TKK^{-1}MK = (\gamma_r^4)^TK^{-1}MK. \tag{8.2.413}$$

This will prove to be a key result.

Conjugate 4-Spinors and Bilinear Forms

With γ_r^4 in mind, we are ready for further definitions/constructions. Suppose u is some real 4-spinor. Define a related *conjugate* 4-spinor $\bar{u}$ by the rule

$$\bar{u} = \gamma_r^4u. \tag{8.2.414}$$

Note, in view of (2.394), that this barring operation is what we might call an *anti-involution*,

$$\bar{\bar{u}} = (\gamma_r^4)^2u = -I^{[4]}u = -u. \tag{8.2.415}$$

We are going to be working with quantities of the form $(\bar{u}, v)$ where v is any other real 4-spinor and the usual real (no complex conjugate) scalar product is employed. Upon employing (2.414) and (2.384), verify that we may write

$$(\bar{u}, v) = (\gamma_r^4 u, v) = (u, [\gamma_r^4]^T v) = -(u, \gamma_r^4 v) = -(u, v)_{\gamma_r^4}. \tag{8.2.416}$$

Here we have introduced, for any matrix G, the definition

$$(u, v)_G = (u, Gv). \tag{8.2.417}$$

Quantities of the form (u, Gv) are called *bilinear forms*. Evidently, according to (2.416), the introduction of conjugate 4-spinors is equivalent (apart from a minus sign) to the use of the bilinear form associated with γ_r^4. Finally, suppose G is a *symmetric* matrix S or an *antisymmetric* matrix A. Verify that in these cases there are the relations

$$(u, v)_S = (v, u)_S \text{ and } (u, v)_A = -(v, u)_A. \tag{8.2.418}$$

Because of these symmetries under the interchange of the arguments u and v, the bilinear forms $(u, v)_S$ and $(u, v)_A$ are said to be *symmetric* and *antisymmetric*, respectively. Note that, by (2.384) and this definition, that the bilinear form $(u, v)_{\gamma_r^4}$ is antisymmetric.

Concept of Transformation Properties

With these definitions behind us, suppose $K(k)$ with $k \in SL(2, \mathbb{C})$ acts on u to produce a transformed spinor that we denote as $\breve{u}$,

$$\breve{u} = K(k)u. \tag{8.2.419}$$

We will also use the notation $\bar{\breve{u}}$ to denote the conjugate of $\breve{u}$. Therefore we may write

$$\bar{\breve{u}} = \gamma_r^4 K(k)u. \tag{8.2.420}$$

Finally, let v be any other real 4-spinor, and act on it to obtain the *transformed* 4-spinor

$$\breve{v} = K(k)v. \tag{8.2.421}$$

Here we again beg the reader's forgiveness for awkward notation. In the present context a bar $\bar{}$ simply denotes multiplication by γ_r^4 as in (2.414); and a breve $\breve{}$ is simply a distinguishing mark as in (2.419). Also, we observe that the term *conjugate* has many meanings/applications. Here we speak of conjugate spinors. In Exercise 3.7.36 we spoke of conjugate matrices and representations.

What we/you will soon explore are the *transformation properties* of $(\bar{\breve{u}}, M\breve{v})$ under the action of $K(k)$ where, as in (2.413), M is any 4×4 matrix. Verify, using the notation just introduced, the properties of K and γ_r^4, and (2.413) that

$$\begin{aligned}(\bar{\breve{u}}, M\breve{v}) = (\gamma_r^4 K u, MKv) = (u, [\gamma_r^4 K]^T MKv) = (u, (\gamma_r^4)^T K^{-1} MKv) = \\ (\gamma_r^4 u, K^{-1} MKv) = (\bar{u}, K^{-1} MKv).\end{aligned} \tag{8.2.422}$$

By looking at the beginning and end of (2.419) we see that it can be rewritten in the form

$$(\bar{\breve{u}}, M\breve{v}) = (\bar{u}, K^{-1} MKv). \tag{8.2.423}$$

This, like (2.413), is also a key result.

Transformation Properties of $I^{[4]}$ and γ^5

Let us consider various possibilities for the matrix M. The simplest possibility is $M = I^{[4]}$. In this case (2.423) becomes

$$(\bar{\breve{u}}, I^{[4]}\breve{v}) = (\bar{u}, K^{-1}I^{[4]}Kv) = (\bar{u}, I^{[4]}v) \Leftrightarrow (\bar{\breve{u}}, I^{[4]}\breve{v}) = (\bar{u}, I^{[4]}v) \text{ or } (\bar{\breve{u}}, \breve{v}) = (\bar{u}, v). \quad (8.2.424)$$

We may say that $I^{[4]}$ is *invariant* (behaves like a *scalar*) under the action of K. Suppose we also describe the result (2.424) in terms of the associated bilinear form $(u, v)_{\gamma_r^4}$. Verify that there is the relation

$$\begin{aligned}&(\breve{u}, I^{[4]}\breve{v})_{\gamma_r^4} = (Ku, Kv)_{\gamma_r^4} = (Ku, \gamma_r^4 Kv) = (u, K^T\gamma_r^4 Kv) = (u, \gamma_r^4 v) = (u, v)_{\gamma_r^4}\\ &\Leftrightarrow (\bar{\breve{u}}, I^{[4]}\breve{v}) = (\bar{u}, I^{[4]}v) \text{ or } (\bar{\breve{u}}, \breve{v}) = (\bar{u}, v) \text{ or } (Ku, Kv)_{\gamma_r^4} = (u, v)_{\gamma_r^4}. \qquad (8.2.425)\end{aligned}$$

Verify that

$$(\bar{u}, v) = (\gamma_r^4 u, v) = (u, [\gamma_r^4]^\dagger, v) = -(u, \gamma_r^4 v) = -(u, v)_{\gamma_r^4}. \qquad (8.2.426)$$

Out of curiosity, verify that

$$(u, v)_{\gamma_r^4} = -u_4v_1 + u_3v_2 - u_2v_3 + u_1v_4. \qquad (8.2.427)$$

Note that the associated bilinear form is manifestly antisymmetric, as expected from (2.384).

The next more complicated possibility is $M = \gamma_r^5$. In this case use of (2.423) and (2.385) gives the result

$$(\bar{\breve{u}}, \gamma_r^5\breve{v}) = (\bar{u}, K^{-1}\gamma_r^5 Kv) = (\bar{u}, \gamma_r^5 v) \qquad (8.2.428)$$

so we may say that γ_r^5 is also a scalar/invariant under the action of K. Verify that, in terms of bilinear forms, there is the associated result

$$\begin{aligned}&(\breve{u}, \breve{v})_{\gamma_r^4\gamma_r^5} = (\breve{u}, \gamma_r^4\gamma_r^5\breve{v}) = (Ku, \gamma_r^4\gamma_r^5 Kv) = (Ku, \gamma_r^4 K\gamma_r^5 v) =\\ &(u, K^T\gamma_r^4 K\gamma_r^5 v) = (u, \gamma_r^4\gamma_5^5 v) = (u, v)_{\gamma_r^4\gamma_r^5}. \qquad (8.2.429)\end{aligned}$$

Verify that

$$(\bar{u}, \gamma_r^5 v) = (\gamma_r^4 u, \gamma_r^5 v) = -(u, \gamma_r^4\gamma_r^5 v) = -(u, v)_{\gamma_r^4\gamma_r^5}. \qquad (8.2.430)$$

Verify using (2.362) and (2.384) that the associated bilinear form is antisymmetric. Out of curiosity verify that

$$(u, v)_{\gamma_r^4\gamma_r^5} = +u_1v_2 - u_2v_1 - u_3v_4 + u_4v_3, \qquad (8.2.431)$$

which is manifestly antisymmetric. We have learned that there are two invariant bilinear forms, namely (2.427) and (2.431), and both are antisymmetric.

Transformation Properties of the γ^μ

With these instructive but relatively simple observations behind us, let us consider other possibilities for the matrix M. Suppose we select the possibilities $M = \gamma^\mu$ for $\mu = 1 \cdot \cdot 4$. Your task in this case is to show that

$$(\bar{\breve{u}}, \gamma^\mu\breve{v}) = \sum_\nu \Lambda^{\mu\nu}(k)(\bar{u}, \gamma^\nu v). \qquad (8.2.432)$$

Note that, because of (2.381), we may also write the real matrix relations

$$(\breve{\bar{u}}, \gamma_r^\mu \breve{v}) = \sum_\nu \Lambda^{\mu\nu}(k)(\bar{u}, \gamma_r^\nu v). \tag{8.2.433}$$

In view of (2.432), it is commonly (although somewhat imprecisely) said that the γ^μ (equivalently, the γ_r^μ) behave like a four-vector under the action of $K(k)$ for $k \in SL(2,\mathbb{C})$ in the same spirit that $I^{[4]}$ and γ_r^5 are said to behave like scalars.[12] According to (2.423) there is the relation

$$(\breve{\bar{u}}, \gamma^\mu \breve{v}) = (\bar{u}, K^{-1}\gamma^\mu K v). \tag{8.2.434}$$

Show that (2.432) is established if there is the relation

$$K^{-1}(k)\gamma^\mu K(k) = \sum_\nu \Lambda^{\mu\nu}(k)\gamma^\nu. \tag{8.2.435}$$

Let us work on verifying (2.435). It helps to separate the problem into two parts. Make the decomposition

$$k = k_b k_r \tag{8.2.436}$$

where

$$k_b = \exp(\lambda \boldsymbol{m} \cdot \hat{\boldsymbol{N}}) \tag{8.2.437}$$

is the $SL(2,\mathbb{C})$ element for a *boost* and

$$k_r = \exp(\theta \boldsymbol{n} \cdot \hat{\boldsymbol{L}}) \tag{8.2.438}$$

is the $SL(2,\mathbb{C})$ element for a *rotation*. Then, by (7.3.378), verify that

$$K(k) = K(k_b k_r) = K(k_b)K(k_r). \tag{8.2.439}$$

Correspondingly, verify that

$$K^{-1}(k)\gamma^\alpha K(k) = K^{-1}(k_r)K^{-1}(k_b)\gamma^\alpha K(k_b)K(k_r). \tag{8.2.440}$$

Conjecture that (2.435) holds for *pure* boosts and for *pure* rotations,

$$K^{-1}(k_b)\gamma^\alpha K(k_b) \overset{?}{=} \sum_\beta \Lambda^{\alpha\beta}(k_b)\gamma^\beta \ \text{ and } \ K^{-1}(k_r)\gamma^\beta K(k_r) \overset{?}{=} \sum_\delta \Lambda^{\beta\delta}(k_r)\gamma^\delta. \tag{8.2.441}$$

Verify the desired result (2.435) then follows from (2.440), (2.441), and (2.219):

$$\begin{aligned} &K^{-1}(k)\gamma^\alpha K(k) = K^{-1}(k_r)K^{-1}(k_b)\gamma^\alpha K(k_b)K(k_r) = \\ &K^{-1}(k_r)\sum_\beta \Lambda^{\alpha\beta}(k_b)\gamma^\beta K(k_r) = \sum_\beta \Lambda^{\alpha\beta}(k_b)K^{-1}(k_r)\gamma^\beta K(k_r) = \\ &\sum_{\beta\delta} \Lambda^{\alpha\beta}(k_b)\Lambda^{\beta\delta}(k_r)\gamma^\delta = \sum_\delta \Lambda^{\alpha\delta}(k_b k_r)\gamma^\delta = \sum_\delta \Lambda^{\alpha\delta}(k)\gamma^\delta. \end{aligned} \tag{8.2.442}$$

[12] Since the γ^μ for $\mu = 1 \cdot \cdot 4$ behave like four-vectors, it makes sense to raise and lower their indices (if desired) using the metric tensor g. See, for example, (2.478).

What remains is to verify the conjectures (2.441).

For simplicity, first work on verifying the second conjecture in (2.441). Verify that

$$K(k_r) = K[\exp(\theta \boldsymbol{n} \cdot \hat{\boldsymbol{L}})) = \exp[\theta K(\boldsymbol{n} \cdot \hat{\boldsymbol{L}})]. \tag{8.2.443}$$

See (7.3.386). Next verify that combining (2.443) and the second conjecture in (2.441) yields the conjecture

$$\exp[-\theta K(\boldsymbol{n} \cdot \hat{\boldsymbol{L}})]\gamma^\beta \exp[\theta K(\boldsymbol{n} \cdot \hat{\boldsymbol{L}})] \overset{?}{=} \sum_\delta \Lambda^{\beta\delta}(k_r)\gamma^\delta. \tag{8.2.444}$$

At this point review Sections 8.1 and 8.2 that described the concept of an adjoint Lie operator, using the symbol #, in the context of Lie operators $: f :$. The same concept can be applied to matrices in terms of commutators. Let A and B be any two $n \times n$ matrices. In this context, define a matrix adjoint operator $\#A\#$ that acts on matrices B by the rule

$$\#A\#B = \{A, B\}. \tag{8.2.445}$$

Then, in complete analogy to the discussion in Sections 8.1 and 8.2, there is the relation

$$\exp(-A)B\exp(A) = \exp(-\#A\#)B, \tag{8.2.446}$$

which may be thought of as the matrix version of Hadamard's lemma. See also (27.11.20) through (27.11.24) in Section 27.11 where this result is again used.

Verify that applying the matrix adjoint operator machinery just described produces, in the present context, the relation

$$\exp[-\theta K(\boldsymbol{n} \cdot \hat{\boldsymbol{L}})]\gamma^\beta \exp[\theta K(\boldsymbol{n} \cdot \hat{\boldsymbol{L}})] = \exp[-\theta \#K(\boldsymbol{n} \cdot \hat{\boldsymbol{L}})\#]\gamma^\beta. \tag{8.2.447}$$

Consequently, employing (2.447) in (2.444) produces the conjecture

$$\exp[-\theta \#K(\boldsymbol{n} \cdot \hat{\boldsymbol{L}})\#]\gamma^\beta \overset{?}{=} \sum_\delta \Lambda^{\beta\delta}[\exp(\theta \boldsymbol{n} \cdot \hat{\boldsymbol{L}})]\gamma^\delta. \tag{8.2.448}$$

Verify that employing (2.269) in (2.448) produces the logically equivalent conjecture

$$\exp[-\theta \#K(\boldsymbol{n} \cdot \hat{\boldsymbol{L}})\#]\gamma^\beta \overset{?}{=} \sum_\delta [\exp(\theta \boldsymbol{n} \cdot \boldsymbol{L})]^{\beta\delta}\gamma^\delta, \tag{8.2.449}$$

which, in turn, produces the logically equivalent conjectures

$$-\theta\{K(\boldsymbol{n} \cdot \hat{\boldsymbol{L}}), \gamma^\beta\} \overset{?}{=} \theta \sum_\delta [\boldsymbol{n} \cdot \boldsymbol{L})]^{\beta\delta}\gamma^\delta, \tag{8.2.450}$$

$$-\{K(\boldsymbol{n} \cdot \hat{\boldsymbol{L}}), \gamma^\beta\} \overset{?}{=} \sum_\delta [\boldsymbol{n} \cdot \boldsymbol{L})]^{\beta\delta}\gamma^\delta. \tag{8.2.451}$$

Let us seek to verify (2.451) for the three specific cases $\boldsymbol{n} = \boldsymbol{e}_1$, $\boldsymbol{n} = \boldsymbol{e}_2$, and $\boldsymbol{n} = \boldsymbol{e}_3$. Verify that if we can do so, then (2.451) follows by linearity. Consider, for example, the case $\boldsymbol{n} = \boldsymbol{e}_3$ so that the conjecture (2.451) becomes the conjecture

$$-\{K(\hat{L}^3), \gamma^\beta\} \overset{?}{=} \sum_\delta [L^3]^{\beta\delta}\gamma^\delta. \tag{8.2.452}$$

Verify that using (2.373) and (2.366) in (2.452) produces the logically equivalent conjectures

$$-(1/2)\{\hat{\sigma}^{12}), \gamma^\beta\} \overset{?}{=} \sum_\delta [L^3]^{\beta\delta}\gamma^\delta, \tag{8.2.453}$$

$$-(1/2)\{\gamma^1\gamma^2, \gamma^\beta\} \overset{?}{=} \sum_\delta [L^3]^{\beta\delta}\gamma^\delta. \tag{8.2.454}$$

Using the Dirac algebra, verify the following commutation relations:

$$-(1/2)\{\gamma^1\gamma^2, \gamma^1\} = -\gamma^2, \tag{8.2.455}$$

$$-(1/2)\{\gamma^1\gamma^2, \gamma^2\} = \gamma^1, \tag{8.2.456}$$

$$-(1/2)\{\gamma^1\gamma^2, \gamma^3\} = 0, \tag{8.2.457}$$

$$-(1/2)\{\gamma^1\gamma^2, \gamma^4\} = 0. \tag{8.2.458}$$

Recall from (7.3.182) that there is the result

$$L^3 = \begin{pmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{8.2.459}$$

Verify, upon comparing (2.455) through (2.459), that the conjecture (2.454) is correct, and therefore the conjecture (2.452) is correct. Similarly, verify that (2.451) also holds for $\boldsymbol{n} = \boldsymbol{e}_1$ and $\boldsymbol{n} = \boldsymbol{e}_2$, and therefore holds for all $\boldsymbol{n}$. Finally, proceed backwards through the chain of logically equivalent conjectures to verify that the initial conjecture, the second conjecture in (2.441), is indeed correct.

Now work on verifying the first conjecture in (2.441). The procedure for doing so is analogous to that just used to verify the second conjecture. Carry out the verification using the relations and conjectures below:

$$K(k_b) = K[\exp(\lambda \boldsymbol{m} \cdot \hat{\boldsymbol{N}})) = \exp[\lambda K(\boldsymbol{m} \cdot \hat{\boldsymbol{N}})], \tag{8.2.460}$$

$$\exp[-\lambda K(\boldsymbol{m} \cdot \hat{\boldsymbol{N}})]\gamma^\beta \exp[\lambda K(\boldsymbol{m} \cdot \hat{\boldsymbol{N}})] \overset{?}{=} \sum_\delta \Lambda^{\beta\delta}(k_b)\gamma^\delta, \tag{8.2.461}$$

$$\exp[-\lambda K(\boldsymbol{m} \cdot \hat{\boldsymbol{N}})]\gamma^\beta \exp[\lambda K(\boldsymbol{m} \cdot \hat{\boldsymbol{N}})] = \exp[-\lambda \#K(\boldsymbol{m} \cdot \hat{\boldsymbol{N}})\#]\gamma^\beta, \tag{8.2.462}$$

$$\exp[-\lambda \#K(\boldsymbol{m} \cdot \hat{\boldsymbol{N}})\#]\gamma^\beta \overset{?}{=} \sum_\delta \Lambda^{\beta\delta}[\exp(\lambda \boldsymbol{m} \cdot \hat{\boldsymbol{N}})]\gamma^\delta, \tag{8.2.463}$$

$$\exp[-\lambda \#K(\boldsymbol{m} \cdot \hat{\boldsymbol{N}})\#]\gamma^\beta \overset{?}{=} \sum_\delta [\exp(\lambda \boldsymbol{m} \cdot \boldsymbol{N})]^{\beta\delta}\gamma^\delta, \tag{8.2.464}$$

$$-\lambda\{K(\boldsymbol{m} \cdot \hat{\boldsymbol{N}}), \gamma^\beta\} \overset{?}{=} \lambda \sum_\delta [\boldsymbol{m} \cdot \boldsymbol{N})]^{\beta\delta}\gamma^\delta, \tag{8.2.465}$$

$$-\{K(\boldsymbol{m} \cdot \hat{\boldsymbol{N}}), \gamma^\beta\} \overset{?}{=} \sum_\delta [\boldsymbol{m} \cdot \boldsymbol{N})]^{\beta\delta}\gamma^\delta, \tag{8.2.466}$$

$$-\{K(\hat{N}^3),\gamma^\beta\} \stackrel{?}{=} \sum_\delta [N^3]^{\beta\delta}\gamma^\delta, \tag{8.2.467}$$

$$-(1/2)\{\hat{\sigma}^{43}),\gamma^\beta\} \stackrel{?}{=} \sum_\delta [N^3]^{\beta\delta}\gamma^\delta, \tag{8.2.468}$$

$$-(1/2)\{\gamma^4\gamma^3,\gamma^\beta\} \stackrel{?}{=} \sum_\delta [N^3]^{\beta\delta}\gamma^\delta, \tag{8.2.469}$$

$$-(1/2)\{\gamma^4\gamma^3,\gamma^1\} = 0, \tag{8.2.470}$$

$$-(1/2)\{\gamma^4\gamma^3,\gamma^2\} = 0, \tag{8.2.471}$$

$$-(1/2)\{\gamma^4\gamma^3,\gamma^3\} = \gamma^4, \tag{8.2.472}$$

$$-(1/2)\{\gamma^4\gamma^3,\gamma^4\} = \gamma^3, \tag{8.2.473}$$

$$N^3 = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}. \tag{8.2.474}$$

Let us pause for a moment to reflect on what has been discovered/accomplished here. We were able to contemplate/determine the action of the $K(k)$ on the γ^μ by the fact that both $K(k)$ and the γ^μ were known 4×4 matrices so that the quantities $K^{-1}\gamma^\mu K$ could be evaluated. Equivalently, because the γ^μ obeyed the Dirac algebra, we were able to use this algebra to determine the action of the $K(\hat{L}^j)$ and the $K(\hat{N}^j)$ on the γ^β as in (2.452) through (2.458) and (2.467) through (2.473).

Transformation Properties of Products of gamma matrices

Consider the case of a product of two *distinct* gamma matrices, $M = \gamma^\mu\gamma^\nu$ with $\mu \neq \mu$. Verify that

$$K^{-1}\gamma^\mu\gamma^\nu K = K^{-1}\gamma^\mu K K^{-1}\gamma^\nu K. \tag{8.2.475}$$

Now use (2.435) in (2.475) to obtain the result

$$K^{-1}\gamma^\mu\gamma^\nu K = \sum_{\alpha\beta} \Lambda^{\mu\alpha}(k)\Lambda^{\nu\beta}(k)\gamma^\alpha\gamma^\beta. \tag{8.2.476}$$

Evidently $\gamma^\mu\gamma^\nu$ transforms like a second rank tensor. Note, according to (2.365), that $\hat{\sigma}^{\mu\nu}$ involves the commutator $\{\gamma^\mu,\gamma^\nu\}$. Show it follows that

$$K^{-1}\hat{\sigma}^{\mu\nu} K = \sum_{\alpha\beta} \Lambda^{\mu\alpha}(k)\Lambda^{\nu\beta}(k)\hat{\sigma}^{\alpha\beta}, \tag{8.2.477}$$

the $\hat{\sigma}^{\mu\nu}$ transform like a second rank antisymmetric tensor.

You have determined the transformation properties of the commutator $\{\gamma^\mu,\gamma^\nu\}$. What can be said about the transformation properties of the anticommutator $\{\gamma^\mu,\gamma^\nu\}_+$? Evaluate $K^{-1}\{\gamma^\mu,\gamma^\nu\}_+K$ using (2.349). Also evaluate it using (2.476), and then simplify your result using (2.349). Verify, with the aid of (6.2.51), that (2.349) and (2.476) are compatible.

Using the Dirac algebra, verify that

$$\sum_{\nu} \gamma_\nu \gamma^\nu = \sum_{\mu\nu} g_{\mu\nu} \gamma^\mu \gamma^\nu = 4I^{[4]}, \tag{8.2.478}$$

and observe from the far right side of (2.478) that $\sum_\nu \gamma_\nu \gamma^\nu$ is invariant, as the notation suggests.

Consider the case of three gamma matrices. Verify, using the Dirac algebra, that the product of any three distinct gamma matrices can be written in the form $\gamma^5\gamma^\mu$. Verify that

$$K^{-1}\gamma^5\gamma^\mu K = \gamma^5 K^{-1}\gamma^\mu K = \sum_\nu \Lambda^{\mu\nu}(k)\gamma^5\gamma^\nu. \tag{8.2.479}$$

Evidently the quantities $\gamma^5\gamma^\mu$, like the quantities γ^μ, also behave as four-vectors.

Consider the case of four gamma matrices. Verify that the product of any four distinct gamma matrices must be proportional to γ^5, whose transformation properties are given by (2.385). Even a bit more can be said. From (2.435), and an obvious extension of (2.476) to the case of four gamma matrices, verify that the gamma matrix products $\gamma^\mu\gamma^\nu\gamma^\sigma\gamma^\tau$ transform like a rank four tensor. Verify, moreover, that there is the relation

$$\gamma^5 = (i/4!) \sum_{\mu\nu\sigma\tau} \epsilon_{\mu\nu\sigma\tau} \gamma^\mu\gamma^\nu\gamma^\sigma\gamma^\tau. \tag{8.2.480}$$

Observe that the invariance of γ^5, already established, is consistent with the invariant appearance of this relation.

Consider the case of five or more gamma matrices. Verify that any product of five or more gamma matrices may be reduced to the product of four or less gamma matrices using the Dirac algebra, and the transformation properties of these products have already been determined.

Summary of Results and Relation to the Clebsch-Gordan Series

In summary, we have found the following: two "scalars", $I^{[4]}$ and γ^5; two "four-vectors", γ^μ and $\gamma^5\gamma^\mu$; and one "antisymmetric tensor", $\hat{\sigma}^{\mu\nu}$. Why should this be? Look again at the bilinear form $(\bar{\breve{u}}, M\breve{v})$ that appears on the left side of (2.423). It contains the two 4-spinors $\breve{u}$ and $\breve{v}$, each of which carries the representation $\Gamma(0,1/2) \oplus \Gamma(1/2,0)$, and a *fixed* matrix M. Evidently the quantities $(\bar{\breve{u}}, M\breve{v})$ are essentially tensor products and may be expected to contain whatever representations of $s\ell(2,\mathbb{C})$ occur in the tensor product of $\Gamma(0,1/2) \oplus \Gamma(1/2,0)$ with itself. Let us see what representations can be found in this tensor product. Verify the tensor product result

$$\begin{aligned}&[\Gamma(0,1/2) \oplus \Gamma(1/2,0)] \times [\Gamma(0,1/2) \oplus \Gamma(1/2,0)] = \\ &[\Gamma(0,1/2) \times \Gamma(0,1/2)] \oplus [\Gamma(0,1/2) \times \Gamma(1/2,0)] \oplus \\ &[\Gamma(1/2,0) \times \Gamma(0,1/2)] \oplus [\Gamma(1/2,0) \times \Gamma(1/2,0)].\end{aligned} \tag{8.2.481}$$

Next verify the Clebsch-Gordan results

$$\Gamma(0,1/2) \times \Gamma(0,1/2) = \Gamma(0,1) \oplus \Gamma(0,0), \tag{8.2.482}$$

$$\Gamma(0,1/2) \times \Gamma(1/2,0) = \Gamma(1/2,1/2), \tag{8.2.483}$$

$$\Gamma(1/2,0) \times \Gamma(0,1/2) = \Gamma(1/2,1/2), \tag{8.2.484}$$

$$\Gamma(1/2,0) \times \Gamma(1/2,0) = \Gamma(1,0) \oplus \Gamma(0,0). \tag{8.2.485}$$

Show it follows that there is the grand Clebsch-Gordan result

$$\begin{aligned}&[\Gamma(0,1/2) \oplus \Gamma(1/2,0)] \times [\Gamma(0,1/2) \oplus \Gamma(1/2,0)] = \\ &2\Gamma(0,0) \oplus 2\Gamma(1/2,1/2) \oplus [\Gamma(0,1) \oplus \Gamma(1,0)],\end{aligned} \tag{8.2.486}$$

which corresponds to the two scalars, two four-vectors, and one antisymmetric tensor, as described above.

Group-Theoretical Nature of Dirac Gamma Matrices

You have verified that the four matrices γ^μ given by (2.350) through (2.353) satisfy the Dirac algebra (2.349). Moreover, in view of (2.365) and (2.373) through (2.378), the γ^μ are related to $s\ell(2,\mathbb{C})$ in that they have the further remarkable property that they *factorize* the $K(\hat{L}^j)$ and $K(\hat{N}^j)$. That is, each $K(\hat{L}^j)$ and $K(\hat{N}^j)$ can be written as the product of two gamma matrices.

But do the gamma matrices have additional group-theoretical significance? Let p be a four-vector with covariant components p_β and suppose a Lorentz group element associated with the $SL(2,\mathbb{C})$ element k acts on p to produce the four-vector $\breve{p}$. Verify that, according to (1.6.286), (1.6.287), and (1.6.289), the four-vector $\breve{p}$ will have covariant components $\breve{p}_\alpha$ given by the relation

$$\breve{p}_\alpha = \sum_\beta \{[\Lambda^T(k)]^{-1}\}^{\alpha\beta} p_\beta = \sum_\beta \{[\Lambda^{-1}(k)]^T\}^{\alpha\beta} p_\beta = \sum_\beta [\Lambda^{-1}(k)]^{\beta\alpha} p_\beta. \tag{8.2.487}$$

[Here we must again apologize for confusing notation: The matrix K defined by (1.6.287) is *not* the matrix $K(k)$ that appears in (7.3.375).] Now consider the matrix, call it $C(k)$, given by the rule

$$C(k) = \sum_\alpha \breve{p}_\alpha K^{-1}(k)\gamma^\alpha K(k) = K^{-1}(k)[\sum_\alpha \breve{p}_\alpha \gamma^\alpha]K(k). \tag{8.2.488}$$

According to (2.435) there is the relation

$$K^{-1}(k)\gamma^\alpha K(k) = \sum_\delta \Lambda^{\alpha\delta}(k)\gamma^\delta. \tag{8.2.489}$$

Now employ (2.487) and then (2.489) in (2.488) to show that

$$\begin{aligned} C(k) &= K^{-1}(k)[\sum_\alpha \breve{p}_\alpha \gamma^\alpha]K(k) = K^{-1}\{\sum_{\alpha\beta} p_\beta \gamma^\alpha [\Lambda^{-1}(k)]^{\beta\alpha}\}K(k) \\ &= \sum_{\alpha\beta\delta} p_\beta \gamma^\delta [\Lambda^{-1}(k)]^{\beta\alpha}\Lambda(k)^{\alpha\delta} = \sum_{\beta\delta} p_\beta \gamma^\delta [\Lambda^{-1}(k)\Lambda(k)]^{\beta\delta} \\ &= \sum_{\beta\delta} p_\beta \gamma^\delta \{I^{[4]}\}^{\beta\delta} = \sum_\delta p_\delta \gamma^\delta. \end{aligned} \tag{8.2.490}$$

You have shown that the matrix $C(k)$ is, in fact, *independent* of k.

Now suppose that p is the momentum four-vector for a particle that has mass m and is at rest,

$$p_\beta = (0, 0, 0, mc). \tag{8.2.491}$$

In this case there is the relation

$$\sum_\delta p_\delta \gamma^\delta = mc\gamma^4 \tag{8.2.492}$$

so that

$$C(k) = mc\gamma^4. \tag{8.2.493}$$

Next verify from (2.355) that γ^4 must be diagonalizable and have real eigenvalues. And verify from the Dirac algebra condition $(\gamma^4)^2 = I^{[4]}$ that its eigenvalues, call them τ, must satisfy $\tau^2 = 1$. Let v be a 4-spinor which is an eigenvector of γ^4 with eigenvalue τ,

$$\gamma^4 v = \tau v. \tag{8.2.494}$$

We will determine such eigenvectors shortly. They will turn out to be complex, but that need not concern us. Meanwhile define, as before, $\breve{v}$ by the rule

$$\breve{v} = K(k)v. \tag{8.2.495}$$

With these definitions in mind, verify the relations

$$mc\gamma^4 v = mc\tau v \tag{8.2.496}$$

and

$$C(k)v = K^{-1}(k)[\sum_\alpha \breve{p}_\alpha \gamma^\alpha]\breve{v} = mc\gamma^4 v = \tau mcv. \tag{8.2.497}$$

Show it follows from (2.495) and (2.497) that

$$[\sum_\alpha \breve{p}_\alpha \gamma^\alpha]\breve{v} = \tau m K(k)v = \tau mc\breve{v}. \tag{8.2.498}$$

Let us rewrite (2.498) in the form

$$[\sum_\alpha \gamma^\alpha \breve{p}_\alpha]\breve{v} = \tau mc\breve{v}. \tag{8.2.499}$$

Observe that on the left side of (2.499) there are the k dependent quantities $\breve{p}_\alpha$ and $\breve{v}$ that carry the $\Gamma(1/2, 1/2)$ and $[\Gamma(0, 1/2) \oplus \Gamma(1/2, 0)]$ representations of $s\ell(2, \mathbb{C})$, respectively. And on the right side of (2.499) we find just $\breve{v}$ which carries the $[\Gamma(0, 1/2) \oplus \Gamma(1/2, 0)]$ representation of $s\ell(2, \mathbb{C})$. Also observe that matrices γ^α are *three*-index quantities because there is the superscript α and the two matrix indices for each gamma matrix. Thus, from a group-theoretical perspective, the three-index quantities γ^α are *Clebsch-Gordan coefficients* that couple the representations $\Gamma(1/2, 1/2)$ and $[\Gamma(0, 1/2) \oplus \Gamma(1/2, 0)]$ to produce the representation $[\Gamma(0, 1/2) \oplus \Gamma(1/2, 0)]$.[13]

[13] Also, from the same group-theoretical perspective, the matrices $M = I^{[4]}$, $M = \gamma^5$, $M = \gamma^\mu$, $M = \gamma^5\gamma^\mu$, and $M = \hat{\sigma}^{\mu\nu}$ are Clebsch-Gordan coefficients that project out from the tensor product appearing on the left side of (2.481) the representations $\Gamma(0, 0)$, $\Gamma(1/2, 1/2)$, and $[\Gamma(0, 1) \oplus \Gamma(1, 0)]$.

Let us check that this possibility/conclusion makes group-theoretical sense. Verify the tensor product result

$$\begin{aligned}&\Gamma(1/2,1/2)\times[\Gamma(0,1/2)\oplus\Gamma(1/2,0)] = \\ &\Gamma(1/2,1/2)\times\Gamma(0,1/2)\oplus\Gamma(1/2,1/2)\times\Gamma(1/2,0).\end{aligned} \tag{8.2.500}$$

Verify the Clebsch-Gordan results

$$\Gamma(1/2,1/2)\times\Gamma(0,1/2)=\Gamma(1/2,0)\oplus\Gamma(1/2,1), \tag{8.2.501}$$

$$\Gamma(1/2,1/2)\times\Gamma(1/2,0)=\Gamma(0,1/2)\oplus\Gamma(1,1/2). \tag{8.2.502}$$

Verify, therefore, that there is the grand Clebsch-Gordan result

$$\begin{aligned}&\Gamma(1/2,1/2)\times[\Gamma(0,1/2)\oplus\Gamma(1/2,0)] = \\ &\Gamma(1/2,0)\oplus\Gamma(1/2,1)\oplus\Gamma(0,1/2)\oplus\Gamma(1,1/2) = \\ &[\Gamma(0,1/2)\oplus\Gamma(1/2,0)]\oplus\Gamma(1/2,1)\oplus\Gamma(1,1/2).\end{aligned} \tag{8.2.503}$$

Evidently the role of the γ^α is to project out, from the tensor product with which (2.503) begins, the representation that appears in square brackets in the last line of (2.503).

Application to the Dirac Equation

The Dirac equation for a *free* particle of mass m reads

$$i\hbar\sum_\mu \gamma^\mu\partial_\mu\psi(x) = mc\psi(x) \tag{8.2.504}$$

where $\psi(x)$ is a 4-spinor *field* that depends on the space-time coordinates x. Dirac's equation is often written in natural units (for which $\hbar = c = 1$) and the summation convention is employed so that it takes the elegant form

$$i\gamma^\mu\partial_\mu\psi = m\psi. \tag{8.2.505}$$

One may also employ the *Feynman* (1918-1988) *slash* notation

$$\partial\!\!\!/ = \sum_\mu \gamma^\mu\partial_\mu \tag{8.2.506}$$

to achieve the even more elegant form

$$i\partial\!\!\!/\psi = m\psi. \tag{8.2.507}$$

Dirac's memorial stone, near Newton's monument in Westminster Abbey, displays his equation in the form

$$i\gamma\cdot\partial\psi = m\psi. \tag{8.2.508}$$

To see this stone, Google the two words Dirac Westminster.

For pedagogical reasons we will use Dirac's equation in the form (2.504) in order to keep track of dimensions. Note that here again it is evident that the gamma matrices play the role of Clebsch-Gordan coefficients. On the left side of (2.504) we have ∂_μ and ψ which carry the representations $\Gamma(1/2,1/2)$ and $\Gamma(0,1/2)\oplus\Gamma(1/2,0)$, respectively. The γ^μ couple them to produce the representation $\Gamma(0,1/2)\oplus\Gamma(1/2,0)$, which is also the representation carried by the ψ appearing on the right side of (2.504). Thus, Dirac's equation is group-theoretically consistent.

Let us seek a plane-wave solution to (2.504) of the form

$$\psi(x) = w\exp[-i(\sum_\mu p_\mu x^\mu)/\hbar]. \tag{8.2.509}$$

As done before in (2.491), we will take p_μ to be specified by the relation

$$p_\mu = (0,0,0,mc), \tag{8.2.510}$$

and we will assume w is a 4-spinor that is independent of x. This ψ has no *spatial* dependence (ψ is translationally invariant) which implies that this proposed Ansatz is intended to describe a free-particle at rest.[14] With regard to temporal dependence, show that

$$\partial_4\psi = (\partial/\partial x^4)\psi = -i(mc/\hbar)w\exp[-i(\sum_\mu p_\mu x^\mu)/\hbar]. \tag{8.2.511}$$

Therefore, in this case, verify that the left side of (2.504) becomes

$$i\hbar\sum_\mu \gamma^\mu\partial_\mu\psi(x) = mc\gamma^4\psi(x) \tag{8.2.512}$$

so that (2.504) becomes

$$mc\gamma^4\psi(x) = mc\psi(x). \tag{8.2.513}$$

Verify that canceling out common factors from both sides of (2.513) yields for w the relation

$$\gamma^4 w = w. \tag{8.2.514}$$

That is, w must be an eigenvector of γ^4 with eigenvalue +1. We will soon see that γ^4 has eigenvectors with eigenvalues ±1 so that (2.494) has solutions for $\tau = \pm 1$. Note that (2.514) is consistent with (2.494).

Let us pause/digress briefly to discuss some commonly employed terminology for solutions of the Dirac equation. Verify, using (2.510) and (1.6.42), that the the Ansatz (2.509) can be rewritten in the form

$$\psi = w\exp[-i\mathcal{E}_0 t/\hbar] \tag{8.2.515}$$

where $\mathcal{E}_0$ is the (manifestly positive) rest energy,

$$\mathcal{E}_0 = mc^2. \tag{8.2.516}$$

[14] We remark that once "at rest" solutions have been found, all other free-particle solutions can be found by acting on the at rest solutions with suitable Lorentz transformations.

Despite the appearance of a *minus* sign in the exponent appearing in (2.515), and also in (2.509), this proposed solution is called a *positive energy* solution. The reason for this terminology has to do with the analogous case of the nonrelativistic *Schrödinger* (1887-1961) equation. The Schrödinger equation for the Schrödinger wave function, call it $\chi(\boldsymbol{r},t)$, reads

$$i\hbar(\partial/\partial t)\chi(\boldsymbol{r},t) = H(q,p)\chi(\boldsymbol{r},t) \tag{8.2.517}$$

where H is the (assumed time independent) Hamiltonian. If we make the separation of variables Ansatz

$$\chi(\boldsymbol{r},t) = u(\boldsymbol{r})f(t) \tag{8.2.518}$$

and specify that u is an eigenfunction of H with eigenvalue E so that

$$Hu = Eu, \tag{8.2.519}$$

then (2.517) has the solution

$$\chi(\boldsymbol{r},t) = u(\boldsymbol{r})\exp[-iEt/\hbar]. \tag{8.2.520}$$

Evidently the argument of the exponential function appearing in (2.520) is *negative* imaginary as the time t becomes evermore positive providing the energy E is *positive*, and vice versa. Observe that the argument of the exponential function appearing in (2.509) eventually becomes negative imaginary as t becomes evermore positive. Correspondingly, (2.509) is called a positive energy solution of the Dirac equation.

Now return to the main discussion. As promised, let us find the eigenvectors of γ^4. Begin by writing w in the form

$$w = \begin{pmatrix} a \\ b \\ c \\ d \end{pmatrix} \tag{8.2.521}$$

where the quantities a through d are to be determined from (2.514). Verify using (2.353) that

$$\gamma^4 w = \begin{pmatrix} id \\ -ic \\ ib \\ -ia \end{pmatrix}, \tag{8.2.522}$$

and consequently the condition (2.514) yields the relations

$$d = -ia \tag{8.2.523}$$

$$c = ib. \tag{8.2.524}$$

Therefore any eigenvector of γ^4 having eigenvalue $+1$ must be of the form

$$w = \begin{pmatrix} a \\ b \\ ib \\ -ia \end{pmatrix}. \tag{8.2.525}$$

Let us pause at this point to seek eigenvectors of γ^4 with eigenvalue -1. Take the complex conjugate of both sides of (2.514) to find the relation

$$(\gamma^4)^* w^* = (\gamma^4 w)^* = w^*. \tag{8.2.526}$$

Since γ^4 is purely imaginary (in a Majorana representation), there is the relation

$$(\gamma^4)^* = -\gamma^4, \tag{8.2.527}$$

from which it follows that

$$\gamma^4 w^* = -w^*. \tag{8.2.528}$$

Therefore the eigenvectors of γ^4 with eigenvalue -1 are of the form

$$w^* = \begin{pmatrix} a^* \\ b^* \\ -ib^* \\ ia^* \end{pmatrix}. \tag{8.2.529}$$

Let us continue on. Evidently there is a two-fold degeneracy for both the eigenvalue $+1$ and -1 eigenvectors. To break this degeneracy it is convenient to employ the matrix M^3 defined by the rule

$$M^3 = i\hat{\sigma}^{12}. \tag{8.2.530}$$

Verify, using the Dirac algebra and (2.349), that there are the relations

$$(M^3)^\dagger = M^3 \tag{8.2.531}$$

and

$$(M^3)^2 = I^{[4]}. \tag{8.2.532}$$

It follows that M^3 can be diagonalized, has real eigenvalues, and the square of these eigenvalues is $+1$. Verify, again using the Dirac algebra, that

$$\{M^3, \gamma^4\} = 0, \tag{8.2.533}$$

which shows that γ^4 and M^3 can be diagonalized simultaneously.

Let us find the simultaneous eigenvectors of γ^4 and M^3. For w of the form (2.521) show, using (2.366), that

$$M^3 w = \begin{pmatrix} ic \\ -id \\ -ia \\ ib \end{pmatrix}. \tag{8.2.534}$$

Therefore, if we demand that

$$M^3 w = w, \tag{8.2.535}$$

verify that there are the relations

$$c = -ia \tag{8.2.536}$$

and

$$d = ib. \tag{8.2.537}$$

Suppose we now seek to satisfy all the demands (2.523), (2.524), (2.536), and (2.537). Verify that combining (2.523) and (2.537) yields the relation

$$b = -a. \tag{8.2.538}$$

Show that inserting (2.538) into (2.525) yields the vector, which we will call $w^{+\uparrow}$, given by the relation

$$w^{+\uparrow} = \begin{pmatrix} a \\ -a \\ -ia \\ -ia \end{pmatrix}. \tag{8.2.539}$$

(Here, in anticipation of subsequent results, we introduce the symbols ↑ and ↓ to indicate what will soon be identified as having spin up and spin down.) Verify that $w^{+\uparrow}$ is a simultaneous eigenvector of both γ^4 and M^3 with eigenvalues $+1$ for each.

Alternatively, if we demand that

$$M^3 w = -w, \tag{8.2.540}$$

verify that there are the relations

$$c = ia \tag{8.2.541}$$

and

$$d = -ib. \tag{8.2.542}$$

Verify that combining (2.523) and (2.542) in this case now yields the relation

$$b = a. \tag{8.2.543}$$

Show that inserting (2.543) into (2.525) yields the vector, which we will call $w^{+\downarrow}$, given by the relation

$$w^{+\downarrow} = \begin{pmatrix} a \\ a \\ ia \\ -ia \end{pmatrix}. \tag{8.2.544}$$

Verify that $w^{+\downarrow}$ is a simultaneous eigenvector of both γ^4 and M^3 with eigenvalue $+1$ for γ^4 and eigenvalue -1 for M^3. Note that the quantity a appearing in $w^{+\uparrow}$ and $w^{+\downarrow}$ is arbitrary and may, for example, be set to 1.

Finally, let us make the definition

$$S^3 = iK(\hat{L}^3). \tag{8.2.545}$$

Verify using (2.373) and (2.530) that

$$S^3 = (1/2)M^3. \tag{8.2.546}$$

Consequently, $w^{+\uparrow}$ is a simultaneous eigenvector of both γ^4 and S^3 with eigenvalue $+1$ for γ^4 and eigenvalue $+1/2$ for S^3. And $w^{+\downarrow}$ is a simultaneous eigenvector of both γ^4 and S^3 with eigenvalue $+1$ for γ^4 and eigenvalue $-1/2$ for S^3. We may say that $w^{+\uparrow}$ is the spinor part of the ψ for a spin 1/2 particle (at rest) having spin up, and $w^{+\downarrow}$ is the spinor part of the ψ for a spin 1/2 particle (at rest) having spin down.

So far we have been discussing positive energy solutions of the Dirac equation. We close this exercise with a brief discussion of negative energy solutions, which also exist. Suppose, instead of (2.509), we make the Ansatz

$$\psi(x) = w \exp[+i(\sum_{\mu} p_\mu x^\mu)/\hbar]. \tag{8.2.547}$$

Observe that the argument of the exponential function appearing in (2.547) eventually becomes *positive* imaginary as t becomes evermore positive. Correspondingly, (2.547) is called a *negative* energy solution.[15] Show that the Ansatz (2.547) satisfies the Dirac equation (2.504) provided w satisfies the relation

$$\gamma^4 w = -w. \tag{8.2.548}$$

That is, w must be an eigenvector of γ^4 with eigenvalue -1.

Consider the vectors (4-spinors) $w^{-\uparrow}$ and $w^{-\downarrow}$ defined by

$$w^{-\uparrow} = (w^{+\downarrow})^* \tag{8.2.549}$$

and

$$w^{-\downarrow} = (w^{+\uparrow})^*. \tag{8.2.550}$$

Verify that

$$\gamma^4 w^{-\uparrow} = [(\gamma^4)^* w^{+\downarrow}]^* = [-\gamma^4 w^{+\downarrow}]^* = -(w^{+\downarrow})^* = -w^{-\uparrow}. \tag{8.2.551}$$

Similarly, verify that

$$\gamma^4 w^{-\downarrow} = -w^{-\downarrow}. \tag{8.2.552}$$

Next, observe from (2.545) that

$$(S^3)^* = -S^3. \tag{8.2.553}$$

Consequently, verify that

$$S^3 w^{-\uparrow} = [(S^3)^* w^{+\downarrow}]^* = [-S^3 w^{+\downarrow}]^* = (1/2)[w^{+\downarrow}]^* = (1/2)w^{-\uparrow}. \tag{8.2.554}$$

Similarly, verify that

$$S^3 w^{-\downarrow} = -(1/2)w^{-\downarrow}. \tag{8.2.555}$$

Thus, $w^{-\uparrow}$ and $w^{-\downarrow}$ behave under the action of γ^4 and S^3 as their notation suggests. Finally, verify from (2.539), (2.544), (2.549), and (2.550) that there are the explicit results

$$w^{-\uparrow} = \begin{pmatrix} a^* \\ a^* \\ -ia^* \\ ia^* \end{pmatrix}, \tag{8.2.556}$$

[15] Motivated by the relation $E = h\nu$, positive energy solutions are also sometimes called *positive frequency* solutions, and negative energy solutions are sometimes called *negative frequency* solutions.

$$w^{-\downarrow} = \begin{pmatrix} a^* \\ -a^* \\ ia^* \\ ia^* \end{pmatrix}. \tag{8.2.557}$$

Here again the quantity a is arbitrary and may, for example, be set to 1.

In summary, when both positive and negative energy solutions (for a particle at rest) are considered, we have seen that there are four possibilities for w, namely $w^{+\uparrow}$, $w^{+\downarrow}$, $w^{-\uparrow}$, and $w^{-\downarrow}$.

What is the use of the negative energy solutions? Very much further discussion would bring us too far afield. But remarkably it can be shown that, taken together, the positive and negative energy solutions can be used to construct a four-component *quantum* field involving creation and destruction operators for particles and their antiparticles. In this construction destruction operators are associated with positive energy solutions and creation operators are associated with negative energy solutions. The result of this construction is a theory that describes simultaneously both spin 1/2 particles and their antimatter counterparts (for example electrons and positrons), and these particles obey Fermi-Dirac statistics. (Thus the four-fold nature of the Dirac equation associated with the four possibilities for w is revealed to be related to the four possibilities of spin up and spin down and matter and antimatter.) Moreover, in the full quantum field version of Dirac theory, there is a ground state called the *vacuum* which corresponds to a (unique) state for which there are no particles. And in the quantum field theory version both particle and antiparticle states have positive energies, and there is complete symmetry between matter and antimatter.

8.2.19. The two preceding Exercises 2.17 and 2.18 in this chapter have, among other things, explored the relations between the 2×2 complex matrices $\hat{L}^j$ and $\hat{N}^j$, that carry the $\Gamma(0,1/2)$ of the Lorentz group Lie algebra, and the 4×4 real matrices $K(\hat{L}^j)$ and $K(\hat{N}^j)$. According to Exercise 7.3.30, the 2×2 complex matrices $\grave{\hat{L}}^j$ and $\grave{\hat{N}}^j$ carry the $\Gamma(1/2,0)$ of the Lorentz group Lie algebra. The purpose of this exercise is to consider the complementary question: what are the relations between the 2×2 complex matrices $\grave{\hat{L}}^j$ and $\grave{\hat{N}}^j$ and the 4×4 real matrices $K(\grave{\hat{L}}^j)$ and $K(\grave{\hat{N}}^j)$? We know from the work of Exercise 2.17 that the matrix set $K(\hat{L}^j)$,$K(\hat{N}^j)$ carries the Lorentz group Lie algebra representation $\Gamma(0,1/2)\oplus\Gamma(1/2,0)$. Could it be that the matrix set $K(\grave{\hat{L}}^j)$,$K(\grave{\hat{N}}^j)$ also carries this representation? If so, the two sets must be related by a similarity transformation (and vice verse).

Begin our/your investigation by showing from (7.3.248), (7.3.249), and (7.3.376) that there are the relations

$$K(\grave{\hat{L}}^j) = K(\hat{L}^j) \tag{8.2.558}$$

and

$$K(\grave{\hat{N}}^j) = -K(\hat{N}^j). \tag{8.2.559}$$

Next verify, using (2.366) through (2.368), (2.373) through (2.375), and the Dirac algebra, that

$$(\gamma^4)^{-1}K(\hat{L}^j)\gamma^4 = K(\hat{L}^j) \tag{8.2.560}$$

from which, by (2.558), it follows that

$$(\gamma^4)^{-1}K(\hat{L}^j)\gamma^4 = K(\grave{\hat{L}}^j). \tag{8.2.561}$$

Also verify, using (2.369) through (2.371), (2.376) through (2.378), and the Dirac algebra, that

$$(\gamma^4)^{-1}K(\hat{N}^j)\gamma^4 = -K(\hat{N}^j) \tag{8.2.562}$$

from which, by (2.559), it follows that

$$(\gamma^4)^{-1}K(\hat{N}^j)\gamma^4 = K(\grave{\hat{N}}^j). \tag{8.2.563}$$

Taken together, (2.561) and (2.563) show that the two sets $K(\hat{L}^j)$,$K(\hat{N}^j)$ and $K(\grave{\hat{L}}^j)$,$K(\grave{\hat{N}}^j)$ are indeed related by a similarity transformation, the similarity transformation provided by γ^4.[16] Finally, verify that the two sets are also related by the similarity transformation provided by $\gamma^5\gamma^4$.

Let us summarize our findings. From Exercise 7.3.30 we learned that the $\Gamma(0, 1/2)$ representation provided by the matrices $\hat{L}^j$,$\hat{N}^j$ is different from (not equivalent to) the $\Gamma(1/2, 0)$ representation provided by the matrices $\grave{\hat{L}}^j$,$\grave{\hat{N}}^j$. Now we have learned that the representations provided by the two sets of matrices $K(\hat{L}^j)$,$K(\hat{N}^j)$ and $K(\grave{\hat{L}}^j)$,$K(\grave{\hat{N}}^j)$ are the same/equivalent, namely the representation $\Gamma(0, 1/2) \oplus \Gamma(1/2, 0)$.

8.2.20. (Under construction) Review Exercise 2.19. The purpose of this exercise is to do something analogous for the representations $\Gamma(0, 1)$, $\Gamma(1, 0)$, and $\Gamma(0, 1) \oplus \Gamma(1, 0)$ using K.

8.2.21. (Under construction) Review Exercise 7.3.34. The purpose of this exercise is to explore, at least to some extent, what special properties matrices $K(k)$ might have if the matrices k have special properties. In particular, we will study what can be said about the case

$$k \in SL(2, \mathbb{C}) = Sp(2, \mathbb{C}) \Leftrightarrow k^T J_2 k = J_2 \tag{8.2.564}$$

without immediately invoking the Dirac machinery.

Apply (7.3.378) to the symplectic condition in (2.557) to show that

$$K(k^T)K(J_2)K(k) = K(J_2). \tag{8.2.565}$$

Using the definition (7.3.375), verify the following relations:

$$K(J_2) = \begin{pmatrix} J_2 & \mathbf{0} \\ \mathbf{0} & J_2 \end{pmatrix} = J', \tag{8.2.566}$$

$$K(k^T) = \begin{pmatrix} \Re k^T & -\Im k^T \\ \Im k^T & \Re k^T \end{pmatrix} = \begin{pmatrix} (\Re k)^T & -(\Im k)^T \\ (\Im k)^T & (\Re k)^T \end{pmatrix}, \tag{8.2.567}$$

and

$$[K(k)]^T = \begin{pmatrix} (\Re k)^T & (\Im k)^T \\ -(\Im k)^T & (\Re k)^T \end{pmatrix}. \tag{8.2.568}$$

[16] Note that the relations (2.561) and (2.563) can also be written in the form $(\gamma^4)^{-1}K(\grave{\hat{L}}^j)\gamma^4 = K(\hat{L}^j)$, etc. Thus, there is complete symmetry between the use of the $\Gamma(0, 1/2)$ and the $\Gamma(1/2, 0)$ representations.

Let J be the matrix

$$J = \begin{pmatrix} \mathbf{0} & I^{[2]} \\ -I^{[2]} & \mathbf{0} \end{pmatrix}. \tag{8.2.569}$$

Verify that

$$J^{-1}[K(k)]^T J = K(k^T). \tag{8.2.570}$$

Show, using (2.559) and (2.563), that (2.558) can be rewritten in the form

$$J^{-1}[K(k)]^T J J' K(k) = J', \tag{8.2.571}$$

from which it follows that

$$[K(k)]^T [JJ'] K(k) = [JJ']. \tag{8.2.572}$$

Define a matrix S by the rule

$$S = JJ' \tag{8.2.573}$$

so that (2.565) can be written as

$$[K(k)]^T S K(k) = S. \tag{8.2.574}$$

[Note that, despite our notation, this matrix S has nothing to do with the matrix S^3 defined by (2.538) and (2.539).] Verify that

$$S = \begin{pmatrix} \mathbf{0} & J_2 \\ -J_2 & \mathbf{0} \end{pmatrix}. \tag{8.2.575}$$

Verify that J and J' commute,

$$\{J, J'\} = 0. \tag{8.2.576}$$

Show that

$$S^T = S, \tag{8.2.577}$$

$$\det(S) = 1, \tag{8.2.578}$$

and

$$S^2 = I^{[4]}. \tag{8.2.579}$$

Evidently S is *real*. Verify from (2.570) and (2.572) that S is also orthogonal,

$$S^T S = I^{[4]}. \tag{8.2.580}$$

A brute force verification using (2.568), while tedious, is possible. But note that (2.570) through (2.572) follow directly from (2.566) and (2.569) and the relations

$$J^T = -J,\ (J')^T = -J',\ \det(J) = \det(J') = 1. \tag{8.2.581}$$

Upon comparing (2.567) with the symplectic condition in (2.557) we see that they have a similar form but J_2 is antisymmetric while S is symmetric. Since S is symmetric, it can be used to define an inner product, and the relation (2.567) can be viewed as a *preservation* condition for this inner product. Suppose u and v are any two four-component real arrays and we define their inner product $(u, v)_S$ by the rule

$$(u, v)_S = (u, Sv) \tag{8.2.582}$$

where the inner product on the right side of (2.575) is the usual real inner product. Note that, since S is real, the quantity $(u, v)_S$ is real if u and v are real. Then, using (2.567), verify that

$$(Ku, Kv)_S = (Ku, SKv) = (u, K^T SKv) = (u, Sv) = (u, v)_S. \tag{8.2.583}$$

That is, the inner product $(u, v)_S$ is invariant under the action of $K(k)$. Moreover, make the definition

$$(u, v)_{S\gamma_r^5} = (u, S\gamma_r^5 v). \tag{8.2.584}$$

Note that $(u, v)_{S\gamma_r^5}$ is also *real*. Then, using (2.567) and (2.384), verify that

$$\begin{aligned}&(Ku, Kv)_{S\gamma_r^5} = (Ku, S\gamma_r^5 Kv) = (Ku, SK\gamma_r^5 v) = \\ &(u, K^T SK\gamma_r^5 v) = (u, S\gamma_r^5 v) = (u, v)_{S\gamma_r^5}.\end{aligned} \tag{8.2.585}$$

Therefore the inner product $(u, v)_{S\gamma_r^5}$ is also invariant under the action of $K(k)$.

But now we are confronted with an embarrassment of riches!

Out of curiosity, verify that

$$(u, v)_S = (u, Sv) = u_1v_4 - u_2v_3 - u_3v_2 + u_4v_1. \tag{8.2.586}$$

8.2.22. (Under Construction) Exercise on use of S rather than γ_r^4 and the existence of more bilinear forms.

8.2.23. (Under Construction) Other Majorana representations.

What is the nature of the inner product $(*, *)_S$? Evidently S is real. Verify from (2.329) and (2.331) that S is also orthogonal,

$$S^T S = I^{[4]}. \tag{8.2.587}$$

Therefore there must be a real orthogonal matrix O such that

$$O^T SO = D \Leftrightarrow S = ODO^T \tag{8.2.588}$$

where D is diagonal. Verify using (2.335) and (2.331) that there is the relation

$$D^2 = O^T SOO^T SO = O^T S^2 O = O^T O = I^{[4]}, \tag{8.2.589}$$

and therefore the diagonal entries of D must have absolute value 1.

Let us try to find O and D. To continue, verify that

$$S = K(-iJ_2) = K(\sigma^2). \tag{8.2.590}$$

Next, using the relation between $\boldsymbol{\sigma}$ and $\boldsymbol{K}$ given by (3.7.169) through (3.7.171), verify that (8.2.57) can also be written in the form

$$\exp[(-i/2)\theta\boldsymbol{n}\cdot\boldsymbol{\sigma}](\boldsymbol{a}\cdot\boldsymbol{\sigma})\exp[(i/2)\theta\boldsymbol{n}\cdot\boldsymbol{\sigma}] = [R(\theta,\boldsymbol{n})\boldsymbol{a}]\cdot\boldsymbol{\sigma}. \tag{8.2.591}$$

(Sorry yet again about the possibly confusing notation! Although they may look related, there is *no* connection between the symbols $\boldsymbol{K}$ and K. Sometimes there are not enough symbols to go around.) Evaluate (2.338) for the case $\boldsymbol{n} = \boldsymbol{e}_1$ and $\boldsymbol{a} = \boldsymbol{e}_2$ so that it becomes

$$\exp[(-i/2)\theta\sigma^1](\sigma^2)\exp[(i/2)\theta\sigma^1] = [R(\theta,\boldsymbol{e}_1)\boldsymbol{e}_2]\cdot\boldsymbol{\sigma}. \tag{8.2.592}$$

Verify that

$$[R(\pi/2,\boldsymbol{e}_1)\boldsymbol{e}_2] = \boldsymbol{e}_3. \tag{8.2.593}$$

Put another way, rotating $\boldsymbol{e}_2$ by $\theta = \pi/2$ about the $\boldsymbol{e}_1$ axis yields $\boldsymbol{e}_3$. See (3.7.205). Consequently, for $\theta = \pi/2$, (2.339) becomes

$$\exp[-i(\pi/4)\sigma^1](\sigma^2)\exp[i(\pi/4)\sigma^1] = \sigma^3. \tag{8.2.594}$$

As a sanity check, verify directly that (2.341) holds by evaluating the indicated exponential functions and carrying out the indicated multiplications. In particular, you should find for the exponential functions the results

$$\exp[\pm i(\pi/4)\sigma^1] = \cos(\pi/4)\sigma^0 \pm i\sin(\pi/4)\sigma^1 = (1/\sqrt{2})\sigma^0 \pm i(1/\sqrt{2})\sigma^1. \tag{8.2.595}$$

See (3.7.192).

Now verify that applying (7.3.378) to both sides of (2.341) yields the result

$$K\{\exp[-i(\pi/4)\sigma^1]\}K(\sigma^2)K\{\exp[i(\pi/4)\sigma^1]\} = K(\sigma^3). \tag{8.2.596}$$

Make the assignment

$$O = K\{\exp[i(\pi/4)\sigma^1]\} \tag{8.2.597}$$

and show that

$$O = (1/\sqrt{2})\begin{pmatrix} \sigma^0 & -\sigma^1 \\ \sigma^1 & \sigma^0 \end{pmatrix}. \tag{8.2.598}$$

Note that, as expected, O is real. Also, using (7.3.381), show that

$$O^{-1} = K\{\exp[-i(\pi/4)\sigma^1]\} \tag{8.2.599}$$

from which it follows that

$$O^{-1} = (1/\sqrt{2})\begin{pmatrix} \sigma^0 & \sigma^1 \\ -\sigma^1 & \sigma^0 \end{pmatrix}. \tag{8.2.600}$$

Verify, by comparing (2.345) and (2.347), that

$$O^{-1} = O^T. \tag{8.2.601}$$

Verify it follows from (2.343) that (2.335) has been achieved with

$$D = K(\sigma^3) = \begin{pmatrix} \sigma_3 & \mathbf{0} \\ \mathbf{0} & \sigma_3 \end{pmatrix} = \text{diag}(1,-1,1,-1). \tag{8.2.602}$$

As a final sanity check on our/your work, verify directly that (2.335) has been achieved using (2.327) for S, (2.345) for O, (2.347) for $O^{-1} = O^T$, and (2.349) for D.

Define matrices $M(k)$ by the rule

$$M(k) = O^T K(k) O = O^{-1} K(k) O. \tag{8.2.603}$$

Verify that, for $k \in SL(2, \mathbb{C}) = Sp(2, \mathbb{C})$, they satisfy the relation chain

$$\begin{aligned} &M^T(k) D M(k) = [O^T K(k) O]^T D [O^T K(k) O] = \\ &[O^T K^T(k)][O D O^T][K(k) O] = O^T [K^T(k) S K(k)] O = \\ &O^T S O = D. \end{aligned} \tag{8.2.604}$$

That is, upon comparing the beginning and end of (2.351), we see that there is the relation

$$M^T(k) D M(k) = D. \tag{8.2.605}$$

Verify also, using (7.3.380), that

$$M(I^{[2]}) = I^{[4]}. \tag{8.2.606}$$

Because D has two positive and two negative diagonal entries we conclude that, for $k \in SL(2, \mathbb{C}) = Sp(2, \mathbb{C})$, the matrices $M(k)$ provide a representation of $SO(2, 2, \mathbb{R})$. See Exercises 3.7.38 and 3.7.40.

Let P be the permutation operator that interchanges the two and three axes and leaves the other axes in peace. That is, P is a linear operator with the actions

$$P\boldsymbol{e}_1 = \boldsymbol{e}_1,\ P\boldsymbol{e}_2 = \boldsymbol{e}_3,\ P\boldsymbol{e}_3 = \boldsymbol{e}_2,\ P\boldsymbol{e}_4 = \boldsymbol{e}_4. \tag{8.2.607}$$

Correspondingly, P has the matrix representation

$$P = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{8.2.608}$$

Verify that P is symmetric, $P^T = P$; is an involution, $P^2 = I^{[4]}$; and is therefore orthogonal, $P^T = P^{-1}$. Define a linear operator $\hat{D}$ by the rule

$$\hat{D} = P^T D P. \tag{8.2.609}$$

Verify that $\hat{D}$ has the matrix representation

$$\hat{D} = \begin{pmatrix} I^{[2]} & \mathbf{0} \\ \mathbf{0} & -I^{[2]} \end{pmatrix} = \mathrm{diag}(1, 1, -1, -1). \tag{8.2.610}$$

Define matrices $\hat{M}(k)$ by the rule

$$\hat{M}(k) = P^T M(k) P. \tag{8.2.611}$$

Verify that, for $k \in SL(2,\mathbb{C}) = Sp(2,\mathbb{C})$, they satisfy the relation chain

$$\begin{aligned}&M^T(k)DM(k) = [O^TK(k)O]^TD[O^TK(k)O] =\\ &[O^TK^T(k)][ODO^T][K(k)O] = O^T[K^T(k)SK(k)]O =\\ &O^TSO = D.\end{aligned} \tag{8.2.612}$$

That is, upon comparing the beginning and end of (2.351), we see that there is the relation

$$M^T(k)DM(k) = D. \tag{8.2.613}$$

Verify also, using (7.3.380), that

$$M(I^{[2]}) = I^{[4]}. \tag{8.2.614}$$

Because D has two positive and two negative diagonal entries we conclude that, for $k \in SL(2,\mathbb{C}) = Sp(2,\mathbb{C})$, the matrices $M(k)$ provide a representation of $SO(2,2,\mathbb{R})$. See Exercises 3.7.38 and 3.7.40.

8.2.24. (Under Construction) Review Exercise 3.7.37 that relates the Lorentz group Lie algebra $so(3,1,\mathbb{R})$ to $so(4,\mathbb{R})$ when working over the complex field, and hence also to $su(2) \oplus su(2)$. See also Exercise 6.2.6.

In the case of the Lorentz group there are the 4×4 *Dirac gamma* matrices γ^μ, with $\mu = 1 \cdot\cdot 4$, that satisfy the anti-commutation rules

$$\{\gamma^\mu, \gamma^\nu\}_+ = \gamma^\mu\gamma^\nu + \gamma^\nu\gamma^\mu = 2g^{\mu\nu}, \tag{8.2.615}$$

and transform under the action of the Lorentz group according to the rules

$$* = *. \tag{8.2.616}$$

For the case of $SO(4,\mathbb{R})$ there are analogous 4×4 matrices; call them Γ^μ. Define them as follows:

$$\Gamma^1 =, \tag{8.2.617}$$

$$\Gamma^2 =, \tag{8.2.618}$$

$$\Gamma^3 =, \tag{8.2.619}$$

$$\Gamma^4 = . \tag{8.2.620}$$

Note they are all real and involve 2×2 blocks featuring the Pauli matrices *. Verify that they satisfy the anti-commutation rules

$$\{\Gamma^\mu, \Gamma^\nu\}_+ = \delta^{\mu\nu}, \tag{8.2.621}$$

and transform under the action of the the rotation group $SO(4,\mathbb{R})$ according to the rules

$$* = *. \tag{8.2.622}$$

Show that there are six linearly independent matrices of the form

$$\Sigma^{\mu\nu} = \{\Gamma^\mu, \Gamma^\nu\} = \Gamma^\mu\Gamma^\nu - \Gamma^\nu\Gamma^\mu. \tag{8.2.623}$$

Show that these matrices form a basis for $so(4,\mathbb{R})$.

Something about $SO(n,\mathbb{R})$ and Clifford algebras.

8.2.25. (Under Construction) Exercise on the Möbius and Lorentz groups.

8.3 Questions of Order and other Miscellaneous Mysteries

Lie operators and Lie transformations have remarkable properties, and in many ways seem to lead lives of their own. The purpose of this section is to discuss various questions of operator ordering that are often confusing to the uninitiated, and sometimes puzzling to even the enlightened. We will also extend some previous results, and resolve some mysteries of sign that arose in previous sections.

8.3.1 Questions of Order and Map Multiplication

Suppose $\mathcal{M}_f$ is a symplectic map that sends the general point z in phase space to the point $\bar{z}$, and suppose $\mathcal{M}_g$ is another symplectic map that sends $\bar{z}$ to the point $\bar{\bar{z}}$. The reason for our naming convention using the subscripts f and g will become apparent shortly. See Figure 3.1

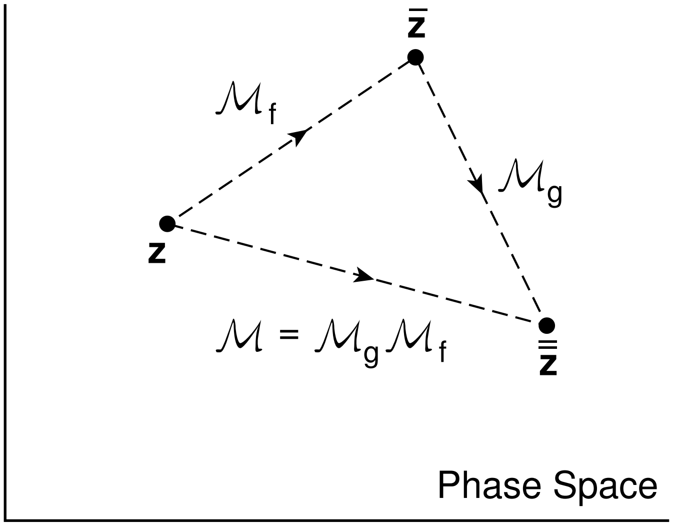

Figure 8.3.1: The composite action of two maps $\mathcal{M}_f$ and $\mathcal{M}_g$.

Equivalently, in the context of charged particle beam transport, we may think of a beam that first passes through beam line element f, the action of which is described by the map $\mathcal{M}_f$, and then through beam line element g whose action is described by the map $\mathcal{M}_g$. See Figure 3.2.

Now consider the composite mapping $\mathcal{M}$ which sends z to $\bar{\bar{z}}$ and which, following usual mathematical notation, would be written in the form

$$\mathcal{M} = \mathcal{M}_g\mathcal{M}_f, \tag{8.3.1}$$

$$\mathcal{M}_f : z \rightarrow \bar{z}, \tag{8.3.2}$$

$$\mathcal{M}_g : \bar{z} \rightarrow \bar{\bar{z}}, \tag{8.3.3}$$

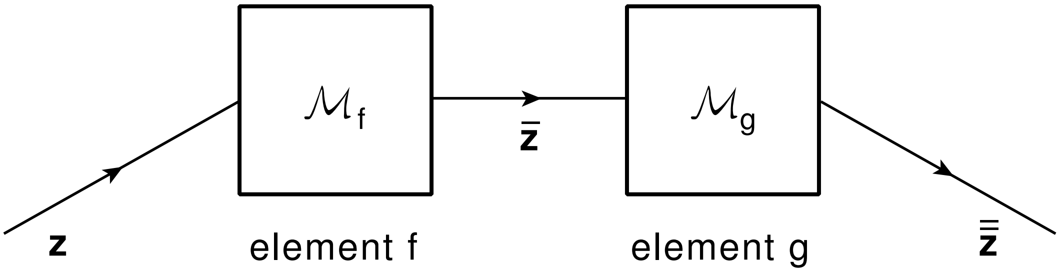

Figure 8.3.2: Successive passage of a trajectory with initial condition z through beam line elements f and g resulting in the intermediate condition $\bar{z}$ and final condition $\bar{\bar{z}}$.

$$\mathcal{M}_g \mathcal{M}_f : z \rightarrow \bar{\bar{z}} \; . \tag{8.3.4}$$

Note that, when reading (3.1) from left to right, the maps $\mathcal{M}_f$ and $\mathcal{M}_g$ occur in the *opposite* order from which they actually act. See Fig. 3.2. That is, $\mathcal{M}_f$ acts first, but appears last in (3.1); and $\mathcal{M}_g$ acts last, but appears first in (3.1). This order follows the standard mathematical convention for maps (including matrices as a special case), and is in accord with the ordering used earlier in Section 6.2 and Equations (6.4.5) and (6.4.7).

Suppose, for purposes of discussion, that both $\mathcal{M}_f$ and $\mathcal{M}_g$ can be written in exponential form using single exponents,

$$\mathcal{M}_f = \exp(: f :), \tag{8.3.5}$$

$$\mathcal{M}_g = \exp(: g :). \tag{8.3.6}$$

In this case (3.2) and (3.3) can be written in the more explicit form

$$\bar{z}(z) = \mathcal{M}_f z = \exp(: f(z) :)z, \tag{8.3.7}$$

$$\bar{\bar{z}}\,(\bar{z}) = \mathcal{M}_g \bar{z} = \exp(: g(\bar{z}) :)\bar{z}. \tag{8.3.8}$$

Also, if we regard $\bar{z}$ as a function of z, as done in (3.7), then (3.8) can also be written in the form

$$\bar{\bar{z}}\,(z) = \bar{\bar{z}}\,(\bar{z}(z)) = \exp(: g(\bar{z}(z)) :)\bar{z}(z). \tag{8.3.9}$$

[Note that the Poisson brackets implied in (3.9) can be evaluated using either the variables z or $\bar{z}$ with the same result. See (6.3.10), (6.3.11), and (6.3.20).] Finally, suppose we substitute (3.7) into (3.9). Doing so gives the result

$$\bar{\bar{z}}\,(z) = \exp(: g(\bar{z}(z)) :) \exp(: f(z) :)z. \tag{8.3.10}$$

This result is simply (3.4) written in explicit form.

Next suppose the identity operator $\mathcal{I}$, written in the form

$$\mathcal{I} = \exp(: f(z) :) \exp(- : f(z) :), \tag{8.3.11}$$

is inserted right after the equal sign in (3.10). This insertion brings (3.10) to the form

$$\bar{\bar{z}}\,(z) = \exp(: f(z) :) \exp(- : f(z) :) \exp(: g(\bar{z}(z)) :) \exp(: f(z) :)z. \tag{8.3.12}$$

Consider the quantity $\exp(-:f(z):)\exp(:g(\overline{z}(z)):)\exp(:f(z):)$ that appears in (3.12). According to (2.20) we have the result

$$\exp(-:f(z):)\exp(:g(\overline{z}(z)):)\exp(:f(z):) = \exp(:\exp(-:f(z):)g(\overline{z}(z)):). \tag{8.3.13}$$

According to (3.7) and (5.4.11) we have the result

$$g(\overline{z}(z)) = g(\exp(:f(z):)z) = \exp(:f(z):)g(z). \tag{8.3.14}$$

With this information in hand, we may rewrite (3.13) in the form

$$\begin{aligned}\exp(-:f(z):)&\exp(:g(\overline{z}(z)):)\exp(:f(z):)\\ &= \exp(:\exp(-:f(z):)g(\overline{z}(z)):)\\ &= \exp(:\exp(-:f(z):)\exp(:f(z):)g(z):)\\ &= \exp(:g(z):).\end{aligned} \tag{8.3.15}$$

Finally, use of (3.15) in (3.12) gives the remarkable result

$$\overline{\overline{z}}\,(z) = \exp(:f(z):)\exp(:g(z):)z. \tag{8.3.16}$$

Observe that (3.4) can be written in the form

$$\overline{\overline{z}}\,(z) = \mathcal{M}z = \mathcal{M}_g\mathcal{M}_f z, \tag{8.3.17}$$

while (3.16) can be written in the form

$$\overline{\overline{z}}\,(z) = \mathcal{M}z = \mathcal{M}_f\mathcal{M}_g z. \tag{8.3.18}$$

What is going on here to produce two seemingly contradictory results? The difference between (3.17) and (3.18) is as follows: In (3.17), as examination of (3.7), (3.8), and (3.10) shows, f is a function of the *initial* variable z while g is a function of the *intermediate* variable $\overline{z}$. By contrast in (3.18), as (3.16) shows, *both* f and g are functions of the *initial* variable z. What we have learned is that if a beam passes successively through beam line elements f and g, and in that order, then the map for the composite system is $\mathcal{M}_f\mathcal{M}_g$ where both f and g are taken to be functions of the initial variable z. We see that when the factors in a map (which is expressed as a product of factors all of the initial variable z) are read from left to right, they are encountered in the *same* order as they are encountered by the beam.

Strictly speaking, the last two sentences in the previous paragraph have been shown to be true for two maps with both maps assumed to be expressible in exponential form using single exponents as in (3.5) and (3.6). However, by similar arguments, analogous results can be shown to hold in general. For example, suppose $\mathcal{M}_f$, $\mathcal{M}_g$, and $\mathcal{M}_h$ are any three (analytic) maps. Then, from (7.8.1), $\mathcal{M}_f$ has a factorization of the form

$$\mathcal{M}_f = \exp(:f_1:)\exp(:f_2^c:)\exp(:f_2^a:)\exp(:f_3:)\exp(:f_4:)\cdots; \tag{8.3.19}$$

and $\mathcal{M}_g$ and $\mathcal{M}_h$ have similar factorizations. Suppose a trajectory with *initial* condition z^i passes successively through the beam line elements f, g, and h described by the maps $\mathcal{M}_f$,

$\mathcal{M}_g$, and $\mathcal{M}_h$, respectively. Then the *final* condition z^f as a result of this passage is given by the relation

$$\begin{aligned} z^f(z^i) &= \mathcal{M}_f\mathcal{M}_g\mathcal{M}_h z^i \\ &= \exp(:f_1:)\exp(:f_2^c:)\exp(:f_2^a:)\exp(:f_3:)\exp(:f_4:)\cdots\times \\ &\quad \exp(:g_1:)\exp(:g_2^c:)\exp(:g_2^a:)\exp(:g_3:)\exp(:g_4:)\cdots\times \\ &\quad \exp(:h_1:)\exp(:h_2^c:)\exp(:h_2^a:)\exp(:h_3:)\exp(:h_4:)\cdots z^i \end{aligned} \tag{8.3.20}$$

when all the homogeneous polynomials f_j, g_j, and h_j are taken to be functions of the initial variable z^i.

8.3.2 Questions of Order in the Linear Case

We are now prepared to revisit some questions of order that were passed over in earlier sections. In (7.2.3) and (7.2.8) we constructed polynomials f_2^a and f_2^c in such a way that

$$\exp(:f_2^a:)z_b = \sum_d P_{bd}z_d, \tag{8.3.21}$$

$$\exp(:f_2^c:)z_d = \sum_e O_{de}z_e. \tag{8.3.22}$$

In so doing, we made the z's transform as the components of a vector under the actions of the matrices P and O. Then we found the result

$$\exp(:f_2^c:)\exp(:f_2^a:)z_b = \sum_e (PO)_{be}z_e. \tag{8.3.23}$$

See (7.2.10) and (7.2.11). Here both f_2^c and f_2^a were quadratic polynomials in the variable z. Since P and O were defined in such a way that the z's transformed under their actions as the components of a vector, we expect to have the matrix product PO as the result of O acting first and then followed by P. On the other hand, since both $\exp(:f_2^c:)$ and $\exp(:f_2^a:)$ are functions of the initial variable z, we expect to have the operator product $\exp(:f_2^c:)$ $\exp(:f_2^a:)$ when $\exp(:f_2^c:)$ acts first and is then followed by the action of $\exp(:f_2^a:)$. But, as we see from (3.21) and (3.22), $\exp(:f_2^a:)$ corresponds to P and $\exp(:f_2^c:)$ corresponds to O. Thus, the orders on both sides of (3.23) are just as they should be.

Next consider the operator and matrix orders in (7.7.34). Here the operator and matrix orders are the *same* rather than reversed! But look at (7.7.26). We see that in this case the z's transformed under the action of the *transposed* matrix M^T. Thus the definition of M as given in (7.7.26) is different from the definitions of P and O as given by (3.21) and (3.22). One definition involved matrix transposition and the other did not. What (7.7.26) and (7.7.34) teach us is that the inclusion of a transpose in the definition of M makes it possible to have both operator and matrix orders the same.

To gain further insight into what is going on, it is useful to consider the general subject of linear operators and matrices. We begin our discussion by examining simple transformation properties of vectors under the action of linear operators. Consider a vector space V spanned by basis vectors $\boldsymbol{e}_\alpha$ that are orthonormal under some scalar product $(,)$. Let $\boldsymbol{\mathcal{L}}$ be a *linear* operator that sends V into itself. Suppose $\boldsymbol{\mathcal{L}}$ sends $\boldsymbol{e}_\alpha$ into $\boldsymbol{f}_\alpha$. Then we have a relation of the form

$$\boldsymbol{f}_\alpha = \boldsymbol{\mathcal{L}}\boldsymbol{e}_\alpha = \sum_\beta L_{\beta\alpha}\boldsymbol{e}_\beta. \tag{8.3.24}$$

The coefficients $L_{\beta\alpha}$ are given in terms of the scalar product by the matrix elements

$$L_{\beta\alpha} = (\boldsymbol{e}_\beta, \boldsymbol{f}_\alpha) = (\boldsymbol{e}_\beta, \boldsymbol{\mathcal{L}}\boldsymbol{e}_\alpha). \tag{8.3.25}$$

Let $\boldsymbol{A}$ be some vector in V. Since the $\boldsymbol{e}_\alpha$ form a basis, $\boldsymbol{A}$ must have an expansion of the form

$$\boldsymbol{A} = \sum_\alpha a_\alpha \boldsymbol{e}_\alpha. \tag{8.3.26}$$

Consider a vector $\boldsymbol{B}$ defined by

$$\boldsymbol{B} = \boldsymbol{\mathcal{L}}\boldsymbol{A}. \tag{8.3.27}$$

It must have an expansion of the form

$$\boldsymbol{B} = \sum_\beta b_\beta \boldsymbol{e}_\beta. \tag{8.3.28}$$

From (3.25) through (3.28) and the orthonormality condition we find that the components b_β are given by the relation

$$\begin{aligned} b_\beta &= (\boldsymbol{e}_\beta, \boldsymbol{B}) = (\boldsymbol{e}_\beta, \boldsymbol{\mathcal{L}}\boldsymbol{A}) = \sum_\alpha a_\alpha (\boldsymbol{e}_\beta, \boldsymbol{\mathcal{L}}\boldsymbol{e}_\alpha) \\ &= \sum_\alpha L_{\beta\alpha} a_\alpha. \end{aligned} \tag{8.3.29}$$

We note that the summation in (3.24) is over the first index in L, and that in (10.6) is over the second. Let us rewrite (3.24) in the form

$$\boldsymbol{f}_\beta = \boldsymbol{\mathcal{L}}\boldsymbol{e}_\beta = \sum_\alpha L_{\alpha\beta}\boldsymbol{e}_\alpha = \sum_\alpha (L^T)_{\beta\alpha}\boldsymbol{e}_\alpha. \tag{8.3.30}$$

(Note that the indices α and β are dummy indices, and can be changed at will.) Upon comparing (3.29) and (3.30), we see that if *components* are transformed by the matrix L, then *basis vectors* are transformed by the transpose matrix L^T, and vice versa.

8.3.3 Application to General Operators and General Monomials to Construct Matrix Representations

Let us apply what we have just learned to operators $\mathcal{M}$ of the general form

$$\mathcal{M} = \exp(:f_1:)\exp(:f_2^c:)\exp(:f_2^a:)\exp(:f_3:)\exp(:f_4:)\cdots, \tag{8.3.31}$$

and monomials $G(\mu;\nu)$ of the form (7.3.1). [Here the f_j are homogeneous polynomials, and are not to be confused with the $\boldsymbol{f}_\alpha$ of (3.24), which are abstract vectors.] We will view these monomials as basis vectors for the vector space of all polynomials. For this purpose, it is convenient to subsume the indices μ, ν into a single index, which we will again call r. (For a concrete way of making a one-to-one correspondence between the indices μ, ν and the integers r, see Section 27.2.) We will thus work with a set of basis monomials G_r, and in accord with (7.3.8) we will assign them a scalar product $\langle , \rangle$ by the rule

$$\langle G_{r'}, G_r \rangle = \delta_{r'r}. \tag{8.3.32}$$

Now let $\mathcal{M}$ act on a general basis vector G_r. Then we find a result of the form

$$\mathcal{M} G_r = \sum_s M_{sr} G_s \tag{8.3.33}$$

where the coefficients M_{sr} are given in terms of the scalar product by the matrix elements

$$M_{sr} = \langle G_s, \mathcal{M} G_r \rangle. \tag{8.3.34}$$

Suppose $\mathcal{N}$ is another operator of the form (3.31). Then we also have the relation

$$\mathcal{N} G_r = \sum_s N_{sr} G_s \tag{8.3.35}$$

with the matrix N_{sr} given by

$$N_{sr} = \langle G_s, \mathcal{N} G_r \rangle. \tag{8.3.36}$$

Now consider the effect of the operator product $\mathcal{M}\mathcal{N}$ on G_r. Here all the Lie generators f_j appearing in $\mathcal{M}$ and $\mathcal{N}$, as well as all the functions G_r, are assumed to depend on the *same* set of variables z. Then, we find the result

$$\begin{aligned} \mathcal{M}\mathcal{N} G_r &= \mathcal{M} \sum_s N_{sr} G_s = \sum_s N_{sr} \mathcal{M} G_s \\ &= \sum_s N_{sr} \sum_t M_{ts} G_t = \sum_{st} M_{ts} N_{sr} G_t \\ &= \sum_t (MN)_{tr} G_t. \end{aligned} \tag{8.3.37}$$

We note that the ordering of the subscripts in (3.33) through (3.37) is analogous to that used in (7.3.37) through (7.3.40). Indeed, let $\mathcal{A}$ and $\mathcal{B}$ be any two *linear operators.* They could, for example, be Lie operators, or products of Lie operators, or sums of products of Lie operators, or infinite sums of products, etc., including Lie transformations and their products such as occur in (3.31). Define associated matrices $O(\mathcal{A})$ and $O(\mathcal{B})$ by rules of the form

$$O_{sr}(\mathcal{B}) = \langle G_s, \mathcal{B} G_r \rangle. \tag{8.3.38}$$

Then, since the G's form a basis (are a complete set), we have the results

$$\mathcal{B} G_r = \sum_s O_{sr}(\mathcal{B}) G_s, \tag{8.3.39}$$

$$\begin{aligned}\mathcal{A}\mathcal{B}G_r &= \mathcal{A}\sum_s O_{sr}(\mathcal{B})G_s = \sum_s O_{sr}(\mathcal{B})\mathcal{A}G_s \\ &= \sum_s O_{sr}(\mathcal{B})\sum_t O_{ts}(\mathcal{A})G_t = \sum_{st} O_{ts}(\mathcal{A})O_{sr}(\mathcal{B})G_t \\ &= \sum_t (O(\mathcal{A})O(\mathcal{B}))_{tr}G_t. \end{aligned} \tag{8.3.40}$$

From (3.38) and (3.40) we obtain the general relation

$$O(\mathcal{A}\mathcal{B}) = O(\mathcal{A})O(\mathcal{B}). \tag{8.3.41}$$

We have found a matrix representation of the algebra of linear operators acting on function space. It can be shown, in the case that these operators are Lie algebra or Lie group elements, that these matrices are related to the adjoint representation. See Section 8.9.[17]

Note that, for a 6-dimensional phase space and for polynomials of degree 0 through m, the matrices O are $[S(m,6)+1] \times [S(m,6)+1]$. See Section 7.10. For example, in the case $m=4$, 210×210 matrices are required. And, in the case $m=8$, 3003×3003 matrices are required.

8.3.4 Application to Linear Transformations of Phase Space

Let us also apply what we have learned to the subject of linear transformations of *phase space* into itself. Set up a Euclidean coordinate system in phase space with unit vectors $\boldsymbol{e}_a$ along the coordinate and momentum axes. Then the general point in phase space may be identified with the vector $\boldsymbol{z}$ from the origin to that point, and $\boldsymbol{z}$ may be written in the form

$$\boldsymbol{z} = \sum_a z_a \boldsymbol{e}_a \tag{8.3.42}$$

where the z_a are the usual coordinate variables. Suppose $\mathcal{L}$ is a linear transformation of phase space into itself, and suppose $\mathcal{L}$ sends the vector $\boldsymbol{z}$ to the vector $\overline{\boldsymbol{z}}$,

$$\overline{\boldsymbol{z}} = \mathcal{L}\boldsymbol{z}. \tag{8.3.43}$$

The vector $\overline{\boldsymbol{z}}$ must have an expansion of the form

$$\overline{\boldsymbol{z}} = \sum_b \overline{z}_b \boldsymbol{e}_b. \tag{8.3.44}$$

Correspondingly, in analogy to (3.25) through (3.29), the quantities $\overline{z}_b$ and z_a are related by the equation

$$\overline{z}_b = \sum_a L_{ba} z_a. \tag{8.3.45}$$

That is, the z's transform as the *components* of a vector, as is consistent with relations of the form (7.1.1) through (7.1.3), (7.6.1), (3.21), and (3.22).

[17] The fact that linear operators acting on function space can be represented by matrices is familiar to any student of Quantum Mechanics. In the context of differential equations and maps, the matrix representation can be realized by *Carleman linearization*, a construction suggested by Poincaré. See the references at the end of this chapter.

8.3.5 Dual role of the Phase-Space Coordinates z_a

So far we have regarded the z_a as the components of a vector as in (3.42). However, the z_a are also *functions* on phase space. Indeed the z_a are special cases of the functions G_r, and, according to (7.3.1) and (7.3.8), satisfy the orthonormality conditions

$$\langle z_a, z_b \rangle = \delta_{ab}. \tag{8.3.46}$$

Suppose $\mathcal{M}$ is of the form (7.7.28). Then, following (3.39), we find the result

$$\bar{z}_b(z) = \mathcal{M} z_b = \sum_a M^1_{ab} z_a \tag{8.3.47}$$

where the matrix M^1 is given by the relation

$$M^1_{ab} = \langle z_a, \mathcal{M} z_b \rangle. \tag{8.3.48}$$

In addition, according to (7.3.41) through (7.3.45) or relations of the form (3.41), we have the result

$$M^1 = \exp(F^1), \tag{8.3.49}$$

where

$$F^1_{ab} = \langle z_a, : f_2 : z_b \rangle. \tag{8.3.50}$$

Now observe that (3.47) can also be written in the form

$$\bar{z}_b(z) = \sum_a [(M^1)^T]_{ba} z_a. \tag{8.3.51}$$

Thus in view of our earlier discussion, see (3.30) for example, and noting that a and b are dummy indices, we conclude the convention used in (7.7.26) is equivalent to viewing the z_a as *basis vectors* (which is consistent with treating the G_r as basis vectors) rather than as components of a vector.

We have learned that the z_a play a dual role. If they are viewed as the components of a displacement vector as in (3.42), then it is appropriate to write their transformation law in the form (3.45) or (7.6.1). If they are viewed as functions, and therefore as special cases of the basis vectors (functions) G_r, then it may be more convenient to write their transformation law in the form (3.47) or, more generally, (3.33).

8.3.6 Extensions

We now turn to extensions of two results found previously. In our initial discussion of symplectic maps in Section 6.1, a symplectic map was defined as a mapping of phase space into itself that obeyed certain equivalent conditions such as (6.1.3) or (6.1.6) or (6.1.10). In Chapter 7 we learned that symplectic maps can be written in terms of Lie transformations, and obtained the factorizations (7.7.23) and (7.8.1). We also know from (5.4.13) and its generalizations that Lie transformations act on functions, and that the action of a Lie transformation on a function is determined once its action is known on phase space. Indeed, if a and b are any functions, then from (7.7.23), or (7.8.1), and (5.4.10) we have the results

$$\mathcal{M}a(z) = a(\mathcal{M}z), \;\; \mathcal{M}a(z)b(z) = \mathcal{M}a(z)\mathcal{M}b(z) = a(\mathcal{M}z)b(\mathcal{M}z). \tag{8.3.52}$$

Thus, we may also view symplectic maps as entities that act on functions. [Note that we have already encountered this idea in (6.3.6) and (7.1.11) when use is made of (7.7.11)]. Conversely, if we view symplectic maps as entities that act on functions, then, since the z_a are functions, we get the action of symplectic maps on phase space from (7.7.11).

The property (3.52) is a consequence of the fact that Lie transformations are isomorphisms with respect to (ordinary) multiplication. See Section 5.4. We also know from Section 5.4 that Lie transformations are isomorphisms with respect to Poisson bracket multiplication. See (5.4.14). It follows from (5.4.15) and its generalizations, and from (7.7.23) or (7.8.1), that we also have the result

$$\mathcal{M}[a, b] = [\mathcal{M}a, \mathcal{M}b]. \tag{8.3.53}$$

Again, this result should already be familiar. When combined with (3.48), it yields the result (6.3.20).

8.3.7 Sign Differences

The last question to be discussed in this section is the difference in sign between relations such as (5.5.1) and (7.2.3). The simple answer is that the sign in (5.5.1) was selected to achieve the correspondence (5.5.13), and that in (7.2.3) was selected to make (7.2.7) hold. But why should the signs turn out to be different? Our discussion of this topic may seem somewhat discursive. However, we shall learn some interesting concepts and facts along the way.

Exercise 3.7.33 studied how, given some matrix representation of a Lie algebra, one might find other similar or possibly different representations. Now let us carry out the analogous discussion for the corresponding Lie group. Suppose some set of matrices gives a respresentation of some group. To every representation matrix M we associate another matrix M' by the rule

$$M' = \bar{M} \tag{8.3.54}$$

where a bar denotes complex conjugation. Then these matrices satisfy the relation

$$M_1' M_2' = (M_1 M_2)', \tag{8.3.55}$$

and therefore also provide a representation of some group. If the matrices M are real, then nothing new has been found. However, if the matrices M are complex and the structure constants of the underlying Lie algebra cannot be made real by some appropriate basis choice, then one must determine whether the resulting group is the same as the original group. If the structure constants are real, then the group will be the same and the representation given by the matrices M' may be different than that given by the matrices M. For example, in the case of the group $SU(3)$, if the matrices M provide the representation $\Gamma(m, n)$, then the matrices M' provide the representation $\Gamma(n, m)$. See Section 5.8.

Suppose, instead of using (3.54) to define M', we use the rule

$$M' = (M^T)^{-1} = (M^{-1})^T. \tag{8.3.56}$$

Then the M' matrices defined in this way also satisfy (3.55), and also provide a representation of the group in question. As an example, consider the case where the matrices M are symplectic. The symplectic condition (3.1.2) can be written in the form

$$M' = (M^T)^{-1} = JMJ^{-1}. \tag{8.3.57}$$

From (3.57) we see that in this case the matrices M' and M are *similar*, and hence the representations of the group in question carried by M' and M are the *same*. As a second example, suppose the matrices M are unitary,

$$M^\dagger = (\bar{M})^T = M^{-1}. \tag{8.3.58}$$

Then we find the result

$$M' = (M^{-1})^T = \bar{M}. \tag{8.3.59}$$

In this case the definitions (3.54) and (3.56) coincide. What happens if the matrices M belong to $SU(2)$? Since these matrices are complex, we might hope that the "priming" operation (3.59) would give something new. However, since matrices in $SU(2)$ are 2×2 and have determinant $+1$, they must also be symplectic. See the comment after Exercise 3.1.3. Consequently, (3.57) must also hold, and we in fact find that both M' and M carry the *same* representation.

Let M^f be a symplectic matrix. Associate with M^f a symplectic map $\mathcal{M}(M^f)$ by the rule

$$\mathcal{M}(M^f)z_a = \sum_b [(M^f)^{-1}]_{ab} z_b. \tag{8.3.60}$$

Note that (3.60) is analogous to (7.7.26) except that M^T has been replaced by M^{-1}. Let M^g be another symplectic matrix, and make the definitions

$$\mathcal{M}_f = \mathcal{M}(M^f), \tag{8.3.61}$$

$$\mathcal{M}_g = \mathcal{M}(M^g). \tag{8.3.62}$$

Then if we regard $\mathcal{M}_f$ and $\mathcal{M}_g$ as composed of Lie transformations all involving the same variable z we find, in analogy to (7.7.33), the result

$$\begin{aligned}
\mathcal{M}_f \mathcal{M}_g z_a &= \mathcal{M}(M^f)\mathcal{M}(M^g) z_a = \mathcal{M}(M^f) \sum_b [(M^g)^{-1}]_{ab} z_b \\
&= \sum_{b,c} [(M^g)^{-1}]_{ab} [(M^f)^{-1}]_{bc} z_c \\
&= \sum_c [(M^g)^{-1}(M^f)^{-1}]_{ac} z_c = \sum_c [(M^f M^g)^{-1}]_{ac} z_c \\
&= \mathcal{M}(M^f M^g) z_a.
\end{aligned} \tag{8.3.63}$$

We see that the definition (3.60) makes it possible to have both operator and matrix orders the same just as the definition (7.7.26) did. This result is not surprising in view of (3.56) and (3.55).

From a group theory perspective, the advantage of (3.60) compared to (7.7.26) is that the computation of M^{-1} is a *group* operation whereas the computation of M^T is not.

Now that we have a relation that has both operator and matrix orders the same, we can compare their respective Lie algebras. Let S^f and S^g be two symmetric matrices and use them to define functions f_2 and g_2 as in (5.5.1) and (5.5.2),

$$f_2 = (1/2)\sum_{a,b} S^f_{ab} z_a z_b, \tag{8.3.64}$$

$$g_2 = (1/2)\sum_{a,b} S^g_{ab} z_a z_b. \tag{8.3.65}$$

Then we have results of the form

$$: f_2 : z = (-JS^f)z, \tag{8.3.66}$$

and hence

$$\exp(: f_2 :)z = \exp(-JS^f)z = [\exp(JS^f)]^{-1}z. \tag{8.3.67}$$

Upon comparing (3.60) and (3.67), we find the results

$$\mathcal{M}_f = \exp(: f_2 :) = \mathcal{M}[\exp(JS^f)], \tag{8.3.68}$$

$$\mathcal{M}_g = \exp(: g_2 :) = \mathcal{M}[\exp(JS^g)]. \tag{8.3.69}$$

Now consider the product $\exp(\epsilon : f_2 :)\exp(\epsilon : g_2 :)\exp(-\epsilon : f_2 :)\exp(-\epsilon : g_2 :)$ where ϵ is a small quantity. Then, as a consequence of (3.63), we find the relation

$$\begin{aligned} &\exp(\epsilon : f_2 :)\exp(\epsilon : g_2 :)\exp(-\epsilon : f_2 :)\exp(-\epsilon : g_2 :) \\ = \;&\mathcal{M}[\exp(\epsilon JS^f)\exp(\epsilon JS^g)\exp(-\epsilon JS^f)\exp(-\epsilon JS^g)]. \end{aligned} \tag{8.3.70}$$

The products occurring in (3.70) may be viewed as the group analog of what would be a commutator at the Lie algebraic level. Indeed, from (2.27) and (2.28) we find through terms of order ϵ^2 the result

$$\exp(\epsilon : f_2 :)\exp(\epsilon : g_2 :)\exp(-\epsilon : f_2 :)\exp(-\epsilon : g_2 :) = \exp(\epsilon^2 : [f_2, g_2] :). \tag{8.3.71}$$

Similarly, from (3.7.34) we find through terms of order ϵ^2 the result

$$\exp(\epsilon JS^f)\exp(\epsilon JS^g)\exp(-\epsilon JS^f)\exp(-\epsilon JS^g) = \exp(\epsilon^2\{JS^f, JS^g\}). \tag{8.3.72}$$

Now compare (3.70) through (3.72). Doing so gives through terms of order ϵ^2 the result

$$\exp(\epsilon^2 : [f_2, g_2] :) = \mathcal{M}[\exp(\epsilon^2\{JS^f, JS^g\})]. \tag{8.3.73}$$

We are ready for the final step. Let h_2 be the second-degree polynomial defined by the relation

$$h_2 = [f_2, g_2]. \tag{8.3.74}$$

Then, with S^h defined by

$$h_2 = (1/2)\sum_{a,b} S^h_{ab} z_a z_b, \tag{8.3.75}$$

we have the result

$$\mathcal{M}_h = \exp(: h_2 :) = \mathcal{M}[\exp(JS^h)]. \tag{8.3.76}$$

Now compare (3.73) and (3.76) to get the result

$$\mathcal{M}[\exp(\epsilon^2 JS^h)] = \mathcal{M}[\exp(\epsilon^2\{JS^f, JS^g\})]. \tag{8.3.77}$$

We see that for consistency we must have the relation

$$JS^h = \{JS^f, JS^g\}. \tag{8.3.78}$$

This relation is identical to that in (5.5.13). The moral of this rather long tale is that the sign in relations such as (5.5.1) was chosen so that, when (3.60) is used, it is possible to have relations of the form (3.68) and to have both operator and matrix orders the same in (3.63); and when the orders are the same it is easy to compare Lie algebras (exponents) as was done in (3.68) through (3.73). On the other hand, the sign in relations such as (7.2.3) was chosen to achieve relations such as (7.2.7) and (7.2.9), which are to be compared to (3.67).

Exercises

8.3.1. Verify (3.20).

8.3.2. From (3.38) show that $O(\mathcal{A}) + O(\mathcal{B}) = O(\mathcal{A} + \mathcal{B})$.

8.3.3. Verify (3.52) using (5.4.13) and (7.7.23) or (7.8.1).

8.3.4. Verify (3.53) using (5.4.15) and (7.7.23) or (7.8.1).

8.3.5. Given (3.56), verify (3.55).

8.3.6. Show that the map (3.60) is indeed symplectic.

8.3.7. Verify (3.66) and (3.67).

8.3.8. Verify (3.70).

8.3.9. Verify (3.71) and (3.72).

8.4 Lie Concatenation Formulas

As an application of the formulas and ideas developed so far, consider the problem of computing the product of two symplectic maps when each is expressed in factored product form. This problem arises in accelerator physics, for example, in the case that one knows the effect of each of two beam elements separately, and one wants to know the net effect when one beam element is followed by another. For simplicity, in this section we will consider maps that send the origin into itself, i.e. maps of the form (7.6.3). The most general case of maps that include leading and trailing translations, i.e. maps of the form (7.7.23), will be treated in the next chapter.

Let $\mathcal{M}_f$ and $\mathcal{M}_g$ denote the symplectic maps given by the expressions

$$\mathcal{M}_f = \exp(:f_2^c:)\exp(:f_2^a:)\exp(:f_3:)\exp(:f_4:)\cdots, \tag{8.4.1}$$

$$\mathcal{M}_g = \exp(:g_2^c:)\exp(:g_2^a:)\exp(:g_3:)\exp(:g_4:)\cdots. \tag{8.4.2}$$

Also, let $\mathcal{M}_h$ be the product of $\mathcal{M}_f$ and $\mathcal{M}_g$,

$$\mathcal{M}_h = \mathcal{M}_f\mathcal{M}_g. \tag{8.4.3}$$

The problem is to find polynomials h_2^c, h_2^a, h_3, etc. such that

$$\mathcal{M}_h = \exp(:h_2^c:)\exp(:h_2^a:)\exp(:h_3:)\exp(:h_4:)\cdots. \tag{8.4.4}$$

That is, the problem is to express $\mathcal{M}_h$ as given by (4.3) in the factored product form (4.4). For simplicity, only expressions for $h_2^c, h_2^a, h_3, \cdots h_8$ will be found explicitly. Here, as described in Section 8.3, all polynomials f_j, g_j, and h_j are taken to be functions of the same variable z.

Before proceeding further, it is necessary to establish a few simple facts. Suppose g_2 is a quadratic polynomial written in the form

$$g_2 = -(1/2)\sum_{de} S_{de}z_d z_e = -(1/2)(z, Sz), \tag{8.4.5}$$

where S is some symmetric matrix. Suppose further that f_m is some homogeneous polynomial of degree m. Then $\exp(:g_2:)f_m$ is also a homogeneous polynomial of degree m. Indeed, we have the result

$$\exp(:g_2:)f_m(z) = f_m[\exp(:g_2:)z] = f_m(M^g z), \tag{8.4.6}$$

where M^g is the linear transformation defined by the equation

$$M^g = \exp(JS). \tag{8.4.7}$$

See (5.4.11) and Section 7.2. Suppose further that g_2^c and g_2^a are quadratic polynomials written in the forms

$$g_2^a = -(1/2)(z, S^a z), \tag{8.4.8}$$

$$g_2^c = -(1/2)(z, S^c z). \tag{8.4.9}$$

Then we have the result

$$\exp(:g_2^c:)\exp(:g_2^a:)f_m(z) = f_m[\exp(:g_2^c:)\exp(:g_2^a:)z] = f_m(R^g z), \tag{8.4.10}$$

where R^g is the linear transformation defined by the equations

$$R^g = P^g O^g, \tag{8.4.11}$$

$$P^g = \exp(JS^a), \tag{8.4.12}$$

$$O^g = \exp(JS^c). \tag{8.4.13}$$

See Section 7.2. Let us introduce the symplectic map $\mathcal{R}_g$ defined by the equation

$$\mathcal{R}_g = \exp(:g_2^c:)\exp(:g_2^a:). \tag{8.4.14}$$

What we have established is the relation

$$\mathcal{R}_g f_m(z) = f_m(R^g z). \tag{8.4.15}$$

Actually, (4.15) is not quite what will be needed. What we will need is the relation

$$(\mathcal{R}_g)^{-1} f_m(z) = f_m[(R^g)^{-1} z]. \tag{8.4.16}$$

This relation can be established in a similar fashion. Note that, thanks to the symplectic condition, the matrix $(R^g)^{-1}$ required in (4.16) is easily calculated using (3.1.9).

We are now ready to continue. Simply from its definition (4.3), $\mathcal{M}_h$ can be written in the form

$$\mathcal{M}_h = \mathcal{R}_f \exp(:f_3:)\exp(:f_4:)\cdots\mathcal{R}_g\exp(:g_3:)\exp(:g_4:)\cdots . \tag{8.4.17}$$

Here we have used (4.14) and an analogous definition for $\mathcal{R}_f$. Next, by insertion of a factor of $\mathcal{R}_g(\mathcal{R}_g)^{-1}$, (4.17) can be rewritten in the form

$$\mathcal{M}_h = \mathcal{R}_f\mathcal{R}_g(\mathcal{R}_g)^{-1}\exp(:f_3:)\exp(:f_4:)\cdots\mathcal{R}_g\exp(:g_3:)\exp(:g_4:)\cdots . \tag{8.4.18}$$

Evidently, comparison of (4.4) and (4.18) shows that h_2^c and h_2^a are determined by the equation

$$\mathcal{R}_h = \mathcal{R}_f\mathcal{R}_g. \tag{8.4.19}$$

Indeed, we have the result

$$R^h = R^g R^f, \tag{8.4.20}$$

where R^g is defined by (4.11) through (4.13), and R^f and R^h are defined by analogous relations. See Section 8.3.

Next define a function F of the Lie operators $:f_3:, :f_4:, \cdots$ by the relation

$$F(:f_3:, :f_4:, \cdots) = \exp(:f_3:)\exp(:f_4:)\cdots . \tag{8.4.21}$$

Evidently (4.18) contains the factor $(\mathcal{R}_g)^{-1}F\mathcal{R}_g$. As a consequence of (2.25) we have the result

$$(\mathcal{R}_g)^{-1}F(:f_3:, :f_4:, \cdots)\mathcal{R}_g = F(:f_3[(R^g)^{-1}z]:, :f_4[(R^g)^{-1}z]:, \cdots). \tag{8.4.22}$$

In order to simplify further expressions, introduce the notation

$$f_m^{tr}(z) = f_m[(R^g)^{-1}z], \tag{8.4.23}$$

which indicates that the homogeneous polynomial $f_m(z)$ of degree m has been *transformed* to the new homogeneous polynomial $f_m[(R^g)^{-1}z]$. With this notation, (4.22) can be written in the more compact form

$$(\mathcal{R}_g)^{-1}F(:f_3:,:f_4:,\cdots)\mathcal{R}_g = F(:f_3^{tr}:,:f_4^{tr}:,\cdots) = \exp(:f_3^{tr}:)\exp(:f_4^{tr}:)\cdots. \tag{8.4.24}$$

Putting together the work done so far, one finds that (4.18) can also be written in the form

$$\mathcal{M}_h = \mathcal{R}_h \exp(:f_3^{tr}:)\exp(:f_4^{tr}:)\cdots\exp(:g_3:)\exp(:g_4:)\cdots. \tag{8.4.25}$$

Upon comparing (4.4) and (4.25), we find the result

$$\exp(:h_3:)\exp(:h_4:)\cdots = \exp(:f_3^{tr}:)\exp(:f_4^{tr}:)\cdots\exp(:g_3:)\exp(:g_4:)\cdots. \tag{8.4.26}$$

We are now prepared to compute $h_3, h_4, \cdots$ in terms of $f_3^{tr}, f_4^{tr}, \cdots$ and $g_3, g_4, \cdots$. The tool for doing so will be the BCH formula as given by (2.27) and (2.28). We will also use the degree function defined in (7.6.13) and the relation (7.6.14). They are reproduced below for ready reference,

$$\deg(f_m) = m, \tag{8.4.27}$$

$$\deg([f_m, f_n]) = m + n - 2. \tag{8.4.28}$$

Consider the result of combining all exponents on the left side of (4.26) into one grand exponent h by repeated use of the BCH formula. Then, thanks to (4.28), it is relatively easy to pick out and collect various terms according to their degree. One finds the result

$$h = h_3 + h_4 + \{(1/2)[h_3, h_4] + h_5\} + \cdots. \tag{8.4.29}$$

Next, consider the result of combining all exponents on the right side of (4.26) into one grand exponent e. One finds the result

$$e = \{f_3^{tr} + g_3\} + \{(1/2)[f_3^{tr}, g_3] + f_4^{tr} + g_4\} + \cdots. \tag{8.4.30}$$

Now compare (4.29) and (4.30). By equating terms of like degree, we immediately obtain the results

$$h_3 = f_3^{tr} + g_3, \tag{8.4.31}$$

$$h_4 = f_4^{tr} + g_4 + [f_3^{tr}, g_3]/2. \tag{8.4.32}$$

With further work, it is possible to find the polynomials h_5, h_6, etc. Doing so one finds, for example, the results

$$h_5 = f_5^{tr} + g_5 - [g_3, f_4^{tr}] + \frac{1}{3} :g_3:^2 f_3^{tr} - \frac{1}{6} :f_3^{tr}:^2 g_3, \tag{8.4.33}$$

$$\begin{aligned} h_6 \;=\;& f_6^{tr} + g_6 - [g_3, f_5^{tr}] + \frac{1}{2} :g_3:^2 f_4^{tr} + \frac{1}{2}[f_4^{tr}, g_4] - \frac{1}{4}[f_4^{tr}, [f_3^{tr}, g_3]] \\ -\;& \frac{1}{4}[g_4, [f_3^{tr}, g_3]] + \frac{1}{24} :f_3^{tr}:^3 g_3 - \frac{1}{8} :g_3:^3 f_3^{tr} \\ +\;& \frac{1}{8}[f_3^{tr}, [g_3, [f_3^{tr}, g_3]]], \end{aligned} \tag{8.4.34}$$

$$
\begin{aligned}
h_7 \;=\;& f_7^{tr} + g_7 - :g_3: f_6^{tr} - :g_4: f_5^{tr} + \frac{1}{2} :g_3:^2 f_5^{tr} \\
+\;& \frac{1}{2} :f_4^{tr}::g_3: f_4^{tr} + :g_4::g_3: f_4^{tr} + \frac{1}{3} :g_3::f_4^{tr}::f_3^{tr}: g_3 \\
-\;& \frac{1}{6} :g_3:^3 f_4^{tr} - \frac{1}{6} :g_4::f_3^{tr}::g_3: f_3^{tr} - \frac{1}{6} :f_4^{tr}::f_3^{tr}::g_3: f_3^{tr} \\
-\;& \frac{1}{3} :g_4::g_3:^2 f_3^{tr} - \frac{1}{3}[:g_3: f_3^{tr}, :g_3: f_4^{tr}] \\
-\;& \frac{1}{120} :f_3^{tr}:^4 g_3 - \frac{1}{30} :g_3::f_3^{tr}:^3 g_3 - \frac{1}{20} :g_3:^2:f_3^{tr}:^2 g_3 \\
+\;& \frac{1}{30} :g_3:^4 f_3^{tr} + \frac{1}{30}[:f_3^{tr}: g_3, :f_3^{tr}:^2 g_3] + \frac{1}{15}[:g_3: f_3^{tr}, :g_3:^2 f_3^{tr}], \qquad (8.4.35)
\end{aligned}
$$

$$
\begin{aligned}
h_8 \;=\;& f_8^{tr} + g_8 - :g_3: f_7^{tr} - :g_4: f_6^{tr} - \frac{1}{2} :g_5: f_5^{tr} \\
+\;& \frac{1}{2} :g_3:^2 f_6^{tr} + \frac{1}{2} :f_5^{tr}::g_3: f_4^{tr} + :g_4::g_3: f_5^{tr} + \frac{1}{2} :g_5::g_3: f_4^{tr} + \frac{1}{3} :g_4:^2: f_4^{tr} \\
+\;& \frac{1}{6} :f_4^{tr}::g_4: f_4^{tr} - \frac{1}{6} :g_3:^3: f_5^{tr} - \frac{1}{12} :f_5^{tr}::f_3^{tr}::g_3: f_3^{tr} - \frac{1}{6} :g_3::f_5^{tr}::g_3: f_3^{tr} \\

-\;& \frac{1}{2} :g_4::g_3:^2 f_4^{tr} - \frac{1}{6}[:g_3: f_3^{tr}, :g_4: f_4^{tr}] - \frac{1}{6} :g_4:^2: g_3: f_3^{tr} \\
+\;& \frac{1}{24} :f_4^{tr}::f_3^{tr}:^2: g_3: f_3^{tr} + \frac{1}{8} :g_3::f_4^{tr}::f_3^{tr}::g_3: f_3^{tr} + \frac{1}{8} :g_3:^2: f_4^{tr}::g_3: f_3^{tr} \\
+\;& \frac{1}{24} :g_3:^4 f_4^{tr} - \frac{1}{24}[:g_3: f_4^{tr}, :f_3^{tr}::g_3: f_3^{tr}] - \frac{1}{12}[:g_3: f_4^{tr}, :g_3:^2 f_3^{tr}] \\
+\;& \frac{1}{24}[:g_3: f_3^{tr}, :f_4^{tr}::g_3: f_3^{tr}] + \frac{1}{8}[:g_3::f_3^{tr}:, :g_3:^2 f_4^{tr}] + \frac{1}{24} :g_4::f_3^{tr}:^2: g_3: f_3^{tr} \\
+\;& \frac{1}{8} :g_4::g_3::f_3^{tr}::g_3: f_3^{tr} + \ \frac{1}{8} :g_4::g_3:^3 f_3^{tr} : + \frac{1}{24}[:g_3: f_3^{tr}, :g_4::g_3: f_3^{tr}] \\
-\;& \frac{1}{720} :f_3^{tr}:^4: g_3: f_3^{tr} - \frac{1}{144} :g_3::f_3^{tr}:^3: g_3: f_3^{tr} - \frac{1}{144}[:g_3: f_3^{tr}, :f_3^{tr}:^2: g_3: f_3^{tr}] \\
-\;& \frac{1}{72} :g_3:^2: f_3^{tr}:^2: g_3: f_3^{tr} - \frac{1}{48}[:g_3: f_3^{tr}, :g_3::f_3^{tr}::g_3: f_3^{tr}] - \frac{1}{72} :g_3:^3: f_3^{tr}::g_3: f_3^{tr} \\
-\;& \frac{1}{48}[:g_3: f_3^{tr}, :g_3:^3 f_3^{tr}] - \frac{1}{144} :g_3:^5 f_3^{tr}. \qquad (8.4.36)
\end{aligned}
$$

Upon examining the expressions for h_4, h_5, h_6, etc. we see that they contain both what we will call *direct* terms and what we will call *feed-up* terms. For example, consider h_4 as given by (4.32). It contains the direct terms f_4^{tr} and g_4 which come from like terms in $\mathcal{M}_f$ and $\mathcal{M}_g$. It also contains the feed-up term $[f_3^{tr}, g_3]$ which comes from lower-order terms in $\mathcal{M}_f$ and $\mathcal{M}_g$. We see that low-order nonlinearities, when combined, can lead to higher-order nonlinearities.

There is also a way of getting relations such as (4.31) through (4.36) directly without use of the BCH formula. Suppose we expand all the exponentials appearing in (4.26). Doing so gives a relation of the form

$$\begin{aligned}&(1+:h_3:+:h_3:^2/2!+\cdots)(1+:h_4:+\cdots)\cdots\\&=(1+:f_3^{tr}:+:f_3^{tr}:^2/2!+\cdots)(1+:f_4^{tr}:+\cdots)\cdots\times\\&(1+:g_3:+:g_3:^2/2!+\cdots)(1+:g_4:+\cdots)\cdots\,.\end{aligned}\tag{8.4.37}$$

Next carry out the indicated multiplications and group terms according to the degree of the polynomial that would be produced if these terms were to act on z. We find the result

$$\begin{aligned}&1+:h_3:+(:h_3:^2/2!+:h_4:)+\cdots=1+(:f_3^{tr}:+:g_3:)\\&+(:f_3^{tr}::g_3:+:f_3^{tr}:^2/2!+:g_3:^2/2!+:f_4^{tr}:+:g_4:)+\cdots\,.\end{aligned}\tag{8.4.38}$$

Now equate terms of like degree to find results of the form

$$:h_3:=:f_3^{tr}:+:g_3:,\tag{8.4.39}$$

$$:h_3:^2/2!+:h_4:=:f_3^{tr}::g_3:+:f_3^{tr}:^2/2!+:g_3:^2/2!+:f_4^{tr}:+:g_4:\,.\tag{8.4.40}$$

Evidently (4.39) is equivalent to (4.31). Also, if we substitute (4.39) into (4.40) and rearrange terms, we find the result

$$\begin{aligned}:h_4:&=&&:f_4^{tr}:+:g_4:+:f_3^{tr}::g_3:-(1/2)(:f_3^{tr}::g_3:+:g_3::f_3^{tr}:)\\&=&&:f_4^{tr}:+:g_4:+(1/2)\{:f_3^{tr}:,:g_3:\}.\end{aligned}\tag{8.4.41}$$

We see, with the aid of (4.3.14), that (4.41) corresponds to (4.32). Similarly, if we retain more terms in (4.38), we can derive the relations (4.33) through (4.36), etc.

There is an equivalent but somewhat more elegant way of carrying out the same calculation. As before we expand all the exponentials appearing on the right side of (4.26); however, we retain the left side in factored product form. As a result we find the relation

$$\begin{aligned}&\exp(:h_3:)\exp(:h_4:)\cdots=(1+:f_3^{\rm tr}:+:f_3^{\rm tr}:^2/2!+\cdots)\times\\&(1+:f_4^{\rm tr}:+\cdots)\cdots\times(1+:g_3:+:g_3^2/2!+\cdots)(1+:g_4:+\cdots)\cdots\\&=1+(:f_3^{\rm tr}:+:g_3:)+(:f_3^{\rm tr}::g_3:+:f_3^{\rm tr}:^2/2!+:g_3:^2/2!+:f_4^{\rm tr}:+:g_4:)+\cdots\,.\end{aligned}\tag{8.4.42}$$

From (4.42) we infer, as before, the relation (4.39). But now we multiply both sides of (4.42) on the left by $\exp(-:h_3:)$ and make use (4.39) to find the result

$$\begin{aligned}&\exp(:h_4:)\cdots=\exp[-(:f_3^{\rm tr}:+:g_3:)]\times[1+(:f_3^{\rm tr}:+:g_3:)\\&+(:f_3^{\rm tr}::g_3:+:f_3^{\rm tr}:^2/2!+:g_3:^2/2!+:f_4^{\rm tr}:+:g_4:)+\cdots].\end{aligned}\tag{8.4.43}$$

Next we expand the exponential on the right side of (4.43) and carry out the indicated multiplications to get the relation

$$\exp(:h_4:)\cdots=1+[(:f_3^{\rm tr}::g_3:-:g_3::f_3^{\rm tr}:)/2+:f_4^{\rm tr}:+:g_4:]+\cdots\,.\tag{8.4.44}$$

At this point we are ready to repeat the process: From (4.44) we infer, again as before, the relation (4.41). Next we multiply both sides of (4.44) on the left by $\exp(-:h_4:)$, make use of (4.41), etc. This process is reminiscent of the factorization algorithm employed in Section 7.6. It is clear that it can be repeated indefinitely to find expressions for the $:h_m:$ for ever larger values of m. The only major problem (which also occurred before) is to write these expressions in commutator form so that the outer colons can be removed [using (5.3.14)] to obtain final results in the form (4.31) through (4.36), etc.

The problem of writing expressions in commutator form is solved by a result of *Dynkin*. Let $x_1, x_2, \cdots x_n$ be a collection of noncommuting variables. Suppose P is a polynomial in these variables of the form

$$P = \sum a_{i_1 i_2 \cdots i_k} x_{i_1} x_{i_2} \cdots x_{i_k}. \tag{8.4.45}$$

Note that each term contains k factors, not necessarily distinct, and therefore P is homogeneous of degree k. For each monomial $x_{i_1} x_{i_2} \cdots x_{i_k}$ form a related multiple commutator $(x_{i_1} x_{i_2} \cdots x_{i_k})^0$ by the rule

$$(x_{i_1} x_{i_2} \cdots x_{i_k})^0 = (1/k)\{\cdots\{x_{i_1}, x_{i_2}\}, x_{i_3}\}, \cdots x_{i_k}\}. \tag{8.4.46}$$

Also suppose it is known in principle that P can be written in terms of commutators (as is our situation thanks to the BCH formula). Then, Dynkin proved, *one* such commutator form for P is

$$P = \sum a_{i_1 i_2 \cdots i_k} (x_{i_1} x_{i_2} \cdots x_{i_k})^0. \tag{8.4.47}$$

Here it is helpful to work out an example. In the process of calculating h_5 based on (4.37) one finds the intermediate result

$$:h_5: = :f_5^{tr}: + :g_5: + :f_4^{tr}::g_3: - :g_3::f_4^{tr}: + P \tag{8.4.48}$$

with P given by the relation

$$\begin{aligned} P(:f_3^{tr}:, :g_3:) = & - :f_3^{tr}:^2:g_3:/6 + :f_3^{tr}::g_3::f_3^{tr}:/3 \\ & + :f_3^{tr}::g_3:^2/3 - :g_3::f_3^{tr}:^2/6 - (2/3):g_3::f_3^{tr}::g_3: \\ & + :g_3:^2:f_3^{tr}:/3. \end{aligned} \tag{8.4.49}$$

The problem is to put P in commutator form. Following (4.46) gives the results

$$\begin{gathered} (:f_3^{tr}:^2:g_3:)^0 = (1/3)\{\{:f_3^{tr}:, :f_3^{tr}:\}, :g_3:\} = 0, \\ (:f_3^{tr}::g_3::f_3^{tr}:)^0 = (1/3)\{\{:f_3^{tr}:, :g_3:\}, :f_3^{tr}:\}, \\ (:f_3^{tr}::g_3:^2)^0 = (1/3)\{\{:f_3^{tr}:, :g_3:\}, :g_3:\}, \\ (:g_3::f_3^{tr}:^2)^0 = (1/3)\{\{:g_3:, :f_3^{tr}:\}, :f_3^{tr}:\}, \\ (:g_3::f_3^{tr}::g_3:)^0 = (1/3)\{\{:g_3:, :f_3^{tr}:\}, :g_3:\}, \\ (:g_3:^2:f_3^{tr}:)^0 = (1/3)\{\{:g_3:, :g_3:\}, :f_3^{tr}:\} = 0. \end{gathered} \tag{8.4.50}$$

Consequently, according to Dynkin, P can be written in the commutator form

$$\begin{aligned} P = & (1/9)\{\{:f_3^{tr}:, :g_3:\}, :f_3^{tr}:\} + (1/9)\{\{:f_3^{tr}:, :g_3:\}, :g_3:\} \\ - & (1/18)\{\{:g_3:, :f_3^{tr}:\}, :f_3^{tr}:\} - (2/9)\{\{:g_3:, :f_3^{tr}:\}, :g_3:\}. \end{aligned} \tag{8.4.51}$$

Note that h_5 as given by (4.48) with P given by (4.51) bears only some resemblence to the h_5 in (4.33). However, repeated use of the antisymmetry condition (3.7.41) gives the results

$$\begin{gathered}\{\{:f_3^{tr}:,:g_3:\},:f_3^{tr}:\}=-\{:f_3^{tr}:,\{:f_3^{tr}:,:g_3:\}\},\\ \{\{:f_3^{tr}:,:g_3:\},:g_3:\}=\{:g_3:,\{:g_3:,:f_3^{tr}:\}\},\\ \{\{:g_3:,:f_3^{tr}:\},:f_3^{tr}:\}=\{:f_3^{tr}:,\{:f_3^{tr}:,:g_3:\}\},\\ \{\{:g_3:,:f_3^{tr}:\},:g_3:\}=-\{:g_3:,\{:g_3:,:f_3^{tr}:\}\}. \qquad (8.4.52)\end{gathered}$$

Inserting these results into P as given by (4.51) brings it to the form

$$P=(1/3)\{:g_3:,\{:g_3:,:f_3^{tr}:\}\}-(1/6)\{:f_3^{tr}:,\{:f_3^{tr}:,:g_3:\}\}, \qquad (8.4.53)$$

and h_5 as given by (4.48) with this P is the "colonized" version of (4.33).

This example illustrates both the use of Dynkin's theorem and a further complication. The complication is to determine when two expressions involving multiple Lie products are in fact equivalent when due account is taken of the antisymmetry condition (3.7.41) and/or the Jacobi condition (3.7.42). One method to compare expressions is to realize the Lie products in terms of commutators and then expand out all commutators to obtain a sum of monomials. If the two monomial sums agree term by term, then the two multiple Lie product expressions are equivalent. For example, expanding out P as given by (4.51) or (4.53) both produce (4.49). However, this expansion method is awkward since the expanded version may contain a very large number of terms. Another method is to employ some *basis* in standard form in which only certain multiple Lie product terms occur (with all other possible terms being brought to standard form by use of the antisymmetry and Jacobi conditions). Two multiple Lie product expressions are then equivalent if they agree term by term when re-expressed in some standard form basis. (Obviously their expanded commutator realizations will then also agree.) Two possible such bases are the *Hall* and *Chen-Fox-Lyndon-Shirshov* bases. See Appendix C.

There are yet another concerns when one is interested in numerical implementations. Because Lie multiplications (Poisson bracketing) are time consuming, it is desirable to minimize their number. For example, if only h_3 through h_5 were needed, the relations (4.32) and (4.33) could be rewritten and utilized in the form

$$h_4=f_4^{tr}+g_4-(1/2)[g_3,f_3^{tr}], \qquad (8.4.54)$$

$$h_5=f_5^{tr}+g_5+[g_3,-f_4^{tr}+(1/3)[g_3,f_3^{tr}]]+(1/6)[f_3^{tr},[g_3,f_3^{tr}]]. \qquad (8.4.55)$$

In this form a total of only three Poisson brackets is required. Also there is the sometimes conflicting desire to rearrange terms so that quantities already calculated can be reused to maximum benefit. Thus, the strategy might change if one wished to compute $h_6, h_7, \cdots$ as well. Finally, in actual practice, the quantities $g_3, g_4, \cdots$ may be *sparse* (most possible monomials in them having vanishing coefficients). In this case it is desirable to arrange the Poisson bracket terms in such a way that Poisson bracket routines designed to exploit sparseness can be employed. [The expansions (4.54) and (4.55) above have been arranged to exploit possible sparseness in g_3.] See Section 27.8.

We close this section by noting that there is yet another way of finding Lie concatenation formulas without needing the BCH coefficients, and it has the added advantage of immediately yielding results in Lie form. At present we do not have at our disposal all the tools required for its presentation. They will be developed in Chapter 10. See Section 10.5 where the subject of Lie concatenation is again discussed.

Exercises

8.4.1. Verify (4.16).

8.4.2. Verify (4.29) and (4.30).

8.4.3. Verify (4.31) through (4.33).

8.4.4. Starting with (4.37), verify (4.38) through (4.41).

8.4.5. Derive (4.48) and (4.49) from (4.37).

8.4.6. Expand out (4.51) and (4.53), and verify that both expansions produce (4.49).

8.4.7. Let us refer to a multiple commutator of the kind that appears in (4.46) as a *left nest*. Show that every left nest can be re-expressed as a *right nest*. That is show, by repeated use of the antisymmetry condition, that there is the relation

$$\begin{aligned}\{\cdots\{x_{i_1},x_{i_2}\},x_{i_3}\},\cdots x_{i_k}\} &= (-1)^{k-1}\{x_{i_k},\{x_{i_{k-1}},\{x_{i_{k-2}},\cdots\{x_{i_2},x_{i_1}\}\cdots\} \\ &= (-1)^{k-1}\#x_{i_k}\#\#x_{i_{k-1}}\#\ \#x_{i_{k-2}}\#\cdots\#x_{i_2}\#x_{i_1}. \qquad (8.4.56)\end{aligned}$$

8.5 Map Inversion and Reverse Factorization

Suppose the map $\mathcal{M}_f$ is written in the factored product form

$$\mathcal{M}_f = \mathcal{R}_f \exp(:f_3:)\exp(:f_4:)\cdots . \qquad (8.5.1)$$

Here, as in the previous section, $\mathcal{R}_f$ denotes the map

$$\mathcal{R}_f = \exp(:f_2^c:)\exp(:f_2^a:) \qquad (8.5.2)$$

that is associated with the linear transformation R^f given by the matrix relation

$$R^f = \exp(JS^a)\exp(JS^c). \qquad (8.5.3)$$

It follows immediately from (5.1) that the *inverse* of $\mathcal{M}_f$ has the representation

$$(\mathcal{M}_f)^{-1} = \cdots\exp(-:f_4:)\exp(-:f_3:)(\mathcal{R}_f)^{-1}. \qquad (8.5.4)$$

Although (5.4) gives a possible representation for the inverse of $\mathcal{M}_f$, it is in the form of a *reverse* factorization. We would also like to have a representation in the standard *forward* factorization. That is, we wish also to have a representation for the inverse of $\mathcal{M}_f$ in the form

$$(\mathcal{M}_f)^{-1} = \mathcal{R}_h \exp(: h_3 :) \exp(: h_4 :) \cdots . \tag{8.5.5}$$

See Section 7.8. This is easily accomplished with the aid of the concatenation formulas of the previous section. We simply write (5.4) and (5.5) in the form

$$\cdots [\exp(- : f_4 :)][\exp(- : f_3 :)][(\mathcal{R}_f)^{-1}] = \mathcal{R}_h \exp(: h_3 :) \exp(: h_4 :) \cdots \tag{8.5.6}$$

where we have used square brackets to indicate that the various maps are to be concatenated together. See Exercise 5.1. In particular, as needed in the next paragraph, we have the results

$$\mathcal{R}_h = (\mathcal{R}_f)^{-1}, \tag{8.5.7}$$

$$R^h = (R^f)^{-1}. \tag{8.5.8}$$

Note again, as a result of the symplectic condition, that the matrix $(R^f)^{-1}$ is easily calculated using (3.1.9).

The relation (5.5) also provides a procedure for reverse factorizing a map. Suppose we wish to represent $\mathcal{M}_f$ in reverse factorized form. That is, we wish to find generators g_m such that

$$\mathcal{M}_f = \mathcal{R}_f \exp(: f_3 :) \exp(: f_4 :) \cdots = \cdots \exp(: g_4 :) \exp(: g_3 :) \mathcal{R}_g. \tag{8.5.9}$$

Simply take the inverse of both sides of (5.9) and use (5.5) to get the relation

$$(\mathcal{R}_g)^{-1} \exp(- : g_3 :) \exp(- : g_4 :) \cdots = \mathcal{R}_h \exp(: h_3 :) \exp(: h_4 :) \cdots . \tag{8.5.10}$$

From (5.10) and (5.7) we find the desired results

$$\mathcal{R}_g = (\mathcal{R}_h)^{-1} = \mathcal{R}_f, \tag{8.5.11}$$

$$g_m = -h_m. \tag{8.5.12}$$

Exercises

8.5.1. Verify (5.7) and (5.8). Show that h_3, h_4, and h_5 are given by the formulas

$$h_3 =, \tag{8.5.13}$$

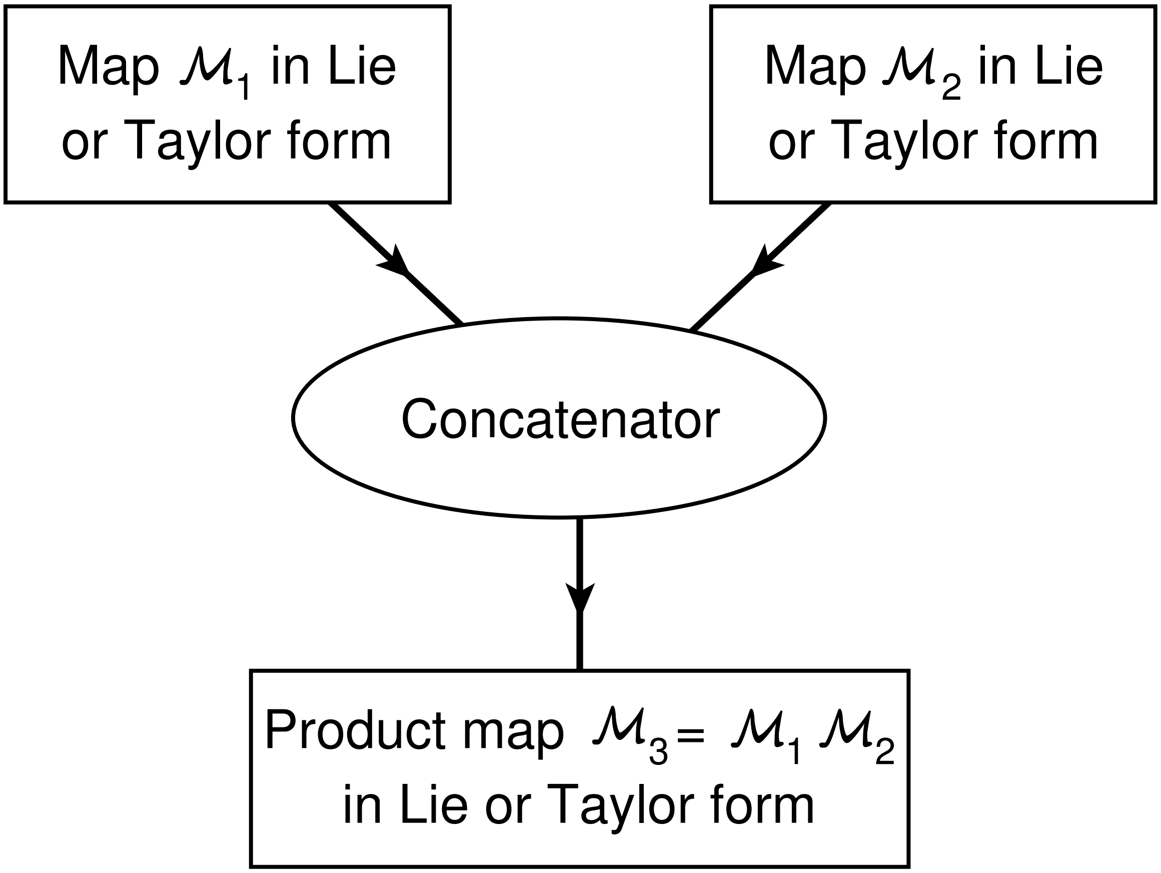
$$h_4 =, \tag{8.5.14}$$

$$h_5 = . \tag{8.5.15}$$

8.5.2. Verify (5.11) and (5.12).

8.6 Taylor and Hybrid Taylor-Lie Concatenation and Inversion

Section 8.4 treated the problem of concatenating two maps, both of which were in factored-product Lie form, to obtain their product, again in factored-product Lie form. We also know that maps can be written in Taylor form. See Section 7.5. For some applications it is useful to have concatenation procedures for which one or more of the maps is in Taylor form. Several possibilities arise, as illustrated in Figure 6.1. Of course, we can always pass back and forth between the Taylor and factored-product Lie forms (see Section 7.6 and Exercise 7.6.12) so that in principle we already have all needed results. However, it is also desirable to have procedures that work directly with Taylor maps. Four cases of particular interest are discussed below.



Map $\mathcal{M}_1$ in Lie or Taylor form
Map $\mathcal{M}_2$ in Lie or Taylor form
Concatenator
Product map $\mathcal{M}_3 = \mathcal{M}_1 \mathcal{M}_2$ in Lie or Taylor form

Figure 8.6.1: Various possibilities for the representation of maps in the operation of concatenation.

Let us begin with the case where both $\mathcal{M}_1$ and $\mathcal{M}_2$ are in Taylor form, and we desire as well to represent the product $\mathcal{M}_3 = \mathcal{M}_1\mathcal{M}_2$ in Taylor form. Suppose that $\mathcal{M}_1$ sends z to $\overline{z}$, and we express this fact in the form of a Taylor series that is truncated beyond terms of degree D,

$$\mathcal{M}_1 : z \to \overline{z} \tag{8.6.1}$$

with

$$\bar{z}_a = \bar{z}_a(z) = \sum_{m=1}^{D} g_a^1(m; z). \tag{8.6.2}$$

Here the $g_a^1(m; z)$ denote homogeneous polynomials of degree m in the variables z. Similarly, $\mathcal{M}_2$ sends $\bar{z}$ to $\bar{\bar{z}}$,

$$\mathcal{M}_2 : \bar{z} \rightarrow \bar{\bar{z}} \tag{8.6.3}$$

with

$$\bar{\bar{z}}_a = \bar{\bar{z}}_a(\bar{z}) = \sum_{m'=1}^{D} g_a^2(m'; \bar{z}). \tag{8.6.4}$$

What we desire is a representation for $\mathcal{M}_3$ of the form

$$\mathcal{M}_3 : z \rightarrow \bar{\bar{z}} \tag{8.6.5}$$

with

$$\bar{\bar{z}}_a = \bar{\bar{z}}_a(z) = \sum_{m''=1}^{D} g_a^3(m''; z). \tag{8.6.6}$$

Upon comparing (6.4) and (6.6) we see that the polynomials g_a^3 are given by the relations

$$g_a^3(m''; z) = P_{m''} \sum_{m'=1}^{D} g_a^2(m'; \bar{z}(z)). \tag{8.6.7}$$

Here $P_{m''}$ denotes a *projection* operator that retains only terms of degree m'' in the variables z.

To verify the truth of (6.7), we observe that the quantities $g_a^2(m', \bar{z})$ in (6.4) are linear combinations of monomials in the $\bar{z}$'s of degree m'. When these monomials are computed using (6.2), the results are linear combinations of monomials in the z's of degree as high as $m'D$. For example, second-order monomials in the $\bar{z}$'s are given by the relation

$$\bar{z}_c \bar{z}_d = \sum_{m'=1}^{D} g_c^1(m'; z) \sum_{m''=1}^{D} g_d^1(m''; z). \tag{8.6.8}$$

From these monomials we need to extract the terms of degree m in the z's in order to find their contribution to the $g_a^3(m; z)$,

$$P_m(\bar{z}_c \bar{z}_d) = \sum_{m'+m''=m} g_c^1(m'; z) g_d^1(m''; z). \tag{8.6.9}$$

We conclude that the operation of concatenating maps in Taylor form involves the multiplication of truncated Taylor series, the extraction of terms of various degrees from the resulting products, and the assembly of linear combinations of these terms to form the truncated Taylor expansion (6.6) for the resulting map $\mathcal{M}_3$. All these operations can in principle be carried out in a straight-forward manner to arbitrary order on a computer using various algorithms for *Truncated Power Series Algebra* (TPSA).

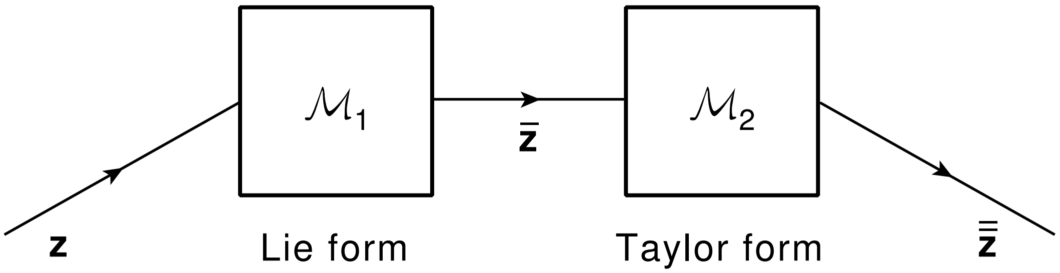


Figure 8.6.2: Product of a map in Lie form with a map in Taylor form.

In a second important case $\mathcal{M}_1$ is in Lie form, $\mathcal{M}_2$ is in Taylor form, and we desire or are content to know their product in Taylor form. See Figure 6.2. According to (6.4) we can express the action of $\mathcal{M}_2$ in Taylor form by writing the relations

$$\bar{\bar{z}}_a\,(\bar{z}) = T_a^D(\bar{z}) \tag{8.6.10}$$

where

$$T_a^D(\bar{z}) = \sum_{m'=1}^{D} g_a^2(m';\bar{z}). \tag{8.6.11}$$

We also have the relations

$$\bar{z}_a(z) = \mathcal{M}_1 z, \tag{8.6.12}$$

$$g_a^2(m';\bar{z}(z)) = g_a^2(m';\mathcal{M}_1 z) = \mathcal{M}_1 g_a^2(m';z). \tag{8.6.13}$$

Here we have used (5.4.13). Consequently, we have the result

$$\bar{\bar{z}}_a\,(z) = \mathcal{M}_1 T_a^D(z). \tag{8.6.14}$$

At this point we recognize that there are three common ways that $\mathcal{M}_1$ may be specified in Lie form. First, suppose that $\mathcal{M}_1$ is given in terms of a single exponent,

$$\mathcal{M}_1 = \exp(:h:), \tag{8.6.15}$$

where h has a homogeneous polynomial expansion of the form

$$h = h_2 + h_3 + \cdots + h_{D+1}. \tag{8.6.16}$$

[Note that, consistent with truncating maps beyond terms of degree D, we have truncated h beyond terms of degree $(D+1)$.] Maps of this kind arise from autonomous systems. See Sections 7.4 and 10.5. In this case we may expand exp$(:h:)$ to get the result

$$\bar{\bar{z}}_a\,(z) = \sum_{\ell=0}^{\infty}(1/\ell!) :h:^{\ell}\, T_a^D(z). \tag{8.6.17}$$

Correspondingly, we have from (6.6) the result

$$g_a^3(m,z) = P_m \sum_{m'=1}^{D}\sum_{\ell=0}^{\infty}(1/\ell!) :h:^{\ell}\, g_a^2(m';z). \tag{8.6.18}$$

In the circumstance that $h_2 = 0$, each sum over ℓ (for a given m and m') reduces to a finite sum because of (7.6.16). In the case that h_2 does not vanish, an infinite sum (for each value of m') is generally required. It can be shown, by an argument similar to that given in Section 10.5, that these sums always converge thanks to the $(1/\ell!)$ factor. However, all the caveats described in Section 4.1 concerning the use of Taylor series to evaluate the exponential function also apply here.

Suppose, as a second possibility, that $\mathcal{M}_1$ is given in the factored product form

$$\mathcal{M}_1 = \mathcal{R}_f \exp(:f_3:) \exp(:f_4:) \cdots \exp(:f_{D+1}:). \tag{8.6.19}$$

Let $\mathcal{N}_f$ be the nonlinear part of $\mathcal{M}_1$,

$$\mathcal{N}_f = \exp(:f_3:) \exp(:f_4:) \cdots \exp(:f_{D+1}:). \tag{8.6.20}$$

According to (6.14) we need to find the quantities

$$\mathcal{M}_1 T_a^D(z) = \mathcal{R}_f \mathcal{N}_f T_a^D(z). \tag{8.6.21}$$

Introduce the intermediate results $\tilde{T}_a^D$ and $\tilde{g}_a^3(m; z)$ defined by the equations

$$\tilde{T}_a^D(z) = \mathcal{N}_f T_a^D(z), \tag{8.6.22}$$

$$\tilde{g}_a^3(m; z) = P_m \sum_{m'=1}^{D} \mathcal{N}_f g_a^2(m'; z). \tag{8.6.23}$$

Then, by construction, we have the relation

$$\tilde{T}_a^D(z) = \sum_{m=1}^{D} \tilde{g}_a^3(m; z). \tag{8.6.24}$$

Next expand the exponentials appearing in (6.20). Doing so brings (6.23) to the form

$$\tilde{g}_a^3(m; z) = P_m \sum_{m'=1}^{D} \sum_{\ell_3=0}^{\infty} (1/\ell_3!) :f_3:^{\ell_3} \cdots \sum_{\ell_{D+1}=0}^{\infty} (1/\ell_{D+1}!) :f_{D+1}:^{\ell_{D+1}} g_a^2(m'; z). \tag{8.6.25}$$

Again because of (7.6.16), each of the sums over $\ell_3 \cdots \ell_{D+1}$ (for a given m and m') reduces to a finite sum. The remaining task is to take $\mathcal{R}_f$ into account. This is easily done. Again by construction we have the relation

$$g_a^3(m; z) = \mathcal{R}_f \tilde{g}_a^3(m; z). \tag{8.6.26}$$

Now use the analog of (8.4.15) to get the final result

$$g_a^3(m; z) = \tilde{g}_a^3(m; R^f z). \tag{8.6.27}$$

A third common possibility is that $\mathcal{M}_1$ arises in Lie form as a result of the use of some kind of Zassenhauss (symplectic integration) approximation. In this case $\mathcal{M}_1$ is typically a product of Lie transformations of the form

$$\mathcal{M}_1 = \exp(w_1 h :A:) \exp(w_2 h :B:) \cdots \exp(w_m h :A:) \tag{8.6.28}$$

where the w_j are various weights and h is the integration step size. See Section 10.8. Here the function A is typically a second-degree polynomial, and the function B has a homogeneous polynomial expansion consisting of terms of degree three and higher. If A is a second-degree polynomial, then $\exp(w_j h : A :)$ is a linear transformation that can be represented by some matrix R, and we can use methods analogous to (6.26) and (6.27). If B consists only of terms of degree three and higher, then $\exp(w_j h : B :)$ can be expanded in a Taylor series to give results analogous to (6.18) and for which only a finite number of ℓ values contribute.

We have seen how to find, in Taylor form, the product of a map in Lie form with a second map in Taylor form. Consider, as case three, the situation in which the two maps to be multiplied are both in Lie form, and we want their product in Taylor form. An obvious approach is to convert the second map from Lie to Taylor form, and then proceed as just described. This conversion is easily carried out as in Exercise 7.6.12. Equivalently, we may use the machinery just developed. The map $\mathcal{M}_2$ can always be written as

$$\mathcal{M}_2 = \mathcal{M}_2 \mathcal{I} \tag{8.6.29}$$

where $\mathcal{I}$ is the identity map. But the identity map has the immediate Taylor expansion

$$\mathcal{I} z_a = z_a. \tag{8.6.30}$$

Therefore, to find $\mathcal{M}_2$ in Taylor form, we simply concatenate $\mathcal{M}_2$ in Lie form with the identity map $\mathcal{I}$ in Taylor form.

As a generalization of this approach, suppose we wish to concatenate m maps in Lie form and obtain the net result in Taylor form,

$$\mathcal{M}_{\rm net} = \mathcal{M}_1 \mathcal{M}_2 \mathcal{M}_3 \cdots \mathcal{M}_m. \tag{8.6.31}$$

Rewrite the desired result in the form

$$\mathcal{M}_{\rm net} = \mathcal{M}_1(\mathcal{M}_2(\mathcal{M}_3 \cdots (\mathcal{M}_m \mathcal{I}) \cdots)), \tag{8.6.32}$$

and observe that each map $\mathcal{M}_j$ in Lie form is now to be concatenated with a map in Taylor form to produce a map again in Taylor form. Thus, after m concatenations [namely, $\mathcal{M}_m \mathcal{I}$, $\mathcal{M}_{m-1}(\mathcal{M}_m \mathcal{I})$, $\mathcal{M}_{m-2}(\mathcal{M}_{m-1}(\mathcal{M}_m \mathcal{I}))$, etc.] we obtain $\mathcal{M}_{\rm net}$ in Taylor form. At this stage we may, if desired, obtain $\mathcal{M}_{\rm net}$ in Lie form from $\mathcal{M}_{\rm net}$ in Taylor form by carrying out the steps of the Factorization Theorem of Section 7.6.

A fourth case of interest is that in which the two maps to be multiplied are both in Lie form, and we also want their product in Lie form. This case has already been discussed in Section 8.4 where the BCH formula was used to find the quantities $h_3, h_4, \cdots$ in the relation (4.26). The result was explicit formulas of the form (4.31) through (4.36). These formulas become ever more complicated as the order is increased.

If one is content with numerical results, which is often the case, then the h_m can be computed algorithmically for any order m, without recourse to the BCH series, by Taylor methods as described above. To be explicit, and with reference to (4.26), define variables $\overline{z}_a(z)$ by the relations

$$\overline{z}_a = \exp(: f_3^{tr} :) \exp(: f_4^{tr} :) \cdots \exp(: g_3 :) \exp(: g_4 :) \cdots z_a. \tag{8.6.33}$$

Then we have the result

$$\exp(:h_3:)\exp(:h_4:)\cdots z_a = \overline{z}_a(z). \tag{8.6.34}$$

Next let $\mathcal{T}^D$ be a *truncation* operator that acts on Taylor series. It is defined to be a linear operator that retains all terms in a Taylor series of degree less than or equal to D, and discards all terms of degree greater than D. With the aid of this operator we may define truncated Taylor series $T_a^D(z)$ by the relation

$$T_a^D(z) = \mathcal{T}^D\overline{z}_a = \mathcal{T}^D\exp(:f_3^{tr}:)\exp(:f_4^{tr}:)\cdots\exp(:g_3:)\exp(:g_4:)\cdots z_a. \tag{8.6.35}$$

Evidently, in view of (7.6.14), to compute the T_a^D it is only necessary to retain the factors containing $f_3^{tr}\cdots f_{D+1}^{tr}$ and $g_3\cdots g_{D+1}$ in (6.35). Moreover, only a finite number of terms need be retained in each exponential series. Therefore, for a fixed D, only a finite number of operations are required to evaluate (6.35) to find the T_a^D. Finally, examination of the proof of the Factorization Theorem of Section 7.6 shows that the desired quantities $h_3\cdots h_{D+1}$ can be found from the T_a^D by a finite number of operations. Moreover, unlike the case of the BCH series whose coefficients are very complicated, the only coefficients required are simply the factorials in the exponential series and those that arise in the use of (7.6.24).

In summary the virtue of the Taylor method just described is that, even when the maps to be concatenated are both in Lie factored product form and the desired product is also required in this form, results can be obtained to any desired degree $(D+1)$ in the Lie generators by means of a relatively simple algorithm. The price to be paid for this simplicity is increased computation [compared to that required for the direct formulas of the form (4.31) through (4.36)] and the increased (but temporary) storage associated with the intermediate truncated Taylor series T_a^D (see Section 7.9).

The last topic to be discussed in this section is the inversion of maps in Taylor form. By way of introduction, consider the simple quadratic equation

$$\overline{x} = \alpha x + \beta x^2. \tag{8.6.36}$$

This equation can immediately be solved to find x in terms of $\overline{x}$,

$$x = \{-\alpha \pm [\alpha^2 + 4\beta\overline{x}]^{1/2}\}/(2\beta). \tag{8.6.37}$$

The solution that vanishes when $\overline{x}=0$ has the expansion

$$\begin{aligned} x &= \{-\alpha + [\alpha^2+4\beta\overline{x}]^{1/2}\}/(2\beta) \\ &= [\alpha/(2\beta)]\{-1+[1+4\beta\overline{x}/\alpha^2]^{1/2}\} \\ &= [\alpha/(2\beta)]\{(1/2)(4\beta\overline{x}/\alpha^2) - (1/8)(4\beta\overline{x}/\alpha^2)^2 + (1/16)(4\beta\overline{x}/\alpha^2)^3 + \cdots\} \\ &= (1/\alpha)\overline{x} - (\beta/\alpha^3)\overline{x}^2 + (2\beta^2/\alpha^5)\overline{x}^3 + \cdots\ . \end{aligned} \tag{8.6.38}$$

Equation (6.36) may be viewed as a one-dimensional Taylor map that sends x to $\overline{x}$, and (6.38) is the Taylor expansion of its inverse.

Suppose we had not been able to solve (6.36) explicitly for x as in (6.37). Is there any other way to obtain the inverse series (6.38)? The answer is yes. The inverse series can also be found by a process of *recursion* or *iteration*: First rewrite (6.36) in the form

$$x = (1/\alpha)\overline{x} - (\beta/\alpha)x^2 = (1/\alpha)\overline{x} + n(x) \tag{8.6.39}$$

where $n(x)$ is the *nonlinear* term

$$n(x) = -(\beta/\alpha)x^2. \tag{8.6.40}$$

Now consider the recursion relation for functions $x^{(m)}(\overline{x})$ specified by the rule

$$x^{(m+1)}(\overline{x}) = (1/\alpha)\overline{x} + n[x^{(m)}(\overline{x})], \tag{8.6.41}$$

with the starting relation

$$x^{(1)}(\overline{x}) = (1/\alpha)\overline{x}. \tag{8.6.42}$$

Upon carrying out the indicated operations, we find the results

$$\begin{aligned} m=1: \quad x^{(1)} &= (1/\alpha)\overline{x}, \\ m=2: \quad x^{(2)} &= (1/\alpha)\overline{x} - (\beta/\alpha)[(1/\alpha)\overline{x}]^2 = (1/\alpha)\overline{x} - (\beta/\alpha^3)\overline{x}^2, \\ m=3: \quad x^{(3)} &= (1/\alpha)\overline{x} - (\beta/\alpha)[(1/\alpha)\overline{x} - (\beta/\alpha^3)\overline{x}^2]^2 \\ &= (1/\alpha)\overline{x} - (\beta/\alpha^3)\overline{x}^2 + (2\beta^2/\alpha^2)\overline{x}^3 + O(\overline{x}^4), \text{ etc.} \end{aligned} \tag{8.6.43}$$

Evidently m applications of the rule (6.41) reproduces the series (6.38) through terms of degree m. We also note the possible appearance, at each stage, of still higher degree terms that may not yet be correct. We may remind ourselves not to bother computing these terms by using the truncation operator $\mathcal{T}^m$. With the aid of this operator, the recursion relation (6.41) can be modified to take the more convenient form

$$x^{(m+1)}(\overline{x}) = (1/\alpha)\overline{x} + \mathcal{T}^{m+1}n[x^{(m)}(\overline{x})]. \tag{8.6.44}$$

The iteration method we have just used to invert the simple quadratic equation (6.34) can also be used to invert general Taylor maps. Let us rewrite the Taylor representation (6.2) for the map $\mathcal{M}_1$ in the form

$$\overline{z}_{b'}(z) = \sum_b R_{b'b}z_b + N_{b'}(z) \tag{8.6.45}$$

where the quantities $N_{b'}(z)$ are nonlinear terms of degree 2 and higher. Equation (6.43) can be partially solved to give the result

$$z_a = (R^{-1}\overline{z})_a + \tilde{N}_a(z)$$

where $\tilde{N}_a$ also contains terms only of degree 2 and higher, and is given by the relation

$$\tilde{N}_a = -\sum_{b'}(R^{-1})_{ab'}N_{b'}. \tag{8.6.46}$$

Note that we have assumed R^{-1} exists, as is required by the inverse function theorem for a map to have an inverse, and as will be the case for symplectic matrices. Now form the recursion relation

$$z_a^{(m+1)}(\overline{z}) = (R^{-1}\overline{z})_a + \mathcal{T}^{m+1}\tilde{N}_a[z^{(m)}(\overline{z})] \tag{8.6.47}$$

with the starting relation

$$z_a^{(1)}(\overline{z}) = (R^{-1}\overline{z})_a. \tag{8.6.48}$$

Application of this recursion relation D times produces the Taylor representation, through terms of degree D, for the map $\mathcal{M}_1^{-1}$.

Finally, we remark that the operations needed to carry out the recursion relation (6.47), as well as the Poisson brackets needed in procedures such as (6.18) and (6.35), can all be performed to arbitrary order on a computer programmed to handle TPSA.

Exercises

8.6.1. According to (4.31) and (4.32) the *direct* determination of h_3 and h_4 requires the computation of *one* Poisson bracket. How many Poisson brackets must be computed to find h_3 and h_4 by Taylor methods? Compare the amounts of work required for the direct and Taylor methods.

8.6.2. Prove that use of the recursion relation (6.47) does indeed produce the Taylor representation of the inverse of (6.45).

8.7 Working with Exponents

8.7.1 Formulas for Combining Exponents

The General Case

Sometimes, as will be shown later, it is useful to be able to write the product of two Lie transformations as a *single* Lie transformation. This is what the BCH formula (2.27) attempts to do. In general, there are no known convenient expressions for all the terms on the right side of (2.29). However, it is possible to sum the series completely with respect to s and the first few powers in t. One such result can be written in the form

$$h = sf + s : f : [1 - \exp(-s : f :)]^{-1}(tg) + O(t^2). \tag{8.7.1}$$

Here the operator expression involving $: f :$ is to be interpreted as the infinite series

$$s : f : [1 - \exp(-s : f :)]^{-1} = s : f : [1 - \sum_{m=0}^{\infty}(-s : f :)^m/m!]^{-1}$$

$$= s : f : [-\sum_{m=1}^{\infty}(-s : f :)^m/m!]^{-1} = 1 + (s/2) : f : +(s^2/12) : f :^2 + \cdots . \tag{8.7.2}$$

Equations (2.27) and (7.1) may be combined to give the result

$$\exp(s : f :)\exp(t : g :) = \exp[s : f : + : \{s : f : [1 - \exp(-s : f :)]^{-1}(tg)\} : +O(t^2)]. \tag{8.7.3}$$

See Appendix C where the $O(t^2)$ term is also worked out.

Suppose we succeed in writing a product of two or more Lie transformations as a single Lie transformation. Then, as shown in Section 7.1, the map corresponding to the product of Lie transformations has an invariant function. See (7.1.12) through (7.1.14). We will learn later that generically symplectic maps do *not* have invariant functions. Correspondingly, the series (7.1) is generally divergent. We recall from Section 7.7 that the Lie algebra $spm(2n, \mathbb{R})$ is *infinite* dimensional. Typically what happens in the infinite dimensional case is that inverses of the form $[1 - \exp(-s : f :)]^{-1}$ may fail to exist. Other difficulties can also arise. Put another way, the BCH series (3.7.34) may have no domain of convergence in the case of an infinite dimensional Lie algebra. See Section 38.7.

The Case of $Sp(2)$

There is one instructive case for which the sum of the BCH series is known exactly. That is the case of $Sp(2)$ or, more generally, $Sp(2, \mathbb{C})$= $SL(2, \mathbb{C})$. We will see that the result is quite complicated. Presumably yet more complicated formulas exist in the Platonic realm for the still more interesting cases of $Sp(4)$, $Sp(6)$, etc. But, to the author's knowledge, these formulas have not yet been brought down to Earth.

Given f_2 and g_2, there are the associated maps

$$\mathcal{M}_f = \exp(: f_2 :), \tag{8.7.4}$$

$$\mathcal{M}_g = \exp(:g_2:). \tag{8.7.5}$$

Our task is to find h_2 such that

$$\mathcal{M}_h = \exp(:h_2:) = \mathcal{M}_f \mathcal{M}_g. \tag{8.7.6}$$

According to (3.64), (3.65), and (3.76) there are symmetric matrices S^f, S^g, and S^h associated with f_2, g_2, and h_2 respectively. Also, according to Section 8.3, our task is equivalent to that of finding the matrix S^h such that

$$\exp(JS^h) = \exp(JS^f)\exp(JS^g). \tag{8.7.7}$$

In the case of $sp(2)$, we know that the vector space of matrices of the form JS is spanned by the matrices B^0, F, and G given by (5.6.7), (5.6.13), and (5.6.14). Upon comparison with the Pauli matrices (5.7.3), we find the results

$$B^0 = i\sigma^2, \tag{8.7.8}$$

$$F = -\sigma^1, \tag{8.7.9}$$

$$G = \sigma^3. \tag{8.7.10}$$

Let us define 3-vectors (with possibly complex components) $\boldsymbol{v}^f$, $\boldsymbol{v}^g$, and $\boldsymbol{v}^h$ by the rules

$$\boldsymbol{v}^f \cdot \boldsymbol{\sigma} = v_1^f\sigma^1 + v_2^f\sigma^2 + v_3^f\sigma^3 = JS^f, \text{ etc.} \tag{8.7.11}$$

With these results and definitions, the condition (7.7) in the $Sp(2)$ case is equivalent to the requirement

$$\exp(\boldsymbol{v}^h \cdot \boldsymbol{\sigma}) = \exp(\boldsymbol{v}^f \cdot \boldsymbol{\sigma})\exp(\boldsymbol{v}^g \cdot \boldsymbol{\sigma}). \tag{8.7.12}$$

The matrix $\exp(\boldsymbol{v}^h \cdot \boldsymbol{\sigma})$ can be found analytically using (5.7.40). We begin by noting that (5.7.40) can be written in the form

$$(\boldsymbol{u} \cdot \boldsymbol{\sigma})(\boldsymbol{v} \cdot \boldsymbol{\sigma}) = \sigma^0 \boldsymbol{u} \cdot \boldsymbol{v} + i(\boldsymbol{u} \times \boldsymbol{v}) \cdot \boldsymbol{\sigma}, \tag{8.7.13}$$

where $\boldsymbol{u}$ and $\boldsymbol{v}$ are any 3-vectors. Next, define the length of $\boldsymbol{v}$, denoted by v, by the rule

$$v = (\boldsymbol{v} \cdot \boldsymbol{v})^{1/2}. \tag{8.7.14}$$

Note that v may possibly be complex, and is specified only up to a sign. Using (7.13) and (7.14), we find the result

$$\begin{aligned} \exp(\boldsymbol{v} \cdot \boldsymbol{\sigma}) &= \cosh(\boldsymbol{v} \cdot \boldsymbol{\sigma}) + \sinh(\boldsymbol{v} \cdot \boldsymbol{\sigma}) \\ &= \sigma^0 \cosh v + \boldsymbol{v} \cdot \boldsymbol{\sigma}(\sinh v)/v. \end{aligned} \tag{8.7.15}$$

We observe that both the functions $\cosh v$ and $(\sinh v)/v$ are even in v, and therefore unaffected by the sign ambiguity in (7.14). At this point it is convenient to introduce the 3-vector $\boldsymbol{\tau}(\boldsymbol{v})$ defined by the equation

$$\boldsymbol{\tau}(\boldsymbol{v}) = \boldsymbol{v}(\tanh v)/v. \tag{8.7.16}$$

Equation (7.16) has as its inverse the relation

$$\boldsymbol{v}(\boldsymbol{\tau}) = \boldsymbol{\tau}(\tanh^{-1}\tau)/\tau \tag{8.7.17}$$

where

$$\tau = (\boldsymbol{\tau}\cdot\boldsymbol{\tau})^{1/2}. \tag{8.7.18}$$

Again observe that $(\tanh v)/v$ and $(\tanh^{-1}\tau)/\tau$ are even functions. With this definition, (7.15) can be written in the equivalent form

$$\exp(\boldsymbol{v}\cdot\boldsymbol{\sigma}) = [\cosh v][\sigma^0 + \boldsymbol{\tau}(\boldsymbol{v})\cdot\boldsymbol{\sigma}]. \tag{8.7.19}$$

Now use (7.19) and (7.13) in (7.12). Doing so gives the result

$$\begin{aligned} & \exp(\boldsymbol{v}^h\cdot\boldsymbol{\sigma}) = [\cosh v^h][\sigma^0 + \boldsymbol{\tau}(\boldsymbol{v}^h)\cdot\boldsymbol{\sigma}] \\ = \ & [\cosh v^f][\sigma^0 + \boldsymbol{\tau}(\boldsymbol{v}^f)\cdot\boldsymbol{\sigma}][\cosh v^g][\sigma^0 + \boldsymbol{\tau}(\boldsymbol{v}^g)\cdot\boldsymbol{\sigma}] \\ = \ & [\cosh v^f][\cosh v^g]\{\sigma^0[1 + \boldsymbol{\tau}(\boldsymbol{v}^f)\cdot\boldsymbol{\tau}(\boldsymbol{v}^g)] \\ + \ & [\boldsymbol{\tau}(\boldsymbol{v}^f) + \boldsymbol{\tau}(\boldsymbol{v}^g) + i\boldsymbol{\tau}(\boldsymbol{v}^f)\times\boldsymbol{\tau}(\boldsymbol{v}^g)]\cdot\boldsymbol{\sigma}\}. \end{aligned} \tag{8.7.20}$$

Use (5.7.41) to equate like terms on both sides of (7.20), and thereby find the relations

$$\cosh v^h = [\cosh v^f][\cosh v^g][1 + \boldsymbol{\tau}(\boldsymbol{v}^f)\cdot\boldsymbol{\tau}(\boldsymbol{v}^g)], \tag{8.7.21}$$

$$(\cosh v^h)\boldsymbol{\tau}(\boldsymbol{v}^h) = [\cosh v^f][\cosh v^g][\boldsymbol{\tau}(\boldsymbol{v}^f) + \boldsymbol{\tau}(\boldsymbol{v}^g) + i\boldsymbol{\tau}(\boldsymbol{v}^f)\times\boldsymbol{\tau}(\boldsymbol{v}^g)]. \tag{8.7.22}$$

Upon dividing (7.22) by (7.21) we obtain the final and remarkable result

$$\boldsymbol{\tau}(\boldsymbol{v}^h) = [\boldsymbol{\tau}(\boldsymbol{v}^f) + \boldsymbol{\tau}(\boldsymbol{v}^g) + i\boldsymbol{\tau}(\boldsymbol{v}^f)\times\boldsymbol{\tau}(\boldsymbol{v}^g)][1 + \boldsymbol{\tau}(\boldsymbol{v}^f)\cdot\boldsymbol{\tau}(\boldsymbol{v}^g)]^{-1}. \tag{8.7.23}$$

Given $\boldsymbol{v}^f$ and $\boldsymbol{v}^g$, (7.23) specifies $\boldsymbol{\tau}(\boldsymbol{v}^h)$ which, in turn by using (7.17), gives $\boldsymbol{v}^h$. Taken together, we will call (7.16), (7.17), and (7.23) the $Sp(2,\mathbb{C})$ BCH *function*.

Let us examine the singularity structure of the $Sp(2,\mathbb{C})$ BCH *function*, namely the relationship between $\boldsymbol{v}^f$, $\boldsymbol{v}^g$, and $\boldsymbol{v}^h$ implied by (7.16), (7.17), and (7.23). We see from (7.16) that $\boldsymbol{\tau}(\boldsymbol{v})$ is analytic in $\boldsymbol{v}$ for small $\boldsymbol{v}$, has poles when $v = i(\pi/2 + n\pi)$, and has an essential singularity at $v = \infty$. We also note that since $\boldsymbol{v}$ is possibly complex, $\boldsymbol{v}$ can tend toward infinity in various directions while v remains bounded. Thus the singularity structure at infinity is quite complicated. Near the origin $\boldsymbol{\tau}(\boldsymbol{v})$ has the convergent expansion

$$\boldsymbol{\tau}(\boldsymbol{v}) = \boldsymbol{v}(1 - v^2/3 + 2v^4/15 - 17v^6/315 + \cdots). \tag{8.7.24}$$

We see from (7.17) that $\boldsymbol{v}(\boldsymbol{\tau})$ is analytic in $\boldsymbol{\tau}$ for small $\boldsymbol{\tau}$ and has branch points at $\tau = \pm 1$. It also has a pole in τ at $\tau = 0$ on the Riemann sheets reached by circling these branch points. Moreover, there is a complicated singularity at infinity. Near the origin on the *principal* sheet $\boldsymbol{v}(\boldsymbol{\tau})$ is analytic and has the convergent expansion

$$\boldsymbol{v}(\boldsymbol{\tau}) = \boldsymbol{\tau}(1 + \tau^2/3 + \tau^4/5 + \tau^6/7 + \cdots). \tag{8.7.25}$$

Finally, we see that (7.23) has the denominator $[1 + \boldsymbol{\tau}(\boldsymbol{v}^f)\cdot\boldsymbol{\tau}(\boldsymbol{v}^g)]$ which can possibly vanish, but cannot vanish for small $\boldsymbol{v}^f$ and $\boldsymbol{v}^g$ because of (7.24). We conclude that the BCH series for

$Sp(2)$ converges for small $\boldsymbol{v}^f$ and $\boldsymbol{v}^g$, but presumably cannot converge everywhere because of the singularities just described. This result is consistent with our expectations. We know that any symplectic matrix can be written in the form (3.8.24). If it were always possible to combine the two exponents in (3.8.24) into one grand exponent using the BCH series, then (3.7.97) could be written in the form (3.7.36), which we know is false. Indeed, the reader will have the pleasure of showing in Exercise 7.9 that the offending singularity is the pole at $\tau = 0$ on a nonprincipal sheet of $\boldsymbol{v}(\boldsymbol{\tau})$.

What is the source of all these singularities? The fault does not lie with the group $Sp(2,\mathbb{C})$ itself. Indeed, if elements of $Sp(2,\mathbb{C})$ are parameterized by 2×2 possibly complex matrices, the operation of group element multiplication is simply matrix multiplication, and entries in the product of two matrices are *entire* functions of the entries in the matrices being multiplied.[18] Rather the fault lies in the use of canonical coordinates of the first kind, which is what the Ansatz (7.12) essentially does. See Section 7.9. And the use of canonical coordinates of the first kind depends on the properties of the exponential map. See Section 3.8. Thus, the source of singularities in this case can be traced back to the (not globally possible/successful) use of the exponential map for $Sp(2,\mathbb{C})$. Seeking the impossible results in singularities.

8.7.2 Nature of Single Exponential Form

Let us explore further what elements of $Sp(2,\mathbb{R})$ can be written in single exponential form. In the case of two-dimensional phase space, the most general (real) f_2 can be written in the form

$$f_2 = -(bp^2 + 2aqp + cq^2)/2, \tag{8.7.26}$$

where a, b, c are (real) parameters. We define an associated symplectic matrix $R(a,b,c)$ by the rule

$$\exp(:f_2:)z_d = \sum_e R_{de} z_e. \tag{8.7.27}$$

Our goal is to find an explicit expression for $R(a,b,c)$ in terms of the quantities a, b, c. So doing amounts to finding the exponential map from $sp(2,\mathbb{R})$ to $Sp(2,\mathbb{R})$.[19]

Direct calculation gives the result

$$:f_2: z_d = -(1/2) : (bp^2 + 2aqp + cq^2) : z_d = \sum_e F_{de} z_e \tag{8.7.28}$$

where F is the Hamiltonian matrix

$$F = \begin{pmatrix} a & b \\ -c & -a \end{pmatrix}. \tag{8.7.29}$$

We readily verify that F has the property

$$F^2 = \Delta I. \tag{8.7.30}$$

[18] An entire function is a function that is analytic everywhere except at infinity.

[19] As announced, we will seek results for the case of $Sp(2,\mathbb{R})$. Partial results are also known for the more complicated case of $Sp(4,\mathbb{R})$. In particular, there is an explicit formula for matrices of the form $\exp(JS^a)$. See the references at the end of this chapter.

Here Δ is the *discriminant* of the quadratic form (7.26),

$$\Delta = a^2 - bc. \tag{8.7.31}$$

We know from Section 7.2 or (7.3.41) that R is given by the relation

$$R = \exp(F) = \cosh(F) + \sinh(F). \tag{8.7.32}$$

The term $\cosh(F)$ has the expansion

$$\begin{aligned} \cosh(F) &= F^0 + F^2/2! + F^4/4! + \cdots \\ &= I(1 + \Delta/2! + \Delta^2/4! + \cdots) \\ &= I\cosh(\Delta^{1/2}). \end{aligned} \tag{8.7.33}$$

Here use has been made of (7.30). For $\sinh(F)$ we find the result

$$\begin{aligned} \sinh(F) &= F + F^3/3! + F^5/5! + \cdots \\ &= F(I + F^2/3! + F^4/5! + \cdots) \\ &= F(1 + \Delta/3! + \Delta^2/5! + \cdots) \\ &= (F/\Delta^{1/2})(\Delta^{1/2} + \Delta^{3/2}/3! + \Delta^{5/2}/5! + \cdots) \\ &= F[\sinh(\Delta^{1/2})]/\Delta^{1/2}. \end{aligned} \tag{8.7.34}$$

Note that both $\cosh(\Delta^{1/2})$ and $\{[\sinh(\Delta^{1/2})]/\Delta^{1/2}\}$ are even functions of $\Delta^{1/2}$, and thus do not depend on which root we take in computing $\Delta^{1/2}$. In fact, they are *analytic* functions of Δ and hence of a, b, c. Putting everything in (7.32) together gives for R the result

$$R = \begin{pmatrix} \cosh(\Delta^{1/2}) + a[\sinh(\Delta^{1/2})]/\Delta^{1/2} & b[\sinh(\Delta^{1/2})]/\Delta^{1/2} \\ -c[\sinh(\Delta^{1/2})]/\Delta^{1/2} & \cosh(\Delta^{1/2}) - a[\sinh(\Delta^{1/2})]/\Delta^{1/2} \end{pmatrix}. \tag{8.7.35}$$

Let us compute the eigenvalues of R. It has the characteristic polynomial

$$P(\lambda) = \det(R - \lambda I) = \lambda^2 - 2\lambda\cosh(\Delta^{1/2}) + 1. \tag{8.7.36}$$

This polynomial has the roots

$$\lambda = \exp(\Delta^{1/2})\ ,\ \exp(-\Delta^{1/2}). \tag{8.7.37}$$

Note that if a, b, c are real, then so is Δ. It follows that $\Delta^{1/2}$ is real if $\Delta \geq 0$, and pure imaginary if $\Delta < 0$. Correspondingly, the eigenvalues of R are real if $\Delta > 0$, and have the *hyperbolic* configuration shown in Case 1 of Figure 3.4.1. If $\Delta < 0$, then the eigenvalues of R are on the unit circle corresponding to the *elliptic* configuration shown in Case 3 of Figure 3.4.1. The possibilities $\Delta = 0$ and $\Delta = -\pi^2$ are discussed further in Exercise 7.11, and correspond to the *parabolic* and *inversion parabolic* configurations shown in Cases 4 and 5 of Figure 3.4.1. We note that the *inversion hyperbolic* configuration shown in Case 2 does *not* occur. It follows that such symplectic matrices cannot be written in single exponential form with real exponents. [The use of complex exponents may be possible in some cases. See Exercises 2.16 and 7.12. But we know that even this expedient fails for the matrices M and N given by (3.7.134) and (3.7.135).] We have proved earlier that all (real) symplectic matrices, including the inversion hyperbolic case, can be written in the product form (3.8.26) with real exponents. Also, all the coefficients in the BCH series are real. It follows that the BCH series must *diverge* if we try to combine the exponents in (3.8.26) for the inversion hyperbolic case: if the series converged, the resulting single exponent would be real, and we have seen that a single real exponent never gives an inversion hyperbolic symplectic matrix.

Exercises

8.7.1. Verify the expansion (7.2).

8.7.2. Verify (7.8) through (7.10).

8.7.3. Verify (7.13).

8.7.4. Verify (7.15).

8.7.5. Given (7.16), verify (7.17).

8.7.6. Verify (7.19) and (7.20).

8.7.7. Verify (7.21) through (7.23).

8.7.8. Verify the singularity statements made about $\boldsymbol{\tau}(\boldsymbol{v})$ and $\boldsymbol{v}(\boldsymbol{\tau})$, and verify (7.24) and (7.25).

8.7.9. Review Exercises 3.7.11 and 5.9.3. Consider the matrix $N = -M$. [Note that this N is not that given by (3.7.105).] Show that N can be written in the form (3.7.36) with S given by the equation

$$S = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}. \tag{8.7.38}$$

Consider the polar decompositions of M and N given by (3.8.1). Show that both M and N have the same P given by (5.9.16). Find the O matrices for M and N. Show that they have the form

$$O = \exp(i\theta\sigma^2), \tag{8.7.39}$$

and find θ in each case. Following (3.8.15) and (3.8.23) find the matrix S^a associated with P and the matrices S^c associated with the matrices O. Compute the corresponding vectors $\boldsymbol{v}^a$, $\boldsymbol{v}^c$, $\boldsymbol{\tau}^a = \boldsymbol{\tau}(\boldsymbol{v}^a)$, and $\boldsymbol{\tau}^c = \boldsymbol{\tau}(\boldsymbol{v}^c)$. Make the identifications $\boldsymbol{v}^a = \boldsymbol{v}^f$, $\boldsymbol{\tau}^a = \boldsymbol{\tau}^f$, $\boldsymbol{v}^c = \boldsymbol{v}^g$, and $\boldsymbol{\tau}^c = \boldsymbol{\tau}^g$. See (3.8.24) and (7.12). Consider the vector $\boldsymbol{v}^h(\theta)$ defined by the relation

$$\exp[\boldsymbol{v}^h(\theta) \cdot \boldsymbol{\sigma}] = \exp(\boldsymbol{v}^f \cdot \boldsymbol{\sigma}) \exp(i\theta\sigma^2). \tag{8.7.40}$$

Use (7.23) to find $\boldsymbol{\tau}^h(\theta) = \boldsymbol{\tau}^h(\boldsymbol{v}^h(\theta))$. Starting from $\theta = 0$, follow the quantities θ, $\boldsymbol{\tau}^h(\theta)$, and $\boldsymbol{v}^h(\theta)$ to the θ value for N. Repeat this same process, again starting at $\theta = 0$, and continuing to the θ value for M. Show that $\boldsymbol{v}^h(\theta)$ is well defined for the θ value corresponding to N and produces (7.38), and that $\boldsymbol{v}^h(\theta)$ is singular at the θ value corresponding to M.

8.7.10. Verify (7.28) through (7.37).

8.7.11. Show that $R = -I$ when $\Delta = -\pi^2$. What happens when $\Delta = -4\pi^2$? Show that R takes the form

$$R = \begin{pmatrix} 1+a & b \\ -c & 1-a \end{pmatrix} \tag{8.7.41}$$

in the case $\Delta = 0$. Show that this R can be diagonalized only if $b = c = 0$. Hint: When $\Delta = 0$, $R = I + F$ and, according to (7.30), $F^2 = 0$. Show that such an F can be diagonalized only if $F = 0$.

8.7.12. Consider the inversion hyperbolic symplectic matrix M given by

$$M = \begin{pmatrix} -\lambda & 0 \\ 0 & -1/\lambda \end{pmatrix} \tag{8.7.42}$$

where λ is real and positive. We know that M cannot be written in single exponent form with a real exponent. But can it be written in single exponent form with a complex exponent? Let S be the symmetric matrix given by

$$S = \begin{pmatrix} 0 & a \\ a & 0 \end{pmatrix}. \tag{8.7.43}$$

Verify the results

$$JS = \begin{pmatrix} a & 0 \\ 0 & -a \end{pmatrix} \tag{8.7.44}$$

and

$$N = \exp(JS) = \begin{pmatrix} \exp(a) & 0 \\ 0 & \exp(-a) \end{pmatrix}. \tag{8.7.45}$$

Evidently M can be written in single exponent form if one can satisfy the relation

$$\exp(a) = -\lambda. \tag{8.7.46}$$

Define a quantity α by the rule

$$\alpha = \log(\lambda). \tag{8.7.47}$$

Show that a solution to (7.46) is

$$a = \alpha + \pi i. \tag{8.7.48}$$

You have shown that, although the inversion hyperbolic symplectic matrix M cannot be written in single exponent form with a real exponent, it can be written in single exponent form with a complex exponent.

8.7.13. For some purposes it is useful to have an $SU(2)$ version of the BCH formula (7.23). Recall the 2×2 matrices K^j defined in Exercise 3.7.30 and manufactured from the Pauli matrices by the rules

$$K^j = (-i/2)\sigma^j. \tag{8.7.49}$$

Verify that they satisfy the multiplication rules

$$K^j K^k = (-1/4)\delta_{jk} I + (1/2)\sum_{\ell} \epsilon_{jk\ell} K^{\ell}, \tag{8.7.50}$$

and recall that these rules can be summarized in the "vector" form

$$(\boldsymbol{a} \cdot \boldsymbol{K})(\boldsymbol{b} \cdot \boldsymbol{K}) = -(1/4)(\boldsymbol{a} \cdot \boldsymbol{b})I + (1/2)(\boldsymbol{a} \times \boldsymbol{b}) \cdot \boldsymbol{K}. \tag{8.7.51}$$

See (3.7.176).

Verify that any matrix $u \in SU(2)$ can be written in the form

$$u(\boldsymbol{v}) = \exp(\boldsymbol{v} \cdot \boldsymbol{K}). \tag{8.7.52}$$

Show that the infinite series implied by (7.52) can be summed to give the explicit result

$$\exp(\boldsymbol{v}\cdot\boldsymbol{K}) = I\cos(v/2) + (\boldsymbol{v}\cdot\boldsymbol{K})(2/v)\sin(v/2) \tag{8.7.53}$$

where

$$v = (\boldsymbol{v}\cdot\boldsymbol{v})^{1/2}. \tag{8.7.54}$$

Define a vector $\boldsymbol{\tau}(\boldsymbol{v})$ by the rule

$$\boldsymbol{\tau}(\boldsymbol{v}) = \boldsymbol{v}(2/v)\tan(v/2). \tag{8.7.55}$$

Show that (7.55) has the inverse

$$\boldsymbol{v}(\boldsymbol{\tau}) = \boldsymbol{\tau}(2/\tau)\tan^{-1}(\tau/2) \tag{8.7.56}$$

where

$$\tau = (\boldsymbol{\tau}\cdot\boldsymbol{\tau})^{1/2}. \tag{8.7.57}$$

Show that (7.53) can also be written in the form

$$\exp(\boldsymbol{v}\cdot\boldsymbol{K}) = \cos(v/2)[I + (\boldsymbol{\tau}\cdot\boldsymbol{K})]. \tag{8.7.58}$$

Given two vectors $\boldsymbol{v}^a$ and $\boldsymbol{v}^b$, your task is to find a third vector $\boldsymbol{v}^c$ such that

$$\exp(\boldsymbol{v}^a\cdot\boldsymbol{K})\exp(\boldsymbol{v}^b\cdot\boldsymbol{K}) = \exp(\boldsymbol{v}^c\cdot\boldsymbol{K}). \tag{8.7.59}$$

Show that there is the formula

$$\boldsymbol{\tau}(\boldsymbol{v}^c) = [\boldsymbol{\tau}(\boldsymbol{v}^a) + \boldsymbol{\tau}(\boldsymbol{v}^b) + (1/2)\boldsymbol{\tau}(\boldsymbol{v}^a)\times\boldsymbol{\tau}(\boldsymbol{v}^b)][1 - (1/4)\boldsymbol{\tau}(\boldsymbol{v}^a)\cdot\boldsymbol{\tau}(\boldsymbol{v}^b)]^{-1}. \tag{8.7.60}$$

8.7.14. Review Exercise 8.7.13. Determine the analytic behavior of $\boldsymbol{v}^c$ as a function of $\boldsymbol{v}^a$ and $\boldsymbol{v}^b$.

8.8 Zassenhaus or Factorization Formulas

The BCH formula (3.7.33) and (3.7.34) attempts to combine two exponents into one. There are related formulas, called *Zassenhaus* formulas, that attempt the reverse: They try to write a single exponent term as a product of several such terms. One simple such formula is the relation

$$\exp(sA + tB) = \exp(sA)\exp(tB)\exp(Z), \tag{8.8.1}$$

where Z has the expansion

$$Z = -(st/2)[A,B] + (s^2t/6)[A,[A,B]] - (st^2/3)[B,[B,A]] + O(s^3t, s^2t^2, st^3). \tag{8.8.2}$$

It will be seen in Sections 10.8 through 10.10 that Zassenhaus formulas are useful in constructing symplectic integrators and computing maps.

Equation (8.1) writes a single exponent term as a product of *three* such terms. It may also be desirable to write a single exponent term as a product of *two* such terms, and to attempt to sum some of the infinite series that occur. Consider (7.3), which gives a formula for combining two exponentials into one grand exponential. Sometimes, as in for example the construction of a factored product decomposition, it is useful to be able to turn the process around. Define a quantity h by writing

$$s : f : [1 - \exp(-s : f :)]^{-1} g = h. \tag{8.8.3}$$

Observe that (8.3) may be solved for the quantity g to give the relation

$$g = \{[1 - \exp(-s : f :)]/[s : f :]\}h. \tag{8.8.4}$$

Here the operator expression appearing on the right of (8.4) is interpreted to be the series

$$\begin{aligned} [1 - \exp(-s : f :)]/[s : f :] &= -\sum_{m=1}^{\infty}(-s)^m : f :^m /[m! s : f :] \\ &= \sum_{m=1}^{\infty}(-s)^{m-1} : f :^{m-1} /m!. \end{aligned} \tag{8.8.5}$$

Now insert (8.3) into (7.3). One finds, upon reading right to left, the result

$$\exp[s : f : +t : h : +O(t^2)] = \exp(s : f :) \exp(t : g :). \tag{8.8.6}$$

Finally, the term of $O(t^2)$ can be taken from the left to the right side of (7.6) to produce the relation

$$\exp[s : f : +t : h :] = \exp(s : f :) \exp(t : g :) \exp[: O(t^2) :]. \tag{8.8.7}$$

Equation (8.7) gives a formula for writing the exponential of the sum of two exponents as a product of two exponentials.

It is worth remarking that the operation described by (8.4), which is required for evaluating (8.7), can be written in a more compact form. First, observe the formal integral identity

$$[1 - \exp(-s : f :)]/[s : f :] = \int_0^1 d\tau \exp(-\tau s : f :). \tag{8.8.8}$$

Let us define the function iex(w), called the *integrated* exponential function, by the rule

$$\text{iex}(w) = \int_0^1 d\tau \exp(\tau w) = (e^w - 1)/w = \sum_{m=0}^{\infty} w^m/(m+1)!. \tag{8.8.9}$$

Evidently iex is an *entire* analytic function. (Like the exponential function, it has no singularities in the complex plane except at infinity, and its Taylor series has an infinite radius of convergence.) By using the identity (8.8) and the definition (8.9), the relation (8.4) can be written in the forms

$$g = \int_0^1 d\tau \exp(-\tau s : f :)h = \text{iex}(-s : f :)h. \tag{8.8.10}$$

But now (5.4.11) can be employed to give the final integral formula

$$g(z) = \int_0^1 d\tau h[\exp(-\tau s : f :)z]. \tag{8.8.11}$$

In summary, we have the operator identity

$$\begin{aligned} &\exp(s : f : + t : h :) = \exp(s : f :) \exp[\mathrm{iex}(-s\#f\#)(t : h :)] \exp[: O(t^2) :] \\ &= \exp(s : f :) \exp[: \mathrm{iex}(-s : f :)(th) :] \exp[: O(t^2) :]. \end{aligned} \tag{8.8.12}$$

We also note that in (8.4), unlike in (7.3), no inverses of the form $[1 - \exp(-s : f :)]^{-1}$ are involved. Instead, we have benign relations like (8.11). Correspondingly, because they presuppose the existence of a single exponent form, Zassenhaus formulas can have better convergence properties than the BCH formula. Finally, we remark that the next few terms in (8.12), those terms proportional to powers of t^2, t^3, $\cdots$, can also be found explicitly. See Exercises 10.3.* and 10.4.*.

Exercises

8.8.1. Derive (8.1) and (8.2) from (3.7.33) and (3.7.34).

8.8.2. Verify the expansion (8.5); derive (8.6) from (7.3) and (8.3).

8.8.3. Verify the integral identity (8.8), and the integral identity and expansion (8.9). Show that the Taylor series for iex(w) has an infinite radius of convergence.

8.8.4. Derive the formula

$$\exp(s : f : + t : h :) = \exp[: O(t^2) :] \exp[\mathrm{iex}(s\#f\#)(t : h :)] \exp(s : f :). \tag{8.8.13}$$

8.9 Ideals, Quotients, and Gradings

We know that the Lie algebra of all Lie operators, which we have called $ispm(2n, \mathbb{R})$, is infinite dimensional. Correspondingly $ISpM(2n, \mathbb{R})$, the group of symplectic maps, is infinite dimensional. Indeed, the factorization (7.7.23) gives a representation of the general analytic symplectic map. We see that the specification of a symplectic map generally requires an infinite number of parameters. This fact produces an awkward situation for human beings and computers, which can only work with a finite number of quantities (and often only with finite precision).

An optimistic perspective on the experimental and theoretical situation, for example in the field of accelerator physics, might be stated as follows: We know that a beam transport system, accelerator, storage ring, or any portion thereof may be described by a symplectic transfer map. However, because we cannot measure or control electromagnetic fields exactly, we are unsure of and unable to control exactly what this map is. Also, since it is impossible to perform computations with an infinite number of variables and to infinite precision, it is necessary to develop various approximation schemes. Thus, we are able to study computationally (and probably theoretically) the detailed properties of only a subset of all symplectic maps. The hope is that if two symplectic maps are in some sense nearly the same, then their behavior [including, in some cases, long-term (repeated iteration) behavior] will be nearly the same. If this were not true from an experimental standpoint, then it would be impossible to build satisfactory storage rings, etc. If this were not true from a theoretical standpoint, then it would be impossible to design storage rings, etc., with any assurance that their actual performance would be satisfactory.

As just described, it is necessary to develop some sort of approximation scheme to treat symplectic maps in a practical way. In this section we will describe truncation schemes that maintain a Lie algebraic structure. We already know from Section 8.4 that the rules for multiplying symplectic maps can be expressed entirely in Lie algebraic terms. Thus, if the truncation scheme maintains a Lie algebraic structure, it follows that maps may either be truncated and then multiplied, or multiplied and then truncated. The results from both procedures are guaranteed to be the same.

For example, consider the Lie algebra spanned by the homogeneous polynomials f_2, f_3, f_4, $\cdots$. Evidently, this Lie algebra is infinite dimensional. Let D be some integer. Suppose we decide to retain only the polynomials f_2, f_3, f_4, $\cdots$ f_{D-1}, and discard all polynomials f_m with $m \geq D$. Correspondingly, in the map $\mathcal{M}$ given by (7.6.3) we drop from the product all f_m with $m \geq D$. Is this a consistent procedure? The answer is yes. As we will see, the discarding of all f_m with $m \geq D$ amounts mathematically to working with a *quotient* Lie algebra and its corresponding quotient group. We note that since $: f_m : z_b$ consists of terms of degree $(m-1)$, the decision to drop the f_m with $m \geq D$ amounts physically to neglecting all aberrations of degree $(D-1)$ and higher.

As a second example, suppose ϵ is a (presumed small) parameter, and consider the quantities $f^{(0)}, \epsilon f^{(1)}, \epsilon^2 f^{(2)}, \epsilon^3 f^{(3)}, \cdots$, where $f^{(0)}, f^{(1)}, f^{(2)}, f^{(3)} \cdots$ are *arbitrary* functions. The quantities $f^{(0)}, \epsilon f^{(1)}, \epsilon^2 f^{(2)}, \epsilon^3 f^{(3)}, \cdots$ also form (with the Poisson bracket as a Lie product) an infinite dimensional Lie algebra. Suppose, as a kind of perturbation theory, we decide to discard all $\epsilon^m f^{(m)}$ with $m > D$ where again D is some integer. Is this a consistent procedure? The answer again is yes. We will see that expanding in powers of ϵ is equivalent to introducing a *grading* into the Lie algebra, and that truncating the expansion is equivalent to using the grading to produce a quotient structure.

With this motivation as background, we are ready to develop some mathematical tools. The first concept we will need is that of an *ideal.* Let L be a Lie algebra, and let L' be a subalgebra of L. For L' to be a subalgebra means that the elements of L' must be in L, and must form a Lie algebra in their own right. That is, by themselves they must satisfy the properties 1 through 5 (as given in Section 3.7) required of a Lie algebra. Let x be any element in L and let x' be any element in L'. Suppose the elements of L' have the property

$$[x, x'] \in L' \text{ for all } x \in L,\ x' \in L'. \tag{8.9.1}$$

That is, no element of L' can be sent beyond L' by taking Lie products with arbitrary elements in L. In this case L' is said to be an *invariant* subalgebra. And if L' is a genuine invariant *sub*algebra, i.e. neither zero nor the full Lie algebra L, it is called an *ideal.*[20]

[20] Here is an opportunity for three more definitions: Recall that a Lie algebra is called *simple* if it has no ideals. Recall also that a Lie algebra or subalgebra is called *Abelian* if the Lie product of any two elements

Suppose a Lie algebra L has a subalgebra L'. Then L' can be used to set up an equivalence relation among the elements of L. Let x_1 and x_2 be any two elements in L. We say that x_2 is *equivalent* to x_1 (and write $x_2 \sim x_1$) if their difference $(x_2 - x_1)$ is in L',

$$x_2 \sim x_1 \Leftrightarrow (x_2 - x_1) \in L'. \tag{8.9.2}$$

(Here the symbol $\Leftrightarrow$ is used to indicate logical implication in both directions.) This equivalence relation can be used to partition the elements of L into *disjoint* equivalence classes. Let the symbols $\{x\}$ denote all the elements of L that are equivalent to some element x. In a Lie algebraic (actually, vector space) context, the collection of these equivalence classes is called a quotient space, and is customarily denoted by the symbols L/L'. See Exercise 9.1.

To get a feeling for this construction, let 0 be the *zero* element in L and consider the set of elements $\{0\}$, the set of elements in L that are equivalent to 0. We see from (9.2) that the set $\{0\}$ is identical to the set of elements L'. Consequently, in the quotient space construction, all elements in L' are identified with (are equivalent to) the zero element in L. That is, we have the logical relation

$$x' \in L' \Leftrightarrow \{x'\} = \{0\}. \tag{8.9.3}$$

Moreover, suppose $x_2 \sim x_1$. Then by (9.2) we have a relation of the form

$$x_2 = x_1 + x' \text{ with } x' \in L'. \tag{8.9.4}$$

Thus, if x_1 and x_2 are equivalent, they differ only by an element that has been identified with zero.

As defined so far, the quotient space L/L' is simply a collection of equivalence classes. We now give it a vector space structure by a simple but ingenious (and, at first sight, confusing) construction. We begin by noting the logical implication

$$x_2 \sim x_1 \Rightarrow ax_2 \sim ax_1, \tag{8.9.5}$$

where a is any scalar. This result follows from (9.4) by noting that ax' belongs to L' if x' belongs to L'. (Remember that L' is an algebra.) Next, suppose that the elements x_1, x_2 and y_1, y_2 satisfy the equivalence relations

$$x_2 \sim x_1 \ , \ y_2 \sim y_1. \tag{8.9.6}$$

Then it follows from (9.4) and its y analog that we have the relation

$$x_2 + y_2 = x_1 + y_1 + x' + y'. \tag{8.9.7}$$

in it vanishes. Colloquially, we say that all elements in an Abelian Lie algebra or subalgebra *commute*. A Lie algebra is called *semisimple* if it has no Abelian ideals. By this definition, a simple Lie algebra is also semisimple. That is, simple Lie algebras form a subset of the set of semisimple Lie algebras. Suppose a Lie algebra L is semisimple but not simple. Then it can be shown that L is the *direct sum* of two or more simple Lie algebras. By direct sum it is meant the all the elements of any simple Lie subalgebra in the sum commute with all the elements of any other simple Lie subalgebra in the sum.

But if x' and y' belong to L', then so must the sum $(x'+y')$. (Again, remember that L' is an algebra.) Thus, we also have the logical implication

$$x_2 \sim x_1 \text{ and } y_2 \sim y_1 \Rightarrow (x_2+y_2) \sim (x_1+y_1). \tag{8.9.8}$$

Now we are ready to give L/L' a *vector space* structure. First, we have to define scalar multiplication. Consider some equivalence class. Then, since equivalence classes are disjoint, each equivalence class may be labelled by any one of its members. Select some member of the equivalence class under consideration, and call it x_1. Then the equivalence class may be given the label $\{x_1\}$. Now let a be any scalar. We define scalar multiplication acting on the element $\{x_1\}$ of L/L' by the rule

$$a\{x_1\} = \{ax_1\}. \tag{8.9.9}$$

Thus, by this definition, scalar multiplication sends equivalence classes into each other. But suppose x_2 also belongs to $\{x_1\}$, and that we had used x_2 to label $\{x_1\}$ instead of x_2. Would this different choice affect the definition (9.9)? It would not. With the choice of x_2 as a label we would have the definition

$$a\{x_2\} = \{ax_2\}. \tag{8.9.10}$$

But, by (9.5), we have the relation

$$\{ax_2\} = \{ax_1\} \tag{8.9.11}$$

because an equivalence class is uniquely defined by any of its members. Thus, scalar multiplication is uniquely defined by the rule (9.9).

Next we define vector addition. Let $\{x_1\}$ and $\{y_1\}$ be two equivalence classes labelled by two members x_1 and y_1. We define addition by the rule

$$\{x_1\} + \{y_1\} = \{(x_1+y_1)\}. \tag{8.9.12}$$

By this definition, addition sends a pair of equivalence classes into some third (not necessarily different) equivalence class. Again, there is the question of uniqueness under the choice of labelling. However, thanks to (9.8), the definition (9.12) is in fact independent of labelling. Note that as a special case of (9.12) we have the relation

$$\{x\} + \{0\} = \{x\}. \tag{8.9.13}$$

That is, the equivalence class $\{0\}$ plays the role of the zero vector in L/L'.

We have given L/L' a vector space structure. What is the dimension of L/L'? Suppose that L' has a basis $b_1, b_2, \cdots$, and that a basis for L is constructed by taking the vectors $b_1, b_2, \cdots$ supplemented by the additional linearly independent vectors $v_1, v_2, \cdots v_n$. Then, we have the dimensional relations

$$\dim L = \dim L' + n \text{ , or } n = \dim L - \dim L'. \tag{8.9.14}$$

Suppose x is any vector in L. Then x has the unique decomposition

$$x = x' + \sum_{i=1}^{n} \xi_i v_i, \tag{8.9.15}$$

where x' is the portion of x spanned by the basis vectors $b_1, b_2, \cdots$. Now form equivalence classes of both sides of (9.15). From the definition (9.12) and (9.3), (9.9), and (9.13) we find the result

$$\{x\} = \{x'\} + \left\{ \sum_{i=1}^{n} \xi_i v_i \right\} = \sum_{i=1}^{n} \xi_i \{v_i\}. \tag{8.9.16}$$

It is easily verified that the vectors $\{v_i\}$ are linearly independent. See Exercise 7.2. Consequently, the quotient space L/L' has dimension n,

$$\dim(L/L') = n = \dim L - \dim L'. \tag{8.9.17}$$

So far we have assumed that L' is a subalgebra. Now make the further supposition that L' is an ideal. In this case we can give the quotient space a *Lie algebraic* structure. We have already seen that the quotient space can be given a vector space structure. What remains is to define a Lie product. Let $\{x_1\}$ and $\{y_1\}$ be two equivalence classes labelled by two members x_1 and y_1. We define a *quotient space* Lie product, denoted by the symbols $[\ ,\ ]_{qs}$, by the rule

$$[\{x_1\}, \{y_1\}]_{qs} = \{[x_1, y_1]\}. \tag{8.9.18}$$

By this definition the quotient space Lie product sends a pair of equivalence classes into some third (not necessarily different) equivalence class. As before there is the question of uniqueness under the choice of labelling. Suppose we use instead labels x_2 and y_2 that satisfy (9.6). Then from (9.4) and its y counterpart we find the result

$$\begin{aligned} [\{x_2\}, \{y_2\}]_{qs} &= \{[x_1 + x', y_1 + y']\} \\ &= \{[x_1, y_1] + [x', y_1] + [x_1, y'] + [x', y']\} \\ &= \{[x_1, y_1]\} + \{[x', y_1]\} + \{[x_1, y']\} + \{[x', y']\} \\ &= [\{x_1\}, \{y_1\}]_{qs} + \{[x', y_1]\} + \{[x_1, y']\} + \{[x', y']\}. \end{aligned} \tag{8.9.19}$$

But, since L' is assumed to be an ideal, all the quantities $[x', y_1]$, $[x_1, y']$, and $[x', y']$ must be in L'. See (9.1). It follows from (9.3) and (9.13) that we have the relation

$$\{[x', y_1]\} + \{[x_1, y']\} + \{[x', y']\} = \{0\} + \{0\} + \{0\} = \{0\}. \tag{8.9.20}$$

Consequently, upon combining (9.19) with (9.20) and again using (9.3), we find the result

$$[\{x_2\}, \{y_2\}]_{qs} = [\{x_1\}, \{y_1\}]_{qs}. \tag{8.9.21}$$

Thus, the quotient space Lie product is uniquely defined by (9.18).

We claim that the addition rule (9.12) and Lie product rule (9.18) together satisfy requirements 1 through 5 for a Lie algebra as given in Section 3.7. For example, if $\{x\}, \{y\}$, and $\{z\}$ are any three equivalence classes, we have from (9.18) the relation

$$[\{x\}, [\{y\}, \{z\}]_{qs}]_{qs} = [\{x\}, \{[y, z]\}]_{qs} = \{[x, [y, z]]\}. \tag{8.9.22}$$

The Jacobi condition requirement follows immediately from (9.22). Verification of the remaining requirements is left as an exercise for the reader. We conclude that if L' is an ideal, the elements of the quotient space L/L' can be viewed as elements of an n dimensional Lie algebra. This Lie algebra is called the *quotient* Lie algebra.

The discussion of the quotient Lie algebra L/L' that we have just worked through may seem overly abstract. It can be made more concrete by using structure constants. See (3.7.40). We know from our previous discussion that L is spanned by the basis vectors $b_1, b_2, b_3 \cdots$ and $v_1, v_2, \cdots v_n$. There are therefore three kinds of Lie products: $[b_i, b_j]$, $[v_i, b_j]$, and $[v_i, v_j]$. Correspondingly, the structure constants are of six kinds: ${}^1c, {}^2c, \cdots {}^6c$. Consider first the Lie products $[b_i, b_j]$. Their results can be written in the form

$$[b_i, b_j] = \sum_k {}^1c_{ij}^k b_k + \sum_k {}^2c_{ij}^k v_k. \tag{8.9.23}$$

If L' is a Lie subalgebra spanned by the b_i, as we have assumed, then the structure constants ${}^2c$ must vanish,

$${}^2c_{ij}^k = 0. \tag{8.9.24}$$

Consider next the Lie products $[v_i, b_j]$. Their results can be written in the form

$$[v_i, b_j] = \sum_k {}^3c_{ij}^k b_k + \sum_k {}^4c_{ij}^k v_k. \tag{8.9.25}$$

If L' is an ideal, as we have also assumed, then the structure constants ${}^4c$ must also vanish,

$${}^4c_{ij}^k = 0. \tag{8.9.26}$$

See (9.1). Finally, the Lie products $[v_i, v_j]$ can be written in the form

$$[v_i, v_j] = \sum_k {}^5c_{ij}^k b_k + \sum_k {}^6c_{ij}^k v_k. \tag{8.9.27}$$

Now form equivalence classes of both sides of (9.27). Then, using (9.3), (9.13), and (9.18), we find the result

$$[\{v_i\}, \{v_j\}]_{qs} = \sum_k {}^6c_{ij}^k \{v_k\}. \tag{8.9.28}$$

We also know from (9.16) that the $\{v_i\}$ span L/L'. From (9.28) we conclude that the ${}^6c_{ij}^k$ are the structure constants of L/L'.

The next topic we need to discuss is that of *quotient groups.* We will see that for every quotient Lie algebra there is a corresponding quotient Lie group. To understand this connection we begin by describing the concept of a quotient group. Suppose G is a group, and suppose G' is a subgroup of G. We use the subgroup G' to set up an equivalence relation in G. Let g_1 and g_2 be any two elements in G. We say that g_2 is equivalent to g_1 (and again use the notation $g_2 \sim g_1$) if there exists a g' in G' such that $g_1^{-1}g_2 = g'$ or, put another way, $g_2 = g_1 g'$:

$$g_2 \sim g_1 \Leftrightarrow g_1^{-1}g_2 = g' \in G' \Leftrightarrow g_2 = g_1 g'. \tag{8.9.29}$$

This equivalence relation can be used to partition the elements of G into disjoint equivalence classes. These equivalence classes are called the (left) *cosets* of G with respect to G'. The collection of all of these cosets is called the *coset space*, and is customarily denoted by the symbols G/G'. See Exercise 5.12.7. If g is an element in G, we use the notation $\{g\}$ to denote all the elements in G that are equivalent to g. Suppose e is the identity element in G. Then it is easily checked that

$$\{g'\} = \{e\}, \tag{8.9.30}$$

where g' is any element in G'.

We next assume that G' is a *normal* or *invariant* subgroup of G. Suppose g is any element of G, and g' is any element of G'. The subgroup G' is called invariant or normal if there is the relation

$$g^{-1}g'g \in G' \text{ for all } g \in G, g' \in G'. \tag{8.9.31}$$

If G' is normal, the collection of equivalence classes (coset space) G/G' can be made into a *group*. This group is called the *quotient* group.

To show that G/G' can be given a group structure, we must set up a rule for multiplying equivalence classes (cosets) in such a way that rules analogous to those given for matrices in Section 3.6 are satisfied. Suppose $\{g_1\}$ and $\{h_1\}$ are two equivalence classes labelled by representative elements g_1 and h_1 in G. We define their product, denoted by the symbols $\{g_1\}\{h_1\}$, to be the equivalence class given by the rule

$$\{g_1\}\{h_1\} = \{g_1h_1\}. \tag{8.9.32}$$

As a special case of (9.32) we find the results

$$\{g_1\}\{e\} = \{g_1e\} = \{g_1\}, \tag{8.9.33}$$

$$\{e\}\{h_1\} = \{eh_1\} = \{h_1\}. \tag{8.9.34}$$

Also, we define $\{g_1\}^{-1}$ by the rule

$$\{g_1\}^{-1} = \{g_1^{-1}\}. \tag{8.9.35}$$

Then, upon combining (9.32) and (9.35), we find the results

$$\{g_1\}\{g_1\}^{-1} = \{g_1g_1^{-1}\} = \{e\}, \tag{8.9.36}$$

$$\{g_1\}^{-1}\{g_1\} = \{g_1^{-1}g_1\} = \{e\}. \tag{8.9.37}$$

Both (9.32) and (9.35) are rules that send equivalence classes to equivalence classes. Of course, as usual, we must verify that the definitions (9.32) and (9.35) are in fact independent of the choice of representative elements selected to label the equivalence classes $\{g_1\}$ and $\{h_1\}$. For example, suppose we decide to designate the equivalence classes $\{g_1\}$ and $\{h_1\}$ by the representatives g_2 and h_2 so that we have the alternate labels $\{g_2\}$ and $\{h_2\}$. Of course g_2 and g_1 are related by (9.29), and h_2 and h_1 are related by an analogous equation. Then we find from (9.32) the result

$$\{g_2\}\{h_2\} = \{g_2h_2\} = \{g_1g'h_1h'\} = \{g_1h_1h_1^{-1}g'h_1h'\} = \{g_1h_1\} = \{g_1\}\{h_1\}. \tag{8.9.38}$$

Here we have used (9.31) and the fact that G' is a group to deduce that $h_1^{-1}g'h_1h'$ is in G'. We conclude that the equivalence class product is uniquely defined by (9.32). Similarly, it can be shown that the equivalence class inverse is uniquely defined by (9.35). See Exercise 9.4. Thus, the quotient group is uniquely defined.

We are now ready to see the connection between quotient Lie algebras and quotient Lie groups. Suppose, for simplicity, that the Lie algebra L is realized as a set of linear operators, with the Lie product being a commutator. Then, as described in Section 3.7, there is (at least locally near the identity) an associated Lie group G obtained by exponentiating L. Also, suppose L has a subalgebra L'. Exponentiating L' gives a Lie subgroup G'. Suppose that L' is an ideal. Then we will discover that G' is normal. Also, since L' is an ideal, we can form the quotient Lie algebra L/L'. Correspondingly, since G' is normal, we can form the quotient group G/G'. We will discover that L/L' is the Lie algebra of G/G'.

To see how this comes about, suppose ℓ is an element of L, and ℓ' is an element of L'. Upon exponentiation we get elements g and g' of G and G', respectively,

$$g = \exp(\ell) \quad , \quad g' = \exp(\ell'). \tag{8.9.39}$$

Now form the combination $g^{-1}g'g$. We find from (9.39) the result

$$g^{-1}g'g = \exp(-\ell)\exp(\ell')\exp(\ell). \tag{8.9.40}$$

Next use the adjoint operator $\#\ell\#$ and a relation of the form (2.16) to rewrite (9.40) in the form

$$g^{-1}g'g = \exp[\exp(-\#\ell\#)\ell']. \tag{8.9.41}$$

Since L' is assumed to be an ideal, we have from (8.1) the result

$$\#\ell\#\ell' = [\ell, \ell'] \in L', \tag{8.9.42}$$

from which it follows that $\exp(-\#\ell\#)\ell'$ is also in L',

$$\exp(-\#\ell\#)\ell' \in L'. \tag{8.9.43}$$

But, from (9.43) it follows that

$$g^{-1}g'g = \exp[\exp(-\#\ell\#)\ell'] \in G'. \tag{8.9.44}$$

Consequently G' is normal, as advertised. The converse can also be proved: If G' with Lie algebra L' is a normal subgroup of a Lie group G with Lie algebra L, then L' is an ideal in L.

To complete our demonstration, we must show that L/L' is the Lie algebra of G/G'. Suppose that x_1 is some element of L, and that it is used to label the equivalence class $\{x_1\}$, which is an element of L/L'. We define $\exp\{x_1\}$, which is supposed to be an element of G/G', by the rule

$$\exp(\{x_1\}) = \{\exp(x_1)\}. \tag{8.9.45}$$

[Note that the { } on the left side of (9.45) refers to the Lie algebraic equivalence class, and that on the right side refers to the group equivalence class.] As a special case of (9.45) we have the relation

$$\exp(\{0\}) = \{\exp(0)\} = \{e\}. \tag{8.9.46}$$

Of course, as usual, we must check that our definition does not depend on the choice of equivalence class labels. Suppose we label $\{x_1\}$ by x_2 where $x_2 \sim x_1$. Then, we find the result

$$\begin{aligned} \exp(\{x_2\}) &= \{\exp(x_2)\} = \{\exp(x_1 + x')\} \\ &= \{\exp(x_1)\exp(-x_1)\exp(x_1 + x')\}. \end{aligned} \tag{8.9.47}$$

Here we have used (9.4). Now use the BCH series (3.7.33) and (3.7.34) to combine the exponents $(-x_1)$ and $(x_1 + x')$. According to (3.7.34), the first thing we must do is add them. We find the result

$$(-x_1) + (x_1 + x') = x' \in L'. \tag{8.9.48}$$

Next, according to (3.7.34), we must find their commutator. Doing so gives the result

$$[(-x_1), (x_1 + x')] = [(-x_1), x'] \in L'. \tag{8.9.49}$$

Here, because L' is an ideal, we have been able to use (9.1). Finally, we must compute an infinite number of higher-order commutators. See (3.7.34) and Appendix C. Examination of the contents of these commutators shows that each of them has a term of the form (9.49) buried inside, and we know this term is in L'. But since L' is an ideal, (9.1) shows that all further commutators will also be in L'. We have learned that all terms that arise when we combine the exponents in $\exp(-x_1)\exp(x_1 + x')$ are in L'. Consequently, the product $\exp(-x_1)\exp(x_1 + x')$ must be in G',

$$\exp(-x_1)\exp(x_1 + x') = g' \in G'. \tag{8.9.50}$$

It follows from (9.47), (9.50), (9.29), and (9.45) that we have the result

$$\begin{aligned} \exp(\{x_2\}) &= \{\exp(x_1)\exp(-x_1)\exp(x_1 + x'\} \\ &= \{\exp(x_1)g'\} = \{\exp(x_1)\} = \exp(\{x_1\}). \end{aligned} \tag{8.9.51}$$

Thus, the definition (9.45) is indeed independent of the choice of equivalence class labels.

The last thing we must show is that products of the form $\exp(\{x_1\})\exp(\{y_1\})$ can be computed from a knowledge only of the quotient Lie algebra L/L'. Suppose $\{x_1\}$ and $\{y_1\}$ are two elements of L/L'. We then find from (9.45) and (9.32) the result

$$\begin{aligned} \exp(\{x_1\})\exp(\{y_1\}) &= \{\exp(x_1)\}\{\exp(y_1)\} \\ &= \{\exp(x_1)\exp(y_1)\}. \end{aligned} \tag{8.9.52}$$

Let us use the BCH series to combine the exponents x_1 and y_1 into one grand exponent z_1. Then we have the relation

$$\exp(x_1)\exp(y_1) = \exp(z_1). \tag{8.9.53}$$

Consequently, we find from (9.52) and (9.53) the result

$$\exp(\{x_1\})\exp(\{y_1\}) = \{\exp(z_1)\} = \exp(\{z_1\}). \tag{8.9.54}$$

From the BCH formula (3.7.34) we know that z_1 is given by the series

$$\begin{aligned} z_1 = x_1 + y_1 &+ (1/2)[x_1, y_1] + (1/12)[x_1, [x_1, y_1]] \\ &+ (1/12)[y_1, [y_1, x_1]] + \cdots . \end{aligned} \tag{8.9.55}$$

Now, form equivalence classes of both sides of (9.55). By making repeated use of (9.12) and (9.18) we find from (9.55) the result

$$\begin{aligned} \{z_1\} &= \{x_1\} + \{y_1\} + (1/2)[\{x_1\}, \{y_1\}]_{qs} + (1/12)[\{x_1\}, [\{x_1\}, \{y_1\}]_{qs}]_{qs} \\ &+ (1/12)[\{y_1\}, [\{y_1\}, \{x_1\}]_{qs}]_{qs} + \cdots . \end{aligned} \tag{8.9.56}$$

We see from (9.54) and (9.56) that the group multiplication rules for the quotient group G/G' are indeed determined by the quotient Lie algebra L/L'.

So far in this section our discussion has been devoted to the general concepts of quotient Lie algebras and their associated quotient Lie groups. We now turn to applying these concepts to $ispm(2n, \mathbb{R})$, the Lie algebra of the group of all symplectic maps acting on a $2n$ dimensional phase space. As mentioned at the beginning of this chapter, we will first restrict our attention to those symplectic maps that send the origin into itself. The general case will be treated at the end of this section. From Section 7.6 we know that the Lie algebra of maps that send the origin into itself is spanned by the Lie operators $: f_2 :, : f_3 :, \cdots$. Let us call this Lie algebra L_2.

Let D be some integer satisfying $D > 2$, and let L_D be the set of Lie operators spanned by all $: f_m :$ with $m \geq D$. From (5.3.14) and (7.6.14) we find the result

$$\{: f_m :, : f_n :\} =: [f_m, f_n] :=: \mathcal{P}_{m+n-2} :, \tag{8.9.57}$$

where we have used the notation $\mathcal{P}_\ell$ to denote the space spanned by all f_ℓ. Observe that if $m \geq D$ and $n \geq D$ (with $D > 2$), then $(m + n - 2) \geq D$. Thus, if $: f_m :$ and $: f_n :$ are in L_D, then so is their Lie product (9.57). It follows that L_D is a subalgebra of L_2.

As a special case of (9.57) we have the result

$$\{: f_2 :, : f_n :\} =: [f_2, f_n] :=: \mathcal{P}_n : . \tag{8.9.58}$$

We see from (9.57) and (9.58) that if $: f_n :$ is in L_D, then so is $\{: f_m :, : f_n :\}$ for all $: f_m :$ in L_2. It follows that L_D is an ideal in L_2.

Suppose we form the quotient algebra L_2/L_D. From our discussion of quotient algebras, we know this construction is equivalent to discarding all $: f_m :$ with $m \geq D$, and retaining only the $: f_\ell :$ with $\ell = 2, 3, \cdots (D - 1)$. We also discard all Lie products $\{: f_m :, : f_n :\}$ when $(m + n - 2) \geq D$. We have seen that dropping all $: f_m :$ with $m \geq D$ is equivalent to ignoring all aberrations of degree $(D - 1)$ and higher. The result of this construction, the quotient algebra L_2/L_D, is a *finite*-dimensional Lie algebra whose dimension equals the number of monomials in the phase-space variables z of degrees $2, 3, \cdots (D-1)$. The number of monomials of degrees $1, 2, 3 \cdots (D - 1)$ is given by $S(D - 1, d)$. (Note that D as defined in this section differs by 2 from that defined in Section 7.9.) Also, we know that the number of monomials of degree 1 (in a d-dimensional phase space) is d. Thus, we conclude that the dimension of L_2/L_D is given by the relation

$$\dim(L_2/L_D) = S(D - 1, d) - d. \tag{8.9.59}$$

This dimension is tabulated in Table 9.1 below for the cases of $d = 4$, $d = 6$, and $d = 8$ and various values of D. Finally, there is a finite-dimensional quotient group corresponding to L_2/L_D. The elements of this group are all symplectic maps of the form

$$\begin{aligned}\mathcal{M} = &\exp(:f_2^c:)\exp(:f_2^a:)\exp(:f_3:)\exp(:f_4:)\cdots\exp(:f_{D-1}:)\times\\ &\exp(:h_D:)\exp(:h_{D+1}:)\cdots,\end{aligned} \tag{8.9.60}$$

Table 8.9.1: Values of $\dim(L_2/L_D)$.

D	dim for $d = 4$	dim for $d = 6$	dim for $d = 8$
4	30	77	156
5	65	203	486
6	121	455	1278
7	205	917	2994
8	325	1709	6426
9	490	2996	12,861
10	710	4998	24,301
11	996	8001	43,749
12	1360	12,369	75,573
13	1815	18,557	125,961

where the f's are specified and the homogeneous polynomial Lie operators $:h_D:$, $:h_{D+1}:$, $\cdots$ can be anything since all such elements are in L'_D and their exponentials are in the normal subgroup G'. We note that (9.60) is a relation of the form $g_2 = g_1 g'$. See (9.29). Consequently, we may view all members of the quotient group as belonging to the equivalence classes $\{\mathcal{M}_f\}$ where

$$\mathcal{M}_f = \exp(:f_2^c:)\exp(:f_2^a:)\exp(:f_3:)\exp(:f_4:)\cdots\exp(:f_{D-1}:). \tag{8.9.61}$$

Since the Lie algebra L_2/L_D is finite dimensional, we might hope to be able to represent it by finite dimensional matrices. This is indeed possible. We will consider first the whole Lie algebra L_1 and show that it has a representation by infinite dimensional matrices.

We can take as a basis for L_1 the Lie operators $: G_t :$. Then, in accord with (3.38), these Lie operators have the associated matrices

$$O_{sr}(: G_t :) = \langle G_s, : G_t : G_r \rangle. \tag{8.9.62}$$

But we also have the result

$$: G_t : G_r = [G_t, G_r] = \sum_{s'} c_{tr}^{s'} G_{s'}, \tag{8.9.63}$$

where the coefficients $c_{tr}^{s'}$ are the structure constants of the underlying Poisson bracket Lie algebra. See (3.7.43). It follows from (9.62) and (9.63) that we have the relation

$$O_{sr}(: G_t :) = c_{tr}^{s}. \tag{8.9.64}$$

We see that the matrix representation of L_1 is determined by the structure constants. Evidently these matrices are infinite dimensional.

Let us pursue the relation (9.64) a bit further. From (5.3.14), (3.41), and (9.63) we have the result

$$\begin{aligned} \{O(: G_t :), O(: G_{t'} :)\} &= O(\{: G_t :, : G_{t'} :\}) = O(: [G_t, G_{t'}] :) \\ &= O(: \sum_{t''} c_{tt'}^{t''} G_{t''} :) = \sum_{t''} c_{tt''}^{t''} O(: G_{t''} :). \end{aligned} \tag{8.9.65}$$

Next take r, s matrix elements of both sides of (9.65). Doing so and expanding the commutator on the left side of (9.65) gives the result

$$\sum_{t''} O_{rt''}(: G_t :) O_{t''s}(: G_{t'} :) - O_{rt''}(: G_{t'} :) O_{t''s}(: G_t :) = \sum_{t''} c_{tt'}^{t''} O_{rs}(: G_{t''} :). \tag{8.9.66}$$

Finally, use (9.64) in (9.66) to find the relation

$$\sum_{t''} c_{tt''}^{r} c_{t's}^{t''} - c_{t't''}^{r} c_{ts}^{t''} - c_{tt'}^{t''} c_{t''s}^{r} = 0. \tag{8.9.67}$$

It is easily verified with the aid of (3.7.44) that (9.67) is equivalent to (3.7.45), which is in turn a consequence of the Jacobi identity. [That the Jacobi identity should be involved should come as no surprise since (5.3.14), which was used in (9.65), is a consequence of the Jacobi identity.] Notice that the steps we have been following are quite general and hold, in fact, for any Lie algebra. We have learned from (9.65) that matrices defined in terms of the structure constants by the relation (9.64) provide a representation of the underlying Lie algebra. Indeed, a moment's reflection reveals that our present discussion is a recapitulation of that given at the end of Section 3.7. That is, we have found the *adjoint* representation of L_1. Finally, we observe that if we exponentiate the matrices (9.64), we get a representation, again called the adjoint representation, of the group. It follows, in the case of the group of all symplectic maps, that the matrix representation given by (3.34) is just the adjoint representation. The matrices in this representation are also infinite dimensional.

We now turn to the case of the Lie algebra L_2/L_D. As in Section 8.6, define a *truncation* (by degree) operator $\mathcal{T}(>m)$ on the basis functions G_r by the rules

$$\deg(G_r) \leq m \Rightarrow \mathcal{T}(>m)G_r = G_r, \tag{8.9.68}$$

$$\deg(G_r) > m \Rightarrow \mathcal{T}(>m)G_r = 0, \tag{8.9.69}$$

and extend $\mathcal{T}(>m)$ to all functions by requiring that it be a *linear* operator. Given any $D > 2$ and any Lie operator $:f:$ in L_2, we define an associated linear operator $\mathcal{L}_D(:f:)$ by the rule

$$\mathcal{L}_D(:f:) = \mathcal{T}(>D-2):f:\mathcal{T}(>D-2). \tag{8.9.70}$$

We note that since (by hypothesis) $:f:$ is in L_2, it can only preserve or raise the degree of any monomial on which it acts. Therefore the operator $\mathcal{T}(>D-2)$ on the far right of (9.70) is actually redundant. We also define $\mathcal{L}_D$ for other linear operators, for example products of Lie operators in L_2, by rules of the form

$$\mathcal{L}_D(:f::g:) = \mathcal{T}(>D-2):f::g:\mathcal{T}(>D-2). \tag{8.9.71}$$

Again, strictly speaking, the $\mathcal{T}(>D-2)$ on the far right of (9.71) is redundant since $:f:$ and $:g:$ are assumed to be in L_2.

This definition has several important properties: Suppose $:f:$ is also in L_D. Then, from (9.57) and (9.68) through (9.70), we find the result

$$:f:\in L_D \Rightarrow \mathcal{L}_D(:f:) = 0. \tag{8.9.72}$$

Next suppose $:f:$ and $:g:$ are in L_2. Then, from (9.57) and (9.68) through (9.71), we have the product rule

$$\begin{aligned} :f:,:g:\in L_2 \;&\Rightarrow\; \mathcal{L}_D(:f:)\mathcal{L}_D(:g:) \\ &=\; \mathcal{T}(>D-2):f:\mathcal{T}(>D-2)\mathcal{T}(>D-2):g:\mathcal{T}(>D-2) \\ &=\; \mathcal{T}(>D-2):f::g:\mathcal{T}(>D-2) = \mathcal{L}_D(:f::g:). \end{aligned} \tag{8.9.73}$$

Here we have used the fact that, since $:f:$ and $:g:$ are in L_2, the truncation operator product $\mathcal{T}(>D-2)\mathcal{T}(>D-2)$ that occurs in the intermediate expression in (9.73) is redundant. From (9.73) it follows that the operators $\mathcal{L}_D(:f:)$ for $:f:$ in L_2 form a Lie algebra. Indeed, we have the result

$$\begin{aligned} :f:,:g:\in L_2 \Rightarrow \{\mathcal{L}_D(:f:), \mathcal{L}_D(:g:)\} &= \mathcal{L}_D(\{:f:,:g:\}) \\ &= \mathcal{L}_D(:[f,g]:). \end{aligned} \tag{8.9.74}$$

Finally we find that all the $\mathcal{L}_D(:f:)$, for fixed D and $:f:$ in L_2, have only a finite number of nonzero matrix elements. Suppose either G_r or G_s have degree greater than $(D-2)$. Then from (9.57) and (9.68) through (9.70) we find the result

$$\begin{aligned} O_{sr}(\mathcal{L}_D(:f:)) &= \langle G_s, \mathcal{T}(>D-2):f:\mathcal{T}(>D-2)G_r\rangle \\ &= 0 \text{ when } \deg(G_r) > D-2 \text{ or } \deg(G_s) > D-2. \end{aligned} \tag{8.9.75}$$

Recall (3.32) and the fact that each monomial has a definite degree.

We now claim that the matrices $O(\mathcal{L}_D(: f :))$ provide a faithful representation of the quotient algebra L_2/L_D. By construction we have the relation

$$O(\mathcal{L}_D(: f : + : g :)) = O(\mathcal{L}_D(: f :)) + O(\mathcal{L}_D(: g :)), \tag{8.9.76}$$

and from (3.41), (9.73), (9.74) we find the relations

$$O(\mathcal{L}_D(: f :))O(\mathcal{L}_D(: g :)) = O(\mathcal{L}_D(: f :: g :)), \tag{8.9.77}$$

$$\{O(\mathcal{L}_D(: f :)), O(\mathcal{L}_D(: g :)\} = O(\mathcal{L}_D(: [f, g] :)). \tag{8.9.78}$$

Consequently, the matrices $O(\mathcal{L}_D(: f :))$ provide a representation of L_2. Also, according to (9.72), all elements in the ideal L_D are mapped to the zero matrix. Therefore, in view of (9.76), the matrix $O(\mathcal{L}_D(: f :))$ depends only on the equivalence class to which $: f :$ belongs. Thus, the matrices $O(\mathcal{L}_D(: f :))$ provide a representation of the quotient algebra L_2/L_D. Finally, it remains to be shown that this representation is *faithful*. That is, given a matrix $O(\mathcal{L}_D(: f :))$, we need to be able to determine the equivalence class to which $: f :$ belongs. Suppose that f is written in the form

$$f = f_2 + f_3 + \cdots f_{D-1}. \tag{8.9.79}$$

Compute the action of $\mathcal{L}_D(: f :)$ on z_a. We find the result

$$\begin{aligned} \mathcal{L}_D(: f :)z_a &= \mathcal{L}_D(: f_2 :)z_a + \mathcal{L}_D(: f_3 :)z_a + \cdots + \mathcal{L}_D(: f_{D-1} :)z_a \\ &= \mathcal{T}(> D-2)(: f_2 : z_a + : f_3 : z_a + \cdots + : f_{D-1} : z_a) \\ &= \mathcal{T}(> D-2)[g_a(1, z) + g_a(2, z) + \cdots + g_a(D-2, z)] \\ &= g_a(1, z) + g_a(2, z) + \cdots g_a(D-2, z). \end{aligned} \tag{8.9.80}$$

Here we have used the notation

$$g_a(m, z) = : f_{m+1} : z_a = [f_{m+1}, z_a], \tag{8.9.81}$$

and observe that the $g_a(m, z)$ are homogeneous polynomials of degree m. As is evident from (9.80), the polynomials $g_a(m, z)$ can be determined from a knowledge of the matrix elements

$$\begin{aligned} O_{ra} &= \langle G_r, \mathcal{L}_D(: f :)z_a\rangle \\ &= \langle G_r, g_a(1, z)\rangle + \langle G_r, g_a(2, z)\rangle + \cdots + \langle G_r, g_a(D-2, z)\rangle \end{aligned} \tag{8.9.82}$$

with the G_r having degree

$$\deg(G_r) \le D - 2. \tag{8.9.83}$$

Since the $g_a(m, z)$ are now known, we can determine the f_m from (9.81). See (7.6.24).

Is the matrix representation of L_2/L_D just described the adjoint representation? It is not. If it were, the matrix elements of $O(\mathcal{L}_D(: f :))$ would be related to the structure constants of the quotient algebra, which are the ${}^6c^s_{tr}$ where both the subscripts s and r refer to basis elements for the quotient algebra. See (9.28) and (9.64). But examination of (9.82) shows that the functions z_a were used to compute matrix elements, and the Lie operators $:z_a:$ are not in L_2, and therefore not even candidates for the quotient algebra L_2/L_D.

Consider the "truncated" analog of (9.61) written in the form

$$\begin{aligned}\mathcal{M}_f^{\mathcal{T}} &= \exp(\mathcal{L}_D(:f_2^c:))\exp(\mathcal{L}_D(:f_2^a:))\exp(\mathcal{L}_D(:f_3:))\times \\ &\quad \exp(\mathcal{L}_D(:f_4:))\cdots\exp(\mathcal{L}_D(:f_{D-1}:)).\end{aligned} \tag{8.9.84}$$

Also, arrange the labelling of the basis functions G_r so that G_0 corresponds to the constant function 1 (the monomial of degree zero), the G_a (with $a = 1\cdots d$) correspond to the linear monomials z_a, and the subsequent monomials G_r [with $r = d+1\cdots S(D-2,d)$] correspond to the monomials of degrees $2, 3, \cdots (D-2)$. Take matrix elements of both sides of (9.84) using the basis G_r with $r = 1, 2\cdots S(D-2,d)$. Doing so gives the result

$$\begin{aligned}M_f^{\mathcal{T}} &= \exp(O(\mathcal{L}_D(:f_2^c:)))\exp(O(\mathcal{L}_D(:f_2^a:)))\exp(O(\mathcal{L}_D(:f_3:)))\times \\ &\quad \exp(O(\mathcal{L}_D(:f_4:)))\cdots\exp(O(\mathcal{L}_D(:f_{D-1}:))).\end{aligned} \tag{8.9.85}$$

Here use has been made of relations of the form (9.76) and (9.77). We see that (9.85) provides a $S(D-2,d)\times S(D-2,d)$ matrix representation of the quotient Lie *group* associated with the quotient Lie algebra L_2/L_D. Moreover, this representation is faithful. To see the truth of this assertion, consider the matrix elements

$$(M_f^{\mathcal{T}})_{ra} = \langle G_r, \mathcal{M}_f^{\mathcal{T}} G_a\rangle = \langle G_r, \mathcal{L}_D(\mathcal{M}_f)G_a\rangle, \tag{8.9.86}$$

with

$$r \in [1, S(D-2,d)] \text{ and } a \in [1,d]. \tag{8.9.87}$$

From these matrix elements we can determine the coefficients in the Taylor series (7.6.1) through terms of degree $(D-2)$, and from these coefficients we can determine the polynomials $f_2^c, f_2^a, f_3, \cdots f_{D-1}$.

The last concept to be discussed in this section is gradings. For our purposes, a *grading* of a vector space V is a decomposition of V into a direct sum of subspaces along with a function *gr* (called the *grading* function) that assigns an integer (called the *grade*) to all the elements of any subspace. For example, we may take as our vector space V the set of all analytic functions $f(z)$ on phase space. Any such function can be decomposed into homogeneous polynomials by writing

$$f = f_0 + f_1 + f_2 + \cdots, \tag{8.9.88}$$

and these polynomials are in the subspaces we have called $\mathcal{P}_m$. In this case we may define the function *gr* by the rule

$$\mathrm{gr}(f_m) = \deg(f_m) = m. \tag{8.9.89}$$

Elements of V that satisfy (9.89) are called *homogeneous*. Suppose there is some multiplication rule, $\circ$, that makes V into an algebra. See Section 3.7. Suppose also that this multiplication rule, and the direct sum decomposition, are such that the product of any two homogeneous elements is also homogeneous. The multiplication rule and grading function are said to be *compatible* if, for all homogeneous elements, we have the relation

$$\mathrm{gr}(f_m \circ g_n) = \mathrm{gr}(f_m) + \mathrm{gr}(g_n). \tag{8.9.90}$$

For example, in the case of functions, we may take for $\circ$ the operation of ordinary function multiplication. Then, if we use the definition (9.89), we find the result

$$\mathrm{gr}(f_m \circ g_n) = \deg(f_m g_n) = m + n = \mathrm{gr}(f_m) + \mathrm{gr}(g_n), \tag{8.9.91}$$

which shows that ordinary function multiplication and the grading function (9.89) are compatible.

Suppose we use Poisson bracket multiplication for $\circ$ instead of ordinary multiplication. Then (4.28) shows that (9.89) is not compatible with Poisson bracket multiplication. However, if we define *gr* by the rule

$$\mathrm{gr}(f_m) = m - 2, \tag{8.9.92}$$

we find the result

$$\begin{aligned}\mathrm{gr}([f_m, g_n]) &= \mathrm{gr}(\mathcal{P}_{m+n-2}) = m + n - 2 - 2 \\ &= m - 2 + n - 2 = \mathrm{gr}(f_m) + \mathrm{gr}(g_n).\end{aligned} \tag{8.9.93}$$

Thus, the grading function (9.92) is compatible with Poisson bracket multiplication. A Lie algebra equipped with a grading (compatible with the Lie product) is called a *graded* Lie algebra.

Given a graded Lie algebra, it is easy to find subalgebras and ideals. Consider the case of analytic functions defined on phase space. Introduce the notation

$$f^{n-2}(z) = f_n(z) \tag{8.9.94}$$

to indicate, in accord with (9.92), that homogeneous polynomials of degree n have grade $(n-2)$. Equivalently, we have the relation

$$\mathrm{gr}(f^m) = m. \tag{8.9.95}$$

We also introduce the notation

$$\mathcal{P}^{n-2} = \mathcal{P}_n \tag{8.9.96}$$

to indicate the subspace of polynomials of degree n and grade $(n-2)$. Finally, we extend the concept of grade to Lie operators by the rule

$$\mathrm{gr}(: f^m :) = \mathrm{gr}(f^m) = m. \tag{8.9.97}$$

Now consider the space of all Lie operators spanned by basis elements of the form $: f^0 :$, $: f^1 :, : f^2 :, \cdots$. Then, because of the relation

$$\begin{aligned}\mathrm{gr}(\{: f^m :, : f^n\}) &= \mathrm{gr}(: [f^m, f^n] :) = \mathrm{gr}([f^m, f^n]) \\ &= \mathrm{gr}(f^m) + \mathrm{gr}(f^n) = m + n,\end{aligned} \tag{8.9.98}$$

we see that

$$\{: f^m :, : f^n :\} \in : \mathcal{P}^{m+n} :, \tag{8.9.99}$$

and hence this space is a Lie algebra. This is just the Lie algebra that we found and called L_2 earlier, and that we now will also call L^0. Similarly, we can use arguments based on grading to show that $L^m = L_{m+2}$ (with $m > 0$) is a subalgebra of $L^0 = L_2$, and also an ideal in L^0. (Indeed, the arguments we used earlier for this purpose were actually grading arguments without being identified as such.)

Note that the Lie algebra $L^{-1} = L_1$ also has L^m as a subalgebra. However L^m is not an ideal in L^{-1} since L^{-1} contains $: f^{-1} :=: f_1 :$ which, according to (9.99), can lower the grade of elements in L^m until they are no longer in L^m. We have seen that L^0 can be approximated by using the finite dimensional quotient algebras $L^0/L^m = L_2/L_{m+2}$. Is there some way that we can approximate L^{-1} in a consistent Lie algebraic way even though L^m is not an ideal in L^{-1}? We would certainly like to do so since maps of the form (7.8.1) are of interest when the origin is not mapped into itself. The answer to the question just posed is yes provided we are willing to treat the f_1 as being in some sense *small.* Fortunately this circumstance is the one usually encountered since, as we will see in Chapter 14, f_1 terms are usually associated with misalignment, misplacement, and mispowering errors, and these errors are generally small.

Before considering the inclusion of small f_1 terms, let us return to the case described at the beginning of this section. Let ϵ be a (presumably small) parameter, and define V to be the vector space spanned by all phase-space functions of the form $f^{(0)}$, $\epsilon f^{(1)}$, $\epsilon^2 f^{(2)} \cdots$. Here the $f^{(n)}$ are *arbitrary* analytic functions not to be confused with the f^n defined earlier. Assign a grade to the subspaces $\epsilon^n f^{(n)}$ and the associated Lie operators $: \epsilon^n f^{(n)} :$ by the rules

$$\mathrm{gr}(\epsilon^n f^{(n)}) = n, \tag{8.9.100}$$

$$\mathrm{gr}(: \epsilon^n f^{(n)} :) = n. \tag{8.9.101}$$

This grading function is evidently compatible with Lie multiplication,

$$\begin{aligned}\mathrm{gr}([\epsilon^m f^{(m)}, \epsilon^n f^{(n)}]) &= \mathrm{gr}(\epsilon^{m+n}[f^{(m)}, f^{(n)}]) \\ &= m + n = \mathrm{gr}(\epsilon^m f^{(m)}) + \mathrm{gr}(\epsilon^n f^{(n)}),\end{aligned} \tag{8.9.102}$$

$$\begin{aligned}\mathrm{gr}(\{: \epsilon^m f^{(m)} : \ , : \epsilon^n f^{(n)} :\}) = \mathrm{gr}(: [\epsilon^m f^{(m)}, \epsilon^n f^{(n)}] :) \\ = \ m + n = \mathrm{gr}(: \epsilon^m f^{(m)} :) + \mathrm{gr}(: \epsilon^n f^{(n)} :).\end{aligned} \tag{8.9.103}$$

Here we have used the fact that $[f^{(m)}, f^{(n)}]$ is again an arbitrary analytic phase-space function. Thus we may use this grading to construct subalgebras, ideals, and quotient algebras. Suppose we define L^n to be the vector space spanned by $\epsilon^n f^{(n)}$, $\epsilon^{n+1} f^{(n+1)}$, $\epsilon^{n+2} f^{(n+2)} \cdots$. Then it is easily verified that the L^n are Lie algebras. Moreover, any L^n for $n > 0$ is an ideal in L^0, and each L^0/L^n is a quotient algebra. Finally, it is evident that working with the quotient algebra L^0/L^n is equivalent to doing perturbation theory in ϵ and retaining only those terms that carry powers of ϵ of the form ϵ^0, $\epsilon^1, \cdots \epsilon^{n-1}$. What we have learned is that *finite* order perturbation theory is a consistent Lie algebraic procedure.

We now turn to the inclusion of small f_1 terms. Again let ϵ be a parameter. Consider now the vector space V spanned by all functions of the form $\epsilon^m f_n$. Assign a grade to these subspaces and their associated Lie operators $: \epsilon^m f_n :$ by the rules

$$\mathrm{gr}(\epsilon^m f_n) = m + n - 2, \tag{8.9.104}$$

$$\mathrm{gr}(:\epsilon^m f_n:) = m + n - 2. \tag{8.9.105}$$

With this definition we find that $\epsilon^2 f_0$, ϵf_1, and f_2 have grade 0; $\epsilon^3 f_0$, $\epsilon^2 f_1$, ϵf_2, and f_3 have grade 1; $\epsilon^4 f_0$, $\epsilon^3 f_1$, $\epsilon^2 f_2$, ϵf_3, and f_4 have grade 2; etc. From the previous discussion it is easy to see that the grading functions (9.104) and (9.105) are compatible with Lie multiplication. Consequently, we may use it as before to construct subalgebras, ideals, and quotient algebras. Let ${}^{\epsilon}L^{\ell}$ denote the vector space of functions spanned by elements of the form $\epsilon^m f_n$ with $(m + n - 2) \geq \ell$ [that is, $\mathrm{gr}(\epsilon^m f_n) \geq \ell$]. Then, following arguments given previously, it is easy to check that the ${}^{\epsilon}L^{\ell}$ (with $\ell \geq 0$) are Lie algebras, ${}^{\epsilon}L^{\ell}$ with $\ell > 0$ is an ideal in ${}^{\epsilon}L^0$, and each ${}^{\epsilon}L^0/{}^{\epsilon}L^{\ell}$ is a quotient algebra. We also see that ${}^{\epsilon}L^0$ contains the element ϵf_1, which can be interpreted as being a small f_1. Finally, we observe that the quotient algebra ${}^{\epsilon}L^0/{}^{\epsilon}L^{\ell}$, for fixed ℓ, is finite dimensional. (These dimensions are listed below in Table 9.2 for the cases of four and six-dimensional phase spaces. In computing these dimensions we set $\epsilon = 1$ and ignored all terms of the form $\epsilon^m f_0$.) Consequently, we have discovered a systematic and Lie algebraically consistent approximation scheme that includes small f_1 terms. This approximation scheme will be studied extensively in the next chapter.

Table 8.9.2: Values of $\dim({}^{\epsilon}L^0/{}^{\epsilon}L^{\ell})$.

ℓ	dim for $d = 4$	dim for $d = 6$
1	14	27
2	34	83
3	69	209
4	125	461
5	209	923
6	329	1715
7	494	3002
8	714	5004
9	1000	8007

11	1819	18,563

Exercises

8.9.1. Review Exercise 5.12.7. Let L be a vector space having a vector subspace L'. Show that (9.2) defines (satisfies the properties of) an equivalence relation among the elements of L.

8.9.2. Verify that the vectors $\{v_i\}$ used in (9.16) are linearly independent. Hint: Assume there exist scalars α_i such that

$$\sum_{i=1}^{n} \alpha_i \{v_i\} = \{0\}.$$

Show that there exists a vector $x' \epsilon L'$ such that

$$\sum_{i=1}^{n} \alpha_i v_i = x'.$$

Show that since $x' \epsilon L'$, it must have an expansion of the form

$$x' = \sum_j \beta_j b_j.$$

Now show that all the coefficients α_i and β_j must vanish.

8.9.3. Verify the relation

$$[\{0\}, \{x\}]_{qs} = \{0\}.$$

Show that the addition rule (9.12) and Lie product rule (9.18) together satisfy requirements 1 through 5 for a Lie algebra as given in Section 3.7.

8.9.4. Verify (9.30). Verify (9.38) in detail. Show that the definition (9.35) is independent of equivalence class labeling if G' is normal. Verify that the definition (9.32) satisfies the associative property

$$\{f_1\}(\{g_1\}\{h_1\}) = (\{f_1\}\{g_1\})\{h_1\}.$$

8.9.5. If G is a group with a subgroup G', the subgroup G' can be used to produce equivalence classes in G in two possibly different ways. First, there is the equivalence relation $\sim$ defined by

$$g_2 \sim g_1 \Leftrightarrow g_1^{-1} g_2 \in G'.$$

Second, there is another equivalence relation, let us denote it by the symbol $\leftrightarrow$, defined by

$$g_2 \leftrightarrow g_1 \Leftrightarrow g_2 g_1^{-1} \in G'.$$

We know that $\sim$ decomposes G into *left* coset equivalence classes. Show that $\leftrightarrow$ is indeed an equivalence relation, and that it decomposes G into *right* coset equivalence classes. Suppose g is any element of G. Let $\{g\}_\ell$ denote the set of all elements in G that are equivalent to g using the relation $\sim$, and let $\{g\}_r$ denote the set of all elements in G that are equivalent to g using the relation $\leftrightarrow$. Show that

$$\{e\}_\ell = \{e\}_r.$$

Next assume that G' is normal. In this case show that

$$\{g\}_\ell = \{g\}_r$$

for any g in G. Thus, left and right cosets are the same if G' is normal.

8.9.6. The *center* of a group G consists of those elements of G that commute with all elements of G. See Exercise 7.2.13. Show that the center of a group is a special case of an invariant (normal) subgroup. Review Exercise 5.11.1.

8.9.7. Verify (9.43).

8.9.8. Show that if G' with Lie algebra L' is a normal subgroup of a Lie group G with Lie algebra L, then L' is an ideal in L.

8.9.9. Starting with (9.64), verify (9.67) and show that it is equivalent to (3.7.42).

8.9.10. Find and describe the adjoint representation of L_2. What is its dimension? Find and describe the adjoint reprsentation of L_2/L_D. What is its dimension?

8.9.11. Verify (9.73) and (9.74).

8.9.12. Verify (9.77) and (9.78).

8.9.13. Verify (9.85).

8.9.14. Consider a 2-dimensional phase space with canonical variables q, p. Referring to (9.70), find the matrix elements of $\mathcal{L}_4(: q^3 :)$ and $\exp(\mathcal{L}_4(: q^3 :))$. See (9.75), (9.84), and (9.85).

8.9.15. Read Exercise 9.14. Find the matrix representations for the Lie algebras L_2/L_3 and L_2/L_4 in the case of a 2-dimensional phase space.

8.9.16. Verify (9.93).

8.9.17. Use the grading (9.104) and (9.105). Show that it is compatible with Lie multiplication.

8.9.18. Let ${}^{\epsilon}L^{\ell}$ denote the vector space of functions spanned by elements of the form $\epsilon^m f_n$ with $(m + n - 2) \geq \ell$. Show that the ${}^{\epsilon}L^{\ell}$ with $\ell \geq 0$ are Lie algebras, ${}^{\epsilon}L^{\ell}$ with $\ell > 0$ is an ideal in ${}^{\epsilon}L^0$, and each ${}^{\epsilon}L^0/{}^{\epsilon}L^{\ell}$ is a quotient Lie algebra. For a given ℓ and assuming a d-dimensional phase space, show that the dimension of ${}^{\epsilon}L^0/{}^{\epsilon}L^{\ell}$ is given in terms of (7.10.4) by the relation

$$\dim({}^{\epsilon}L^0/{}^{\epsilon}L^{\ell}) = S(\ell + 1, d). \tag{8.9.106}$$

In computing these dimensions, set $\epsilon = 1$ and ignore all terms of the form $\epsilon^m f_0$. Verify Table 9.2.

8.9.19. Review Exercise 8.2.12. This exercise is a continuation of that exercise. Our task is to show that the $L^{\alpha} = L(K^{\alpha})$ form a basis for $so(6, \mathbb{R})$. This task could be carried out by computing all the L^{α} and verifying that they are indeed linearly independent. Instead, we will use an approach that is less tedious but also more abstract.

Suppose, to the contrary, that the $L^{\alpha} = L(K^{\alpha})$ do not form a basis, and are therefore not linearly independent. Then there are constants λ_{α}, not all zero, such that

$$\sum_{\alpha} \lambda_{\alpha} L^{\alpha} = 0. \tag{8.9.107}$$

Use the constants λ_{α} to form an $su(4)$ element, call it $K(\lambda)$, by the rule

$$K(\lambda) = \sum_{\alpha} \lambda_{\alpha} K^{\alpha}. \tag{8.9.108}$$

We know that $K(\lambda) \neq 0$ because the K^{α} are linearly independent and not all the λ_{α} are zero. Show that

$$L[K(\lambda)] = \sum_{\alpha} \lambda_{\alpha} L(K^{\alpha}) = \sum_{\alpha} \lambda_{\alpha} L^{\alpha} = 0. \tag{8.9.109}$$

Next, let $\mathcal{I}$ be the set of all elements in $su(4)$ of the form

$$K(\sigma) = \sum_{\alpha} \sigma_\alpha K^\alpha \tag{8.9.110}$$

such that

$$L[K(\sigma)] = 0. \tag{8.9.111}$$

Show that $\mathcal{I}$ is a Lie subalgebra of $su(4)$. That is, show that $\mathcal{I}$ is a linear vector space and verify that

$$L[\{K(\sigma), K(\sigma')\}] = \{L[K(\sigma)], L[K(\sigma')]\} = 0 \tag{8.9.112}$$

so that $\{K(\sigma), K(\sigma')\} \in \mathcal{I}$ if $K(\sigma) \in \mathcal{I}$ and $K(\sigma') \in \mathcal{I}$. Finally, show that

$$L[\{K^\beta, K(\sigma)\}] = \{L(K^\beta), L[K(\sigma)]\} = 0 \tag{8.9.113}$$

for any β and any $K(\sigma) \in \mathcal{I}$. It follows that $\mathcal{I}$ is an *invariant* subalgebra of $su(4)$. Also, we know that $\mathcal{I}$ is not empty because, by hypothesis, it contains $K(\lambda)$. Nor is it all of $su(4)$ because, for example, inspection of (2.164) shows that $L(K^1) \neq 0$. Therefore $\mathcal{I}$ is an *ideal*. But, this is a contradiction because $su(4)$ is supposed to be *simple*, i.e. have no ideals. See Section 3.7.6.

Chapter 9

Inclusion of Translations in the Calculus

9.1 Introduction

In Chapter 8 we dealt with, among other things, the restricted problem of concatenating maps, all of which had the property of sending the origin into itself. In this chapter we consider the general case. Let $\mathcal{M}_f$ and $\mathcal{M}_g$ denote the general symplectic maps given by the expressions

$$\mathcal{M}_f = \exp(:f_1:)\exp(:f_2^c:)\exp(:f_2^a:)\exp(:f_3:)\exp(:f_4:)\cdots, \tag{9.1.1}$$

$$\mathcal{M}_g = \exp(:g_1:)\exp(:g_2^c:)\exp(:g_2^a:)\exp(:g_3:)\exp(:g_4:)\cdots. \tag{9.1.2}$$

Also, let $\mathcal{M}_h$ be the product of $\mathcal{M}_f$ and $\mathcal{M}_g$,

$$\mathcal{M}_h = \mathcal{M}_f\mathcal{M}_g. \tag{9.1.3}$$

Given $\mathcal{M}_f$ and $\mathcal{M}_g$, our problem will be to find polynomials h_1, h_2^c, h_2^a, h_3, h_4, etc. such that

$$\mathcal{M}_h = \exp(:h_1:)\exp(:h_2^c:)\exp(:h_2^a:)\exp(:h_3:)\exp(:h_4:)\cdots. \tag{9.1.4}$$

For future use it is convenient to use the notation

$$\mathcal{R}_f = \exp(:f_2^c:)\exp(:f_2^a:),\ \text{etc.} \tag{9.1.5}$$

In this notation, our goal is to write $\mathcal{M}_h$ in the form

$$\mathcal{M}_h = \exp(:h_1:)\mathcal{R}_h\exp(:h_3:)\exp(:h_4:)\cdots. \tag{9.1.6}$$

Section 9.2 treats the special case where both the maps $\mathcal{M}_f$ and $\mathcal{M}_g$ produce only constant and linear terms when acting on z_a. This is the case of $ISp(2n,\mathbb{R})$ where all the nonlinear generators $f_3, f_4, \cdots$ and $g_3, g_4, \cdots$ are assumed to be zero. See Section 6.2 and Exercise 7.7.2. In this case we will be able to solve all possible problems to our hearts' content.

Subsequent sections will treat the general case where the nonlinear generators are also present. In this case, following the discussion in Section 8.9, we will find it necessary to introduce a grading in which f_1 and g_1 are treated as being small.

9.2 The Inhomogeneous Symplectic Group $ISp(2n,\mathbb{R})$

The *inhomogeneous* symplectic group $ISp(2n,\mathbb{R})$ consists of all transformations of phase space of the form

$$\bar{z}_a = \delta_a + \sum_b R_{ab} z_b \tag{9.2.1}$$

where the δ_a are arbitrary constants and R is a symplectic matrix. It is closely related to the *Jacobi* group. See Exercises 6.2.2, 7.7.2, and 7.7.3. We already know from Section 7.7 that there is a map $\mathcal{M}$ such that

$$\bar{z} = \mathcal{M} z, \tag{9.2.2}$$

and $\mathcal{M}$ has the factorization

$$\mathcal{M} = \exp(:f_2^c:)\exp(:f_2^a:)\exp(:g_1:). \tag{9.2.3}$$

Indeed, f_2^a and f_2^c are determined by R using (7.6.17), (7.2.2), (7.2.3), and (7.2.8); and g_1 is given in terms of δ by (7.7.3). Lie operators of the form $:f_1$ and $:f_2:$ provide a basis for $isp(2n,\mathbb{R})$, the Lie algebra of $ISp(2n,\mathbb{R})$. The purpose of this section is to state and prove various rearrangement, factorization, and concatenation formulas for the inhomogeneous symplectic group.

9.2.1 Rearrangement Formula

We begin with a *rearrangement* formula. Let us rewrite (2.3) in the form

$$\mathcal{M}_f = \mathcal{R}_f \exp(:g_1:) \tag{9.2.4}$$

with $\mathcal{R}_f$ being the linear map defined by (1.5). In terms of this notation we have the results

$$\mathcal{R}_f z = R_f z, \tag{9.2.5}$$

$$\exp(:g_1:)z = z + \delta, \tag{9.2.6}$$

$$\bar{z} = \mathcal{M}_f z = \mathcal{R}_f \exp(:g_1:)z = \mathcal{R}_f(z+\delta) = \delta + R_f z. \tag{9.2.7}$$

Next let δ' be another set of constants. Using (7.7.3), define a first-degree polynomial f_1 such that

$$\exp(:f_1:)z = z + \delta'. \tag{9.2.8}$$

Consider the map $\exp(:f_1:)\mathcal{R}_f$. It has the action

$$\exp(:f_1:)\mathcal{R}_f z = \exp(:f_1:)R_f z = R_f(z+\delta') = R_f\delta' + R_f z. \tag{9.2.9}$$

Upon comparing (2.7) and (2.9) we see that there will be the equality

$$\mathcal{R}_f \exp(:g_1:) = \exp(:f_1:)\mathcal{R}_f \tag{9.2.10}$$

provided there is the relation

$$R_f\delta' = \delta. \tag{9.2.11}$$

We will call the relation specified by (2.10) and (2.11) a rearrangement formula.

There is another way to obtain the rearrangement formula. Insert the identity factor $\mathcal{R}_f^{-1}\mathcal{R}_f$ on the right side of (2.4) to get the result

$$\mathcal{M}_f = \mathcal{R}_f \exp(: g_1 :)\mathcal{R}_f^{-1}\mathcal{R}_f. \tag{9.2.12}$$

Next make use of (8.2.25) to write

$$\mathcal{R}_f \exp(: g_1 :)\mathcal{R}_f^{-1} = \exp(: \mathcal{R}_f g_1 :). \tag{9.2.13}$$

Now define a first-degree polynomial f_1 by the rule

$$f_1 = \mathcal{R}_f g_1. \tag{9.2.14}$$

We have found the result

$$\mathcal{M}_f = \mathcal{R}_f \exp(: g_1 :) = \exp(: f_1 :)\mathcal{R}_f \tag{9.2.15}$$

with f_1 and g_1 related by (2.14).

What remains is to make (2.15) more explicit. According to the work of Section 7.7 there are the relations

$$f_1(z) = (J\delta', z), \tag{9.2.16}$$

$$g_1(z) = (J\delta, z). \tag{9.2.17}$$

Consequently, (2.15) can be rewritten in the form

$$(J\delta', z) = f_1(z) = \mathcal{R}_f g_1 = .\mathcal{R}_f(J\delta, z) = (J\delta, R_f z) = (R_f^T J\delta, z). \tag{9.2.18}$$

Upon comparing the left and right sides of (2.18) we conclude that

$$J\delta' = R_f^T J\delta. \tag{9.2.19}$$

Now multiply both sides of (2.19) by $-R_f J$. Doing so to the left side of (2.19) yields the result

$$-R_f JJ\delta' = R_f\delta'. \tag{9.2.20}$$

And doing so to the right side of (2.19) yields the result

$$-R_f J R_f^T J\delta = -JJ\delta = \delta. \tag{9.2.21}$$

Upon comparing the right sides of (2.20) and (2.21) we see that (2.11) has been recovered.

9.2.2 Factorization Formula

The next result to obtain is a *factorization* formula. Given any two homogeneous polynomials h_1 and h_2 (of degrees 1 and 2, respectively), there exist related polynomials f_1, f_2 that satisfy the *factorization formula*

$$\exp(: h_1 + h_2 :) = \exp(: f_2 :)\exp(: f_1 :). \tag{9.2.22}$$

There are at least two ways to prove (2.22). The first amounts to combining the two exponents on the right side of (2.22), and then matching terms with the left side. Consider all Lie products made from f_1 and f_2. We observe that all Lie products containing two or more f_1 factors, for example $[f_1,[f_1,f_2]]$, must give only constant terms, and hence their associated Lie operators vanish. Let s and t be small parameters. According to formula (8.7.3), we have the result

$$\begin{aligned}&\exp(s:f_2:)\exp(t:f_1:)=\\&\exp[s:f_2:+:\{s:f_2:[1-\exp(-s:f_2:)]^{-1}(tf_1)\}:+:O(t^2):],\end{aligned}\tag{9.2.23}$$

where the notation $:O(t^2):$ indicates Lie operators that contain at least *two* factors of t. But the presence of two factors of t requires the presence of two factors of f_1 and hence, by the previous observation these Lie operators must all vanish. It follows that (2.23) is *exact* for f_1 and f_2. Now set $s=t=1$ in (2.23) and combine the result so obtained with (2.22) to get the relation

$$\exp(:h_1+h_2:)=\exp[:f_2:+:\{:f_2:[1-\exp(-:f_2:)]^{-1}f_1\}:].\tag{9.2.24}$$

Upon comparing like terms in (2.6), we find the relations

$$f_2=h_2,\tag{9.2.25}$$

$$\begin{aligned}h_1&=:f_2:[1-\exp(-:f_2:)]^{-1}f_1\\&=:h_2:[1-\exp(-:h_2:)]^{-1}f_1.\end{aligned}\tag{9.2.26}$$

Finally, (2.26) may be solved for f_1 to give the relation

$$\begin{aligned}f_1&=\{[1-\exp(-:h_2:)]/[:h_2:]\}h_1\\&=\text{iex}(-:h_2:)h_1.\end{aligned}\tag{9.2.27}$$

See (8.8.9). We note that f_1 and f_2 are well defined by (2.27) and (2.25) for all h_1 and h_2.

The converse question is more difficult: given f_1 and f_2, does (2.26) always define an h_1? Or equivalently, in view of (2.27), does $[\text{iex}(-:f_2:)]^{-1}f_1$ always exist? If not, then it is not possible to write every inhomogeneous symplectic group element in terms of a single exponential. See Exercise 2.3 for a discussion of this question.

There is a second derivation of (2.25) and (2.27) that is worth knowing. Consider the functions $\overline{z}_a$ defined by the relation

$$\overline{z}_a=\exp(:sh_2+th_1:)z_a.\tag{9.2.28}$$

As before, s and t are parameters. Expanding (2.28) in a power series gives the result

$$\overline{z}_a=\sum_{n=0}^{\infty}[(:sh_2+th_1:)^n/n!]z_a.\tag{9.2.29}$$

Next expand the powers in (2.29). For $n \geq 1$ we have the result

$$\begin{aligned}(: sh_2 + th_1 :)^n &= (s : h_2 : + t : h_1 :)^n \\ &= s^n : h_2 :^n + ts^{n-1} \sum_{m=0}^{n-1} : h_2 :^m : h_1 :: h_2 :^{n-m-1} + O(t^2). \end{aligned} \quad (9.2.30)$$

Here we have kept track of the fact that $: h_1 :$ and $: h_2 :$ may not commute. Observe that the terms in (2.30) proportional to t^2 must have two factors of $: h_1 :$ and are therefore of the form

$$t^2 \text{ terms} \sim (: h_2 :)^\alpha : h_1 : (: h_2 :)^\beta : h_1 : (: h_2 :)^\gamma \quad (9.2.31)$$

where α, β, γ satisfy the relations

$$\begin{aligned}&\alpha + \beta + \gamma = n - 2, \\ &\alpha \geq 0 \ , \ \beta \geq 0 \ , \ \gamma \geq 0. \end{aligned} \quad (9.2.32)$$

From (7.6.16) it is easy to verify the relation

$$(: h_2 :)^\alpha : h_1 : (: h_2 :)^\beta : h_1 : (: h_2 :)^\gamma z_a = 0. \quad (9.2.33)$$

Similarly, analogous results hold for terms having three or more factors of $: h_1 :$. It follows that all the $O(t^2)$ terms in (2.30 annihilate the z_a. Thus, we find the exact result

$$\begin{aligned}&\exp(: sh_2 + th_1 :)z_a = \\ &\left\{ \sum_{n=0}^{\infty} s^n : h_2 :^n /n! + t \sum_{n=1}^{\infty} (s^{n-1}/n!) \sum_{m=0}^{n-1} : h_2 :^m : h_1 :: h_2 :^{n-m-1} \right\} z_a. \end{aligned} \quad (9.2.34)$$

The first term on the right side of (2.34) sums to the exponential function,

$$\sum_{n=0}^{\infty} s^n : h_2 :^n /n! = \exp(s : h_2 :). \quad (9.2.35)$$

The second term sums to a relation involving the exponential and integrated exponential functions,

$$\sum_{n=1}^{\infty} \sum_{m=0}^{n-1} (1/n!) : sh_2 :^m : th_1 :: sh_2 :^{n-m-1} = \exp(s : h_2 :)\text{iex}(-\#sh_2\#) : th_1 : . \quad (9.2.36)$$

See Appendix C. As a consequence of relations of the form (8.2.22), we have the result

$$\text{iex}(-\#sh_2\#) : th_1 := : \text{iex}(- : sh_2 :)th_1 : . \quad (9.2.37)$$

Putting (2.34) through (2.37) together gives the relation

$$\exp(: sh_2 + th_1 :)z_a = \exp(s : h_2 :)[1 + : \text{iex}(- : sh_2 :)th_1 :]z_a. \quad (9.2.38)$$

Suppose we define f_1 by writing

$$f_1 = \mathrm{iex}(- : sh_2 :)h_1. \tag{9.2.39}$$

Again from (7.6.16) we have the relation

$$[1 + t : f_1 :]z_a = \exp(t : f_1 :)z_a. \tag{9.2.40}$$

We conclude that (2.38) can be rewritten in the form

$$\exp(: sh_2 + th_1 :)z_a = \exp(s : h_2 :)\exp(t : f_1 :)z_a. \tag{9.2.41}$$

Since the operator factors on both sides of (2.23) are manifestly group elements (symplectic maps), we get the group (map) factorization relation

$$\exp(: sh_2 + th_1 :) = \exp(s : h_2 :)\exp(t : f_1 :) \tag{9.2.42}$$

with f_1 defined by (2.39). Now put $s = t = 1$ in (2.39) and (2.42) and make the definition (2.25) to recover (2.22), (2.25), and (2.27).

9.2.3 Concatenation Formulas

We have found the rearrangement formula given by (2.10) and (2.11) and the factorization formula given by (2.22), (2.25, and (2.27). We now turn to the easier subjects of concatenation formulas. Let $\mathcal{M}_f$ and $\mathcal{M}_g$ be the inhomogeneous symplectic group maps

$$\mathcal{M}_f = \exp(: f_1 :)\exp(: f_2^c :)\exp(: f_2^a :) = \exp(: f_1 :)\mathcal{R}_f, \tag{9.2.43}$$

$$\mathcal{M}_g = \exp(: g_1 :)\exp(: g_2^c :)\exp(: g_2^a :) = \exp(: g_1 :)\mathcal{R}_g. \tag{9.2.44}$$

Also, let $\mathcal{M}_h$ be the product of $\mathcal{M}_f$ and $\mathcal{M}_g$ as in (1.3). We wish to find polynomials h_1, h_2^c, and h_2^a such that

$$\mathcal{M}_h = \mathcal{M}_f\mathcal{M}_g = \exp(: h_1 :)\exp(: h_2^c :)\exp(: h_2^a :) = \exp(: h_1 :)\mathcal{R}_h. \tag{9.2.45}$$

From (2.43) and (2.44) we have the result

$$\mathcal{M}_f\mathcal{M}_g = \exp(: f_1 :)\mathcal{R}_f\exp(: g_1 :)\mathcal{R}_g. \tag{9.2.46}$$

Insert an identity factor of the form $\mathcal{R}_f^{-1}\mathcal{R}_f$ into (2.46) to find the relation

$$\mathcal{M}_f\mathcal{M}_g = \exp(: f_1 :)\mathcal{R}_f\exp(: g_1 :)\mathcal{R}_f^{-1}\mathcal{R}_f\mathcal{R}_g. \tag{9.2.47}$$

From (2.13) we conclude that (2.47) can be rewritten in the form

$$\begin{aligned}\mathcal{M}_f\mathcal{M}_g &= \exp(: f_1 :)\exp(: \mathcal{R}_f g_1 :)\mathcal{R}_f\mathcal{R}_g \\ &= \exp(: f_1 + \mathcal{R}_f g_1 :)\mathcal{R}_f\mathcal{R}_g.\end{aligned} \tag{9.2.48}$$

Here we have used the fact that the Lie operators associated with first-degree polynomials commute. (See Exercise 2.4.) Now compare (2.45) and (2.48) to get the concatenation formulas

$$h_1 = f_1 + \mathcal{R}_f g_1, \tag{9.2.49}$$

$$\mathcal{R}_h = \mathcal{R}_f\mathcal{R}_g. \tag{9.2.50}$$

We note that (2.50) is identical to (8.4.19), as expected, and consequently we also have the corresponding matrix relation (8.4.20) as before.

Exercises

9.2.1. Read (2.22) from right to left. That is, assume that f_1 and f_2 are two given homogeneous polynomials (of degrees 1 and 2, respectively), and we wish to find h_1 and h_2. From Exercise 7.7.2 we know that $: f_1 :$ and $: f_2 :$ generate a Lie algebra. Also, we know from the BCH formula (3.7.33) and (3.7.34) that all terms that occur when we combine the exponents on the right side of (2.22) must be in this Lie algebra. Show that the most general such term is of the form $: h_1 + h_2 :$ where h_1 and h_2 have degrees 1 and 2, respectively. Show from (8.7.3) that h_1 as defined by the first line in (2.26) does indeed have degree 1, so that terms of like degree have indeed been equated.

9.2.2. The purpose of this exercise is to convert (2.27) into an explicit matrix equation. Since h_1 is a given degree 1 polynomial, it can be written in the form

$$h_1 = \sum_a h_1^a z_a \tag{9.2.51}$$

where the h_1^a are known coefficients. From (7.6.16) the action of $: h_2 :$ on the z_a is a relation of the form

$$: h_2 : z_a = \sum_{a'} H_{a'a} z_{a'}. \tag{9.2.52}$$

The matrix H is given in terms of the scalar product (7.3.8) by the relation

$$H_{a'a} = (z_{a'}, : h_2 : z_a). \tag{9.2.53}$$

Define a matrix O in terms of H by the rule

$$O = \text{iex}(-H) = \sum_{m=0}^{\infty} (-H)^m/(m+1)!. \tag{9.2.54}$$

Show that the series (2.54) converges for any matrix H, and therefore O is well defined. Next verify the relation

$$\text{iex}(- : h_2 :) z_a = \sum_{a'} O_{a'a} z_{a'}. \tag{9.2.55}$$

Suppose we write f_1 in the form

$$f_1 = \sum_{a'} f_1^{a'} z_{a'}. \tag{9.2.56}$$

Show that (2.27) implies the relation

$$f_1^{a'} = \sum_a O_{a'a} h_1^a. \tag{9.2.57}$$

What remains is to determine more explicitly the matrix H. Following (7.2.3), let us write h_2 in the form

$$h_2 = -(1/2) \sum_{de} S_{de} z_d z_e \tag{9.2.58}$$

where S is a symmetric matrix. Following (7.2.4), show that

$$H = (JS)^T = -SJ = J(JSJ) = JS' \tag{9.2.59}$$

where

$$S' = JSJ. \tag{9.2.60}$$

Show that S' is symmetric.

9.2.3. This exercise examines the following question: given f_2^c, f_2^a, and f_1, when do there exist h_1 and h_2 such that there is the relation

$$\exp(:f_2^c:)\exp(:f_2^a:)\exp(:f_1:) = \exp(:h_1 + h_2:)? \tag{9.2.61}$$

Thanks to Section 8.7 we know that such a relation is not always possible even when f_1 is absent (and its presence never helps). So we should phrase the question more narrowly: given f_2 and f_1, when do there exist an h_1 and h_2 such that (2.22) holds? Even this question is too broad. Given an $\mathcal{R}$ such as in (1.5), we are in effect given a symplectic matrix R and the requirement

$$\mathcal{R}z_a = \sum_b R_{ab} z_b. \tag{9.2.62}$$

There may be *many* f_2 such that

$$\mathcal{R} = \exp(:f_2:) \tag{9.2.63}$$

and (2.62) holds. Give an explicit example of this fact. [Hint: look at (7.2.23).] Thus, the question should be made still narrower: Given f_1 and a symplectic matrix R with the property that there exists some f_2 such that (2.62) and (2.63) hold, when do there exist h_1 and h_2 such that

$$\mathcal{R}\exp(:f_1:) = \exp(:h_1 + h_2:)? \tag{9.2.64}$$

We will begin with the case of 2-dimensional phase space. Following (8.7.25), let us write h_2 in the form

$$h_2 = -(bp^2 + 2aqp + cq^2)/2. \tag{9.2.65}$$

With this definition, show from (8.7.27) and (8.7.28) that the H matrix of (2.53) is given by the relation

$$H = F^T = \begin{pmatrix} a & -c \\ b & -a \end{pmatrix}. \tag{9.2.66}$$

Like F, the matrix H has the property

$$H^2 = \Delta I \tag{9.2.67}$$

where Δ is the discriminant (8.7.30). We are now prepared to compute O as given by (2.54). From (2.54) and (8.7.9) derive the formal result

$$\begin{aligned} O &= \text{iex}(-H) = \sum_{m=0}^{\infty}(-H)^m/(m+1)! = -[\exp(-H) - I]/H \\ &= -[\cosh(H) - \sinh(H) - I]/H = [\sinh(H)]/H - [\cosh(H) - I]/H. \end{aligned} \tag{9.2.68}$$

Show using (2.67) that the series in (2.68) have the sums

$$[\sinh(H)]/H = I[\sinh(\Delta^{1/2})]/\Delta^{1/2}, \tag{9.2.69}$$

$$-[\cosh(H) - I]/H = -H[\cosh(\Delta^{1/2}) - 1]/\Delta. \tag{9.2.70}$$

Thus, show that O has the explicit matrix form

$$O = \tag{9.2.71}$$
$$\begin{pmatrix} [\sinh(\Delta^{1/2})]/\Delta^{1/2} - a[\cosh(\Delta^{1/2}) - 1]/\Delta & c[\cosh(\Delta^{1/2}) - 1]/\Delta \\ -b[\cosh(\Delta^{1/2}) - 1]/\Delta & [\sinh(\Delta^{1/2})]/\Delta^{1/2} + a[\cosh(\Delta^{1/2}) - 1]/\Delta \end{pmatrix}.$$

Note that O is well defined for all values of a, b, c as expected. Verify that O has the determinant

$$\det(O) = 2[\cosh(\Delta^{1/2}) - 1]/\Delta. \tag{9.2.72}$$

It follows that O is not invertible when $\Delta = -4\pi^2, -16\pi^2, \cdots$. Indeed, inspection of (2.71) shows that O vanishes identically for these Δ values! Give a geometrical argument showing that this must be the case. From looking at (2.57) we conclude that, given f_1, h_1 cannot be determined when O is not invertible. Therefore, we are tempted to conclude that our single-exponent goal (2.64) cannot be accomplished in this case. However, we see from (8.7.34) that R is the *identity* matrix when $\Delta = -4\pi^2, -16\pi^2, \cdots$. In this case we may take $f_2 = 0$ and $h_2 = f_2 = 0$. Show that O is then the identity matrix, and the single-exponent goal is trivially achieved. We conclude, despite our fears to the contrary, that the single-exponent goal (2.64) can always be achieved in the 2-dimensional phase-space case. What about the cases of higher dimensional phase spaces, say 4 and 6-dimensional phase spaces? These cases appear to be more difficult. They will be treated after we have developed a theory of normal forms for quadratic polynomials.

9.2.4. Verify that Lie operators associated with first-degree polynomials commute. That is, let f_1 and g_1 be any two first-degree polynomials. Show that

$$\{: f_1 :, : g_1 :\} =: [f_1, g_1] := 0 \tag{9.2.73}$$

using (5.3.14), (5.3.21), and (7.6.14). From Exercise 7.7.2 we know that Lie operators of the form $: f_1 :$ and $: f_2 :$ comprise the Lie algebra $isp(2n,\mathbb{R})$. Show that the subalgebra composed of Lie operators of the form $: f_1 :$ comprises a subalgebra that is an ideal in $isp(2n,\mathbb{R})$. Show that $isp(2n,\mathbb{R})$ is not semisimple. See Section 8.9. It is in fact the *semi-direct sum* of the Lie subalgebra generated by Lie operators of the form $: f_2 :$, namely the subalgebra $sp(2n,\mathbb{R})$, and the Lie subalgebra generated by Lie operators of the form $: f_1 :$, namely the Lie subalgebra of the translation group. The sum is called *semi-direct* because Lie operators of the form $: f_2 :$ and do not commute with Lie operators of the form $: f_1 :$. Instead, Lie operators of the form $: f_2 :$ have a nontrivial action on first-order polynomials and, correspondingly, on Lie operators of the form $: f_1 :$. See Section 25.2.1.

9.2.5. Equation (2.22) gives a reverse factorization. Consider the problem of making the forward factorization

$$\exp(: h_1 + h_2 :) = \exp(: g_1 :) \exp(: g_2 :). \tag{9.2.74}$$

Show that in this case one has the results

$$g_2 = h_2, \tag{9.2.75}$$

$$g_1 = \text{iex}(:h_2:)h_1. \tag{9.2.76}$$

Hint: Either invert both sides of (2.22), or use (2.22), (2.10), and (2.11).

9.2.6. Review (2.1) through (2.3) and (7.7.3). Consider the general $ISp(2n,\mathbb{R})$ element $\mathcal{M}$ given by (2.3). When $g_1 = 0$ we know that $\mathcal{M}$ has the origin as a fixed point. The purpose of this exercise is to show that when $g_1 \neq 0$ the map $\mathcal{M}$ generally still has a fixed point. Suppose that $\mathcal{M}$ has a fixed point z^f. Show from (2.1) that there must then be the relation

$$z^f = \delta + Rz^f, \tag{9.2.77}$$

from which it follows that z^f is uniquely defined by the relation

$$z^f = -(R-I)^{-1}\delta \tag{9.2.78}$$

provided the matrix $(R-I)$ has an inverse. For $(R-I)$ to have an inverse it must be the case that

$$\det(R-I) \neq 0. \tag{9.2.79}$$

Consequently, provided R does not have $+1$ as an eigenvalue, $\mathcal{M}$ has a fixed point z^f given by (2.78), and this fixed point is unique. In particular, if the eigenvalues of R lie on the unit circle so that tunes are defined, no tune may be integer.

Provide an example of a symplectic matrix R, with some eigenvalue equal $+1$, for which $\mathcal{M}$ does not have a fixed point for some $g_1 \neq 0$. For example, study in detail the 2×2 case for which

$$R = \begin{pmatrix} 1 & \lambda \\ 0 & 1 \end{pmatrix} \tag{9.2.80}$$

where λ is an arbitrary parameter. Show that, when $\delta_2 \neq 0$, $\mathcal{M}$ has no fixed point. Show that, when $\delta_2 = 0$ and $\lambda \neq 0$, $\mathcal{M}$ has a whole line of fixed points and therefore does not have a unique fixed point. What happens when $\lambda = 0$?

Given $\mathcal{M}$ and any degree one polynomial h_1, define a map $\mathcal{N}$ by the relation

$$\mathcal{N} = \exp(:h_1:)\mathcal{M}\exp(-:h_1:). \tag{9.2.81}$$

Show that, when

$$h_1 = (z, Jz^f), \tag{9.2.82}$$

there is the relation

$$\mathcal{N} = \mathcal{R}. \tag{9.2.83}$$

Thus, show that generally $\mathcal{M}$ has the factorization

$$\mathcal{M} = \exp(-:h_1:)\mathcal{R}\exp(:h_1:) \tag{9.2.84}$$

with h_1 given by (2.82), z^f being the fixed point of $\mathcal{M}$, and $\mathcal{R}$ being the linear part of $\mathcal{M}$. However, not all $\mathcal{M}$ can be written in the form (2.84) because we know from the work of the previous paragraph that there are some $\mathcal{M}$ that do not have a fixed point.

9.2.7. Consider a generating function of the form

$$g(u) = (k, u) + (1/2)(u, Wu) \tag{9.2.85}$$

where k is a vector with $2n$ entries and W is a general $2n \times 2n$ symmetric matrix. That is, g consists of arbitrary linear and quadratic parts. Using (6.7.21), find the associated symplectic map $\mathcal{M}$ for any Darboux matrix α, and show that $\mathcal{M}$ is an element of $ISp(2n, \mathbb{R})$.

9.3 Lie Concatenation in the General Nonlinear Case

We now turn to the general case $ISpM(2n, \mathbb{R})$ where we have to take into account the presence of the nonlinear generators $f_3, f_4 \cdots$ and $g_3, g_4 \cdots$. In this case, the Lie algebras are infinite dimensional and, as described in Section 8.9, we will introduce a quotient-space structure in order to produce an approximation scheme. This quotient-space structure will be based on the grading given by (8.9.78) and (8.9.79). As we will see, it amounts to treating the quantities f_1 and g_1 in (1.1) and (1.2) as being small.

For purposes of illustration, we will begin our discussion with the case in which we retain only f_3 and f_4 in (1.1) and g_3 and g_4 in (1.2). Correspondingly, we will only retain h_3 and h_4 in (1.3). In addition, we will let ϵ be a parameter which we will initially regard as small, but will eventually set equal to one. Now consider terms of the form $\epsilon^m f_n$, and corresponding terms for the g's and h's. We assign these terms a grade following (8.9.78) and (8.9.79),

$$\text{grade } 0: \quad \epsilon^2 f_0, \epsilon f_1, f_2; \tag{9.3.1}$$

$$\text{grade } 1: \quad \epsilon^3 f_0, \epsilon^2 f_1, \epsilon f_2, f_3; \tag{9.3.2}$$

$$\text{grade } 2: \quad \epsilon^4 f_0, \epsilon^3 f_1, \epsilon^2 f_2, \epsilon f_3, f_4. \tag{9.3.3}$$

We have already seen that these elements span the quotient Lie algebra ${}^{\epsilon}L^0/{}^{\epsilon}L^3$, and we will work within this quotient Lie algebra and its corresponding quotient group. Note that since we will be working with Lie operators, and the Lie operator for a constant function vanishes, terms of the form $\epsilon^m f_0$ actually play no role.

Following the notation (2.26) and (8.4.14), let us rewrite (1.1), (1.2), and (1.4) in the form

$$\mathcal{M}_f = \exp(:\epsilon f_1:)\mathcal{R}_f \exp(:f_3:)\exp(:f_4:), \tag{9.3.4}$$

$$\mathcal{M}_g = \exp(:\epsilon g_1:)\mathcal{R}_g \exp(:g_3:)\exp(:g_4:), \tag{9.3.5}$$

$$\mathcal{M}_h = \exp(:\epsilon h_1:)\mathcal{R}_h \exp(:h_3:)\exp(:h_4:). \tag{9.3.6}$$

Here we have replaced f_1 by ϵf_1, etc. Upon comparing (3.4) through (3.6), we see that performing the multiplication (1.3) requires that all first-order exponents be moved to the extreme left. We will do this in steps. Let us write the product (1.3) in the form

$$\mathcal{M}_h = \exp(:\epsilon f_1:)\mathcal{R}_f \exp(:f_3:)\exp(:f_4:)\exp(:\epsilon g_1:)\mathcal{R}_g \exp(:g_3:)\exp(:g_4:). \tag{9.3.7}$$

The first step will be to move the first-order exponent, g_1 in this case, to the left of f_4. We begin with the relation

$$\begin{aligned} \exp(:f_4:)\exp(:\epsilon g_1:) &= \exp(:\epsilon g_1:)\exp(-:\epsilon g_1:)\exp(:f_4:)\exp(:\epsilon g_1:) \\ &= \exp(:\epsilon g_1:)\exp(:\exp(-:\epsilon g_1:)f_4:). \end{aligned} \tag{9.3.8}$$

Here use has been made of (8.2.20). Now we use the relation

$$\begin{aligned} : \exp(- : \epsilon g_1 :) f_4 :=: & \left[\sum_{m=0}^{\infty} (: -\epsilon g_1 :^m /m!) f_4 \right] : \\ = & \ : [f_4 - \epsilon : g_1 : f_4 + (\epsilon^2/2!) : g_1 :^2 f_4 - (\epsilon^3/3!) : g_1 :^3 f_4] : . \end{aligned} \tag{9.3.9}$$

Note that the apparently infinite series in (3.9) actually terminates because of (7.6.16). Also, use has been made of (5.3.21).

Let us rewrite (3.8) and (3.9) in the form

$$\exp(: f_4 :) \exp(: \epsilon g_1 :) = \exp(: \epsilon g_1 :) \exp(: j_1^{(2)} + j_2^{(2)} + j_3^{(2)} + j_4^{(2)} :) \tag{9.3.10}$$

where the $j_i^{(2)}$ are the homogeneous polynomials

$$j_1^{(2)} = -(\epsilon^3/3!) : g_1 :^3 f_4, \tag{9.3.11}$$

$$j_2^{(2)} = (\epsilon^2/2!) : g_1 :^2 f_4, \tag{9.3.12}$$

$$j_3^{(2)} = -\epsilon : g_1 : f_4, \tag{9.3.13}$$

$$j_4^{(2)} = f_4. \tag{9.3.14}$$

Here a subscript on a j indicates the *degree* of the polynomial. Observe from (3.3) that all the j polynomials have *grade* two. Hence they also all carry a superscript 2 in parentheses to indicate this fact. Next we use the factorization theorem to write the product representation

$$\exp(: j_1^{(2)} + j_2^{(2)} + j_3^{(2)} + j_4^{(2)} :) = \exp(: k_1 :) \exp(: k_2 :) \exp(: k_3 :) \exp(: k_4 :). \tag{9.3.15}$$

Without loss of generality we may require that the k_i are in the Lie algebra generated by the $j_i^{(2)}$ and are also in ${}^{\epsilon}L^0/{}^{\epsilon}L^3$. It follows that we have the relations

$$k_i = j_i^{(2)}. \tag{9.3.16}$$

Now combine (3.10) and (3.15) to obtain the result

$$\begin{aligned} \exp(: f_4 :) \ & \exp(: \epsilon g_1 :) = \exp(: \epsilon g_1 :) \exp(: k_1 :) \exp(: k_2 :) \exp(: k_3 :) \exp(: k_4 :) \\ & = \exp(: \epsilon g_1 + k_1 :) \exp(: k_2 :) \exp(: k_3 :) \exp(: k_4 :). \end{aligned} \tag{9.3.17}$$

Observe that in relations such as (3.11) through (3.14), powers of ϵ are correlated with powers of $: g_1 :$. Thus, we may simply view the introduction of ϵ as a way of counting powers of g_1. Correspondingly, after obtaining final results, we may set $\epsilon = 1$ to obtain, under the assumption that g_1 itself is small, a set of formulas that make systematic expansions in the size of g_1. The final result of this process for the work done thus far is a formula that can be written as

$$\exp(: f_4 :) \exp(: g_1 :) = \exp(: h_1^4 :) \exp(: h_2^4 :) \exp(: h_3^4 :) \exp(: h_4^4 :) \tag{9.3.18}$$

where the h_i^4 are given by the relations

$$h_1^4 = g_1 - (1/3!) : g_1 :^3 f_4, \tag{9.3.19}$$

$$h_2^4 = (1/2!) : g_1 :^2 f_4, \tag{9.3.20}$$

$$h_3^4 = - : g_1 : f_4, \tag{9.3.21}$$

$$h_4^4 = f_4. \tag{9.3.22}$$

Here the subscript on h denotes its degree, and the superscript 4 indicates that it is associated with f_4. (Unlike the notation used earlier, the superscript on h is *not* a grade.) Note that in moving g_1 to the left of f_4 we have *generated* the third and second-degree polynomials h_3^4 and h_2^4 as well as the additional first-degree term in h_1^4. This generation of lower-order terms is a nonlinear *feed-down* effect. It shows, for example, that a misplaced octupole can produce sextupole, quadrupole, and steering-like effects.

We have seen how to move a first-order exponent to the left of f_4. The second step is to move such an exponent to the left of f_3. Let us now call the first-order exponent $\tilde{g}_1$. Then, in analogy to (3.8) and (3.9) find the relations

$$\exp(: f_3 :)\exp(: \epsilon\tilde{g}_1 :) = \exp(: \epsilon\tilde{g}_1 :)\exp(: \exp(- : \epsilon\tilde{g}_1 :)f_3 :), \tag{9.3.23}$$

$$: \exp(- : \epsilon\tilde{g}_1 :)f_3 :=: [f_3 - \epsilon : \tilde{g}_1 : f_3 + (\epsilon^2/2!) : \tilde{g}_1 :^2 f_3] : . \tag{9.3.24}$$

As before, we rewrite these relations in the form

$$\exp(: f_3 :)\exp(: \epsilon\tilde{g}_1 :) = \exp(: \epsilon\tilde{g}_1 :)\exp(: \tilde{j}_1^{(1)} + \tilde{j}_2^{(1)} + \tilde{j}_3^{(1)} :), \tag{9.3.25}$$

where the $\tilde{j}_i^{(1)}$ are now the homogeneous polynomials

$$\tilde{j}_1^{(1)} = (\epsilon^2/2!) : \tilde{g}_1 :^2 f_3, \tag{9.3.26}$$

$$\tilde{j}_2^{(1)} = -\epsilon : \tilde{g}_1 : f_3, \tag{9.3.27}$$

$$\tilde{j}_3^{(1)} = f_3. \tag{9.3.28}$$

We note that all the terms on the left sides of the relations (3.26) through (3.28) are of grade one. Hence all the $\tilde{j}$'s carry, within parentheses, a superscript of 1. Again, as before, we use the factorization theorem to write the representation

$$\exp(: \tilde{j}_1^{(1)} + \tilde{j}_2^{(1)} + \tilde{j}_3^{(1)} :) = \exp(: \tilde{k}_1 :)\exp(: \tilde{k}_2 :)\exp(: \tilde{k}_3 :)\exp(: \tilde{k}_4 :). \tag{9.3.29}$$

At this point there are two new features to the calculation: First, we have included a fourth-degree polynomial $\tilde{k}_4$ on the right side of (3.29) even though the highest degree polynomial on the left of (3.29), namely $\tilde{j}_3^{(1)}$, is of degree three. This is done for the sake of consistency since our calculation is being carried out in the quotient algebra ${}^{\epsilon}L^0/{}^{\epsilon}L^3$, which contains fourth-degree generators. Second, since the $\tilde{k}_i$ are in the Lie algebra generated by the $\tilde{j}_i^{(1)}$ and also in ${}^{\epsilon}L^0/{}^{\epsilon}L^3$, they may contain terms of grade 1 and grade 2. Therefore we make the decompositions

$$\tilde{k}_1 = \tilde{k}_1^{(1)} + \tilde{k}_1^{(2)}, \tag{9.3.30}$$

$$\tilde{k}_2 = \tilde{k}_2^{(1)} + \tilde{k}_2^{(2)}, \tag{9.3.31}$$

$$\tilde{k}_3 = \tilde{k}_3^{(1)} + \tilde{k}_3^{(2)}, \tag{9.3.32}$$

$$\tilde{k}_4 = \tilde{k}_4^{(2)}. \tag{9.3.33}$$

[Note that according to (3.1) through (3.3) there is no fourth-degree polynomial of grade 1.] Now use the BCH formula and the decompositions (3.30) through (3.33) to combine all exponents on the right side of (3.29) into one grand exponent. We find, through terms of grade 2, the result

$$\exp(:\tilde{k}_1:)\exp(:\tilde{k}_2:)\exp(:\tilde{k}_3:)\exp(:\tilde{k}_4:) = \exp(:\ell_1 + \ell_2 + \ell_3 + \ell_4:) \tag{9.3.34}$$

where the ℓ_i are given by the relations

$$\ell_1 = \tilde{k}_1^{(1)} + \tilde{k}_1^{(2)} + [\tilde{k}_1^{(1)}, \tilde{k}_2^{(1)}]/2, \tag{9.3.35}$$

$$\ell_2 = \tilde{k}_2^{(1)} + \tilde{k}_2^{(2)} + [\tilde{k}_1^{(1)}, \tilde{k}_3^{(1)}]/2, \tag{9.3.36}$$

$$\ell_3 = \tilde{k}_3^{(1)} + \tilde{k}_3^{(2)} + [\tilde{k}_2^{(1)}, \tilde{k}_3^{(1)}]/2, \tag{9.3.37}$$

$$\ell_4 = \tilde{k}_4^{(2)}. \tag{9.3.38}$$

Upon comparing (3.29) and (3.34) we find the results

$$\ell_i = \tilde{j}_i \text{ for } i = 1 \text{ to } 3, \tag{9.3.39}$$

$$\ell_4 = 0. \tag{9.3.40}$$

We thus have the relations

$$\tilde{j}_1^{(1)} = \tilde{k}_1^{(1)} + \tilde{k}_1^{(2)} + [\tilde{k}_1^{(1)}, \tilde{k}_2^{(1)}]/2, \tag{9.3.41}$$

$$\tilde{j}_2^{(1)} = \tilde{k}_2^{(1)} + \tilde{k}_2^{(2)} + [\tilde{k}_1^{(1)}, \tilde{k}_3^{(1)}]/2, \tag{9.3.42}$$

$$\tilde{j}_3^{(1)} = \tilde{k}_3^{(1)} + \tilde{k}_3^{(2)} + [\tilde{k}_2^{(1)}, \tilde{k}_3^{(1)}]/2, \tag{9.3.43}$$

$$0 = \tilde{k}_4^{(2)}, \tag{9.3.44}$$

and these relations must be solved for the $\tilde{k}_i^{(1)}$ and $\tilde{k}_i^{(2)}$. To carry out this task, we equate terms of like grade in (3.41) through (3.44) to find the results

$$\tilde{k}_1^{(1)} = \tilde{j}_1^{(1)}, \tag{9.3.45}$$

$$\tilde{k}_2^{(1)} = \tilde{j}_2^{(1)}, \tag{9.3.46}$$

$$\tilde{k}_3^{(1)} = \tilde{j}_3^{(1)}, \tag{9.3.47}$$

$$\tilde{k}_1^{(2)} = -[\tilde{k}_1^{(1)}, \tilde{k}_2^{(1)}]/2 = -[\tilde{j}_1^{(1)}, \tilde{j}_2^{(1)}]/2, \tag{9.3.48}$$

$$\tilde{k}_2^{(2)} = -[\tilde{k}_1^{(1)}, \tilde{k}_3^{(1)}]/2 = -[\tilde{j}_1^{(1)}, \tilde{j}_3^{(1)}]/2, \tag{9.3.49}$$

$$\tilde{k}_3^{(2)} = -[\tilde{k}_2^{(1)}, \tilde{k}_3^{(1)}]/2 = -[\tilde{j}_2^{(1)}, \tilde{j}_3^{(1)}]/2, \tag{9.3.50}$$

$$\tilde{k}_4^{(2)} = 0. \tag{9.3.51}$$

Now put the results (3.26) through (3.28), (3.30) through (3.33), and (3.45) through (3.51) together to get the relations

$$\tilde{k}_1 = (\epsilon^2/2) : \tilde{g}_1 :^2 f_3 - (\epsilon^3/4)[: \tilde{g}_1 :^2 f_3, : \tilde{g}_1 : f_3], \tag{9.3.52}$$

$$\tilde{k}_2 = -\epsilon : \tilde{g}_1 : f_3 - (\epsilon^2/4)[: \tilde{g}_1 :^2 f_3, f_3], \tag{9.3.53}$$

$$\tilde{k}_3 = f_3 + (\epsilon/2)[: \tilde{g}_1 : f_3, f_3], \tag{9.3.54}$$

$$\tilde{k}_4 = 0. \tag{9.3.55}$$

Finally, as before, these relations should be evaluated with $\epsilon = 1$. The net result is the formula

$$\exp(: f_3 :) \exp(: \tilde{g}_1 :) = \exp(: h_1^3 :) \exp(: h_2^3 :) \exp(: h_3^3 :) \exp(: h_4^3 :) \tag{9.3.56}$$

where the h_i^3 are given by the relations

$$h_1^3 = \tilde{g}_1 + (1/2) : \tilde{g}_1 :^2 f_3 - (1/4)[: \tilde{g}_1 :^2 f_3, : \tilde{g}_1 : f_3], \tag{9.3.57}$$

$$h_2^3 = - : \tilde{g}_1 : f_3 - (1/4)[: \tilde{g}_1 :^2 f_3, f_3], \tag{9.3.58}$$

$$h_3^3 = f_3 + (1/2)[: \tilde{g}_1 : f_3, f_3], \tag{9.3.59}$$

$$h_4^3 = 0. \tag{9.3.60}$$

We note that moving $\tilde{g}_1$ past f_3 is more difficult than moving g_1 past f_4! This greater difficulty occurs because, as is evident from (3.57) through (3.60), the feed-down terms are more complicated.

We have seen how to move a first-degree exponent past f_4 and f_3, and how to calculate (within the quotient algebra ${}^{\epsilon}L^0/{}^{\epsilon}L^3$) the feed-down terms left in its wake. The penultimate step is to move the first-degree exponent past $\mathcal{R}_f$ and then combine it with f_1. But this we know how to do exactly using the concatenation formulas (2.34) through (2.38) for the inhomogeneous symplectic group. Finally, we have to combine the results obtained so far with the remaining factors $\mathcal{R}_g \exp(: g_3 :) \exp(: g_4 :)$ in (3.7). This we also know how to do exactly using the concatenation formulas of Section 8.4. Thus, we have explored in some detail how to perform concatenation within the quotient group generated by the Lie algebra ${}^{\epsilon}L^0/{}^{\epsilon}L^3$.

Two tasks remain. The first is to find a convenient way of evaluating the symplectic matrices associated with the feed-down linear transformations of the form $\exp(: h_2^n :)$. This subject has already been treated in Chapter 4.

The second task is to find results for the larger quotient algebras ${}^{\epsilon}L^0/{}^{\epsilon}L^{\ell}$ with $\ell > 3$. A suitable Mathematica program for this purpose is presented in Appendix E. Essentially two problems must be solved to carry out the second task. First, we need formulas of the kind (3.15) and (3.29). Given a set of graded polynomials $j_i^{(n)}$, we need formulas for the k_m that appear in the product representation

$$\exp(: j_1^{(n)} + j_2^{(n)} + j_3^{(n)} + \cdots :) = \exp(: k_1 :) \exp(: k_2 :) \exp(: k_3 :) \cdots . \tag{9.3.61}$$

Second, let us write a relation of the form

$$\exp(:f_n:)\exp(:g_1:)=\exp(:h_1^n:)\exp(:h_2^n:)\exp(:h_3^n:)\cdots, \tag{9.3.62}$$

where, as before, we have used the notation h_i^n to denote the polynomial of degree i that results from moving $:g_1:$ past $:f_n:$. For this relation we need formulas for the h_i^n in terms of g_1 and f_n. We summarize below the results we have already found for the quotient algebra ${}^{\epsilon}L^0/{}^{\epsilon}L^3$ and, as a more complicated example found using the program in Appendix E, the results for the quotient algebra ${}^{\epsilon}L^0/{}^{\epsilon}L^5$.

Formulas for the k_i in (3.61) in the quotient algebra ${}^{\epsilon}L^0/{}^{\epsilon}L^3$.

n=2

$$k_i=j_1^{(2)},\ i=1\text{ to }4. \tag{9.3.63}$$

n=1

$$k_1=j_1^{(1)}-[j_1^{(1)},j_2^{(1)}]/2, \tag{9.3.64}$$

$$k_2=j_2^{(1)}-[j_1^{(1)},j_3^{(1)}]/2, \tag{9.3.65}$$

$$k_3=j_3^{(1)}-[j_2^{(1)},j_3^{(1)}]/2, \tag{9.3.66}$$

$$k_4=0. \tag{9.3.67}$$

Formulas for the h_i^n in (3.62) in the quotient algebra ${}^{\epsilon}L^0/{}^{\epsilon}L^3$.

$$h_1^4=g_1-(1/3!):g_1:^3 f_4, \tag{9.3.68}$$

$$h_2^4=(1/2!):g_1:^2 f_4, \tag{9.3.69}$$

$$h_3^4=-:g_1:f_4, \tag{9.3.70}$$

$$h_4^4=f_4. \tag{9.3.71}$$

$$h_1^3=g_1+(1/2!):g_1:^2 f_3-(1/4)[:g_1:^2 f_3,:g_1:f_3], \tag{9.3.72}$$

$$h_2^3=-:g_1:f_3-(1/4)[:g_1:^2 f_3,f_3], \tag{9.3.73}$$

$$h_3^3=f_3+(1/2)[:g_1:f_3,f_3], \tag{9.3.74}$$

$$h_4^3=0. \tag{9.3.75}$$

Formulas for the k_i in (3.61) in the quotient algebra ${}^{\epsilon}L^0/{}^{\epsilon}L^5$.

n=4

$$k_i=j_i^{(4)},i=1,6. \tag{9.3.76}$$

n=3

$$k_1=j_1^{(3)}, \tag{9.3.77}$$

$$k_2=j_2^{(3)}, \tag{9.3.78}$$

$$k_3=j_3^{(3)}, \tag{9.3.79}$$

$$k_4=j_4^{(3)}, \tag{9.3.80}$$

$$k_5=j_5^{(3)}, \tag{9.3.81}$$

$$k_6 = 0. \tag{9.3.82}$$

n=2

$$k_1 = j_1^{(2)} + [j_2^{(2)}, j_1^{(2)}]/2, \tag{9.3.83}$$

$$k_2 = j_2^{(2)} + [j_3^{(2)}, j_1^{(2)}], \tag{9.3.84}$$

$$k_3 = j_3^{(2)} + [j_3^{(2)}, j_2^{(2)}]/2 + [j_4^{(2)}, j_1^{(2)}], \tag{9.3.85}$$

$$k_4 = j_4^{(2)} + [j_4^{(2)}, j_2^{(2)}], \tag{9.3.86}$$

$$k_5 = [j_4^{(2)}, j_3^{(2)}], \tag{9.3.87}$$

$$k_6 = 0. \tag{9.3.88}$$

n=1

$$\begin{aligned} k_1 &= j_1^{(1)} + [j_2^{(1)}, j_1^{(1)}]/2 - [j_1^{(1)}, j_3^{(1)}, j_1^{(1)}]/6 + [j_2^{(1)}, j_2^{(1)}, j_1^{(1)}]/6 \\ &- [j_1^{(1)}, j_3^{(1)}, j_2^{(1)}, j_1^{(1)}]/8 - [j_2^{(1)}, j_1^{(1)}, j_3^{(1)}, j_1^{(1)}]/24 \\ &+ [j_2^{(1)}, j_2^{(1)}, j_2^{(1)}, j_1^{(1)}]/24, \end{aligned} \tag{9.3.89}$$

$$\begin{aligned} k_2 &= j_2^{(1)} + [j_3^{(1)}, j_1^{(1)}]/2 - [j_2^{(1)}, j_3^{(1)}, j_1^{(1)}]/12 + [j_3^{(1)}, j_2^{(1)}, j_1^{(1)}]/6 \\ &- [j_2^{(1)}, j_3^{(1)}, j_2^{(1)}, j_1^{(1)}]/24 - [j_3^{(1)}, j_1^{(1)}, j_3^{(1)}, j_1^{(1)}]/24 \\ &+ [j_3^{(1)}, j_2^{(1)}, j_2^{(1)}, j_1^{(1)}]/24, \end{aligned} \tag{9.3.90}$$

$$\begin{aligned} k_3 &= j_3^{(1)} + [j_3^{(1)}, j_2^{(1)}]/2 - [j_2^{(1)}, j_3^{(1)}, j_2^{(1)}]/6 + [j_3^{(1)}, j_3^{(1)}, j_1^{(1)}]/6 \\ &+ [j_2^{(1)}, j_2^{(1)}, j_3^{(1)}, j_2^{(1)}]/24 - [j_2^{(1)}, j_3^{(1)}, j_3^{(1)}, j_1^{(1)}]/8 + [j_3^{(1)}, j_2^{(1)}, j_3^{(1)}, j_1^{(1)}]/24 \\ &+ [j_3^{(1)}, j_3^{(1)}, j_2^{(1)}, j_1^{(1)}]/24, \end{aligned} \tag{9.3.91}$$

$$k_4 = -[j_3^{(1)}, j_3^{(1)}, j_2^{(1)}]/12 + [j_3^{(1)}, j_2^{(1)}, j_3^{(1)}, j_2^{(1)}]/24 - [j_3^{(1)}, j_3^{(1)}, j_3^{(1)}, j_1^{(1)}]/24, \tag{9.3.92}$$

$$k_5 = [j_3^{(1)}, j_3^{(1)}, j_3^{(1)}, j_2^{(1)}]/24, \tag{9.3.93}$$

$$k_6 = 0. \tag{9.3.94}$$

Formulas for the h_i^n in (3.62) in the quotient algebra ${}^{\epsilon}L^0/{}^{\epsilon}L^5$.

$$h_1^6 = g_1 - (1/120) : g_1 :^5 f_6, \tag{9.3.95}$$

$$h_2^6 = (1/24) : g_1 :^4 f_6, \tag{9.3.96}$$

$$h_3^6 = -(1/6) : g_1 :^3 f_6, \tag{9.3.97}$$

$$h_4^6 = (1/2) : g_1 :^2 f_6, \tag{9.3.98}$$

$$h_5^6 = - : g_1 : f_6, \tag{9.3.99}$$

$$h_6^6 = f_6; \tag{9.3.100}$$

$$h_1^5 = g_1 + (1/24) : g_1 :^4 f_5, \tag{9.3.101}$$

$$h_2^5 = -(1/6) : g_1 :^3 f_5, \tag{9.3.102}$$

$$h_3^5 = (1/2) : g_1 :^2 f_5, \tag{9.3.103}$$

$$h_4^5 = - : g_1 : f_5, \tag{9.3.104}$$

$$h_5^5 = f_5, \tag{9.3.105}$$

$$h_6^5 = 0; \tag{9.3.106}$$

$$h_1^4 = g_1 + j_1^4 + [j_2^4, j_1^4]/2, \tag{9.3.107}$$

$$h_4^4 = j_4^4 + [j_4^4, j_2^4]/2, \tag{9.3.110}$$

$$h_5^4 = [j_4^4, j_3^4]/2, \tag{9.3.111}$$

$$h_6^4 = 0, \tag{9.3.112}$$

where

$$j_1^4 = - : g_1 :^3 f_4/6, \tag{9.3.113}$$

$$j_2^4 =: g_1 :^2 f_4/2, \tag{9.3.114}$$

$$j_3^4 = - : g_1 : f_4, \tag{9.3.115}$$

$$j_4^4 = f_4; \tag{9.3.116}$$

$$\begin{aligned} h_1^3 \;=\;& g_1 + j_1^3 + [j_2^3, j_1^3]/2 - [j_1^3, j_3^3, j_1^3]/6 + [j_2^3, j_2^3, j_1^3]/6 - [j_1^3, j_3^3, j_2^3, j_1^3]/8 \\ -\;& [j_2^3, j_1^3, j_3^3, j_1^3]/24 + [j_2^3, j_2^3, j_2^3, j_1^3]/24, \end{aligned} \tag{9.3.117}$$

$$\begin{aligned} h_2^3 \;=\;& j_2^3 + [j_3^3, j_1^3]/2 - [j_2^3, j_3^3, j_1^3]/12 + [j_3^3, j_2^3, j_1^3]/6 - [j_2^3, j_3^3, j_2^3, j_1^3]/24 \\ -\;& [j_3^3, j_1^3, j_3^3, j_1^3]/24 + [j_3^3, j_2^3, j_2^3, j_1^3]/24, \end{aligned} \tag{9.3.118}$$

$$\begin{aligned} h_3^3 \;=\;& j_3^3 + [j_3^3, j_2^3]/2 - [j_2^3, j_3^3, j_2^3]/6 + [j_3^3, j_3^3, j_1^3]/6 + [j_2^3, j_2^3, j_3^3, j_2^3]/24 \\ -\;& [j_2^3, j_3^3, j_3^3, j_1^3]/8 + [j_3^3, j_2^3, j_3^3, j_1^3]/24 + [j_3^3, j_3^3, j_2^3, j_1^3]/24, \end{aligned} \tag{9.3.119}$$

$$h_4^3 = -[j_3^3, j_3^3, j_2^3]/12 + [j_3^3, j_2^3, j_3^3, j_2^3]/24 - [j_3^3, j_3^3, j_3^3, j_1^3]/24, \tag{9.3.120}$$

$$h_5^3 = [j_3^3, j_3^3, j_3^3, j_2^3]/24, \tag{9.3.121}$$

$$h_6^3 = 0, \tag{9.3.122}$$

where

$$j_1^3 =: g_1 :^2 f_3/2, \tag{9.3.123}$$

$$j_2^3 = - : g_1 : f_3, \tag{9.3.124}$$

$$j_3^3 = f_3. \tag{9.3.125}$$

Here for multiple Poisson brackets we have used the notation

$$[a_1, a_2, a_3] = [a_1, [a_2, a_3]], \tag{9.3.126}$$

$$[a_1, a_2, a_3, a_4] = [a_1, [a_2, [a_3, a_4]]]. \tag{9.3.127}$$

Note that for ${}^\epsilon L^0/{}^\epsilon L^5$ the feed-down terms are quite complicated. Also, note that the terms h_5^4, h_4^3, and h_5^3 are nonzero. Consequently there can also be, in effect, nonlinear feed-up terms due to translations in phase space. Finally, we see that the ${}^\epsilon L^0/{}^\epsilon L^3$ formulas (3.68) through (3.75) are special cases of the ${}^\epsilon L^0/{}^\epsilon L^5$ formulas for h_i^4 and h_i^3 in which higher-power terms in g_1 are neglected.

We close this section with an observation that will be of relevance for the work of the next section. Observe that the relations (3.25) and (3.29) can be written in the form

$$\exp(:f_3:)\exp(:\epsilon g_1:) = \exp(:k_1^{(0)}:)\exp(:k_1^{(1)} + k_1^{(2)}:)\exp(:k_2^{(1)} + k_2^{(2)}:)\exp(:k_3^{(1)} + k_3^{(2)}:). \tag{9.3.128}$$

Here, for convenience, we have dropped the tildes and we have defined the $k_i^{(n)}$ by the relations

$$k_1^{(0)} = \epsilon g_1, \tag{9.3.129}$$

$$k_1^{(1)} = (\epsilon^2/2) : g_1 :^2 f_3, \tag{9.3.130}$$

$$k_1^{(2)} = -(\epsilon^3/4)[: g_1 :^2 f_3, : g_1 : f_3], \tag{9.3.131}$$

$$k_2^{(1)} = -\epsilon : g_1 : f_3, \tag{9.3.132}$$

$$k_2^{(2)} = -(\epsilon^2/4)[: g_1 :^2 f_3, f_3], \tag{9.3.133}$$

$$k_3^{(1)} = f_3, \tag{9.3.134}$$

$$k_3^{(2)} = (\epsilon/2)[: g_1 : f_3, f_3]. \tag{9.3.135}$$

See (3.1) through (3.3) and (3.52) through (3.55). We see that several of the exponents contain terms of different grades. We will therefore refer to expressions of the form (3.128) as *mixed* grade factorizations.

From the Lie algebraic perspective of working within ${}^\epsilon L^0/{}^\epsilon L^3$ we could as well sought relations of the form

$$\begin{aligned}\exp(:f_3:)\exp(:\epsilon g_1:) = {}& \exp(:\hat{k}_1^{(0)}:)\exp(:\hat{k}_1^{(1)}:)\exp(:\hat{k}_1^{(2)}:) \times \\ & \exp(:\hat{k}_2^{(0)}:)\exp(:\hat{k}_2^{(1)}:)\exp(:\hat{k}_2^{(2)}:) \times \\ & \exp(:\hat{k}_3^{(1)}:)\exp(:\hat{k}_3^{(2)}:)\exp(:\hat{k}_4^{(2)}:).\end{aligned} \tag{9.3.136}$$

Here we have used hats to indicate that the $\hat{k}_i^{(n)}$ may differ from the $k_i^{(n)}$. (They are actually the same for the algebra ${}^\epsilon L^0/{}^\epsilon L^3$, but they may differ for relations analagous to (3.136) in the case of algebras having a larger maximum grade.) Note that in the factorization (3.136) each exponent has a single grade. [And, according to (3.1) through (3.3), each exponent carries a single power of ϵ.] We will call factorizations of this kind *single* grade factorizations.

Once again ϵ serves as a counting parameter and, having obtained a single grade factorization of the form (3.136), we may set $\epsilon = 1$. Evidently, since we are working within a quotient algebra based on grade, setting $\epsilon = 1$ in either a mixed grade or a single grade factorization gives equivalent results.

Exercises

9.3.1. Verify the relations (3.8) through (3.22).

9.3.2. Verify the relations (3.30) through (3.38). Note that Poisson brackets between grade one and grade two polynomials, and Poisson brackets between two grade two polynomials, vanish in the quotient algebra ${}^{\epsilon}L^0/{}^{\epsilon}L^3$.

9.3.3. Verify the relations (3.39) through (3.55).

9.3.4.

9.3.5.

9.4 Canonical Treatment of Translations

The Lie concatenation formulas for maps that send the origin into itself, see Sections 8.4 and 10.12, were relatively easy to derive. By contrast, the concatenation formulas just derived in the previous section, where translations were included, seem much more complicated. In this section we will show how the translation case can be handled using a concatenator for the simpler origin-preserving case. This will be done by *enlarging* the $2n$-dimensional phase space to include the extra variables q_{n+1} and p_{n+1}. For this reason, the method will be referred to as a *canonical* treatment of translations.

9.4.1 Preliminaries

Since the origin-preserving concatenation formulas do not depend on the phase-space dimension, the only costs associated with increased phase-space dimension are those of increased storage and slower execution when a concatenator is realized as computer code. The advantages of this approach are simplicity and reliability. If one has a reliable origin-preserving concatenator, one can construct from it a self-checking concatenator for general maps.

Those who have been meticulous to do the Exercises in this book will recognize that Exercise 7.7.2 showed that the Jacobi Lie algebra $j(2n,\mathbb{R})$ is homomorphic to the inhomogeneous symplectic Lie algebra $isp(2n,\mathbb{R})$ of Section 9.2, and Exercise 7.7.3 treated, among other things, the relation between $j(2n,\mathbb{R})$ and the symplectic group Lie algebra $sp[2(n+1),\mathbb{R}]$ for a phase space having two additional dimensions. We begin our discussion here by further elaborating on this theme. Subsequently we will treat $ISpM(2n,\mathbb{R})$ and $ispm(2n,\mathbb{R})$, the full nonlinear case of all symplectic maps.

Let us use the symbol $\hat{z}$ to denote the coordinates in the $(2n+2)$-dimensional enlarged phase space,

$$\hat{z} = (q_1 \cdots q_n, q_{n+1}, p_1 \cdots p_n, p_{n+1}). \tag{9.4.1}$$

We will also use the notation $\hat{\mathcal{M}}_{\hat{f}}$ to denote a symplectic (and origin-preserving) map acting on the enlarged phase space. For what follows we will want to consider special maps $\hat{\mathcal{M}}_{\hat{h}}$ on the enlarged phase space that have the property

$$\hat{\mathcal{M}}_{\hat{h}} q_{n+1} = q_{n+1}. \tag{9.4.2}$$

Such maps obviously form a group. Moreover, they have a factorization of the form

$$\hat{\mathcal{M}}_{\hat{h}} = \hat{\mathcal{R}}_{\hat{h}} \exp(:\hat{h}_3:)\exp(:\hat{h}_4:)\cdots \tag{9.4.3}$$

where the linear part $\hat{\mathcal{R}}_{\hat{h}}$ has the property

$$\hat{\mathcal{R}}_{\hat{h}} q_{n+1} = q_{n+1}, \tag{9.4.4}$$

and the $\hat{h}_m(\hat{z})$ that describe the nonlinear part are independent of p_{n+1},

$$\partial \hat{h}_m(\hat{z})/\partial p_{n+1} = 0. \tag{9.4.5}$$

To see that this is so, equate terms of like degree on both sides of (4.2). From (7.6.14) there is the result

$$[\exp(:\hat{h}_3:)\exp(:\hat{h}_4:)\cdots]q_{n+1} = q_{n+1} + O(\hat{z}^2). \tag{9.4.6}$$

Therefore (4.2) requires the relation

$$q_{n+1} = \hat{\mathcal{M}}_{\hat{h}} q_{n+1} = \hat{\mathcal{R}}_{\hat{h}}[q_{n+1} + O(\hat{z}^2)] = \hat{\mathcal{R}}_{\hat{h}} q_{n+1} + O(\hat{z}^2), \tag{9.4.7}$$

and equating terms of first degree yields (4.4).

Now that (4.4) is established, multiply both sides of (4.2) by $\hat{\mathcal{R}}_{\hat{h}}^{-1}$ to find the result

$$\hat{\mathcal{R}}_{\hat{h}}^{-1}\hat{\mathcal{M}}_{\hat{h}} q_{n+1} = \hat{\mathcal{R}}_{\hat{h}}^{-1} q_{n+1} = q_{n+1} \tag{9.4.8}$$

from which it follows that

$$[\exp(:\hat{h}_3:)\exp(:\hat{h}_4:)\cdots]q_{n+1} = q_{n+1}. \tag{9.4.9}$$

Evaluate both sides of (4.9) through terms of degree 2. Doing so gives the relation

$$q_{n+1} + :\hat{h}_3: q_{n+1} + O(\hat{z}^3) = q_{n+1}, \tag{9.4.10}$$

and equating terms of like degree gives the relation

$$0 =: \hat{h}_3 : q_{n+1} = [\hat{h}_3, q_{n+1}] = -\partial \hat{h}_3/\partial p_{n+1}, \tag{9.4.11}$$

which establishes (4.5) for the case $m = 3$. From (4.11) we also conclude that

$$\exp(:\hat{h}_3:)q_{n+1} = q_{n+1}. \tag{9.4.12}$$

Finally, multiply both sides of (4.9) by $\exp(-:\hat{h}_3:)$ to find the result

$$[\exp(:\hat{h}_4:)\exp(:\hat{h}_5:)\cdots]q_{n+1} = \exp(-:\hat{h}_3:)q_{n+1} = q_{n+1}. \tag{9.4.13}$$

Expanding both sides of (4.13) and equating terms of like degree shows that (4.5) also holds for the case $m = 4$, etc.

Let us explore the consequences of (4.4) in detail. For simplicity, consider the case of a phase space that is initially two dimensional ($n = 1$) and is enlarged to become four dimensional. The results for general n can easily be inferred from what we will find for the

$n = 1$ case. Suppose $\hat{R}^{\hat{h}}$ is the matrix associated with $\hat{\mathcal{R}}_{\hat{h}}$. In the 4×4 case we have decided to consider, and in view of (4.4) with $n = 1$, it has the general form

$$\hat{R}^{\hat{h}} = \left(\begin{array}{cccc} \hat{R}^{\hat{h}}_{11} & \hat{R}^{\hat{h}}_{12} & \hat{R}^{\hat{h}}_{13} & \hat{R}^{\hat{h}}_{14} \\ \hat{R}^{\hat{h}}_{21} & \hat{R}^{\hat{h}}_{22} & \hat{R}^{\hat{h}}_{23} & \hat{R}^{\hat{h}}_{24} \\ 0 & 0 & 1 & 0 \\ \hat{R}^{\hat{h}}_{41} & \hat{R}^{\hat{h}}_{42} & \hat{R}^{\hat{h}}_{43} & \hat{R}^{\hat{h}}_{44} \end{array} \right). \tag{9.4.14}$$

Here we have used the ordering

$$\hat{z} = (q_1, p_1; q_2, p_2). \tag{9.4.15}$$

However, since $\hat{R}_{\hat{h}}$ is a symplectic map, $\hat{R}^{\hat{h}}$ must be a symplectic matrix. Enforcing the symplectic condition (3.1.2) or (3.1.10) gives, among others, the relations

$$\hat{R}^{\hat{h}}_{a4} = \delta_{a4}. \tag{9.4.16}$$

It follows that $\hat{R}^{\hat{h}}$ has the more specific form

$$\hat{R}^{\hat{h}} = \left(\begin{array}{cccc} \hat{R}^{\hat{h}}_{11} & \hat{R}^{\hat{h}}_{12} & \hat{R}^{\hat{h}}_{13} & 0 \\ \hat{R}^{\hat{h}}_{21} & \hat{R}^{\hat{h}}_{22} & \hat{R}^{\hat{h}}_{23} & 0 \\ 0 & 0 & 1 & 0 \\ \hat{R}^{\hat{h}}_{41} & \hat{R}^{\hat{h}}_{42} & \hat{R}^{\hat{h}}_{43} & 1 \end{array} \right). \tag{9.4.17}$$

Introduce the 2×2 matrix $\bar{R}^{\hat{h}}$ defined by the upper-left 2×2 block in $\hat{R}^{\hat{h}}$,

$$\bar{R}^{\hat{h}} = \left(\begin{array}{cc} \hat{R}^{\hat{h}}_{11} & \hat{R}^{\hat{h}}_{12} \\ \hat{R}^{\hat{h}}_{21} & \hat{R}^{\hat{h}}_{22} \end{array} \right), \tag{9.4.18}$$

and let $\breve{R}^{\hat{h}}$ be the 4×4 matrix

$$\breve{R}^{\hat{h}} = \left(\begin{array}{cc} \bar{R}^{\hat{h}} & 0 \\ 0 & I \end{array} \right). \tag{9.4.19}$$

Also, define quantities $\alpha^{\hat{h}}_2$ and $\delta^{\hat{h}}_a$ for $a = 1$ to 2 by the rules

$$\alpha^{\hat{h}}_2 = \hat{R}^{\hat{h}}_{43}/2, \tag{9.4.20}$$

$$\delta^{\hat{h}}_1 = -\hat{R}^{\hat{h}}_{42}, \tag{9.4.21}$$

$$\delta^{\hat{h}}_2 = \hat{R}^{\hat{h}}_{41}, \tag{9.4.22}$$

and define associated polynomials h_1 and $\hat{h}^2_1$ by the rules

$$h_1(z) = \delta^{\hat{h}}_2 q_1 - \delta^{\hat{h}}_1 p_1 = \delta^{\hat{h}}_2 z_1 - \delta^{\hat{h}}_1 z_2 = (z, (\delta^{\hat{h}})^*), \tag{9.4.23}$$

$$\hat{h}^2_1(\hat{z}) = q_2 h_1(z). \tag{9.4.24}$$

Here we have used the notation of Section 7.7, and z denotes the original phase-space variables,

$$z = (q_1, p_1).$$

The superscript indicates that $\hat{h}_1^2$ is homogeneous of degree *two* in the variables $\hat{z}$, and the subscript indicates that it is homogeneous of degree *one* with respect to the variables z.

Note that h_1 has the property

$$: h_1 : z_a = \delta_a^{\hat{h}}. \tag{9.4.25}$$

Correspondingly, $\hat{h}_1^2$ has the properties

$$: \hat{h}_1^2 : z_a =: q_2 h_1(z) : z_a = [q_2 h_1(z), z_a] = q_2[h_1(z), z_a] = q_2 : h_1 : z_a = q_2 \delta_a^{\hat{h}}, \tag{9.4.26}$$

$$: \hat{h}_1^2 :^m z_a = 0 \text{ for } m > 1, \tag{9.4.27}$$

$$: \hat{h}_1^2 : q_2 = [q_2 h_1(z), q_2] = 0, \tag{9.4.28}$$

$$: \hat{h}_1^2 : p_2 = [q_2 h_1(z), p_2] = h_1(z), \tag{9.4.29}$$

$$: \hat{h}_1^2 :^m p_2 = 0 \text{ for } m > 1. \tag{9.4.30}$$

Then, with these definitions, we assert that $\hat{\mathcal{R}}_{\hat{h}}$ has the unique factorization

$$\hat{\mathcal{R}}_{\hat{h}} = \hat{\mathcal{F}}_{\hat{h}} \hat{\mathcal{R}}_{\hat{h}_1^2} \check{\mathcal{R}}_{\hat{h}} \tag{9.4.31}$$

where

$$\hat{\mathcal{F}}_{\hat{h}} = \exp(: \alpha_2^{\hat{h}} q_2^2 :), \tag{9.4.32}$$

$$\hat{\mathcal{R}}_{\hat{h}_1^2} = \exp(: \hat{h}_1^2 :), \tag{9.4.33}$$

and $\check{\mathcal{R}}_{\hat{h}}$ is a linear symplectic map whose associated matrix $\check{R}^{\hat{h}}$ is given by (4.19).

If correct, the operator assertion (4.31) is equivalent to the matrix assertion

$$\hat{R}^{\hat{h}} = \check{R}^{\hat{h}} \hat{R}^{\hat{h}_1^2} \hat{F}^{\hat{h}} \tag{9.4.34}$$

where $\hat{R}^{\hat{h}_1^2}$ and $\hat{F}^{\hat{h}}$ are the matrices associated with $\hat{\mathcal{R}}_{\hat{h}_1^2}$ and $\hat{\mathcal{F}}_{\hat{h}}$. Let us find these matrices. From (4.26) through (4.30) we see that $\hat{\mathcal{R}}_{\hat{h}_1^2}$ has the property

$$\hat{\mathcal{R}}_{\hat{h}_1^2} z_a = z_a + q_2 \delta_a^{\hat{h}}, \tag{9.4.35}$$

$$\hat{\mathcal{R}}_{\hat{h}_1^2} q_2 = q_2, \tag{9.4.36}$$

$$\hat{\mathcal{R}}_{\hat{h}_1^2} p_2 = p_2 + h_1(z) = p_2 + (z, (\delta^{\hat{h}})^*). \tag{9.4.37}$$

It follows that the matrix $\hat{R}^{\hat{h}_1^2}$ is given by the relation

$$\hat{R}^{\hat{h}_1^2} = \begin{pmatrix} 1 & 0 & \delta_1^{\hat{h}} & 0 \\ 0 & 1 & \delta_2^{\hat{h}} & 0 \\ 0 & 0 & 1 & 0 \\ \delta_2^{\hat{h}} & -\delta_1^{\hat{h}} & 0 & 1 \end{pmatrix}. \tag{9.4.38}$$

Finding $\hat{F}^{\hat{h}}$ is easier. A simple calculation gives the result

$$\hat{F}^{\hat{h}} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & \hat{R}^{\hat{h}}_{43} & 1 \end{pmatrix}. \tag{9.4.39}$$

Let us solve (4.34) for $\check{R}^{\hat{h}}$ to find the relation

$$\check{R}^{\hat{h}} = \hat{R}^{\hat{h}}(\hat{F}^{\hat{h}})^{-1}(\hat{R}^{\hat{h}_1^2})^{-1}. \tag{9.4.40}$$

Carrying out the indicated multiplications gives the result

$$\check{R}^{\hat{h}} = \begin{pmatrix} \hat{R}^{\hat{h}}_{11} & \hat{R}^{\hat{h}}_{12} & \epsilon_1 & 0 \\ \hat{R}^{\hat{h}}_{21} & \hat{R}^{\hat{h}}_{22} & \epsilon_2 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \tag{9.4.41}$$

where

$$\epsilon_1 = \hat{R}^{\hat{h}}_{13} + \hat{R}^{\hat{h}}_{11}\hat{R}^{\hat{h}}_{42} - \hat{R}^{\hat{h}}_{12}\hat{R}^{\hat{h}}_{41} = \hat{R}^{\hat{h}}_{13} - \hat{R}^{\hat{h}}_{11}\delta^{\hat{h}}_1 - \hat{R}^{\hat{h}}_{12}\delta^{\hat{h}}_2, \tag{9.4.42}$$

$$\epsilon_2 = \hat{R}^{\hat{h}}_{23} + \hat{R}^{\hat{h}}_{21}\hat{R}^{\hat{h}}_{42} - \hat{R}^{\hat{h}}_{22}\hat{R}^{\hat{h}}_{41} = \hat{R}^{\hat{h}}_{23} - \hat{R}^{\hat{h}}_{21}\delta^{\hat{h}}_1 - \hat{R}^{\hat{h}}_{22}\delta^{\hat{h}}_2. \tag{9.4.43}$$

Next, because $\hat{R}^{\hat{h}}$, $(\hat{F}^{\hat{h}})^{-1}$, and $(\hat{R}^{\hat{h}_1^2})^{-1}$ are symplectic matrices ($\mathcal{R}_{\hat{h}}$, $\mathcal{F}_{\hat{h}}$, and $\mathcal{R}_{\hat{h}_1^2}$ are symplectic maps), $\check{R}^{\hat{h}}$ must be a symplectic matrix. The symplectic condition (3.1.10) yields for $\check{R}^{\hat{h}}$ as given by (4.41) the relations

$$\epsilon_a = 0 \text{ for } a = 1 \text{ to } 2, \tag{9.4.44}$$

$$\hat{R}^{\hat{h}}_{11}\hat{R}^{\hat{h}}_{22} - \hat{R}^{\hat{h}}_{12}\hat{R}^{\hat{h}}_{21} = 1. \tag{9.4.45}$$

From (4.44) we conclude that the ϵ_a entries in (4.41) must vanish, and therefore (4.34) is correct with $\check{R}^{\hat{h}}$ given by (4.19). The relation (4.45) is the condition that $\bar{R}^{\hat{h}}$ and hence $\check{R}^{\hat{h}}$ be symplectic matrices. Finally (4.42) and (4.43), when combined with (4.44), show that the matrix $\hat{R}^{\hat{h}}$ in (4.17) must have the form

$$\hat{R}^{\hat{h}} = \begin{pmatrix} \hat{R}^{\hat{h}}_{11} & \hat{R}^{\hat{h}}_{12} & (\bar{R}^{\hat{h}}\delta^{\hat{h}})_1 & 0 \\ \hat{R}^{\hat{h}}_{21} & \hat{R}^{\hat{h}}_{22} & (\bar{R}^{\hat{h}}\delta^{\hat{h}})_2 & 0 \\ 0 & 0 & 1 & 0 \\ \delta^{\hat{h}}_2 & -\delta^{\hat{h}}_1 & \hat{R}^{\hat{h}}_{43} & 1 \end{pmatrix}. \tag{9.4.46}$$

With what we have learned we are now prepared to show how general maps (including translations) for the case of $2n$-dimensional phase space can be imbedded in the set of $(2n+2)$-dimensional origin preserving maps. We will first consider maps with no nonlinear part, and then move on to the general case.

9.4.2 Case of Maps with No Nonlinear Part

Enlarging

Let $\mathcal{M}_f$ be an inhomogeneous symplectic group map acting on the original $2n$-dimensional phase space z. As in (2.31), it may be written in the form

$$\mathcal{M}_f = \exp(: f_1 :)\mathcal{R}_f. \tag{9.4.47}$$

Define a function $\hat{f}_1^2(\hat{z})$ by the rule

$$\hat{f}_1^2(\hat{z}) = (q_{n+1})f_1(z). \tag{9.4.48}$$

As before, the superscript indicates that $\hat{f}_1^2$ is homogeneous of degree *two* in the variables $\hat{z}$, and the subscript indicates that it is homogeneous of degree *one* with respect to the variables z. Now define a map $\hat{\mathcal{M}}_{\hat{f}}$ on the enlarged phase space by the rule

$$\hat{\mathcal{M}}_{\hat{f}} = \exp(: \hat{f}_1^2 :)\check{\mathcal{R}}_{\hat{f}}. \tag{9.4.49}$$

Here $\check{\mathcal{R}}_{\hat{f}}$ is a linear map with the associated matrix $\check{R}_{\hat{f}}$ given by

$$\check{R}^{\hat{f}} = \begin{pmatrix} R^f & 0 \\ 0 & I \end{pmatrix} \tag{9.4.50}$$

where R^f is the matrix associated with $\mathcal{R}_f$, I denotes the 2×2 identity matrix acting on the q_{n+1}, p_{n+1} space, and the 0's denote rectangular matrices of zeroes. Evidently, we have mapped an element of the inhomogeneous symplectic group in $2n$ dimensions into an element of the homogeneous (origin-preserving) symplectic group in $(2n+2)$ dimensions. This process will be called *enlarging*.

What is the effect of $\hat{\mathcal{M}}_{\hat{f}}$ on the enlarged phase space? Evidently we immediately have the relation

$$\hat{\mathcal{M}}_{\hat{f}} q_{n+1} = q_{n+1}. \tag{9.4.51}$$

To explore matters further suppose, in analogy with (4.25), that f_1 has the property

$$: f_1 : z_a = \delta_a^f. \tag{9.4.52}$$

See (7.7.1) through (7.7.6). Then $\hat{f}_1^2$ has the properties

$$\begin{aligned} : \hat{f}_1^2 : z_a &= \; : (q_{n+1})f_1(z) : z_a = [(q_{n+1})f_1(z), z_a] \\ &= (q_{n+1})[f_1(z), z_a] = (q_{n+1}) : f_1 : z_a = (q_{n+1})\delta_a^f, \end{aligned} \tag{9.4.53}$$

$$: \hat{f}_1^2 :^m z_a = 0 \text{ for } m > 1, \tag{9.4.54}$$

$$: \hat{f}_1^2 : (q_{n+1}) = [(q_{n+1})f_1(z), (q_{n+1})] = 0, \tag{9.4.55}$$

$$: \hat{f}_1^2 : (p_{n+1}) = [(q_{n+1})f_1(z), (p_{n+1})] = f_1(z), \tag{9.4.56}$$

$$: \hat{f}_1^2 :^m (p_{n+1}) = 0 \text{ for } m > 1. \tag{9.4.57}$$

Let $\hat{\mathcal{R}}_{\hat{f}_1^2}$ denote the map

$$\hat{\mathcal{R}}_{\hat{f}_1^2} = \exp(:\hat{f}_1^2:). \tag{9.4.58}$$

From (4.53) through (4.57) we see that $\hat{\mathcal{R}}_{\hat{f}_1^2}$ has the property

$$\hat{\mathcal{R}}_{\hat{f}_1^2} z_a = z_a + (q_{n+1})\delta_a^f, \tag{9.4.59}$$

$$\hat{\mathcal{R}}_{\hat{f}_1^2} q_{n+1} = q_{n+1}, \tag{9.4.60}$$

$$\hat{\mathcal{R}}_{\hat{f}_1^2} p_{n+1} = p_{n+1} + f_1(z) = p_{n+1} + (z, (\delta^f)^*). \tag{9.4.61}$$

See also (7.7.3).

It follows from (4.59) through (4.61) that the action of $\hat{\mathcal{R}}_{\hat{f}_1^2}$ can be represented by a matrix $\hat{R}^{\hat{f}_1^2}$. In the simplest case that the original phase space is two dimensional, this matrix is 4×4 and is given by the relation

$$\hat{R}^{\hat{f}_1^2} = \begin{pmatrix} 1 & 0 & \delta_1^f & 0 \\ 0 & 1 & \delta_2^f & 0 \\ 0 & 0 & 1 & 0 \\ \delta_2^f & -\delta_1^f & 0 & 1 \end{pmatrix}. \tag{9.4.62}$$

Here we have used the ordering (4.15) and the J of (3.2.11). Evidently (4.62) is analogous to (4.38).

Finally, let us find the effect of $\hat{\mathcal{M}}_{\hat{f}}$. According to (4.49) and (4.58), it can be written in the form

$$\hat{\mathcal{M}}_{\hat{f}} = \hat{\mathcal{R}}_{\hat{f}_1^2} \check{\mathcal{R}}_{\hat{f}}. \tag{9.4.63}$$

It follows that the action of $\hat{\mathcal{M}}_{\hat{f}}$ can be represented by the matrix $\hat{R}^{\hat{f}}$ given by the relation

$$\hat{R}^{\hat{f}} = \check{R}^{\hat{f}} \hat{R}^{\hat{f}_1^2}. \tag{9.4.64}$$

See (8.4.19) and (8.4.20). Carrying out the indicated multiplication gives (in the 4×4 case) the result

$$\hat{R}^{\hat{f}} = \begin{pmatrix} R_{11}^f & R_{12}^f & (R^f\delta^f)_1 & 0 \\ R_{21}^f & R_{22}^f & (R^f\delta^f)_2 & 0 \\ 0 & 0 & 1 & 0 \\ \delta_2^f & -\delta_1^f & 0 & 1 \end{pmatrix}. \tag{9.4.65}$$

which is analogous to (4.46).

Shrinking

We have defined enlarged maps and have studied their effect on the enlarged phase space. Let us now explore how they behave under multiplication. Suppose $\mathcal{M}_f$ and $\mathcal{M}_g$ are any two inhomogeneous symplectic group maps, and $\hat{\mathcal{M}}_{\hat{f}}$ and $\hat{\mathcal{M}}_{\hat{g}}$ are their enlargements. We can form corresponding maps $\mathcal{M}_h$ and $\hat{\mathcal{M}}_{\hat{h}}$ by the products

$$\mathcal{M}_h = \mathcal{M}_f \mathcal{M}_g, \tag{9.4.66}$$

$$\hat{\mathcal{M}}_{\hat{h}} = \hat{\mathcal{M}}_{\hat{f}}\hat{\mathcal{M}}_{\hat{g}}. \tag{9.4.67}$$

The product (4.66) involves the concatenation of maps that include translations, and its calculation entails the derivation and use of complicated (and only partially known) feed-down formulae as described in the previous section. By contrast, the product (4.67) is for origin-preserving maps in the enlarged 8-dimensional phase space. Its computation involves only the use of far simpler universal dimension-independent origin-preserving concatenation rules. What we wish to learn is whether $\mathcal{M}_h$ can be deduced from a knowledge of $\hat{\mathcal{M}}_{\hat{h}}$. The process of constructing $\mathcal{M}_h$ from $\hat{\mathcal{M}}_{\hat{h}}$ will be called *shrinking*. See Figure 9.4.1 for a pictorial presentation of this question.

To answer this question, let us compute $\hat{R}^{\hat{h}}$, the matrix corresponding to $\hat{\mathcal{M}}_{\hat{h}}$. It is given by the relation

$$\begin{aligned}
\hat{R}^{\hat{h}} = \hat{R}^{\hat{g}}\hat{R}^{\hat{f}} \quad &= \begin{pmatrix} R^g_{11} & R^g_{12} & (R^g\delta^g)_1 & 0 \\ R^g_{21} & R^g_{22} & (R^g\delta^g)_2 & 0 \\ 0 & 0 & 1 & 0 \\ \delta^g_2 & -\delta^g_1 & 0 & 1 \end{pmatrix}\begin{pmatrix} R^f_{11} & R^f_{12} & (R^f\delta^f)_1 & 0 \\ R^f_{21} & R^f_{22} & (R^f\delta^f)_2 & 0 \\ 0 & 0 & 1 & 0 \\ \delta^f_2 & -\delta^f_1 & 0 & 1 \end{pmatrix} \\
&= \begin{pmatrix} R^h_{11} & R^h_{12} & (R^h\delta^f + R^g\delta^g)_1 & 0 \\ R^h_{21} & R^h_{22} & (R^h\delta^f + R^g\delta^g)_2 & 0 \\ 0 & 0 & 1 & 0 \\ * & * & * & 1 \end{pmatrix}.
\end{aligned} \tag{9.4.68}$$

Here,

$$R^h = R^g R^f. \tag{9.4.69}$$

As before, for simplicity, we have treated the case where the original phase space is two dimensional, and the enlarged phase space is four dimensional. Again, the result in this case is sufficient to deduce the result in any dimension. Finally, we have not computed the starred entries in the bottom row of $\hat{R}^{\hat{h}}$. See Exercise 4.10.

We observe, as a consequence of (4.69), that the matrix R^h can be read off from the upper-left corner of $\hat{R}^{\hat{h}}$. Also, upon comparison of (4.68) with (4.46), we expect the upper two entries of the penultimate column of $\hat{R}^{\hat{h}}$ to be the entries of the vector $(R^h\delta^h)$. Therefore, from (4.46) and (4.68), we get the relation

$$R^h\delta^h = R^h\delta^f + R^g\delta^g. \tag{9.4.70}$$

In view of (4.69), the relation (4.70) can also be written in the form

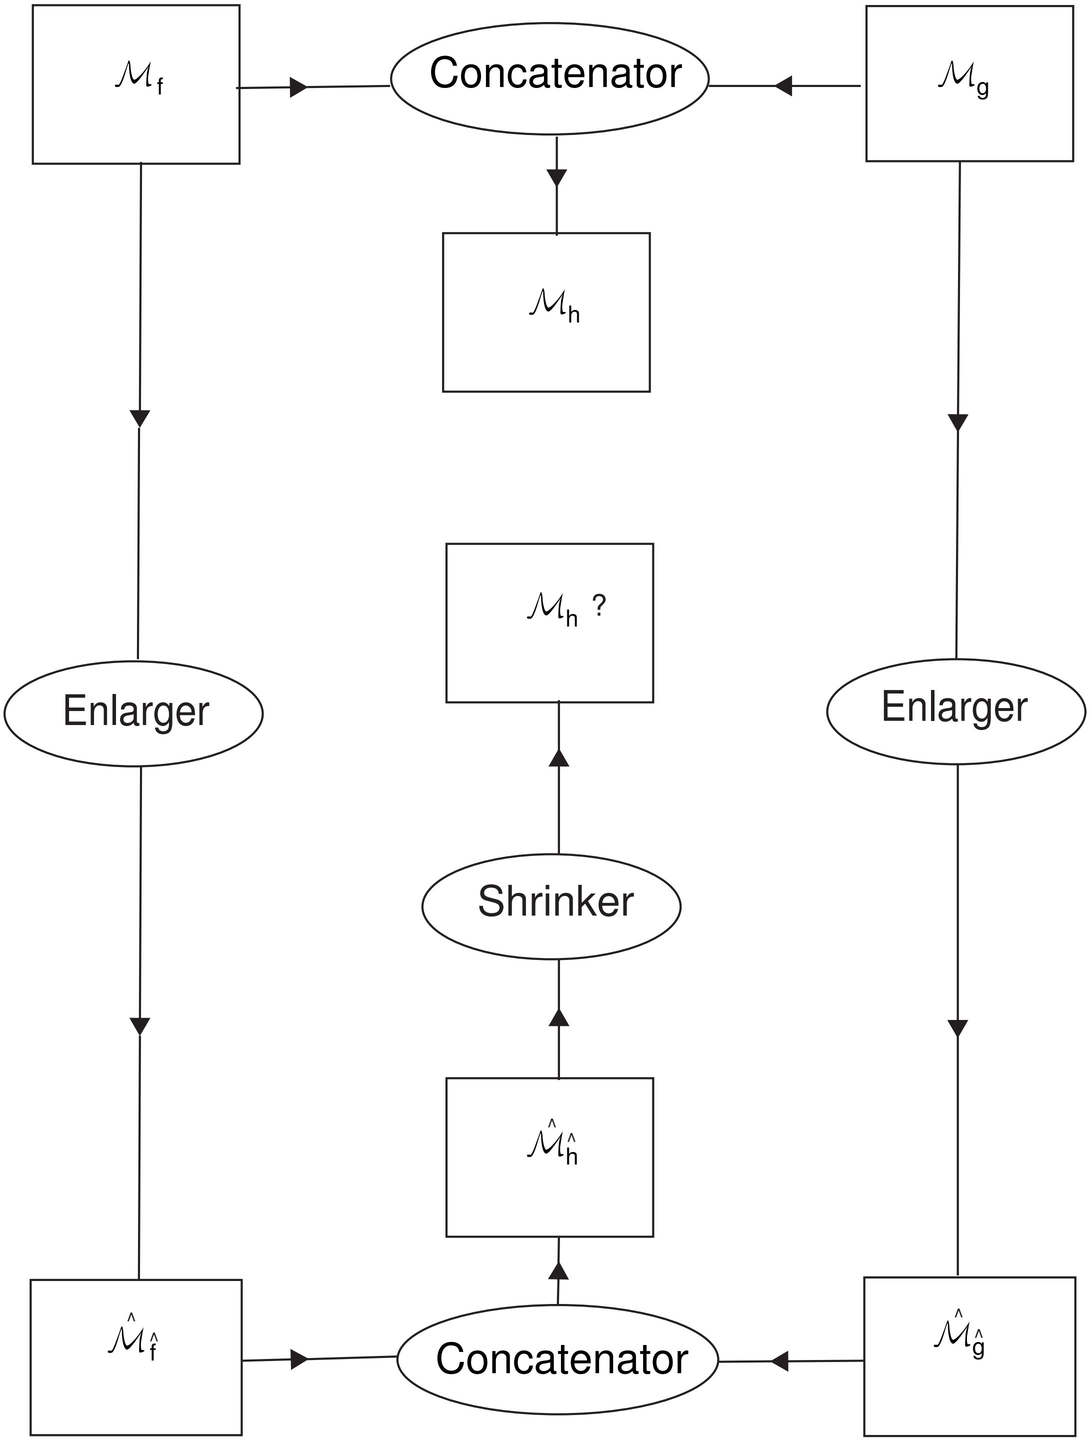
$$\delta^h = \delta^f + (R^f)^{-1}\delta^g, \tag{9.4.71}$$

from which it follows that

$$(z, J\delta^h) = (z, J\delta^f) + (z, J(R^f)^{-1}\delta^g). \tag{9.4.72}$$

But from the symplectic condition (3.1.2) there is the relation

$$J(R^f)^{-1} = (R^f)^T J. \tag{9.4.73}$$



$\mathcal{M}_{\mathrm{f}}$
Concatenator
$\mathcal{M}_{\mathrm{g}}$
$\mathcal{M}_{\mathrm{h}}$
$\mathcal{M}_{\mathrm{h}}$?
Enlarger
Enlarger
Shrinker
$\hat{\mathcal{M}}_{\hat{\mathrm{h}}}$
$\hat{\mathcal{M}}_{\hat{\mathrm{f}}}$
Concatenator
$\hat{\mathcal{M}}_{\hat{\mathrm{g}}}$

Figure 9.4.1: Concatenation of origin-preserving maps in an enlarged phase space to find equivalent results for maps, including translations, in the original phase space. The concatenator depicted at the top of the figure works with the usual phase space. When translations are taken into account, it involves the use of complicated feed-down formulae as illustrated in Section 9.3. The concatenator at the bottom of the figure works in an enlarged phase space, and employs the far-simpler concatenation rules for origin preserving maps.

Consequently, (4.72) can also be written in the form

$$(z, J\delta^h) = (z, J\delta^f) + (R^f z, J\delta^g). \tag{9.4.74}$$

Finally, use of (7.7.3) gives the result

$$h_1(z) = f_1(z) + g_1(R^f z) \tag{9.4.75}$$

or, equivalently,

$$h_1(z) = f_1(z) + \mathcal{R}_f g_1(z). \tag{9.4.76}$$

But (4.75), along with (4.69), are the rules (2.37) and (2.38) for concatenating inhomogeneous symplectic group maps. We conclude that, in the case of inhomogeneous symplectic group maps, the map $\mathcal{M}_h$ can indeed be deduced from $\hat{\mathcal{M}}_{\hat{h}}$.

9.4.3 Case of General Maps

Enlarging

We now turn to the general case $ISpM(2n, \mathbb{R})$ for maps $\mathcal{M}_f$ and $\mathcal{M}_g$ of the form (1.1) and (1.2). The enlargement process will be carried out as before to yield the maps $\hat{\mathcal{M}}_{\hat{f}}$ and $\hat{\mathcal{M}}_{\hat{g}}$. For example, the map $\hat{\mathcal{M}}_{\hat{f}}$ is given by

$$\hat{\mathcal{M}}_{\hat{f}} = \exp(:\hat{f}_1^2:)\check{\mathcal{R}}_{\hat{f}}\exp(:\hat{f}_3^3:)\exp(:\hat{f}_4^4:)\cdots \tag{9.4.77}$$

where $\hat{f}_1^2$ and $\check{\mathcal{R}}_{\hat{f}}$ are given by (4.48) and (4.50) as before, and

$$\hat{f}_m^m(\hat{z}) = f_m(z),\ m = 3, 4, \cdots . \tag{9.4.78}$$

Next form the product map

$$\hat{\mathcal{M}}_{\hat{h}} = \hat{\mathcal{M}}_{\hat{f}}\hat{\mathcal{M}}_{\hat{g}}. \tag{9.4.79}$$

Since $\hat{\mathcal{M}}_{\hat{h}}$ sends the origin into itself, it has a factorization of the form

$$\hat{\mathcal{M}}_{\hat{h}} = \hat{\mathcal{R}}_{\hat{h}}\hat{\mathcal{N}}_{\hat{h}}. \tag{9.4.80}$$

The linear map $\hat{\mathcal{R}}_{\hat{h}}$ will be described by a matrix $\hat{R}^{\hat{h}}$, and from the relation

$$\hat{\mathcal{R}}_{\hat{h}} = \hat{\mathcal{R}}_{\hat{f}}\hat{\mathcal{R}}_{\hat{g}} \tag{9.4.81}$$

we have the rule

$$\hat{R}^{\hat{h}} = \hat{R}^{\hat{g}}\hat{R}^{\hat{f}}. \tag{9.4.82}$$

The nonlinear map $\hat{\mathcal{N}}_{\hat{h}}$ will have a representation of the form

$$\hat{\mathcal{N}}_{\hat{h}} = \exp(:\hat{h}_3:)\exp(:\hat{h}_4:)\cdots \tag{9.4.83}$$

with the $\hat{h}_m$ given by the relations of the form (8.4.31) through (8.4.36) already found in Section 8.4. Our task now is to extract $\mathcal{M}_h$ from $\hat{\mathcal{M}}_{\hat{h}}$.

Let us first examine $\hat{\mathcal{R}}_{\hat{h}}$ and its associated matrix $\hat{R}^{\hat{h}}$. We know that $\hat{\mathcal{M}}_{\hat{h}}$ has the property (4.2) since by construction the maps $\hat{\mathcal{M}}_{\hat{f}}$ and $\hat{\mathcal{M}}_{\hat{g}}$ have this property, and such maps form a group. Consequently $\hat{\mathcal{R}}_{\hat{h}}$ satisfies (4.4). It follows, in analogy with (4.46) when written out for the full 8×8 case, that the matrix $\hat{R}^{\hat{h}}$ has the form

$$\hat{R}^{\hat{h}} = \left(\begin{array}{cccccccc} R^h_{11} & R^h_{12} & R^h_{13} & R^h_{14} & R^h_{15} & R^h_{16} & (R^h\delta^h)_1 & 0 \\ R^h_{21} & R^h_{22} & R^h_{23} & R^h_{24} & R^h_{25} & R^h_{26} & (R^h\delta^h)_2 & 0 \\ R^h_{31} & R^h_{32} & R^h_{33} & R^h_{34} & R^h_{35} & R^h_{36} & (R^h\delta^h)_3 & 0 \\ R^h_{41} & R^h_{42} & R^h_{43} & R^h_{44} & R^h_{45} & R^h_{46} & (R^h\delta^h)_4 & 0 \\ R^h_{51} & R^h_{52} & R^h_{53} & R^h_{54} & R^h_{55} & R^h_{56} & (R^h\delta^h)_5 & 0 \\ R^h_{61} & R^h_{62} & R^h_{63} & R^h_{64} & R^h_{65} & R^h_{66} & (R^h\delta^h)_6 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ \delta^h_2 & -\delta^h_1 & \delta^h_4 & -\delta^h_3 & \delta^h_6 & -\delta^h_5 & \hat{R}^{\hat{h}}_{87} & 1 \end{array} \right). \tag{9.4.84}$$

We can read off the entries in δ^h from the bottom row of (4.84), and from these entries construct $h_1(z)$. Specifically, if we write

$$h_1(z) = (z, (\delta^h)^*), \tag{9.4.85}$$

then we have the relation

$$[(\delta^h)^*]_b = (\hat{R}^{\hat{h}})_{8b} \text{ for } b \in [1, 6]. \tag{9.4.86}$$

Again see Section 7.7.

Next let $\check{\mathcal{R}}^{\hat{h}}$ be the symplectic map described by the matrix $\check{R}^{\hat{h}}$ with

$$\check{R}^{\hat{h}} = \begin{pmatrix} R^h & 0 \\ 0 & I \end{pmatrix}. \tag{9.4.87}$$

Here R^h is the 6×6 matrix obtained earlier, and I denotes the 2×2 identity matrix. It follows that $\hat{\mathcal{R}}_{\hat{h}}$ can be rewritten in the form

$$\hat{\mathcal{R}}_{\hat{h}} = \exp(\alpha^h_2 : q^2_{n+1} :) \exp(: q_{n+1} h_1 :) \check{\mathcal{R}}_{\hat{h}} \tag{9.4.88}$$

with $n = 3$. Here α^h_2 is given by the relation

$$\alpha^h_2 = R^h_{87}/2. \tag{9.4.89}$$

The quantity α^h_2 is not presently of direct interest to us, but if desired it can be computed from the entries in $\hat{R}^{\hat{f}}$ and $\hat{R}^{\hat{g}}$. See Exercise 4.10.

We next turn to the nonlinear part $\hat{\mathcal{N}}_{\hat{h}}$. We know from (4.5) that the $\hat{h}_m$ are independent of p_{n+1}. Therefore the $\hat{h}_m$ must have expansions of the form

$$\hat{h}_m(\hat{z}) = h^m_m(z) + (q_{n+1}) h^m_{m-1}(z) + \cdots + (q_{n+1})^m h^m_0(z). \tag{9.4.90}$$

Here the superscript m on the quantity h^m_ℓ indicates that the quantity is associated with $\hat{h}_m$, and the subscript ℓ indicates that the quantity is homogeneous of degree ℓ in the variables z. Let us explore the consequences of this expansion. In Section 9.3 we employed an expansion in powers of ϵ where ϵ was a measure of the smallness of the first-degree generators. See, for example, relations of the kind (3.10) through (3.14). From this perspective, the expansion (4.90) is an expansion in powers of q_{n+1} with q_{n+1} playing the role of ϵ. Compare also (3.1) and (4.48). (See also Exercise 4.11.) Moreover, the use of the standard concatenator for origin preserving maps in the enlarged phase space produces power series expansions in the quantity q_{n+1} automatically!

Shrinking by Concatenation

Equally pleasant is the fact that this concatenator can be used to construct a *shrinker*. Since the quantities $[(q_{n+1}^{m-\ell})h_\ell^m]$ form a basis for the (p_{n+1} independent) polynomials of degree m in the enlarged phase space, $\hat{\mathcal{N}}_{\hat{h}}$ must have a factorization of the form

$$\begin{aligned}\hat{\mathcal{N}}_{\hat{h}} = \quad & \exp(:\alpha_3 q_{n+1}^3:)\exp(:\alpha_4 q_{n+1}^4:)\exp(:\alpha_5 q_{n+1}^5:)\cdots\times\\ & \exp(:q_{n+1}^2\tilde{h}_1^3:)\exp(:q_{n+1}^3\tilde{h}_1^4:)\exp(:q_{n+1}^4\tilde{h}_1^5:)\cdots\times\\ & \exp(:q_{n+1}\tilde{h}_2^3:)\exp(:q_{n+1}^2\tilde{h}_2^4:)\exp(:q_{n+1}^3\tilde{h}_2^5:)\cdots\times\\ & \exp(:\tilde{h}_3^3:)\exp(:q_{n+1}\tilde{h}_3^4:)\exp(:q_{n+1}^2\tilde{h}_3^5:)\cdots\times\\ & \exp(:\tilde{h}_4^4:)\exp(:q_{n+1}\tilde{h}_4^5:)\exp(:q_{n+1}^2\tilde{h}_4^6:)\cdots\times\\ & \exp(:\tilde{h}_5^5:)\exp(:q_{n+1}\tilde{h}_5^6:)\exp(:q_{n+1}^2\tilde{h}_5^7:)\cdots,\end{aligned} \tag{9.4.91}$$

where the quantities $\tilde{h}_\ell^m$ are yet to be determined. In a moment we will see that the $\tilde{h}_\ell^m$ can be computed using the concatenator. But first we observe that (4.91) is a *single grade* factorization with q_{n+1} playing the role of ϵ. See the end of Section 9.3. We may therefore set $q_{n+1} = 1$ in (4.91) and (4.88) to obtain $\mathcal{M}_h$ from $\hat{\mathcal{M}}_{\hat{h}}$. So doing gives the result

$$\begin{aligned}\mathcal{M}_h = \quad & \exp(:h_1^2:)\mathcal{R}_h\exp(:\tilde{h}_1^3+\tilde{h}_1^4+\tilde{h}_1^5+\cdots)\times\\ & \exp(:\tilde{h}_2^3:)\exp(:\tilde{h}_2^4:)\exp(:\tilde{h}_2^5:)\cdots\times\\ & \exp(:\tilde{h}_3^3:)\exp(:\tilde{h}_3^4:)\exp(:\tilde{h}_3^5:)\cdots\times\\ & \exp(:\tilde{h}_4^4:)\exp(:\tilde{h}_4^5:)\exp(:\tilde{h}_4^6:)\cdots\times\\ & \exp(:\tilde{h}_5^5:)\exp(:\tilde{h}_5^6:)\exp(:\tilde{h}_5^7:)\cdots.\end{aligned} \tag{9.4.92}$$

Here $\mathcal{R}_h$ is a linear map whose associated matrix is R^h, and

$$h_1^2(z) = h_1(z). \tag{9.4.93}$$

The second two factors in (4.92) can be rearranged using the results of Section 9.2,

$$\mathcal{R}_h\exp(:\tilde{h}_1^3+\tilde{h}_1^4+\tilde{h}_1^5+\cdots) = \exp(:\check{h}_1:)\mathcal{R}_h \tag{9.4.94}$$

where

$$\check{h}_1 = \mathcal{R}_h(\tilde{h}_1^3+\tilde{h}_1^4+\tilde{h}_1^5+\cdots). \tag{9.4.95}$$

Consequently, $\mathcal{M}_h$ can also be written in the form

$$\begin{aligned}\mathcal{M}_h = \quad & \exp(:h_1^2 + \check{h}_1:) \times \\ & \mathcal{R}_h \exp(:\tilde{h}_2^3:)\exp(:\tilde{h}_2^4:)\exp(:\tilde{h}_2^5:)\cdots \times \\ & \exp(:\tilde{h}_3^3:)\exp(:\tilde{h}_3^4:)\exp(:\tilde{h}_3^5:)\cdots \times \\ & \exp(:\tilde{h}_4^4:)\exp(:\tilde{h}_4^5:)\exp(:\tilde{h}_4^6:)\cdots \times \\ & \exp(:\tilde{h}_5^5:)\exp(:\tilde{h}_5^6:)\exp(:\tilde{h}_5^7:)\cdots . \end{aligned} \tag{9.4.96}$$

Finally, the factors appearing in each of the lines in (4.96) beyond the first line may be combined using the concatenator for origin preserving maps in the original $2n$-dimensional phase space to obtain $\mathcal{M}_h$ in the final form (1.6). We have constructed a shrinker based on the assumption that the terms $\tilde{h}_\ell^m$ appearing in (4.91) can be found.

Illustration for the quotient algebra L^0/L^3

What remains to be shown is how the $\tilde{h}_\ell^m$ can be computed from the $\hat{h}_m$ in (4.83) and (4.90) using the concatenator for origin preserving maps in the enlarged $(2n+2)$-dimensional phase space. Since the procedure requires several steps, it is best illustrated first for a relatively simple example. Suppose we are working in the quotient algebra L^0/L^3. Then $\hat{\mathcal{N}}_{\hat{h}}$ has the form

$$\begin{aligned}\hat{\mathcal{N}}_{\hat{h}} = \quad & \exp(:h_3^3 + q_{n+1}h_2^3 + q_{n+1}^2 h_1^3 + q_{n+1}^3 h_0^3:) \times \\ & \exp(:h_4^4 + q_{n+1}h_3^4 + q_{n+1}^2 h_2^4 + q_{n+1}^3 h_1^4 + q_{n+1}^4 h_0^4:). \end{aligned} \tag{9.4.97}$$

Since the generators have *no* p_{n+1} dependence, they are in involution with powers of q_{n+1}, and these powers may be removed to the far right so that we may also write

$$\begin{aligned}\hat{\mathcal{N}}_{\hat{h}} = \quad & \exp(:h_3^3 + q_{n+1}h_2^3 + q_{n+1}^2 h_1^3:) \times \\ & \exp(:h_4^4 + q_{n+1}h_3^4 + q_{n+1}^2 h_2^4 + q_{n+1}^3 h_1^4:) \times \\ & \exp(:q_{n+1}^3 h_0^3:)\exp(:q_{n+1}^4 h_0^4:). \end{aligned} \tag{9.4.98}$$

Now we are ready to begin.

Isolation of linear in z generators

The *linear* in z generator $q_{n+1}^2 h_1^3$, which produces a translation in the $2n$-dimensional phase space, may be isolated by writing the identity

$$\hat{\mathcal{N}}_{\hat{h}} = \exp(:q_{n+1}^2 h_1^3:)[\exp(-:q_{n+1}^2 h_1^3:)\hat{\mathcal{N}}_{\hat{h}}] \tag{9.4.99}$$

and making the definition

$$^1\hat{\mathcal{N}}_{\hat{h}} = [\exp(-:q_{n+1}^2 h_1^3:)\hat{\mathcal{N}}_{\hat{h}}]. \tag{9.4.100}$$

Upon manipulating exponents using the BCH theorem we find that $^1\hat{\mathcal{N}}_{\hat{h}}$ has the form

$$\begin{aligned}{}^1\hat{\mathcal{N}}_{\hat{h}} = \quad & \exp(:{}^1h_3^3 + q_{n+1}\,{}^1h_2^3:) \times \\ & \exp(:{}^1h_4^4 + q_{n+1}\,{}^1h_3^4 + q_{n+1}^2\,{}^1h_2^4 + q_{n+1}^3\,{}^1h_1^4:) \times \\ & \exp(:q_{n+1}^3\,{}^1h_0^3:)\exp(:q_{n+1}^4\,{}^1h_0^4:), \end{aligned} \tag{9.4.101}$$

and we conclude that

$$\tilde{h}_1^3 = h_1^3. \tag{9.4.102}$$

Here the superscript 1 in ${}^1\hat{\mathcal{N}_{\hat{h}}}$ indicates that one isolation step has been taken; and the superscript 1 in ${}^1h_\ell^m$ indicates that one isolation step has been taken and that the ${}^1h_\ell^m$ may differ from the previous h_ℓ^m.

Next the linear in z generator $q_{n+1}^3\ {}^1h_1^4$, which which also produces a translation in the $2n$-dimensional phase space, may be isolated by writing the identity

$${}^1\hat{\mathcal{N}_{\hat{h}}} = \exp(:q_{n+1}^3\ {}^1h_1^4:)[\exp(-:q_{n+1}^3\ {}^1h_1^4:)\ {}^1\hat{\mathcal{N}_{\hat{h}}}] \tag{9.4.103}$$

and making the definition

$${}^2\hat{\mathcal{N}_{\hat{h}}} = [\exp(-:q_{n+1}^3\ {}^1h_1^4:)\ {}^1\hat{\mathcal{N}_{\hat{h}}}]. \tag{9.4.104}$$

Again, upon manipulating exponents using the BCH theorem, we find that ${}^2\hat{\mathcal{N}_{\hat{h}}}$ has the form

$$\begin{aligned}{}^2\hat{\mathcal{N}_{\hat{h}}} = \quad & \exp(:{}^2h_3^3 + q_{n+1}\ {}^2h_2^3:) \times \\ & \exp(:{}^2h_4^4 + q_{n+1}\ {}^2h_3^4 + q_{n+1}^2\ {}^2h_2^4:) \times \\ & \exp(:q_{n+1}^3\ {}^2h_0^3:)\exp(:q_{n+1}^4\ {}^2h_0^4:),\end{aligned} \tag{9.4.105}$$

and we conclude that

$$\tilde{h}_1^4 = {}^1h_1^4. \tag{9.4.106}$$

Here the superscript 2 in ${}^2\hat{\mathcal{N}_{\hat{h}}}$ indicates that a second isolation step has been taken; and the superscript 2 in ${}^2h_\ell^m$ indicates that a second isolation step has been taken and that the ${}^2h_\ell^m$ may differ from the previous ${}^1h_\ell^m$.

Inspection of (4.105) indicates that all linear in z generators have now been isolated away. We are ready to begin isolating the *quadratic* in z generators.

Isolation of quadratic in z generators

The quadratic in z generator $q_{n+1}\ {}^2h_2^3$, which produces a linear transformation in the $2n$-dimensional phase space, may be isolated by writing the identity

$${}^2\hat{\mathcal{N}_{\hat{h}}} = \exp(:q_{n+1}\ {}^2h_2^3:)[\exp(-:q_{n+1}\ {}^2h_2^3:)\ {}^2\hat{\mathcal{N}_{\hat{h}}}] \tag{9.4.107}$$

and making the definition

$${}^3\hat{\mathcal{N}_{\hat{h}}} = [\exp(-:q_{n+1}\ {}^2h_2^3:)\ {}^2\hat{\mathcal{N}_{\hat{h}}}]. \tag{9.4.108}$$

Now use of the BCH theorem shows that ${}^3\hat{\mathcal{N}_{\hat{h}}}$ has the form

$$\begin{aligned}{}^3\hat{\mathcal{N}_{\hat{h}}} = \quad & \exp(:{}^3h_3^3:) \times \\ & \exp(:{}^3h_4^4 + q_{n+1}\ {}^3h_3^4 + q_{n+1}^2\ {}^3h_2^4:) \times \\ & \exp(:q_{n+1}^3\ {}^3h_0^3:)\exp(:q_{n+1}^4\ {}^3h_0^4:),\end{aligned} \tag{9.4.109}$$

and we conclude that

$$\tilde{h}_2^3 = {}^2h_2^3. \tag{9.4.110}$$

Next the quadratic in z generator $q_{n+1}^2\ {}^3h_2^4$, which also produces a linear transformation in the $2n$-dimensional phase space, may be isolated by writing the identity

$$ {}^3\hat{\mathcal{N}}_{\hat{h}} = \exp(:q_{n+1}^2\ {}^3h_2^4:)[\exp(-:q_{n+1}^2\ {}^3h_2^4:)\ {}^3\hat{\mathcal{N}}_{\hat{h}}] \tag{9.4.111}$$

and making the definition

$$ {}^4\hat{\mathcal{N}}_{\hat{h}} = [\exp(-:q_{n+1}^2\ {}^3h_2^4:)\ {}^3\hat{\mathcal{N}}_{\hat{h}}]. \tag{9.4.112}$$

Now use of the BCH theorem shows that ${}^4\hat{\mathcal{N}}_{\hat{h}}$ has the form

$$\begin{aligned} {}^4\hat{\mathcal{N}}_{\hat{h}} = \quad & \exp(:{}^4h_3^3:)\times \\ & \exp(:{}^4h_4^4 + q_{n+1}\ {}^4h_3^4:)\times \\ & \exp(:q_{n+1}^3\ {}^4h_0^3:)\exp(:q_{n+1}^4\ {}^4h_0^4:), \end{aligned} \tag{9.4.113}$$

and we conclude that

$$\tilde{h}_2^4 = {}^3h_2^4. \tag{9.4.114}$$

Inspection of (4.113) indicates that all quadratic in z generators have now been isolated away. We are ready to begin isolating the *cubic* in z generators.

Isolation of cubic in z generators

The cubic in z generator ${}^4h_3^3$, which produces a quadratic plus higher-order transformation in the $2n$-dimensional phase space, may be isolated by writing the identity

$$ {}^4\hat{\mathcal{N}}_{\hat{h}} = \exp(:{}^4h_3^3:)[\exp(-:{}^4h_3^3:)\ {}^4\hat{\mathcal{N}}_{\hat{h}}] \tag{9.4.115}$$

and making the definition

$$ {}^5\hat{\mathcal{N}}_{\hat{h}} = [\exp(-:{}^4h_3^3:)\ {}^4\hat{\mathcal{N}}_{\hat{h}}]. \tag{9.4.116}$$

Now use of the BCH theorem shows that ${}^5\hat{\mathcal{N}}_{\hat{h}}$ has the form

$$\begin{aligned} {}^5\hat{\mathcal{N}}_{\hat{h}} = \quad & \exp(:{}^5h_4^4 + q_{n+1}\ {}^5h_3^4:)\times \\ & \exp(:q_{n+1}^3\ {}^5h_0^3:)\exp(:q_{n+1}^4\ {}^5h_0^4:), \end{aligned} \tag{9.4.117}$$

and we conclude that

$$\tilde{h}_3^3 = {}^4h_3^3. \tag{9.4.118}$$

Next the cubic in z generator $q_{n+1}\ {}^5h_3^4$, which also produces a quadratic plus higher-order transformation in the $2n$-dimensional phase space, may be isolated by writing the identity

$$ {}^5\hat{\mathcal{N}}_{\hat{h}} = \exp(:q_{n+1}\ {}^5h_3^4:)[\exp(-:q_{n+1}\ {}^5h_3^4:)\ {}^5\hat{\mathcal{N}}_{\hat{h}}] \tag{9.4.119}$$

and making the definition

$$ {}^6\hat{\mathcal{N}}_{\hat{h}} = [\exp(-:q_{n+1}\ {}^5h_3^4:)\ {}^5\hat{\mathcal{N}}_{\hat{h}}]. \tag{9.4.120}$$

Now use of the BCH theorem shows that ${}^6\hat{\mathcal{N}}_{\hat{h}}$ has the form

$$\begin{aligned} {}^6\hat{\mathcal{N}}_{\hat{h}} = \quad & \exp(:{}^6h_4^4:)\times \\ & \exp(:q_{n+1}^3\,{}^6h_0^3:)\exp(:q_{n+1}^4\,{}^6h_0^4:), \end{aligned} \tag{9.4.121}$$

and we conclude that

$$\tilde{h}_3^4 = {}^5h_3^4. \tag{9.4.122}$$

Inspection of (4.121) indicates that all cubic in z generators have now been isolated away. We are ready to begin isolating the *quartic* in z generators.

Isolation of quartic in z generators

The remaining quartic in z generator ${}^6h_4^4$, which produces a cubic plus higher-order transformation in the $2n$-dimensional phase space, may be isolated by writing the identity

$${}^6\hat{\mathcal{N}}_{\hat{h}} = \exp(:{}^6h_4^4:)[\exp(-:{}^6h_4^4:)\,{}^6\hat{\mathcal{N}}_{\hat{h}}] \tag{9.4.123}$$

and making the definition

$${}^7\hat{\mathcal{N}}_{\hat{h}} = [\exp(-:{}^6h_4^4:)\,{}^6\hat{\mathcal{N}}_{\hat{h}}]. \tag{9.4.124}$$

Now use of the BCH theorem shows that ${}^7\hat{\mathcal{N}}_{\hat{h}}$ has the form

$${}^7\hat{\mathcal{N}}_{\hat{h}} = \exp(:q_{n+1}^3\,{}^7h_0^3:)\exp(:q_{n+1}^4\,{}^7h_0^4:), \tag{9.4.125}$$

and we conclude that

$$\tilde{h}_4^4 = {}^6h_4^4. \tag{9.4.126}$$

Overview

Inspection of (4.125) indicates that, in the case of L^0/L^3, we have achieved our goal. Namely, by repeated isolating and concatenating, we eventually achieved the factorization (4.91). All z-dependent generators have been isolated away, and all that remains are generators that depend solely on q_{n+1}. These remaining generators have no effect on the the $2n$-dimensional phase space variables z, and therefore ${}^7\hat{\mathcal{N}}_{\hat{h}}$ acts as the identity map $\mathcal{I}$ on the z phase space.

We note that while these steps are somewhat difficult to characterize analytically (which is to be expected because the results of Section 9.3 were complicated), they are easy to implement numerically.

Is there a pattern in what we have done? Review of the steps we have taken shows that we have extracted the $\tilde{h}_\ell^m$ in a particular order. Let r be a *running* index. Table 4.1 below shows the order in which we have extracted the $\tilde{h}_\ell^m$. Here we have defined the difference d by the relation

$$d = m - \ell \tag{9.4.127}$$

so that q_{n+1} and $\tilde{h}_\ell^m$ occur in the combination $q_{n+1}^d\,\tilde{h}_\ell^m$.

Let us make the definition

$${}^0\hat{\mathcal{N}}_{\hat{h}} = \hat{\mathcal{N}}_{\hat{h}}. \tag{9.4.128}$$

Table 9.4.1: Order in which the $\tilde{h}_\ell^m$ are to be extracted for the case L^0/L^3.

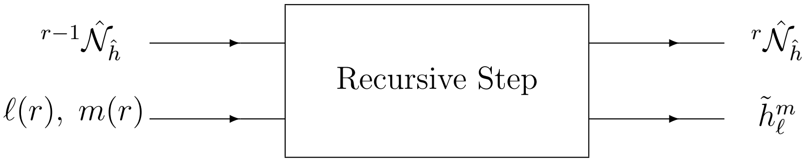
r	ℓ	m	d
1	1	3	2
2	1	4	3
3	2	3	1
4	2	4	2
5	3	3	0
6	3	4	1
7	4	4	0

Then we may view the whole process as being recursive. At any given stage a map ${}^{r-1}\hat{\mathcal{N}}_{\hat{h}}$ and a pair of indices $\ell(r)$ and $m(r)$ are provided as input, and a map ${}^{r}\hat{\mathcal{N}}_{\hat{h}}$ and polynomial $\tilde{h}_\ell^m$ are produced as output. See Figure 4.2. The polynomial $\tilde{h}_\ell^m$ is determined by examination of ${}^{r-1}\hat{\mathcal{N}}_{\hat{h}}$ and given by the rule

$$\tilde{h}_\ell^m = {}^{r-1}h_\ell^m. \tag{9.4.129}$$

The map ${}^{r}\hat{\mathcal{N}}_{\hat{h}}$ is given by carrying out the concatenation

$${}^{r}\hat{\mathcal{N}}_{\hat{h}} = \exp(- : q_{n+1}^d \tilde{h}_\ell^m :) \times {}^{r-1}\hat{\mathcal{N}}_{\hat{h}}. \tag{9.4.130}$$



${}^{r-1}\hat{\mathcal{N}}_{\hat{h}}$
$\ell(r),\ m(r)$
Recursive Step
${}^{r}\hat{\mathcal{N}}_{\hat{h}}$
$\tilde{h}_\ell^m$

Figure 9.4.2: A recursive step that takes a map ${}^{r-1}\hat{\mathcal{N}}_{\hat{h}}$ and a pair of indices $\ell(r)$ and $m(r)$ as input, and produces a map ${}^{r}\hat{\mathcal{N}}_{\hat{h}}$ and polynomial $\tilde{h}_\ell^m$ as output.

Shrinking in the General Case

It is now a simple matter to generalize to higher-order cases. For example, Table 4.2 shows the extraction order to be used when working with maps through 7th order, the order that is available using the concatenation rules provided by (8.4.31) through (8.4.36).

Finally, we note that the procedure is self checking. For the final value of r the corresponding map ${}^{r}\hat{\mathcal{N}}_{\hat{h}}$ will have the property that all its generators have no z dependence; they can depend only on q_{n+1}. We have already seen this for the map ${}^{7}\hat{\mathcal{N}}_{\hat{h}}$ when working with third-order maps. See (4.125). The same will be true of the map ${}^{33}\hat{\mathcal{N}}_{\hat{h}}$ when working with maps through 7th order. Conversely, if all the factors in (4.91) are concatenated together, the result must be the original map $\hat{\mathcal{N}}_{\hat{h}}$.

Table 9.4.2: Order in which the $\tilde{h}_{\ell}^{m}$ are to be extracted for the case L^0/L^7.

r	ℓ	m	d
1	1	3	2
2	1	4	3
3	1	5	4
4	1	6	5
5	1	7	6
6	1	8	7
7	2	3	1
8	2	4	2

Exercises

9.4.1. Verify that maps $\hat{\mathcal{M}}$ satisfying (4.2) form a group.

9.4.2. Prove (4.5) in detail.

9.4.3. Verify that the symplectic condition requires the relations (4.16).

9.4.4. Verify (4.25) through (4.30).

9.4.5. Verify (4.38) and (4.39).

9.4.6. Verify (4.41) through (4.43).

9.4.7. Verify (4.44) through (4.46).

9.4.8. Verify (4.53) through (4.62).

9.4.9. Verify (4.65).

9.4.10. Consider two *linear* symplectic maps $\hat{\mathcal{M}}_{\hat{f}}$ and $\hat{\mathcal{M}}_{\hat{g}}$ of the factored form

$$\hat{\mathcal{M}}_{\hat{f}} = \exp(:\alpha_2^{\hat{f}} q_{n+1}^2:)\exp(:q_{n+1}f_1(z):)\check{\mathcal{R}}_{\hat{f}}, \tag{9.4.131}$$

$$\hat{\mathcal{M}}_{\hat{g}} = \exp(:\alpha_2^{\hat{g}} q_{n+1}^2:)\exp(:q_{n+1}g_1(z):)\check{\mathcal{R}}_{\hat{g}}, \tag{9.4.132}$$

where $\check{\mathcal{R}}_{\hat{f}}$ and $\check{\mathcal{R}}_{\hat{g}}$ leave the q_{n+1}, p_{n+1} subspace invariant,

$$\check{\mathcal{R}}_{\hat{f}} q_{n+1} = q_{n+1}, \text{ etc.}, \tag{9.4.133}$$

$$\check{\mathcal{R}}_{\hat{f}} p_{n+1} = p_{n+1}, \text{ etc.} \tag{9.4.134}$$

Show that (4.106) and (4.107) plus the symplectic condition require that the associated matrices $\check{R}^{\hat{f}}$ etc. be of the general form (4.50). Let $\hat{\mathcal{M}}_{\hat{h}}$ be the product of $\hat{\mathcal{M}}_{\hat{f}}$ and $\hat{\mathcal{M}}_{\hat{g}}$,

$$\begin{aligned}\hat{\mathcal{M}}_{\hat{h}} &= \hat{\mathcal{M}}_{\hat{f}}\hat{\mathcal{M}}_{\hat{g}} = \exp(:\alpha_2^{\hat{f}} q_{n+1}^2:)\exp(:q_{n+1}f_1(z):)\check{\mathcal{R}}_{\hat{f}} \times \\ &\quad \exp(:\alpha_2^{\hat{g}} q_{n+1}^2:)\exp(:q_{n+1}g_1(z):)\check{\mathcal{R}}_{\hat{g}}.\end{aligned} \tag{9.4.135}$$

Show, by manipulating the various factors involved, that $\hat{\mathcal{M}}_{\hat{h}}$ can be re-expressed in the factored form

$$\begin{aligned}\hat{\mathcal{M}}_{\hat{h}} &= \exp\{: q_{n+1}^2 : (\alpha_2^{\hat{f}} + \alpha_2^{\hat{g}} + [f_1(z), \check{\mathcal{R}}_{\hat{f}} g_1(z)]/2) :\} \times \\ &\quad \exp\{: q_{n+1}(f_1(z) + \check{\mathcal{R}}_{\hat{f}} g_1(z)) :\}\check{\mathcal{R}}_{\hat{f}}\check{\mathcal{R}}_{\hat{g}}.\end{aligned} \tag{9.4.136}$$

Thus, if we write $\hat{\mathcal{M}}_{\hat{h}}$ as

$$\hat{\mathcal{M}}_{\hat{h}} = \exp(:\alpha_2^{\hat{h}} q_{n+1}^2:)\exp(:q_{n+1}h_1(z):)\check{\mathcal{R}}_{\hat{h}}, \tag{9.4.137}$$

there are the relations

$$\alpha_2^{\hat{h}} = \alpha_2^{\hat{f}} + \alpha_2^{\hat{g}} + [f_1(z), \check{\mathcal{R}}_{\hat{f}} g_1(z)]/2, \tag{9.4.138}$$

$$h_1(z) = f_1(z) + \check{\mathcal{R}}_{\hat{f}} g_1(z), \tag{9.4.139}$$

$$\check{\mathcal{R}}_{\hat{h}} = \check{\mathcal{R}}_{\hat{f}}\check{\mathcal{R}}_{\hat{g}}. \tag{9.4.140}$$

Carry out the indicated multiplication in (4.68) and verify that your results are equivalent to those found above.

9.4.11. Problem about the relation between the inhomogeneous symplectic map Lie algebra ${}^{\epsilon}L^0/{}^{\epsilon}L^{\ell}$ in $2n$ dimensions and the subgroup of the homogeneous symplectic map Lie algebra L^0/L^{ℓ} in $2n+2$ dimensions produced by all p_{n+1} independent generators.

9.4.12. Verify that a factorization of the form (4.91) is possible.

9.4.13. Verify the relations (4.93) through (4.96).

9.4.14. Verify that $\hat{\mathcal{N}}_{\hat{h}}$ has the form (4.97) when one works in the quotient algebra L^0/L^3.

9.4.15. Verify (4.98) through (4.103).

9.4.16. Verify that extracting the $\tilde{h}_{\ell}^{m}$ in the order given by Table 4.1 or 4.2 never results, during the extraction process, in the "reappearance" in the subsequent maps ${}^{r}\hat{\mathcal{N}}_{\hat{h}}$ of any of the previously removed terms.

9.5 Map Inversion and Reverse and Mixed Factorizations

Much of the discussion of this section is analogous to that of Section 8.5. Suppose, as in (1.1), that the map $\mathcal{M}_f$ is written in the standard factored product form

$$\mathcal{M}_f = \exp(:f_1:)\mathcal{R}_f \exp(:f_3:)\exp(:f_4:)\cdots\,. \tag{9.5.1}$$

Here, as in Section 8.5, $\mathcal{R}_f$ denotes the map

$$\mathcal{R}_f = \exp(:f_2^c:)\exp(:f_2^a:) \tag{9.5.2}$$

with the associated matrix R^f given by the relation

$$R^f = \exp(JS^a)\exp(JS^c). \tag{9.5.3}$$

It follows immediately from (5.1) that the *inverse* of $\mathcal{M}_f$ has the representation

$$(\mathcal{M}_f)^{-1} = \cdots \exp(-:f_4:)\exp(-:f_3:)(\mathcal{R}_f)^{-1}\exp(-:f_1:). \tag{9.5.4}$$

As before we observe that (5.4) gives a representation for the inverse of $\mathcal{M}_f$ in the form of a reverse factorization, and that we would also like to have a representation in the standard forward factorization

$$(\mathcal{M}_f)^{-1} = \exp(:h_1:)\mathcal{R}_h \exp(:h_3:)\exp(:h_4:)\cdots\,. \tag{9.5.5}$$

See Section 7.8. This is easily accomplished with the aid of the concatenation formulas of the previous section. We simply write (5.4) and (5.5) in the form

$$\begin{aligned}&\cdots[\exp(-:f_4:)][\exp(-:f_3:)][(\mathcal{R}_f)^{-1}][\exp(-:f_1:)] =\\ &\exp(:h_1:)\mathcal{R}_h \exp(:h_3:)\exp(:h_4:)\cdots\end{aligned} \tag{9.5.6}$$

where we have used square brackets to indicate that the various maps are to be concatenated together. Note that in this case (8.5.7) no longer holds because of the feed-down terms produced by moving the f_1 factor in (5.6) to the left.

The relation (5.5) also provides a procedure for reverse factorizing a map. Suppose we wish to represent $\mathcal{M}_f$ in reverse factorized form. That is, we wish to find generators g_m such that

$$\begin{aligned}\mathcal{M}_f = \quad &\exp(:f_1:)\mathcal{R}_f \exp(:f_3:)\exp(:f_4:)\cdots =\\ \cdots \quad &\exp(:g_4:)\exp(:g_3:)\mathcal{R}_g \exp(:g_1:).\end{aligned} \tag{9.5.7}$$

Simply take the inverse of both sides of (5.7) and use (5.5) to get the relation

$$\begin{aligned}&\exp(-:g_1:)(\mathcal{R}_g)^{-1}\exp(-:g_3:)\exp(-:g_4:)\cdots =\\ &\exp(:h_1:)\mathcal{R}_h \exp(:h_3:)\exp(:h_4:)\cdots\,.\end{aligned} \tag{9.5.8}$$

From (5.8) we find the desired results

$$\mathcal{R}_g = (\mathcal{R}_h)^{-1}, \tag{9.5.9}$$

$$g_m = -h_m. \tag{9.5.10}$$

We close this section with a remark about mixed factorizations. See Section 7.8. Suppose, for example, we desire a mixed factorization for $\mathcal{M}_f$ of the form

$$\mathcal{M}_f = \mathcal{R}_{f'} \exp(: f_3' :) \exp(: f_4' :) \cdots \exp(: f_1'). \tag{9.5.11}$$

That is, we wish to move the f_1 term in (5.1) to the far right, but keep the remaining factors in ascending order. Comparison of (5.7) and (5.11) gives the result

$$f_1' = g_1, \tag{9.5.12}$$

and the relation

$$\mathcal{R}_{f'} \exp(: f_3' :) \exp(: f_4' :) \cdots = \cdots \exp(: g_4 :) \exp(: g_3 :)\mathcal{R}_g. \tag{9.5.13}$$

The remaining factors $\mathcal{R}_{f\prime}$, $: f_3' :$, $: f_4' : \cdots$ can be gotten by applying the concatenation formulas of Section 8.4 to the right side of (5.13). That is, we write (5.13) in the form

$$\mathcal{R}_{f'} \exp(: f_3' :) \exp(: f_4' :) = \cdots [\exp(: g_4 :)][\exp(: g_3 :)][\mathcal{R}_g]. \tag{9.5.14}$$

where the square brackets indicate that the various maps are to be concatenated together.

There is a relation between f_1 and f_1' that could have been examined in the previous section, or even in Section 7.7, but can just as conveniently be discussed here. See Exercises 5.1 and 5.2. Let us write (5.1) and (5.11) in the forms

$$\mathcal{M}_f = \exp(: f_1 :)\mathcal{S}_f, \tag{9.5.15}$$

$$\mathcal{M}_f = \mathcal{S}_{f'} \exp(: f_1' :), \tag{9.5.16}$$

with

$$\mathcal{S}_f = \mathcal{R}_f \exp(: f_3 :) \exp(: f_4 :) \cdots , \tag{9.5.17}$$

$$\mathcal{S}_{f'} = \mathcal{R}_{f'} \exp(: f_3' :) \exp(: f_4' :) \cdots . \tag{9.5.18}$$

Following Section 7.7, let us also write f_1 and f_1' in the forms

$$f_1(z) = -(\delta, Jz), \tag{9.5.19}$$

$$f_1'(z) = -(\delta', Jz). \tag{9.5.20}$$

Then we have the relations

$$\delta_a' = \mathcal{S}_f z_a\big|_{z=\delta}, \tag{9.5.21}$$

$$\delta_a = (\mathcal{S}_f)^{-1} z_a\big|_{z=\delta'}. \tag{9.5.22}$$

To see the truth of (5.21) and (5.22), apply $\mathcal{M}_f$ in both its representations (5.15) and (5.16) to the origin. Consider first the representation (5.16). We know that by construction, see (5.18), the map $\mathcal{S}_{f'}$ sends the origin into itself. Therefore, since maps act in the order in which they occur when read from left to right (see Section 8.3), the first factor in (5.16) acts on the origin and leaves it in peace. Also, from Section 7.7, we know that $\exp(:f_1':)$ sends the origin into δ'. Consequently, we find the result

$$\mathcal{M}_f z_a|_{z=0} = \delta'_a. \tag{9.5.23}$$

Consider next the representation (5.15). The first factor, $\exp(:f_1:)$, sends the origin into δ. Subsequently $\mathcal{S}_f$ acts on δ to give the net result

$$\mathcal{M}_f z_a|_{z=0} = \mathcal{S}_f z_a|_{z=\delta}\,. \tag{9.5.24}$$

Upon comparing (5.23) and (5.24) we see that (5.21) and (5.22) are indeed correct. For another set of similar relations, see Exercise 5.3.

Exercises

9.5.1. Derive (5.21) starting with (7.7.13) and (7.7.23).

9.5.2. Consider a 2-dimensional phase space and suppose that $\mathcal{S}_{f'}$ has the simple form

$$\mathcal{S}_{f'} = \exp(:q^4:). \tag{9.5.25}$$

Working within the quotient group generated by the Lie algebra L^0/L^3, use (3.18) and (3.22) to verify (5.21).

9.5.3. Verify the relations

$$\mathcal{M}_f z_a\,|_{z=-\delta} = 0\ , \tag{9.5.26}$$

$$(\mathcal{M}_f)^{-1} z_a\,|_{z=0} = -\delta_a\ . \tag{9.5.27}$$

Derive the relations

$$-\delta'_a = \mathcal{S}_{f'} z_a|_{z=-\delta}\,, \tag{9.5.28}$$

$$-\,\delta_a = (\mathcal{S}_{f'})^{-1}\, z_a\big|_{z=-\delta'}\,. \tag{9.5.29}$$

Hint: Apply $\mathcal{M}_f$ as given by (5.15) and (5.16) to the phase-space point $(-\delta)$.

9.6 Taylor and Hybrid Taylor-Lie Concatenation and Inversion

This section extends the results of Section 8.6 to the case where the map to be treated may have constant terms. Again all the possibilities illustrated in Figure 8.6.1 may arise, and we will discuss those of greatest interest.

Suppose, as described in the beginning of Section 8.6, that both the maps $\mathcal{M}_1$ and $\mathcal{M}_2$ are in Taylor form, and we also desire to represent their product in Taylor form. We consider first the best of all possible circumstances. In that circumstance $\mathcal{M}_1$ sends the phase-space point z^0 to the intermediate point $\bar{z}^0$,

$$\mathcal{M}_1 : z^0 \rightarrow \bar{z}^0, \tag{9.6.1}$$

and we assume that $\mathcal{M}_1$ has a known Taylor expansion about z^0. Also, $\mathcal{M}_2$ sends the intermediate point $\bar{z}^0$ to the final point $\bar{\bar{z}}^0$,

$$\mathcal{M}_2 : \bar{z}^0 \rightarrow \bar{\bar{z}}^0, \tag{9.6.2}$$

and we assume that $\mathcal{M}_2$ has a known Taylor expansion about $\bar{z}^0$. What we desire is a Taylor expansion about the point z^0 for the product map $\mathcal{M}_3$ that sends z^0 immediately to $\bar{\bar{z}}^0$,

$$\mathcal{M}_3 : z^0 \rightarrow \bar{\bar{z}}^0. \tag{9.6.3}$$

This desire is easily met. Introduce the deviation variables ζ_a by writing

$$z_a = z_a^0 + \zeta_a. \tag{9.6.4}$$

Then, by assumption, $\mathcal{M}_1$ has a known truncated Taylor expansion of the form

$$\bar{z}_a = \bar{z}_a(z) = \bar{z}_a^0 + \sum_{m=1}^{D} g_a^1(m;\zeta). \tag{9.6.5}$$

Introduce as well the deviation variables $\bar{\zeta}_a$ by writing

$$\bar{z}_a = \bar{z}_a^0 + \bar{\zeta}_a. \tag{9.6.6}$$

Then $\mathcal{M}_2$ is assumed to have the known truncated Taylor expansion

$$\bar{\bar{z}}_a = \bar{\bar{z}}_a\,(\bar{z}) = \bar{\bar{z}}_a^0 + \sum_{m'=1}^{D} g_a^2(m';\bar{\zeta}). \tag{9.6.7}$$

Now use (6.5) and (6.6) to write the relation

$$\bar{\zeta}_a = \bar{\zeta}_a(\zeta) = \sum_{m=1}^{D} g_a^1(m;\zeta). \tag{9.6.8}$$

Also introduce the deviation variables $\overline{\overline{\zeta}}_a$, defined by

$$\overline{\overline{z}}_a = \overline{\overline{z}}^0_a + \overline{\overline{\zeta}}_a, \tag{9.6.9}$$

to rewrite (6.7) in the form

$$\overline{\overline{\zeta}}_a = \overline{\overline{\zeta}}_a (\overline{\zeta}) = \sum_{m'=1}^{D} g^2_a(m';\overline{\zeta}). \tag{9.6.10}$$

Then $\mathcal{M}_3$ has the expansion

$$\overline{\overline{z}}_a = \overline{\overline{z}}_a (z) = \overline{\overline{z}}^0_a + \overline{\overline{\zeta}}_a (\zeta) = \overline{\overline{z}}^0_a + \sum_{m''=1}^{D} g^3_a(m'';\zeta) \tag{9.6.11}$$

where the polynomials g^3_a are given by the relations

$$g^3_a(m'';\zeta) = P_{m''} \sum_{m'=1}^{D} g^2_a(m';\overline{\zeta}(\zeta)). \tag{9.6.12}$$

As before, $P_{m''}$ denotes a projection operator that retains only terms of degree m'' in the variables ζ. Also, all the required operations can again be carried out using TPSA. We see that the relations (6.8), (6.10), and (6.12) are completely analogous to the relations (8.6.2), (8.6.4), and (8.6.7) for the case of no translations. Indeed, with the use of deviation variables, all the methods of Section 8.6 can be employed. For example, a deviation variable map of the form (6.8) can be inverted by the recursion method.

Often the optimal circumstance we have just treated does not hold. It may be that $\mathcal{M}_1$ sends z^0 to $\overline{z}^0$ and $\mathcal{M}_2$ sends $\overline{z}^0$ to $\overline{\overline{z}}^0$ as before and as described by (6.1) and (6.2). However, it may happen that $\mathcal{M}_2$ does not have a known Taylor expansion about $\overline{z}^0$. Instead, we assume that $\mathcal{M}_2$ has a known Taylor expansion about a point $\overline{z}'$ that is near $\overline{z}^0$. With the introduction of suitable deviation variables if necessary, and without loss of generality, we may consider truncated Taylor series of the form

$$\overline{z}_a = \overline{z}_a(z) = \sum_{m=0}^{D} g^1_a(m;z) \tag{9.6.13}$$

and

$$\overline{\overline{z}}_a = \overline{\overline{z}}_a (\overline{z}) = \sum_{m'=0}^{D} g^2_a(m';\overline{z}). \tag{9.6.14}$$

The relations (8.6.2) and (8.6.4) have simply been modified so that all summations over m and m' begin with 0 instead of 1, and we assume that the constant term $g^1_a(0;z)$ is small. See Exercise 6.*. Finally, we make the expansion

$$\overline{\overline{z}}_a = \overline{\overline{z}}_a (z) = \sum_{m''=0}^{D} g^3_a(m'';z) \tag{9.6.15}$$

and find that the polynomials g_a^3 are given by the relations

$$g_a^3(m'';z) = P_{m''} \sum_{m'=0}^{D} g_a^2(m';\bar{z}(z)). \tag{9.6.16}$$

Suppose the maps $\mathcal{M}_1$ and $\mathcal{M}_2$ are symplectic. Then, in the terminology of Section 7.5, the truncated Taylor series (6.13) and (6.14) are symplectic D-jets (about the origin). It is important to remark at at this juncture that the concatenation of two symplectic D-jets does not generally yield a *symplectic* D-jet if $\mathcal{M}_1$ has nonvanishing constant terms $g_a^1(0;z)$ so that $\mathcal{M}_1$ does not send the origin into itself. Correspondingly, the factorization theorems of Sections 7.6 and 7.7 generally do not apply to the D-jet (6.15) for $\mathcal{M}_3$. The problem is that truncation of the Taylor expansion of a symplectic map, in this case the map $\mathcal{M}_2$, generally violates the symplectic condition, and this violation can feed down to low orders in the presence of translations. See, for example, Exercise 6.*.

There is a second point that we should also recognize. Suppose that the Taylor expansion for $\mathcal{M}_2$ is not truncated. That is, consider letting $D \to \infty$ in (6.14) and (6.16). Then it may happen that the series (5.16) diverges. This will happen if the point $\bar{z}_a(0)$ lies outside the convergence domain of the homogeneous polynomial expansion for $\mathcal{M}_2$. See Exercise 1.4.4 and Chapter 26. We conclude that translations must be handled with care.

Let $\mathcal{J}_3$ denote the D-jet (6.15). We expect that if the translation part of $\mathcal{M}_1$ is small, then $\mathcal{J}_3$ will be nearly symplectic. It should therefore be possible to construct a D-jet that is symplectic and near $\mathcal{J}_3$ in the sense that the two jets differ only by appropriate powers of the small translation terms. Indeed, this is what the method of Section 9.3 accomplishes when maps are represented in Lie form. That is, suppose the two maps $\mathcal{M}_1$ and $\mathcal{M}_2$ are written in Lie form and are concatenated using the method of Section 9.3, and suppose that the resulting map is then expanded as a Taylor series about the origin and truncated beyond terms of degree D. This resulting D-jet will be symplectic, and will be near $\mathcal{J}_3$.

Given a D-jet that is nearly a symplectic jet, there are many procedures for constructing nearby jets that are symplectic. The method just described is only one such procedure. Another convenient procedure is to employ methods analogous to those used in Section 7.6 to prove the factorization theorem.

Let $\mathcal{J}_3'$ be the jet obtained from $\mathcal{J}_3$ by removing its translation part. That is, $\mathcal{J}_3'$ sends z to $\bar{\bar{z}}'$ according to the rule

$$\bar{\bar{z}}_a' = \sum_{m=1}^{D} g_a^3(m;z), \tag{9.6.17}$$

and thus sends the origin into itself. Examine the matrix (linear) part of $\mathcal{J}_3'$ described by the terms $g_a^3(1;z)$. These terms correspond to a matrix that is nearly symplectic. Replace this matrix by a matrix that is exactly symplectic using one of the matrix symplectification methods of Chapter 4. Call this matrix R, and let $\mathcal{R}$ be its corresponding linear symplectic map. Finally, let $\mathcal{J}_3''$ be the jet that results from replacing the $g_a^3(1;z)$ terms in (6.17) by $(Rz)_a$.

Next apply $\mathcal{R}^{-1}$ to $\mathcal{J}_3''$ to get a result of the form

$$(\mathcal{R}^{-1}\mathcal{J}_3''z)_a = z_a + r_a(>1), \tag{9.6.18}$$

which is analogous to (7.6.19). As before, the remainder term $r_a(>1)$ will have a quadratic piece and still higher degree terms,

$$r_a(>1) = \hat{g}_a(2;z) + r_a(>2). \tag{9.6.19}$$

Because $\mathcal{J}_3$ is not a symplectic jet, the quadratic piece will generally not satisfy the analog of (7.6.23). However, we may still define an f_3 by the rule

$$f_3 = -(1/3)\sum_{ab} \hat{g}_a(2;z) J_{ab} z_b, \tag{9.6.20}$$

which is analogous to (7.6.26). (Indeed, Section 17.11 shows that this prescription is unique.) From this f_3 we produce the quadratic polynomials $\tilde{g}_a(2;z)$ by the rules

$$\tilde{g}_a(2;z) =: f_3 : z_a. \tag{9.6.21}$$

Because $\mathcal{J}_3$ is nearly symplectic, the polynomials $\hat{g}_a(2;z)$ and $\tilde{g}_a(2;z)$ will be nearly the same. We therefore may replace $\hat{g}_a(2;z)$ by $\tilde{g}_a(2,z)$ and, in so doing, obtain a nearby map that is more nearly symplectic.

It should now be as clear to the reader as it is to the writer that the steps just described can be applied repeatedly to yield a sequence of homogeneous polynomials $f_3, f_4 \cdots f_{D+1}$. Also, by Section 7.7, there is an f_1 polynomial that will reproduce the translation part $g_a^3(0;z)$ in (6.15). Consequently, we have found the approximate result

$$\mathcal{M}_3 \simeq \mathcal{R} \exp(: f_3 :) \cdots \exp(: f_{D+1} :) \exp(: f_1 :). \tag{9.6.22}$$

Finally, the map on the right side of (6.22) may be expanded in a Taylor series and truncated beyond terms of degree D. Doing so yields a symplectic D-jet that is close to $\mathcal{J}_3$.

After this pleasant digression, let us return to the subject of map concatenation. In analogy to the discussion of Section 8.6, the next topic to be treated is the case where $\mathcal{M}_1$ is in Lie form and $\mathcal{M}_2$ is in Taylor form. See Figure 8.6.2. In this case the definition (8.6.11) must be extended to become

$$T_a^D(\bar{z}) = \sum_{m'=0}^{D} g_a^2(m';\bar{z}) \tag{9.6.23}$$

to include the possibility that $\mathcal{M}_2$ may have a translation part. The remaining relations (8.6.10) and (8.6.12) through (8.6.14) continue to hold. In particular, we still have the result

$$\bar{\bar{z}}_a(z) = \mathcal{M}_1 T_a^D(z). \tag{9.6.24}$$

Again, there are three common ways that $\mathcal{M}_1$ may be specified in Lie form. First suppose, as before, that $\mathcal{M}_1$ is given in terms of a single exponent,

$$\mathcal{M}_1 = \exp(: h :), \tag{9.6.25}$$

where h now has a homogeneous polynomial expansion of the form

$$h = h_1 + h_2 + \cdots h_{D+1}. \tag{9.6.26}$$

We still have the relation (8.6.17) and the result

$$g_a^3(m;z) = P_m \sum_{m'=0}^{D} \sum_{\ell=0}^{\infty} (1/\ell!) :h:^\ell g_a^2(m';z). \tag{9.6.27}$$

As before, there are caveats about the rate at which the sum over ℓ converges. Moreover, as illustrated for a special example in Section 10.5, the sum over ℓ may also fail to converge. As in Section 10.5, this possible divergence is not due to any defect in the method of direct Taylor summation, but rather indicates that $\mathcal{M}_1$ may fail to exist, and shows that Hamiltonians for which $h_1 \neq 0$ must be treated with care.

Next we suppose, as a second possibility, that $\mathcal{M}_1$ is given in the factored product form

$$\mathcal{M}_1 = \exp(:f_1:)\mathcal{R}_f \exp(:f_3:) \cdots \exp(:f_{D+1}:). \tag{9.6.28}$$

Handling this possibility is straight forward. Suppose that $\exp(:f_1:)$ has the effect

$$\exp(:f_1:)z_a = z_a + k_a. \tag{9.6.29}$$

Then the results (8.6.20) through (8.6.25) continue to hold except that the sums over m and m' begin at 0 instead of 1, and (8.6.27) is modified to become

$$g_a^3(m;z) = P_m \sum_{m'=0}^{D} \tilde{g}_a[m'; R^f(z+k)]. \tag{9.6.30}$$

The third possibility is that $\mathcal{M}_1$ arises as a result of some symplectic integration approximation and is therefore given as a product of Lie transformations of the form

$$\mathcal{M}_1 = \exp[(w_1 h:A:) \exp(w_2 h:B:) \cdots \exp(w_m h:A:). \tag{9.6.31}$$

As before, B typically has a homogeneous polynomial expansion consisting of terms of degree three and higher. However, if $\mathcal{M}_1$ has a translation part, A will contain terms of degree one as well as a second-degree terms. In this case we make use of (2.4) or (2.62) to factorize the terms of the form $\exp(w_j h:A:)$. With this accomplished, we may proceed as before using the tools already developed.

At this point we should remark that if $\mathcal{M}_1$ has a translation part, then the D-jet produced for $\mathcal{M}_3$ in each of the three possibilities just described will again not be a symplectic D-jet, and for the same reason as before. Also, nearby symplectic D-jets can again be constructed. For example, the procedure based on the methods of the factorization theorem will work as before.

The last topic to be discussed in this section is the inversion of maps in Taylor form including the possibility of translations. When translations are included, (8.6.40) takes the form

$$\overline{z}_{b'} = k_{b'} + \sum_b R_{b'b} z_b + N_{b'}(z). \tag{9.6.32}$$

This equation can be partially solved to give the result

$$z_a = [R^{-1}(\overline{z} - k)]_a + \tilde{N}_a(z) \tag{9.6.33}$$

where $\tilde{N}_a$ is again given by (8.6.41), and therefore contains terms only of degree 2 and higher. Now form the recursion relation

$$z_a^{(m+1)}(\overline{z}) = [R^{-1}(\overline{z} - k)]_a + \mathcal{T}^{m+1}\tilde{N}_a[z^{(m)}(\overline{z})] \tag{9.6.34}$$

with the starting relation

$$z_a^{(1)}(\overline{z}) = [R^{-1}(\overline{z} - k)]_a. \tag{9.6.35}$$

Here the translation quantities k_b are to be treated as small, and a monomial in *all* the variables z_a and k_b is regarded as having degree d if the sum of *all* the exponents in the monomial adds up to d. Correspondingly, the operator $\mathcal{T}^d$ in (6.34) is now defined in terms of this total degree. Application of the recursion relation (6.34) D times produces a D-jet representation for the map $\mathcal{M}_1^{-1}$.

As the reader should expect by now, if $\mathcal{M}_1$ has a translation part (as we have assumed), then the D-jet for $\mathcal{M}_1^{-1}$ obtained in this way will generally not be symplectic. But again, nearby symplectic D-jets can be constructed from this D-jet.

Finally, we remark that the concatenation and inversion methods of this section can, if desired, be employed in the formulas of Section 9.4 to compute reverse and mixed factorizations.

9.6.1.

9.7 The Lie Algebra of the Group of all Symplectic Maps Is Simple

Section 8.9 described what it means for a Lie algebra to be simple. In this section we will show that $ispm(2n, \mathbb{R})$, the Lie algebra of the group of all symplectic maps, is simple.

Chapter 10

Computation of Transfer Maps

Much of the material in the previous chapters dealt with the general problem of representing and manipulating symplectic maps. This chapter, along with some that follow, deals with the *computation* of transfer maps. For the most part we will deal with the symplectic case, but there are ready extensions to the general case that can be found by replacing Hamiltonian vector fields by general vector fields.

10.1 Equation of Motion

10.1.1 Background and Derivation

Let $H(z,t)$ be a general, possibly time-dependent, Hamiltonian. We know from Theorem 6.4.1 that following the flow specified by H produces a symplectic transfer map $\mathcal{M}(t)$. Let z^i denote a general initial condition. Then we have the relations

$$z(t) = \mathcal{M}(t)z^i, \tag{10.1.1}$$

$$\mathcal{M}(t^i) = \mathcal{I}. \tag{10.1.2}$$

Our goal is to find an equation of motion for $\mathcal{M}$.

Suppose $g(z)$ is any function of the phase-space variables z (but not explicitly of the time t). By (8.3.52) we have the relation

$$g(z) = g(\mathcal{M}z^i) = \mathcal{M}g(z^i). \tag{10.1.3}$$

Now differentiate both sides of (1.3) along the flow specified by H. We find the result

$$\dot{g}(z) = \dot{\mathcal{M}}g(z^i). \tag{10.1.4}$$

But from (1.7.4) we also have the relation

$$\dot{g}(z) = [g(z), H(z,t)]. \tag{10.1.5}$$

With the aid of (1.1), (8.3.52), and (8.3.53) this relation can be rewritten in the form

$$\begin{aligned}
\dot{g}(z) &= [g(z), H(z,t)] = [g(\mathcal{M}z^i), H(\mathcal{M}z^i,t)] \\
&= [\mathcal{M}g(z^i), \mathcal{M}H(z^i,t)] = \mathcal{M}[g(z^i), H(z^i,t)] \\
&= \mathcal{M}[-H(z^i,t), g(z^i)] = \mathcal{M} : -H(z^i,t) : g(z^i).
\end{aligned} \tag{10.1.6}$$

Now compare (1.4) and (1.6). Doing so gives the result

$$\dot{\mathcal{M}} g(z^i) = \mathcal{M} : -H(z^i, t) : g(z^i). \tag{10.1.7}$$

However, g is an arbitrary function. We conclude that (1.7) is equivalent to the *operator* equation of motion

$$\dot{\mathcal{M}} = \mathcal{M} : -H : . \tag{10.1.8}$$

We note that this result agrees with the result (7.4.9) that was obtained earlier for the special case of autonomous Hamiltonians.

10.1.2 Perturbation/Splitting Theory and Reverse Factorization

In some cases the Hamiltonian can be split into the sum of two terms so that it can be written in the form

$$H(z, t) = H_0(z, t) + H_1(z, t). \tag{10.1.9}$$

Often the motion governed by H_0 can be determined and the effect of H_1 may be viewed as a perturbation. Let $\mathcal{M}_0$ be the map produced by H_0. That is, $\mathcal{M}_0$ satisfies the equation of motion

$$\dot{\mathcal{M}}_0 = \mathcal{M}_0 : -H_0 : \tag{10.1.10}$$

with the initial condition

$$\mathcal{M}_0(t^i) = \mathcal{I}. \tag{10.1.11}$$

For the $\mathcal{M}$ produced by H let us write the representation

$$\mathcal{M} = \mathcal{M}_1 \mathcal{M}_0 \tag{10.1.12}$$

where the map $\mathcal{M}_1$ remains to be determined. We will call the Ansatz (1.12) a *reverse* factorization.

What is the equation of motion for $\mathcal{M}_1$? From (1.8), (1.9), and (1.12) we find the result

$$\begin{aligned} \dot{\mathcal{M}} &= \dot{\mathcal{M}}_1 \mathcal{M}_0 + \mathcal{M}_1 \dot{\mathcal{M}}_0 = \mathcal{M} : -H := \mathcal{M}_1 \mathcal{M}_0 : -H : \\ &= \mathcal{M}_1 \mathcal{M}_0 : -H_0 : + \, \mathcal{M}_1 \mathcal{M}_0 : -H_1 : . \end{aligned} \tag{10.1.13}$$

Use of (1.10) gives the relation

$$\mathcal{M}_1 \dot{\mathcal{M}}_0 = \mathcal{M}_1 \mathcal{M}_0 : -H_0 :, \tag{10.1.14}$$

and consequently (1.13) can be reduced to the relation

$$\dot{\mathcal{M}}_1 \mathcal{M}_0 = \mathcal{M}_1 \mathcal{M}_0 : -H_1 : \tag{10.1.15}$$

from which it follows that

$$\dot{\mathcal{M}}_1 = \mathcal{M}_1 \mathcal{M}_0 : -H_1 : \mathcal{M}_0^{-1}. \tag{10.1.16}$$

Given H_1 and $\mathcal{M}_0$, let us define an *interaction* Hamiltonian H_1^{int} by the rule

$$H_1^{\text{int}}(z^i, t) = H_1(\mathcal{M}_0 z^i, t). \tag{10.1.17}$$

[We note that, because $\mathcal{M}_0(t)$ is time dependent, in general $H_1^{\rm int}$ will depend on time even if H_1 happens to be time independent.] Then, as a consequence of (8.2.25), we have the result

$$\mathcal{M}_0 : -H_1 : \mathcal{M}_0^{-1} =: -H_1^{\rm int} : . \tag{10.1.18}$$

Upon combining (1.16) and (1.18) we find the equation of motion

$$\dot{\mathcal{M}}_1 = \mathcal{M}_1 : -H_1^{\rm int} : . \tag{10.1.19}$$

Finally, we observe from (1.2) and (1.11) that $\mathcal{M}_1$ also has the initial condition

$$\mathcal{M}_1(t^i) = \mathcal{I}. \tag{10.1.20}$$

10.1.3 Perturbation/Splitting Theory and Forward Factorization

For the $\mathcal{M}$ produced by H let us write, instead of (1.12), the representation

$$\mathcal{M} = \mathcal{M}_0\mathcal{N}_1 \tag{10.1.21}$$

where the map $\mathcal{N}_1$ remains to be determined. We will call the Ansatz (1.21) a *forward* factorization.

Note that the $\mathcal{N}_1$ in (1.21) and the $\mathcal{M}_1$ in (1.12) are generally different. Indeed, we may rewrite (1.12) in the form

$$\mathcal{M} = \mathcal{M}_1\mathcal{M}_0 = \mathcal{M}_0\mathcal{M}_0^{-1}\mathcal{M}_1\mathcal{M}_0 \tag{10.1.22}$$

from which it follows that

$$\mathcal{N}_1 = \mathcal{M}_0^{-1}\mathcal{M}_1\mathcal{M}_0. \tag{10.1.23}$$

We see that if a reverse factorization has been found so that both $\mathcal{M}_0$ and $\mathcal{M}_1$ are known, then (1.21) and (1.23) provide the associated forward factorization.

10.2 Series (Dyson) Solution

Readers familiar with Quantum Mechanics will recognize a similarity between equations (1.8), (1.17), and (1.19) and analogous quantum mechanical results. This is to be expected because Quantum Mechanics and Classical Mechanics have closely related Lie algebraic structures. Because of this similiarity, many mathematical tools originally developed for Quantum Mechanics can also be applied in Classical Mechanics. Indeed, these tools could have (and, in retrospect, should have) been developed first in the context of Classical Mechanics.

One such tool is *Neumann* iteration. Suppose both sides of (1.8) are integrated with respect to time from the initial time t^i to the variable time t. So doing, and making use of (1.2), gives the integral equation

$$\mathcal{M}(t) = \mathcal{I} + \int_{t^i}^{t} dt'\mathcal{M}(t') : -H(t') : . \tag{10.2.1}$$

(Here, for notational simplicity, we have suppressed the fact that H also depends on z^i.) Now iterate (2.1) by substituting the right side back into the integral. If this is done once, we obtain the result

$$\mathcal{M}(t) = \mathcal{I} + \int_{t^i}^{t} dt' : -H(t') : + \int_{t^i}^{t} dt' \int_{t^i}^{t'} dt'' \mathcal{M}(t'') : -H(t'') :: -H(t') : . \tag{10.2.2}$$

Evidently, repeated iteration gives the result

$$\mathcal{M}(t) = \mathcal{I} + \int_{t^i}^{t} dt' : -H(t') : + \int_{t^i}^{t} dt' \int_{t^i}^{t'} dt'' : -H(t'') :: -H(t') : + \cdots . \tag{10.2.3}$$

Note that (2.3) is in effect an expansion in powers of H, and that the factors in the integrands occur in *chronological* order – with earlier times preceding later times. We conclude that $\mathcal{M}$ can be expressed as an infinite sum of multiple *time-ordered* integrals over the Lie operators $: -H(t) :$. In the context of Quantum Mechanics, the analog of the series (2.3) is the *Dyson* series. Also note that Neumann iteration is the map counterpart of Picard iteration. Compare (1.3.8) and (1.3.9) with (2.1) through (2.3).

The series (2.3) bears a certain resemblance to the exponential series. Consider m-dimensional Euclidean space. It is easily verified that the volume of the region $t^i \le t_m \le t_{m-1} \le \cdots \le t_2 \le t_1 \le t$ is related to the volume of the region $[t^i, t] \times [t^i, t] \times [t^i, t] \cdots$ (m factors) by the proportionality constant $(m!)$. Indeed, we have the relation

$$\begin{aligned} \int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2 \int_{t^i}^{t_2} dt_3 \cdots \int_{t^i}^{t_{m-1}} dt_m &= (1/m!) \int_{t^i}^{t} dt_1 \int_{t^i}^{t} dt_2 \cdots \int_{t^i}^{t} dt_m \\ &= (1/m!) \left[\int_{t^i}^{t} dt' \right]^m . \end{aligned} \tag{10.2.4}$$

Consequently, we may write the identity

$$\begin{aligned} &\int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2 \cdots \int_{t^i}^{t_{m-1}} dt_m : -H(t_m) :: -H(t_{m-1}) : \cdots : -H(t_1) : \\ &= (1/m!) \int_{t^i}^{t} dt_1 \int_{t^i}^{t} dt_2 \cdots \int_{t^i}^{t} dt_m T : -H(t_m) :: -H(t_{m-1}) : \cdots : -H(t_1) : \\ &= (1/m!) T \left[\int_{t^i}^{t} dt' : -H(t') : \right]^m . \end{aligned} \tag{10.2.5}$$

Here the *time-ordering* symbol T indicates that the factors in the operator product $: -H(t_m) : \cdots : -H(t_1) :$ are to be rearranged so that operators with earlier times precede those with later times. Finally, with the aid of (2.5), we may write the series (2.3) in the form

$$\mathcal{M}(t) = \mathcal{I} + T \sum_{m=1}^{\infty} (1/m!) \left[\int_{t^i}^{t} dt' : -H(t') : \right]^m = T \exp \left[\int_{t^i}^{t} dt' : -H(t') : \right] . \tag{10.2.6}$$

The right side of (2.6) is often called a *time-ordered exponential.* However, as neat as this expression may appear to be, in reality it is simply the series (2.3).

We close this section by noting that our discussion of the series solution to (1.8) applies equally well to (1.19). Consequently, $\mathcal{M}_1$ has the series solution

$$\mathcal{M}_1(t) = T\exp\left[\int_{t^i}^{t} dt' : -H_1^{\rm int}(t') :\right]. \tag{10.2.7}$$

This result for $\mathcal{M}_1$ may be viewed as an expansion in powers of $H_1^{\rm int}$.

Exercises

10.2.1. Verify (2.4) by performing the indicated integrations on each side.

10.2.2. Suppose $F(z,t)$ and $G(z,t)$ are two Hamiltonians that are in *involution.* That is, we assume

$$[F(z,t), G(z,t')] = 0 \text{ for all } t, t'. \tag{10.2.8}$$

Correspondingly, there will be the Lie operator commutation relation

$$\{: F(z,t) :, : G(z,t') :\} = 0 \text{ for all } t, t'. \tag{10.2.9}$$

Let $\mathcal{M}_F(t^{\rm in}, t^{\rm fin})$ and $\mathcal{M}_G(t^{\rm in}, t^{\rm fin})$ be the maps generated by F and G, respectively. Define a sum Hamiltonian $H(z,t)$ by writing

$$H(z,t) = F(z,t) + G(z,t), \tag{10.2.10}$$

and let $\mathcal{M}_H(t^{\rm in}, t^{\rm fin})$ be the map generated by H. Your task is to show that

$$\mathcal{M}_H(t^{\rm in}, t^{\rm fin}) = \mathcal{M}_F(t^{\rm in}, t^{\rm fin})\mathcal{M}_G(t^{\rm in}, t^{\rm fin}) = \mathcal{M}_G(t^{\rm in}, t^{\rm fin})\mathcal{M}_F(t^{\rm in}, t^{\rm fin}). \tag{10.2.11}$$

Begin by making the Ansatz

$$\mathcal{M}_H(t^{\rm in}, t) = \mathcal{M}_?(t^{\rm in}, t)\mathcal{M}_G(t^{\rm in}, t) \tag{10.2.12}$$

where the map $\mathcal{M}_?(t^{\rm in}, t)$ remains to be determined. Verify that taking the time derivative of both sides of (2.12) produces the result

$$\begin{aligned} \dot{\mathcal{M}}_H &= \dot{\mathcal{M}}_?\mathcal{M}_G + \mathcal{M}_?\dot{\mathcal{M}}_G = \mathcal{M}_H : -H := \mathcal{M}_?\mathcal{M}_G : -H : \\ &= \mathcal{M}_?\mathcal{M}_G : -F : + \mathcal{M}_?\mathcal{M}_G : -G : . \end{aligned} \tag{10.2.13}$$

Next find the equation of motion for $\mathcal{M}_?$. To do so, verify that

$$\mathcal{M}_?\dot{\mathcal{M}}_G = \mathcal{M}_?\mathcal{M}_G : -G :, \tag{10.2.14}$$

and consequently (2.13) can be reduced to the relation

$$\dot{\mathcal{M}}_?\mathcal{M}_G = \mathcal{M}_?\mathcal{M}_G : -F : . \tag{10.2.15}$$

At this point imagine that the series solution (2.3) is used to represent $\mathcal{M}_G$. Verify that doing so gives the result

$$\mathcal{M}_G(t^{\rm in},t) = \mathcal{I} + \int_{t^{\rm in}}^{t} dt' : -G(t') : + \int_{t^{\rm in}}^{t} dt' \int_{t^{\rm in}}^{t'} dt'' : -G(t'') :: -G(t') : + \cdots . \quad (10.2.16)$$

Employ the assumption (2.9) and the representation (2.16) to conclude that

$$\mathcal{M}_G : -F :=: -F : \mathcal{M}_G, \quad (10.2.17)$$

from which it follows that (2.15) can be rewritten in the form

$$\dot{\mathcal{M}}_? \mathcal{M}_G = \mathcal{M}_? : -F : \mathcal{M}_G, \quad (10.2.18)$$

and consequently

$$\dot{\mathcal{M}}_? = \mathcal{M}_? : -F : . \quad (10.2.19)$$

Finally, observe from (2.12) that $\mathcal{M}_?$ has the initial condition

$$\mathcal{M}_?(t^{\rm in}, t^{\rm in}) = \mathcal{I}. \quad (10.2.20)$$

It follows from (2.19) and (2.20) that

$$\mathcal{M}_?(t^{\rm in}, t^{\rm fin}) = \mathcal{M}_F(t^{\rm in}, t^{\rm fin}), \quad (10.2.21)$$

and insertion of (2.21) into the Ansatz (2.12) proves the first part of (2.11).

In an analogous way, prove the second part of (2.11) by making the Ansatz

$$\mathcal{M}_H(t^{\rm in}, t) = \mathcal{M}_?(t^{\rm in}, t)\mathcal{M}_F(t^{\rm in}, t). \quad (10.2.22)$$

10.3 Exponential (Magnus) Solution

The series solutions (2.6) and (2.7) for the transfer map, or equivalently (2.3), have the defect that they are not manifestly symplectic. Indeed, if the series are truncated, the resulting maps are generally not symplectic. Moreover, maps in series form are somewhat difficult to concatenate. For these reasons, it is also useful to have solutions in exponential form. Possibilities include the single exponential form and various factored product forms. Here we consider the single exponential form.

Let us seek a solution to the equation of motion (1.8), or (1.19), of the form

$$\mathcal{M}(t) = \exp(: F(z^i, t) :). \quad (10.3.1)$$

We know that in general there is no such solution. Indeed, even in the simplest linear case of $Sp(2)$, maps cannot generally be written in single exponent form. See Section 8.7. Nevertheless we will pursue the assumption (3.1) to see where it leads. We will find an expansion for F in terms of powers of H, and the convergence of this expansion will determine the validity of the assumption.

Let us differentiate both sides of (3.1). Doing so gives the relation

$$\dot{\mathcal{M}} = \exp(:F:)\mathrm{iex}(-\#F\#) : \dot{F} := \mathcal{M}\mathrm{iex}(-\#F\#) : \dot{F} : . \tag{10.3.2}$$

Here we have used results from Appendix C. Now insert the equation of motion (1.8) into (3.2) to get the relation

$$: -H := \mathrm{iex}(-\#F\#) : \dot{F} : . \tag{10.3.3}$$

This relation can be solved to produce an equation of motion for the Lie operator $:F:$,

$$: \dot{F} := [\mathrm{iex}(-\#F\#)]^{-1} : -H : . \tag{10.3.4}$$

According to Appendix C, the operator $[\mathrm{iex}(-\#F\#)]^{-1}$ has an expansion in powers of $\#F\#$ of the form

$$[\mathrm{iex}(-\#F\#)]^{-1} = \sum_{m=0}^{\infty} b_m(\#F\#)^m. \tag{10.3.5}$$

Consequently, (3.4) can be rewritten in the form

$$: \dot{F} := \sum_{m=0}^{\infty} b_m(\#F\#)^m : -H : = : [\sum_{m=0}^{\infty} b_m : F :^m (-H)] : . \tag{10.3.6}$$

Here we have also used (8.2.2). Now remove the outside colons from both sides of (3.6). So doing gives an equation of motion for F,

$$\dot{F} = \sum_{m=0}^{\infty} b_m : F :^m (-H) = [\mathrm{iex}(- : F :)]^{-1}(-H), \tag{10.3.7}$$

which could have been deduced directly by "decolonizing" (3.4). This equation is to be solved with the initial condition

$$F(t^i) = 0, \tag{10.3.8}$$

which follows from (1.2).

Let us try to solve (3.7) by perturbation theory. Replace H by ϵH, and assume F has an expansion of the form

$$F = \sum_{n=1}^{\infty} \epsilon^n F_n. \tag{10.3.9}$$

(This procedure is equivalent to the introduction of a grading, and the expansion obtained is often called the *Magnus* expansion. See Section 8.9.) Put the expansion (3.9) into (3.7) to get the result

$$\sum_{n=1}^{\infty} \epsilon^n \dot{F}_n = \sum_{m=0}^{\infty} b_m(: \sum_{n=1}^{\infty} \epsilon^n F_n :)^m(-\epsilon H). \tag{10.3.10}$$

Now equate powers of ϵ. So doing gives the results

$$\dot{F}_1 = -H, \tag{10.3.11}$$

$$\dot{F}_2 = (1/2) : F_1 : (-H), \tag{10.3.12}$$

$$\dot{F}_3 = (1/12) : F_1 :^2 (-H) + (1/2) : F_2 : (-H), \tag{10.3.13}$$

$$\dot{F}_4 = (1/2) : F_3 : (-H) + (1/12)(: F_1 :: F_2 : + : F_2 :: F_1 :)(-H), \tag{10.3.14}$$

$$\dot{F}_n = \text{ something involving } H \text{ and the } : F_m : \text{ with } m < n. \tag{10.3.15}$$

Here we have used the values for the coefficients b_m given in Appendix C. The equations (3.11) through (3.15) are to be solved with the initial conditions

$$F_n(t^i) = 0. \tag{10.3.16}$$

The equations for the $\dot{F}_n$ can be integrated numerically or solved by quadrature. Evidently (3.11) with the initial condition (3.16) has the solution

$$F_1(t) = \int_{t^i}^{t} dt_1[-H(t_1)]. \tag{10.3.17}$$

Now substitute (3.17) into (3.12) to get the result

$$\begin{aligned} \dot{F}_2(t_1) &= (1/2)\int_{t^i}^{t_1} dt_2 : -H(t_2) : [-H(t_1)] \\ &= (1/2)\int_{t^i}^{t_1} dt_2[-H(t_2), -H(t_1)]. \end{aligned} \tag{10.3.18}$$

This equation can be integrated, again with the initial condition (3.16), to give the result

$$F_2(t) = (1/2)\int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2[-H(t_2), -H(t_1)]. \tag{10.3.19}$$

Let us introduce the short-hand notation $-j$ for the quantity $-H(t_j)$. With this notation, (3.19) can be written in the more compact form

$$F_2(t) = (1/2)\int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2[-2, -1]. \tag{10.3.20}$$

Similarly, again using this notation, we find the result

$$\begin{aligned} &F_3(t) = (1/6)\int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2 \int_{t^i}^{t_2} dt_3 \times \\ &\{2[-3,[-2,-1]] - [-2,[-3,-1]]\} \\ &= (1/6)\int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2 \int_{t^i}^{t_2} dt_3 \times \\ &\{[-1,[-2,-3]] + [-3,[-2,-1]]\}. \end{aligned} \tag{10.3.21}$$

Here $2[-3,[-2,-1]]$ is short hand for $2[-H(t_3),[-H(t_2),-H(t_1)]]$, etc. And for F_4 we find the result

$$\begin{aligned} F_4(t) = \quad & (1/12)\int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2 \int_{t^i}^{t_2} dt_3 \int_{t^i}^{t_3} dt_4 \times \\ & \{+3[-4,[-3,[-2,-1]]] - [-4,[-2,[-3,-1]]] \\ & -[-3,[-4,[-2,-1]]] - [-3,[-2,[-4,-1]]] \\ & -[-2,[-4,[-3,-1]]] + [-2,[-3,[-4,-1]]]\}. \end{aligned} \tag{10.3.22}$$

See Exercise 3.3.

At this point at least three comments are in order. First, we recognize from the structure of the equations (3.11) through (3.15) that the quantity ϵ serves only as a "counting" parameter that counts powers of H, and therefore we may now set $\epsilon = 1$. The net result is an expansion of F in powers of H. Next we see from (3.15) that the F_n can be determined successively, and consequently a solution by numerical methods or by quadrature is always possible. Third, we see that all the quantities on the right side of the equations (3.11) through (3.15) lie in the Lie algebra generated by the $H(z^i, t)$ for different values of t. (That is, all the quantities consist of H and Poisson brackets involving only factors of H.) In particular, if all the $H(z^i, t)$ are in *involution*,

$$[H(z^i, t), H(z^i, t')] = 0, \tag{10.3.23}$$

then we have the results

$$F_n = 0 \text{ for } n > 1, \tag{10.3.24}$$

and

$$\mathcal{M}(t) = \exp\left[\int_{t^i}^{t} dt' : -H(t') :\right]. \tag{10.3.25}$$

Note that (3.25) is consistent with (2.6) because if (3.23) holds, then time ordering makes no difference. Finally, if the Hamiltonian is autonomous, then the integral in (3.25) can be done to give the result (7.4.7).

We close this section with the reminder that the discussion we have just given for the solution of (1.8) for $\mathcal{M}$ applies equally well to the solution of (1.19) for $\mathcal{M}_1$. In the case of $\mathcal{M}_1$, the associated exponential quantity F can be developed as an expansion in powers of H_1^{int}. And, since H_1^{int} may be small, it could be the case that $\mathcal{M}_1$ can be written in single exponent form.

Exercises

10.3.1. Verify (3.11) through (3.15).

10.3.2. Verify (3.17) through (3.20).

10.3.3. Verify (3.21) through (3.22). Hint: To do so, use the identity (5.3.14) and the Jacobi identity; and verify and employ integral identities of the form

$$\int_{t^i}^{t} dt_1 \int_{t^i}^{t} dt_2 ** = \int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2 ** + \int_{t^i}^{t} dt_2 \int_{t^i}^{t_2} dt_1 **, \tag{10.3.26}$$

where $**$ denotes some common integrand.

10.4 Factored Product Solution: Powers of H Expansion

As before, let us replace H by ϵH so that the the equation of motion (1.8) becomes

$$\dot{\mathcal{M}} = \mathcal{M} : -\epsilon H : . \tag{10.4.1}$$

Suppose also that we factor $\mathcal{M}$ in the form

$$\mathcal{M} = \mathcal{M}_1\mathcal{M}_2\mathcal{M}_3\mathcal{M}_4\cdots \tag{10.4.2}$$

where

$$\mathcal{M}_m = \exp(:\epsilon^m G_m:) \tag{10.4.3}$$

and the functions G_m are to be determined. [Note that (4.2) is a forward factorization.] Next differentiate the Ansatz (4.2) to find the result

$$\begin{aligned}\dot{\mathcal{M}} &= \dot{\mathcal{M}}_1\mathcal{M}_2\mathcal{M}_3\mathcal{M}_4\cdots + \mathcal{M}_1\dot{\mathcal{M}}_2\mathcal{M}_3\mathcal{M}_4\cdots \\ &\quad +\mathcal{M}_1\mathcal{M}_2\dot{\mathcal{M}}_3\mathcal{M}_4\cdots + \mathcal{M}_1\mathcal{M}_2\mathcal{M}_3\dot{\mathcal{M}}_4\cdots \\ &\quad +\cdots,\end{aligned} \tag{10.4.4}$$

from which it follows using (4.1) and (4.2) that

$$\begin{aligned}\mathcal{M}^{-1}\dot{\mathcal{M}} &= \cdots\mathcal{M}_4^{-1}\mathcal{M}_3^{-1}\mathcal{M}_2^{-1}\mathcal{M}_1^{-1}\dot{\mathcal{M}}_1\mathcal{M}_2\mathcal{M}_3\mathcal{M}_4\cdots \\ &\quad +\cdots\mathcal{M}_4^{-1}\mathcal{M}_3^{-1}\mathcal{M}_2^{-1}\dot{\mathcal{M}}_2\mathcal{M}_3\mathcal{M}_4\cdots \\ &\quad +\cdots\mathcal{M}_4^{-1}\mathcal{M}_3^{-1}\dot{\mathcal{M}}_3\mathcal{M}_4\cdots \\ &\quad +\cdots\mathcal{M}_4^{-1}\dot{\mathcal{M}}_4\cdots \\ &\quad +\cdots = :-\epsilon H:.\end{aligned} \tag{10.4.5}$$

The various terms in (4.5) can be simplified by the use of adjoint operators. For example, we have the result

$$\begin{aligned}&\cdots\mathcal{M}_4^{-1}\mathcal{M}_3^{-1}\mathcal{M}_2^{-1}\mathcal{M}_1^{-1}\dot{\mathcal{M}}_1\mathcal{M}_2\mathcal{M}_3\mathcal{M}_4\cdots = \\ &\quad\cdots\exp(-\#\epsilon^4G_4\#)\exp(-\#\epsilon^3G_3\#)\exp(-\#\epsilon^2G_2\#)\mathcal{M}_1^{-1}\dot{\mathcal{M}}_1.\end{aligned} \tag{10.4.6}$$

Also, there are relations of the form

$$\mathcal{M}_m^{-1}\dot{\mathcal{M}}_m = \text{ iex }(-\#\epsilon^m G_m\#):\epsilon^m\dot{G}_m:. \tag{10.4.7}$$

Upon using (4.7) and relations of the form (4.6) we find that (4.5) can be rewritten in the form

$$\begin{aligned}&\cdots\exp(-\#\epsilon^4G_4\#)\exp(-\#\epsilon^3G_3\#)\exp(-\#\epsilon^2G_2\#)\text{ iex}(-\#\epsilon G_1\#):\epsilon\dot{G}_1: \\ &+\cdots\exp(-\#\epsilon^4G_4\#)\exp(-\#\epsilon^3G_3\#)\text{ iex }(-\#\epsilon^2G_2\#):\epsilon^2\dot{G}_2: \\ &+\cdots\exp(-\#\epsilon^4G_4\#)\text{ iex }(-\#\epsilon^3G_3\#):\epsilon^3\dot{G}_3: \\ &+\cdots\text{ iex}(-\#\epsilon^4G_4\#):\epsilon^4\dot{G}_4:+\cdots = :-\epsilon H:.\end{aligned} \tag{10.4.8}$$

The colons can now be removed from both sides of (4.8) to give the equivalent result

$$\begin{aligned}&\cdots\exp(-:\epsilon^4G_4:)\exp(-:\epsilon^3G_3:)\exp(-:\epsilon^2G_2:)\text{ iex}(-:\epsilon G_1:)\epsilon\dot{G}_1 \\ &+\cdots\exp(-:\epsilon^4G_4:)\exp(-:\epsilon^3G_3:)\text{ iex }(-:\epsilon^2G_2:)\epsilon^2\dot{G}_2 \\ &+\cdots\exp(-:\epsilon^4G_4:)\text{ iex }(-:\epsilon^3G_3:)\epsilon^3\dot{G}_3 \\ &+\cdots\text{ iex}(-:\epsilon^4G_4:)\epsilon^4\dot{G}_4+\cdots = -\epsilon H.\end{aligned} \tag{10.4.9}$$

Recall that the integrated exponential function has the expansion.

$$\begin{aligned} \text{iex}(w) &= \int_0^1 d\tau \exp(\tau w) = (e^w - 1)/w = \sum_{m=0}^{\infty} w^m/(m+1)! \\ &= 1 + w/2 + w^2/3 + w^3/4 + w^4/5 + \cdots . \end{aligned} \tag{10.4.10}$$

Using this expansion we may expand each of the lines in (4.9) as a Taylor series in ϵ. We find, for example, the results

$$\begin{aligned} &\cdots \exp(- : \epsilon^4 G_4 :) \exp(- : \epsilon^3 G_3 :) \exp(- : \epsilon^2 G_2 :) \text{ iex}(- : \epsilon G_1 :) \epsilon \dot{G}_1 = \\ &\epsilon \dot{G}_1 + \epsilon^2[-(1/2) : G_1 : \dot{G}_1] + \epsilon^3[*] + \epsilon^4[*] + \cdots , \end{aligned} \tag{10.4.11}$$

$$\begin{aligned} &\cdots \exp(- : \epsilon^4 G_4 :) \exp(- : \epsilon^3 G_3 :) \text{ iex } (- : \epsilon^2 G_2 :) \epsilon^2 \dot{G}_2 = \\ &\epsilon^2 \dot{G}_2 + \epsilon^3[*] + \epsilon^4[*] + \cdots , \end{aligned} \tag{10.4.12}$$

$$\begin{aligned} &\cdots \exp(- : \epsilon^4 G_4 :) \text{ iex } (- : \epsilon^3 G_3 :) \epsilon^3 \dot{G}_3 = \\ &\epsilon^3 \dot{G}_3 + \epsilon^4[*] + \cdots , \end{aligned} \tag{10.4.13}$$

$$\begin{aligned} &\cdots \text{ iex}(- : \epsilon^4 G_4 :) \epsilon^4 \dot{G}_4 = \\ &\epsilon^4 \dot{G}_4 + \cdots . \end{aligned} \tag{10.4.14}$$

Next equate powers of ϵ on both sides of (4.9). So doing gives, for example through powers of ϵ^4, the results

$$\epsilon \dot{G}_1 = -\epsilon H, \tag{10.4.15}$$

$$\epsilon^2[\dot{G}_2 - (1/2) : G_1 : \dot{G}_1] = 0, \tag{10.4.16}$$

$$\epsilon^3[\dot{G}_3 +] = 0, \tag{10.4.17}$$

$$\epsilon^4[\dot{G}_4 +] = 0. \tag{10.4.18}$$

We conclude that the G_n obey the equations of motion

$$\dot{G}_1 = -H, \tag{10.4.19}$$

$$\dot{G}_2 = (1/2) : G_1 : \dot{G}_1 = (1/2) : G_1 : (-H), \tag{10.4.20}$$

$$\dot{G}_3 = ?(1/12) : G_1 :^2 (-H) + (1/2) : G_2 : (-H), \tag{10.4.21}$$

$$\dot{G}_4 = ?(1/2) : G_3 : (-H) + (1/12)(: G_1 :: G_2 : + : G_2 :: G_1 :)(-H), \cdots \tag{10.4.22}$$

$$\dot{G}_n = \text{ something involving } H \text{ and the } : G_m : \text{ with } m < n. \tag{10.4.23}$$

These equations of motion are to be solved with the initial conditions

$$G_n(t^i) = 0. \tag{10.4.24}$$

The equations for the $\dot{G}_n$ can be integrated numerically or solved by quadrature. Evidently (4.19) with the initial condition (4.24) has the solution

$$G_1(t) = \int_{t^i}^{t} dt_1[-H(t_1)]. \tag{10.4.25}$$

Now substitute (4.25) into (4.20) to get the result

$$\begin{aligned}\dot{G}_2(t_1) &= (1/2)\int_{t^i}^{t_1} dt_2 : -H(t_2) : [-H(t_1)] \\ &= (1/2)\int_{t^i}^{t_1} dt_2[-H(t_2), -H(t_1)].\end{aligned} \tag{10.4.26}$$

This equation can be integrated, again with the initial condition (4.24), to give the result

$$G_2(t) = (1/2)\int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2[-H(t_2), -H(t_1)]. \tag{10.4.27}$$

Let us introduce the short-hand notation $-j$ for the quantity $-H(t_j)$. With this notation, (4.27) can be written in the more compact form

$$G_2(t) = (1/2)\int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2[-2, -1]. \tag{10.4.28}$$

Similarly, again using this notation, we find the result

$$\begin{aligned}&G_3(t) =?(1/6)\int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2 \int_{t^i}^{t_2} dt_3 \times \\ &\{2[-3, [-2, -1]] - [-2, [-3, -1]]\} \\ &= (1/6)\int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2 \int_{t^i}^{t_2} dt_3 \times \\ &\{[-1, [-2, -3]] + [-3, [-2, -1]]\}.\end{aligned} \tag{10.4.29}$$

Here $2[-3, [-2, -1]]$ is short hand for $2[-H(t_3), [-H(t_2), -H(t_1)]]$, etc. And for G_4 we find the result

$$\begin{aligned}G_4(t) =? \quad &(1/12)\int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2 \int_{t^i}^{t_2} dt_3 \int_{t^i}^{t_3} dt_4 \times \\ &\{+3[-4, [-3, [-2, -1]]] - [-4, [-2, [-3, -1]]] \\ &-[-3, [-4, [-2, -1]]] - [-3, [-2, [-4, -1]]] \\ &-[-2, [-4, [-3, -1]]] + [-2, [-3, [-4, -1]]]\}.\end{aligned} \tag{10.4.30}$$

See Exercise 4.1.

At this point at least three comments are in order. First, we recognize from the structure of the equations (4.19) through (4.23) that the quantity ϵ serves only as a "counting" parameter that counts powers of H, and therefore we may now set $\epsilon = 1$. Next we see from (4.23) that the G_n can be determined successively, and consequently a solution by numerical methods or by quadrature is always possible. Third, we see that all the quantities on the right side of the equations (4.19) through (4.23) lie in the Lie algebra generated by the $H(z^i,t)$ for different values of t. (That is, all the quantities consist of H and Poisson brackets involving only factors of H.) In particular, if all the $H(z^i,t)$ are in *involution*,

$$[H(z^i,t),H(z^i,t')]=0, \tag{10.4.31}$$

then we have the results

$$G_n = 0 \text{ for } n>1, \tag{10.4.32}$$

and we again find the result

$$\mathcal{M}(t)=\exp\left[\int_{t^i}^{t} dt' : -H(t') :\right]. \tag{10.4.33}$$

Finally, if the Hamiltonian is autonomous, then the integral in (4.33) can be done to give the result (7.4.7).

We close this section with the reminder that the discussion we have just given for the solution of (1.8) for $\mathcal{M}$ applies equally well to the solution of (1.19) for $\mathcal{M}_1$. In the case of $\mathcal{M}_1$, the associated quantities G_n can be developed as expansions in powers of H_1^{int}. Note that in this context we have put ourselves in a notationally awkward position: The $\mathcal{M}_1$ appearing in (1.12) is different from and should not be confused with the $\mathcal{M}_1$ appearing in (4.2).

Exercises

10.4.1. Suppose that $\mathcal{M}$ obeys the equation of motion (4.1) and that $\mathcal{M}$ is factored in the *reversed* product form

$$\mathcal{M}=\cdots\mathcal{M}_4\mathcal{M}_3\mathcal{M}_2\mathcal{M}_1 \tag{10.4.34}$$

where

$$\mathcal{M}_m=\exp(:\epsilon^m G_m^{\text{rev}}:) \tag{10.4.35}$$

and the functions G_m^{rev} are to be determined. Find equations of motion for these functions.

10.5 Factored Product Solution: Taylor Expansion about Design Orbit

10.5.1 Background

The discussion so far has been quite general in that no particular use has been made of Taylor expansions in the phase-space variables z. In this section we will explore the use of factored product representations such as those described in Sections 7.6 and 7.8.

Let $H(z,t)$ be a general, possibly time-dependent, Hamiltonian. Suppose that $z^d(t)$ is some given trajectory (which is assumed to be known and will be called the *design* trajectory), and that our task is to characterize all trajectories near z^d. Introduce $2n$ new *deviation* variables ζ by the rule

$$z=z^d+\zeta. \tag{10.5.1}$$

The transformation (5.1) is canonical. Consequently, the time evolution of the deviation variables ζ will also be described by some Hamiltonian. Call this Hamiltonian $H^{\text{new}}(\zeta, t)$. Evidently, the problem of studying trajectories near z^d is equivalent to studying the trajectories governed by $H^{\text{new}}(\zeta, t)$ in the case where ζ is small.

What is the relation between $H(z, t)$ and $H^{\text{new}}(\zeta, t)$? Define a function $\bar{H}(\zeta, t)$ by the rule

$$\bar{H}(\zeta, t) = H[z^d(t) + \zeta, t]. \tag{10.5.2}$$

Here the time dependence of $\bar{H}(\zeta, t)$ arises both from the possible time dependence of H and the time dependence of the design orbit $z^d(t)$. Next suppose that the quantity $\bar{H}(\zeta, t)$ is expressed as a power series in ζ by making the expansion

$$\bar{H}(\zeta, t) = \sum_{m=0}^{\infty} \bar{H}_m(\zeta, t). \tag{10.5.3}$$

Here each quantity $\bar{H}_m(\zeta, t)$ is a homogeneous polynomial of degree m in the components of ζ. Then we claim that $H^{\text{new}}(\zeta, t)$ is given by the relation

$$H^{\text{new}}(\zeta, t) = \sum_{m=2}^{\infty} \bar{H}_m(\zeta, t). \tag{10.5.4}$$

There are at least two ways to verify the truth of (5.4). In analogy with (4.8.2), let us write

$$z^d = (\beta_1 \cdots \beta_n, \alpha_1 \cdots \alpha_n), \tag{10.5.5}$$

$$\zeta = (Q_1 \cdots Q_n, P_1 \cdots P_n). \tag{10.5.6}$$

Introduce the mixed-variable generating function $F_2(q, P, t)$ by the rule

$$F_2(q, P, t) = \sum_{\ell=1}^{n} [\alpha_\ell(t) q_\ell - \beta_\ell(t) P_\ell + q_\ell P_\ell]. \tag{10.5.7}$$

Then, following the rules (4.8.4) and (4.8.5), we find the results

$$Q_\ell = \partial F_2 / \partial P_\ell = q_\ell - \beta_\ell(t), \tag{10.5.8}$$

$$p_\ell = \partial F_2 / \partial q_\ell = P_\ell + \alpha_\ell(t), \tag{10.5.9}$$

which are equivalent to the relation (5.1). Also, following the standard rules, the transformed Hamiltonian produced by the symplectic (canonical) transformation associated with (5.7) is given by the relation

$$H^{\text{new}}(Q, P, t) = H^{\text{new}}(\zeta, t) = H^{\text{old}}(z^d + \zeta, t) + \partial F_2/\partial t = \bar{H}(\zeta, t) + \partial F_2/\partial t. \tag{10.5.10}$$

But from (5.7) we find the result

$$\partial F_2/\partial t = \sum_{\ell=1}^{n} [\dot{\alpha}_\ell(t) q_\ell - \dot{\beta}_\ell(t) P_\ell] = \sum_{\ell=1}^{n} [\dot{\alpha}_\ell(t) \beta_\ell(t) + \dot{\alpha}_\ell(t) Q_\ell - \dot{\beta}_\ell P_\ell] \tag{10.5.11}$$

so that

$$H^{\rm new}(Q,P,t) = H^{\rm new}(\zeta,t) = \bar{H}(\zeta,t) + \sum_{\ell=1}^{n}[\dot{\alpha}_\ell(t)\beta_\ell(t) + \dot{\alpha}_\ell(t)Q_\ell - \dot{\beta}_\ell P_\ell]. \qquad (10.5.12)$$

We see that the second term on the far right of (5.12), the $\partial F_2/\partial t$ component of $H^{\rm new}$, consists only of terms independent of ζ and terms linear in ζ. Consequently, consistent with the claim made in (5.2) through (5.4), the quadratic and higher-order terms in ζ that appear in the expansions of $\bar{H}(\zeta,t)$ and $H^{\rm new}(\zeta,t)$ agree. Also, again consistent with (5.4), we know that $H^{\rm new}(\zeta,t)$ cannot contain terms linear in ζ, for otherwise $\zeta = 0$ would not be a possible trajectory for the equations of motion generated by $H^{\rm new}$. Finally, terms in $H^{\rm new}$ independent of ζ make no contribution to the equations of motion and, consistent with (5.4), can simply be dropped.

A second way to verify the truth of (5.4) is simply to examine equations of motion. According to (5.2.3) a general trajectory satisfies the equation of motion

$$\dot{z} = J\partial_z H(z,t), \qquad (10.5.13)$$

and the given trajectory z^d satisfies the equation of motion

$$\dot{z}^d = J\partial_z H(z,t)\big|_{z=z^d}. \qquad (10.5.14)$$

Also, as is easily verified from (5.2) and (5.3), we have the result

$$\partial_z H(z,t)|_{z=z^d} = \partial_\zeta \bar{H}_1(\zeta,t). \qquad (10.5.15)$$

Now let us insert (5.1) through (5.3) into (5.13) to get the relation

$$\dot{z} = \dot{z}^d + \dot{\zeta} = J\partial_z H(z,t) = J\partial_\zeta H(z^d+\zeta,t) = J\partial_\zeta \bar{H}(\zeta,t) = J\partial_\zeta \sum_{m=1}^{\infty} \bar{H}_m(\zeta,t). \qquad (10.5.16)$$

Finally, subtract (5.14) from (5.16) and use (5.15) and (5.4) to find the result

$$\dot{\zeta} = J\partial_\zeta \sum_{m=1}^{\infty} \bar{H}_m(\zeta,t) - J\partial_\zeta \bar{H}_1(\zeta,t) = J\partial_\zeta \sum_{m=2}^{\infty} \bar{H}_m(\zeta,t) = J\partial_\zeta H^{\rm new}(\zeta,t). \qquad (10.5.17)$$

We see that the time evolution of the deviation variables ζ is indeed governed by $H^{\rm new}$, as claimed. We also note that, according to (5.14) and (5.15), the equation of motion for the design trajectory itself is provided by the relation

$$\dot{z}^d = J\partial_\zeta \bar{H}_1(\zeta,t). \qquad (10.5.18)$$

We close this subsection by observing that there is a variant definition of $H^{\rm new}$ that is often convenient. The relation (5.4) can be rewritten in the form

$$H^{\rm new}(\zeta,t) = \sum_{m=2}^{\infty} \bar{H}_m(\zeta,t) = \bar{H}(\zeta,t) - \bar{H}_0(\zeta,t) - \bar{H}_1(\zeta,t). \qquad (10.5.19)$$

Since term $\bar{H}_0(\zeta,t)$ is independent of ζ, it makes no contribution to the equations of motion and therefore may be dropped. Consequently we may make the alternate definition

$$H^{\rm new}(\zeta,t) = \bar{H}(\zeta,t) - \bar{H}_1(\zeta,t). \qquad (10.5.20)$$

Note that all the definitions (5.12), (5.19), and (5.20) are in closed form and do not actually involve the summation of infinite series.

10.5.2 Term by Term Procedure

To continue the general discussion, let us write H^{new} as given by (5.4) in the form

$$H^{\text{new}} = H_2 + H_3 + H_4 + \cdots = H_2 + H_r. \tag{10.5.21}$$

Alternatively, we may expand H^{new} as given by (5.10) or (5.20) in homogeneous polynomials (in the components of ζ) and omit any irrelevant H_0 term to obtain the same result. Let $\mathcal{M}$ be the transfer map associated with H^{new}. In accord with the spirit of (1.9) and (1.12), let us factor $\mathcal{M}$ in the form

$$\mathcal{M} = \mathcal{M}_r\mathcal{M}_2. \tag{10.5.22}$$

Here, as in (5.21), we use the subscript "r" to denote "remaining" terms. [Note that (5.22) is a reverse factorization.] Following the discussion of Section 10.1, we will require that $\mathcal{M}_2$ obey the equation of motion

$$\dot{\mathcal{M}}_2 = \mathcal{M}_2 : -H_2 : . \tag{10.5.23}$$

Correspondingly, $\mathcal{M}_r$ will obey the equation of motion

$$\dot{\mathcal{M}}_r = \mathcal{M}_r : -H_r^{\text{int}} :, \tag{10.5.24}$$

where the interaction Hamiltonian H_r^{int} is given by rule

$$H_r^{\text{int}}(\zeta^i, t) = H_r(\mathcal{M}_2\zeta^i, t). \tag{10.5.25}$$

We will now describe how to compute $\mathcal{M}_2$ and $\mathcal{M}_r$. Let us begin with $\mathcal{M}_2$. Since H_2 is a quadratic Hamiltonian, its associated transfer map $\mathcal{M}_2$ must be linear. Let $\overline{\zeta}(t)$ be the result of $\mathcal{M}_2(t)$ acting on ζ^i. Then there is a symplectic matrix R such that

$$\overline{\zeta}_a(t) = \mathcal{M}_2(t)\zeta_a^i = \sum_b R_{ab}(t)\zeta_b^i, \tag{10.5.26}$$

or, in more compact vector and matrix notation,

$$\overline{\zeta}(t) = R(t)\zeta^i. \tag{10.5.27}$$

Thus, the computation of $\mathcal{M}_2$ is equivalent to finding the matrix R. Since H_2 is quadratic, there is an associated symmetric matrix $S(t)$ such that H_2 is given by the relation

$$H_2(\zeta^i, t) = (1/2)\sum_{a,b} S_{ab}(t)\zeta_a^i\zeta_b^i. \tag{10.5.28}$$

In analogy with (8.3.64) and (8.3.66), we have the result

$$: -H_2 : \zeta^i = JS\zeta^i. \tag{10.5.29}$$

Suppose both sides of (5.23) are applied to the quantity ζ^i. For the left side we find the result

$$\dot{\mathcal{M}}_2\zeta^i = \dot{\overline{\zeta}} = \dot{R}\zeta^i. \tag{10.5.30}$$

For the right side we find the result

$$\mathcal{M}_2 : -H_2 : \zeta^i = \mathcal{M}_2 JS\zeta^i = JS\mathcal{M}_2\zeta^i = JSR\zeta^i. \tag{10.5.31}$$

Now compare the right sides of (5.30) and (5.31). Since ζ^i is an arbitrary vector, we conclude that R must obey the matrix differential equation

$$\dot{R} = JSR. \tag{10.5.32}$$

Also, the requirement that $\mathcal{M}_2$ be the identity operator $\mathcal{I}$ when $t = t^i$ makes R subject to the initial condition

$$R(t^i) = I. \tag{10.5.33}$$

The differential equation (5.32) with the initial condition (5.33) has a unique solution whose computation, in most cases, requires numerical integration. [The system (5.32) is equivalent to $(2n)^2$ first-order coupled and time-dependent linear equations.] In the special case when the matrices $JS(t)$ and $JS(t')$ commute for all times t and t', one has, in analogy to (3.25), the explicit solution

$$R(t) = \exp\left[\int_{t^i}^{t} JS(t')dt'\right]. \tag{10.5.34}$$

[Indeed, it can be shown that the solution to (5.32) depends entirely upon the Lie algebra generated by the matrices $JS(t)$.] In the even more special case that S (and therefore H_2) is time independent, the integration required in (5.34) is immediate, and one obtains the result

$$R = \exp[(t - t^i)JS]. \tag{10.5.35}$$

In either of the cases corresponding to (5.34) and (5.35) one can write

$$\mathcal{M}_2 = \exp(: f_2 :), \tag{10.5.36}$$

with f_2 given by the relation

$$f_2 = -\int_{t^i}^{t} H_2(t')dt'. \tag{10.5.37}$$

In the general case, if desired, one may polar decompose R in analogy to (6.2.2) and, in analogy to (7.2.10), write $\mathcal{M}_2$ in the form

$$\mathcal{M}_2 = \exp(: f_2^c :)\exp(: f_2^a :). \tag{10.5.38}$$

We turn now to the calculation of $\mathcal{M}_r$. We begin by making the computation of H_r^{int} more explicit. By definition, H_r consists of terms of degree 3 and higher,

$$H_r = H_3 + H_4 + \cdots . \tag{10.5.39}$$

Also, in view of (5.25) and the fact that $\mathcal{M}_2$ produces a linear transformation when acting on ζ^i [see (5.26) and (5.27)], it follows that H_r^{int} has the decomposition

$$H_r^{\text{int}} = H_3^{\text{int}} + H_4^{\text{int}} + \cdots , \tag{10.5.40}$$

where each term $H_m^{\rm int}$ is a homogeneous polynomial of degree m given by the relation

$$H_m^{\rm int}(\zeta^i, t) = H_m(\mathcal{M}_2\zeta^i, t). \tag{10.5.41}$$

[We note in passing that the operations involved in computing (5.41) using (5.26) are analogous to those employed in (8.4.23) except that R^{-1} is replaced by R.]

To see how this works out in a specific case, consider the computation of $H_3^{\rm int}$. The terms of still higher degree are handled analogously. Suppose that H_3 is written in the explicit form

$$H_3(\zeta^i, t) = \sum_{abc} T_{abc}(t)\zeta_a^i\zeta_b^i\zeta_c^i, \tag{10.5.42}$$

where T_{abc} is a set of (possibly time-dependent) coefficients. Then use of (5.41) gives the relation

$$H_3^{\rm int}(\zeta^i, t) = \sum_{abc} T_{abc}(\mathcal{M}_2\zeta_a^i)(\mathcal{M}_2\zeta_b^i)(\mathcal{M}_2\zeta_c^i). \tag{10.5.43}$$

However, thanks to (5.26), the terms on the right side of (5.43) may be evaluated explicitly so that $H_3^{\rm int}$ can be expressed in the form

$$H_3^{\rm int}(\zeta^i, t) = \sum_{abc}\sum_{a'b'c'} T_{abc}R_{aa'}R_{bb'}R_{cc'}\zeta_{a'}^i\zeta_{b'}^i\zeta_{c'}^i. \tag{10.5.44}$$

Finally, the sums in (5.44) can be grouped so that $H_3^{\rm int}$ can be written in the final form

$$H_3^{\rm int}(\zeta^i, t) = \sum_{a'b'c'} T_{a'b'c'}^{\rm int}(t)\,\zeta_{a'}^i\zeta_{b'}^i\zeta_{c'}^i, \tag{10.5.45}$$

where $T^{\rm int}$ is defined by the equation

$$T_{a'b'c'}^{\rm int}(t) = \sum_{abc} T_{abc}(t)R_{aa'}(t)R_{bb'}(t)R_{cc'}(t). \tag{10.5.46}$$

As mentioned earlier, because of the time dependence of R, note that $H_3^{\rm int}$ is in general *time dependent* even if H_3 is not.

Let us write $\mathcal{M}_r$ in reversed factorized form. See Section 7.8. Since $H_r^{\rm int}$ consists of terms of degree 3 and higher, $\mathcal{M}_r$ can be written as the product

$$\mathcal{M}_r = \cdots\mathcal{M}_5\mathcal{M}_4\mathcal{M}_3, \tag{10.5.47}$$

where each factor $\mathcal{M}_m$ is generated by the homogeneous polynomial function $f_m(\zeta^i)$,

$$\mathcal{M}_m = \exp(:f_m:). \tag{10.5.48}$$

[Note that (5.47) is also a reversed factorization.] Our goal is to find equations of motion for the f_m.

From the factorization (5.47) and the product rule for differentiation, it follows that $\dot{\mathcal{M}}_r$ can be written in the form

$$\dot{\mathcal{M}}_r = \cdots + \cdots\dot{\mathcal{M}}_5\mathcal{M}_4\mathcal{M}_3 + \cdots\mathcal{M}_5\dot{\mathcal{M}}_4\mathcal{M}_3 + \cdots\mathcal{M}_5\mathcal{M}_4\dot{\mathcal{M}}_3. \tag{10.5.49}$$

Suppose (5.49) is substituted into the equation of motion (5.24) and both sides of the resulting relation are multiplied by $\mathcal{M}_r^{-1}$. So doing gives the result

$$\begin{aligned} \mathcal{M}_r^{-1}\dot{\mathcal{M}}_r &= \cdots + \mathcal{M}_3^{-1}\mathcal{M}_4^{-1}\mathcal{M}_5^{-1}\dot{\mathcal{M}}_5\mathcal{M}_4\mathcal{M}_3 + \mathcal{M}_3^{-1}\mathcal{M}_4^{-1}\dot{\mathcal{M}}_4\mathcal{M}_3 + \mathcal{M}_3^{-1}\dot{\mathcal{M}}_3 \\ &= :-H_r^{\text{int}}: . \end{aligned} \tag{10.5.50}$$

The various terms appearing in (5.50) can be simplified by the use of adjoint operators. For example, we have the result

$$\mathcal{M}_3^{-1}\mathcal{M}_4^{-1}\mathcal{M}_5^{-1}\dot{\mathcal{M}}_5\mathcal{M}_4\mathcal{M}_3 = \exp(-\#f_3\#)\exp(-\#f_4\#)\mathcal{M}_5^{-1}\dot{\mathcal{M}}_5. \tag{10.5.51}$$

See (8.2.23). Also, we have the relation

$$\mathcal{M}_m^{-1}\dot{\mathcal{M}}_m = \text{iex}(-\#f_m\#) : \dot{f}_m : . \tag{10.5.52}$$

See Appendix C. Upon using (5.51) and (5.52) in (5.50), we find that (5.50) can be rewritten in the form

$$\begin{aligned} \cdots &+ \exp(-\#f_3\#)\exp(-\#f_4\#)\,\text{iex}(-\#f_5\#) : \dot{f}_5 : \\ &+ \exp(-\#f_3\#)\,\text{iex}(-\#f_4\#) : \dot{f}_4 : \\ &+ \text{iex}(-\#f_3\#) : \dot{f}_3 :=: -H_r^{\text{int}} : . \end{aligned} \tag{10.5.53}$$

At this stage the colons can be removed from both sides of (5.53) to give the result

$$\begin{aligned} \cdots &+ \exp(-:f_3:)\exp(-:f_4:)\,\text{iex}(-:f_5:)\dot{f}_5 \\ &+ \exp(-:f_3:)\,\text{iex}(-:f_4:)\dot{f}_4 \\ &+ \text{iex}(-:f_3:)\dot{f}_3 = -H_r^{\text{int}}. \end{aligned} \tag{10.5.54}$$

Let us examine both sides of (5.54) with the aim of equating terms of like degree. From the expansion (8.8.9) we find the result

$$\text{iex}(-:f_m:)\dot{f}_m = (1 - :f_m:/2! + :f_m:^2/3! - \cdots)\dot{f}_m. \tag{10.5.55}$$

According to (7.6.16), the terms of the right side of (5.55) have degrees m, $2m-2$, $3m-4$, etc. Consequently, upon using (5.40), and equating terms of like degree in (5.54), we find the result

$$\begin{aligned} P_m[\cdots &+ \exp(-:f_3:)\exp(-:f_4:)\,\text{iex}(-:f_5:)\dot{f}_5 \\ &+ \exp(-:f_3:)\,\text{iex}(-:f_4:)\dot{f}_4 \\ &+ \text{iex}(-:f_3:)\dot{f}_3] = -H_m^{\text{int}}. \end{aligned} \tag{10.5.56}$$

Here P_m denotes a *projection* operator that projects out terms of degree m. For example, we have the results

$$P_3[\cdots + \text{iex}(-:f_3:)\dot{f}_3] = \dot{f}_3, \tag{10.5.57}$$

$$P_4[\cdots + \text{iex}(-:f_3:)\dot{f}_3] = \dot{f}_4 - (:f_3:/2!)\dot{f}_3, \tag{10.5.58}$$

$$P_5[\cdots + \text{iex}(-:f_3:)\dot{f}_3] = \dot{f}_5 - :f_3:\dot{f}_4 + (:f_3:^2/3!)\dot{f}_3. \tag{10.5.59}$$

The relations (5.56) can now be solved for the various $\dot{f}_m$. We find, for example, through $m = 8$, the results

$$\dot{f}_3 = -H_3^{\rm int}, \tag{10.5.60}$$

$$\dot{f}_4 = -H_4^{\rm int} + (:f_3:/2)(-H_3^{\rm int}), \tag{10.5.61}$$

$$\dot{f}_5 = -H_5^{\rm int} + :f_3:(-H_4^{\rm int}) + (1/3):f_3:^2(-H_3^{\rm int}), \tag{10.5.62}$$

$$\begin{aligned}\dot{f}_6 = & - H_6^{\rm int} + :f_3:(-H_5^{\rm int}) + (1/2):f_4:(-H_4^{\rm int}) \\ & + (1/4):f_4::f_3:(-H_3^{\rm int}) + (1/2):f_3:^2(-H_4^{\rm int}) \\ & + (1/8):f_3:^3(-H_3^{\rm int}),\end{aligned} \tag{10.5.63}$$

$$\begin{aligned}\dot{f}_7 = & - H_7^{\rm int} + :f_3:(-H_6^{\rm int}) + :f_4:(-H_5^{\rm int}) + :f_4::f_3:(-H_4^{\rm int}) \\ & + (1/3):f_4::f_3:^2(-H_3^{\rm int}) + (1/2):f_3:^2(-H_5^{\rm int}) \\ & + (1/6):f_3:^3(-H_4^{\rm int}) + (1/30):f_3:^4(-H_3^{\rm int}),\end{aligned} \tag{10.5.64}$$

$$\begin{aligned}\dot{f}_8 = & - H_8^{\rm int} + :f_3:(-H_7^{\rm int}) + :f_4:(-H_6^{\rm int}) + :f_4::f_3:(-H_5^{\rm int}) \\ & + (1/2):f_4::f_3:^2(-H_4^{\rm int}) + (1/8):f_4::f_3:^3(-H_3^{\rm int}) \\ & + (1/2):f_5:(-H_5^{\rm int}) + (1/2):f_5::f_3:(-H_4^{\rm int}) \\ & + (1/6):f_5::f_3:^2(-H_3^{\rm int}) + (1/2):f_3:^2(-H_6^{\rm int}) \\ & + (1/3):f_4:^2(-H_4^{\rm int}) + (1/6):f_4:^2:f_3:(-H_3^{\rm int}) \\ & + (1/6):f_3:^3(-H_5^{\rm int}) + (1/24):f_3:^4(-H_4^{\rm int}) \\ & + (1/144):f_3:^5(-H_3^{\rm int}),\end{aligned} \tag{10.5.65}$$

$$\dot{f}_m = \text{ something involving } H_m \text{ and the } f_\ell \text{ and } H_\ell \text{ with } \ell < m. \tag{10.5.66}$$

What have we accomplished? From (5.22), (5.38), (5.47), and (5.48) we see that $\mathcal{M}$ has been computed in a reverse factorized product form; and we have found how to calculate the $\mathcal{M}_m$. To find $\mathcal{M}_2$ we need to integrate the equations (5.32) with the initial condition (5.33). Here it is assumed that $z^d(t)$ is known so that H_2 and hence S is known. See (5.28). If this is not the case, then we must also integrate the equations (5.14) or (5.18). That is, we must integrate the equations (5.14) [or (5.18)] and (5.32) as a coupled set. To find the f_m that define $\mathcal{M}_r$ according to (5.47) and (5.48), we must also integrate the equations of motion for the f_m as given by (5.60) through (5.66). The requirement that $\mathcal{M}_r$ be the identity operator $\mathcal{I}$ when $t = t^i$ makes the f_m subject to the initial condition

$$f_m(t^i) = 0. \tag{10.5.67}$$

We note from the form of equations (5.60) through (5.66) that the computation of the f_m requires a knowledge of the $H_\ell^{\rm int}$ with $\ell \leq m$. The computation of $H_\ell^{\rm int}(t)$ in turn requires a knowledge of $R(t)$. [See, for example, (5.43) through (5.46).] Consequently, the equations of motion (5.60) through (5.66) for the f_m must be integrated simultaneously with the equations (5.32) for R. [Moreover, in general $z^d(t)$ must also be known to compute $H_\ell^{\rm int}(t)$.

Thus, if $z^d(t)$ is not known explicitly, then the equations (5.14) or (5.18) must in general also be in the set of equations to be integrated.]

We close this section with the observation that the equations of motion (5.60) through (5.66) for the f_m, like equations (3.11) through (3.15) for the F_n, have the property that the f_m can be determined successively. This property has two consequences. First, a solution of the equations of motion for R, f_3, f_4, $\cdots f_m$ by numerical methods is always possible for any m. Moreover, solution by *quadrature* is also possible. For example, assuming that R has already been determined, (5.60) can be integrated immediately to give the result

$$f_3(\zeta^i,t) = \int_{t^i}^{t} dt_1[-H_3^{\rm int}(\zeta^i,t_1)]. \tag{10.5.68}$$

Here we have used (5.67). Next, this result for f_3 can be substituted into (5.61) and the resulting expression for $\dot{f}_4$ can be integrated to give the relation

$$f_4(\zeta^i,t) = \int_{t^i}^{t} dt_1[-H_4^{\rm int}(\zeta^i,t_1)] + (1/2)\int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2[-H_3^{\rm int}(\zeta^i,t_2), -H_3^{\rm int}(\zeta^i,t_1)]. \tag{10.5.69}$$

Similarly, one finds for f_5 the result

$$\begin{aligned}
f_5 &= \int_{t^i}^{t} dt_1[-H_5^{\rm int}(t_1)]\\
&+ \int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2[-H_3^{\rm int}(t_2), -H_4^{\rm int}(t_1)]\\
&+ (1/3)\int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2 \int_{t^i}^{t_2} dt_3[-H_3^{\rm int}(t_3),[-H_3^{\rm int}(t_2), -H_3^{\rm int}(t_1)]]\\
&+ (1/3)\int_{t^i}^{t} dt_1 \int_{t^i}^{t_1} dt_2 \int_{t^i}^{t_2} dt_3[-H_3^{\rm int}(t_2),[-H_3^{\rm int}(t_3), -H_3^{\rm int}(t_1)]].
\end{aligned} \tag{10.5.70}$$

Evidently, one can find explicit integral representations for all the f_m. We note that to determine any f_m it is necessary to know only the $H_\ell^{\rm int}$ with $\ell \le m$. Moreover, if the $H_\ell^{\rm int}$ do not commute (are not in involution) at different times, which is usually the case, there are feed-up effects: lower-order terms in the Hamiltonian can contribute to higher-order Lie generators. Specifically, we see that the f_m all lie in the Lie algebra generated by the $H_\ell^{\rm int}$. Finally, suppose the time dependencies of the various $H_\ell^{\rm int}$ are sufficiently simple that all the integrations occurring in (5.68), (5.69), (5.70), and analogous expressions for the other f_m can be carried out analytically. Then the equations of motion (5.60) through (5.66) can in principle be solved directly by symbolic manipulation to obtain complete analytic expressions for all desired f_m.

We close this subsection by noting that for simplicity we have derived formulas for R and the f_m when the map $\mathcal{M}$ is written in *reversed* factorized product form. That is, we have written $\mathcal{M}$ in the form

$$\mathcal{M} = \cdots \mathcal{M}_5\mathcal{M}_4\mathcal{M}_3\mathcal{M}_2. \tag{10.5.71}$$

See (5.22) and (5.47). Of course, once we have found $\mathcal{M}$ is reversed factorized product form, we can convert it to the *forward* factorized product form

$$\mathcal{M} = \mathcal{M}_2'\mathcal{M}_3'\mathcal{M}_4'\mathcal{M}_5' \cdots \tag{10.5.72}$$

by means of concatenation formulas. Recall Section 8.4. Alternatively, as will be seen in the next section, there are formulas for the associated R' and f_m', analogous to those for R and the f_m, when $\mathcal{M}$ is written in forward factorized product form. Finally we note, from the work of Section 8.5, that there is a standard procedure for passing from forward to reverse factorized forms.

Exercises

10.5.1. The purpose of this exercise is to verify the relation (5.18) from another perspective. Begin by showing that by Taylor's theorem there is the relation

$$\bar{H}_1(\zeta, t) = \sum_a [\partial H(z,t)/\partial z_a]|_{z=z^d(t)}\zeta_a, \tag{10.5.73}$$

and consequently

$$\partial \bar{H}_1(\zeta, t)/\partial \zeta_a = [\partial H(z,t)/\partial z_a]|_{z=z^d(t)}. \tag{10.5.74}$$

Now verify it follows that

$$J\partial_\zeta \bar{H}_1(\zeta, t) = J[\partial_z H(z,t)]|_{z=z^d(t)} = \dot{z}^d. \tag{10.5.75}$$

10.5.2. Consider a general Hamiltonian system with Hamiltonian $H(z,t)$, and suppose $z^d(t)$ is any particular trajectory for (solution to) the equations of motion associated with this Hamiltonian. Form the variational equations about the trajectory $z^d(t)$. Show that the variational equations also arise from a Hamiltonian, and that this Hamiltonian is the quadratic Hamiltonian $\bar{H}_2$ that appears in the sum (5.3). Show that integrating (5.32) with the initial condition (5.33) provides all possible solutions to the variational equations.

10.6 Forward Factorization and Lie Concatenation Revisited

10.6.1 Preliminary Discussion

The previous section derived a reversed factorized product solution to the equation of motion (1.8) for $\mathcal{M}$. For this present section, and other purposes as well, it is useful to also have formulas for a forward factorized product solution. We begin by finding them.

The main purpose of this section, which is really a diversion from the logical presentation of methods for the computation of maps, is to provide another derivation of the Lie concatenation formulas of Section 8.4. Subsequent sections will return to the main subject of this chapter.

10.6.2 Forward Factorization

As before we write

$$\mathcal{M} = \mathcal{M}_r \mathcal{M}_2 \tag{10.6.1}$$

and require that $\mathcal{M}_2$ again satisfy (5.23). Then we find, as before, that $\mathcal{M}_r$ obeys the equation of motion

$$\dot{\mathcal{M}}_r = \mathcal{M}_r : -H_r^{\text{int}} : \tag{10.6.2}$$

with H_r^{int} again given by (5.25). Now, however, we write $\mathcal{M}_r$ in the forward factorized form

$$\mathcal{M}_r = \mathcal{M}_3 \mathcal{M}_4 \mathcal{M}_5 \cdots \tag{10.6.3}$$

with

$$\mathcal{M}_m = \exp(: f_m :). \tag{10.6.4}$$

We will obtain equations of motion for the f_m shortly, but imagine for the moment that they have already been found and solved. Then we may write $\mathcal{M}$ in the form

$$\mathcal{M} = \exp(: f_3 :) \exp(: f_4 :) \exp(: f_5 :) \cdots \mathcal{M}_2. \tag{10.6.5}$$

Algebraic manipulation now gives the equivalent result

$$\begin{aligned} \mathcal{M} &= \mathcal{M}_2 \mathcal{M}_2^{-1} \exp(: f_3 :) \mathcal{M}_2 \mathcal{M}_2^{-1} \exp(: f_4 :) \mathcal{M}_2 \mathcal{M}_2^{-1} \exp(: f_5 :) \cdots \mathcal{M}_2 \\ &= \mathcal{M}_2 \exp(: f_3^{tr} :) \exp(: f_4^{tr} :) \exp(: f_5^{tr} :) \cdots \end{aligned} \tag{10.6.6}$$

where

$$f_m^{tr} = \mathcal{M}_2^{-1} f_m. \tag{10.6.7}$$

We see that $\mathcal{M}$ as given by (6.6) and (6.7) is in the desired forward factorized product form.

It remains to find the f_m. Differentiating (6.3) gives the result

$$\dot{\mathcal{M}}_r = \dot{\mathcal{M}}_3 \mathcal{M}_4 \mathcal{M}_5 \cdots + \mathcal{M}_3 \dot{\mathcal{M}}_4 \mathcal{M}_5 \cdots + \mathcal{M}_3 \mathcal{M}_4 \dot{\mathcal{M}}_5 \cdots + \cdots . \tag{10.6.8}$$

Next, substitution of (6.8) into the equation of motion (6.2) produces the relation

$$\begin{aligned} \mathcal{M}_r^{-1} \dot{\mathcal{M}}_r &= \cdots \mathcal{M}_5^{-1} \mathcal{M}_4^{-1} \mathcal{M}_3^{-1} \dot{\mathcal{M}}_3 \mathcal{M}_4 \mathcal{M}_5 \cdots + \cdots \mathcal{M}_5^{-1} \mathcal{M}_4^{-1} \dot{\mathcal{M}}_4 \mathcal{M}_5 \cdots \\ &+ \cdots \mathcal{M}_5^{-1} \dot{\mathcal{M}}_5 \cdots + \cdots =: -H_r^{\text{int}} : . \end{aligned} \tag{10.6.9}$$

As in the previous section, the various terms in (6.9) can be simplified by the use of adjoint operators. For example, we have the result

$$\cdots \mathcal{M}_5^{-1} \mathcal{M}_4^{-1} \mathcal{M}_3^{-1} \dot{\mathcal{M}}_3 \mathcal{M}_4 \mathcal{M}_5 \cdots = \cdots \exp(-\#f_5\#) \exp(-\#f_4\#) \mathcal{M}_3^{-1} \dot{\mathcal{M}}_3. \tag{10.6.10}$$

Again we recall the relation

$$\mathcal{M}_m^{-1} \dot{\mathcal{M}}_m = \text{ iex } (-\#f_m\#) : \dot{f}_m : . \tag{10.6.11}$$

Upon using (6.10) and (6.11) in (6.9) we find that it can be rewritten in the form

$$\begin{aligned} &\cdots \exp(-\#f_5\#) \exp(-\#f_4\#) \text{ iex}(-\#f_3\#) : \dot{f}_3 : \\ &+ \cdots \exp(-\#f_5\#) \text{ iex } (-\#f_4\#) : \dot{f}_4 : \\ &+ \cdots \text{ iex}(-\#f_5\#) : \dot{f}_5 :=: -H_r^{\text{int}} : . \end{aligned} \tag{10.6.12}$$

The colons can now be removed from both sides of (6.12) to give the equivalent result

$$\begin{aligned}
&\cdots \exp(- : f_5 :) \exp(- : f_4 :) \operatorname{iex}(- : f_3 :) \dot{f}_3 \\
&+ \cdots \exp(- : f_5 :) \operatorname{iex}\, (- : f_4 :) \dot{f}_4 \\
&+ \cdots \ \operatorname{iex}(- : f_5 :) \dot{f}_5 \\
&+ \cdots = -H_r^{\text{int}}.
\end{aligned} \tag{10.6.13}$$

Finally, similar to the procedure in the previous section, we equate terms of like degree in (6.13). So doing gives the equations of motion

$$\dot{f}_3 = -H_3^{\text{int}}, \tag{10.6.14}$$

$$\dot{f}_4 = -H_4^{\text{int}} + (: f_3 : /2)(-H_3^{\text{int}}), \tag{10.6.15}$$

$$\dot{f}_5 = -H_5^{\text{int}} - (1/6) : f_3 :^2 (-H_3^{\text{int}}) + : f_4 : (-H_3^{\text{int}}), \tag{10.6.16}$$

$$\begin{aligned}
\dot{f}_6 \ \ = \ \ & -H_6^{\text{int}} + (1/24) : f_3 :^3 (-H_3^{\text{int}}) + (1/2) : f_4 : (-H_4^{\text{int}}) \\
& -(1/4) : f_4 :: f_3 : (-H_3^{\text{int}}) + : f_5 : (-H_3^{\text{int}}),
\end{aligned} \tag{10.6.17}$$

$$\begin{aligned}
\dot{f}_7 \ \ = \ \ & -H_7^{\text{int}} - (1/120) : f_3 :^4 (-H_3^{\text{int}}) + (1/6) : f_4 :: f_3 :^2 (-H_3^{\text{int}}) \\
& -(1/2) : f_4 :^2 (-H_3^{\text{int}}) + : f_5 : (-H_4^{\text{int}}) + : f_6 : (-H_3^{\text{int}}),
\end{aligned} \tag{10.6.18}$$

$$\begin{aligned}
\dot{f}_8 \ \ = \ \ & -H_8^{\text{int}} + (1/720) : f_3 :^5 (-H_3^{\text{int}}) - (1/24) : f_4 :: f_3 :^3 (-H_3^{\text{int}}) \\
& -(1/6) : f_4 :^2 (-H_4^{\text{int}}) + (1/6) : f_4 :^2 : f_3 : (-H_3^{\text{int}}) + (1/2) : f_5 : (-H_5^{\text{int}}) \\
& +(1/12) : f_5 :: f_3 :^2 (-H_3^{\text{int}}) - (1/2) : f_5 :: f_4 : (-H_3^{\text{int}}) + : f_6 : (-H_4^{\text{int}}) \\
& + : f_7 : (-H_3^{\text{int}}),
\end{aligned} \tag{10.6.19}$$

$$\dot{f}_m = \text{ expression involving } H_m^{\text{int}} \text{ and the } f_\ell \text{ and } H_\ell^{\text{int}} \text{ with } \ell < m. \tag{10.6.20}$$

As before, these equations can be integrated with the initial condition (5.67).

10.6.3 Alternate Derivation of Lie Concatenation Formulas

The tools are now in hand to carry out the main task of this section: an alternate derivation of the Lie concatenation formulas. According to (8.4.26) in Section 8.4, the problem is to find the h_m in the relation

$$\exp(: h_3 :) \exp(: h_4 :) \cdots = \exp(: f_3^{tr} :) \exp(: f_4^{tr} :) \cdots \exp(: g_3 :) \exp(: g_4 :) \cdots . \tag{10.6.21}$$

[Note that here the f_m^{tr} are given by (8.4.23) and not by (6.7).] To do this, we employ a trick. Define a one-parameter family of maps $\mathcal{N}(\lambda)$ by the rule

$$\mathcal{N}(\lambda) = \exp(\lambda : f_3^{tr} :) \exp(\lambda : f_4^{tr} :) \cdots \exp(\lambda : g_3 :) \exp(\lambda : g_4 :) \cdots . \tag{10.6.22}$$

Then, by construction, $\mathcal{N}(\lambda)$ has the properties

$$\mathcal{N}(0) = \mathcal{I}, \tag{10.6.23}$$

$$\mathcal{N}(1) = \exp(:h_3:)\exp(:h_4:)\cdots\ , \tag{10.6.24}$$

$$\mathcal{N}^{-1}(\lambda) = \cdots\exp(-\lambda:g_4:)\exp(-\lambda:g_3:)\cdots\exp(-\lambda:f_4^{tr}:)\exp(-\lambda:f_3^{tr}:). \tag{10.6.25}$$

From Section 6.4 we know that there is an associated Hamiltonian $H(\lambda)$. In this case, in analogy to (1.8), it can be found from the relation

$$:-H:=\mathcal{N}^{-1}\dot{\mathcal{N}} \tag{10.6.26}$$

where a dot denotes differentiation with respect to λ. From (6.22) we find the result

$$\begin{aligned}
\dot{\mathcal{N}} &= \exp(\lambda:f_3^{tr}:):f_3^{tr}:\exp(\lambda:f_4^{tr}:)\cdots\exp(\lambda:g_3:)\exp(\lambda:g_4:)\cdots \\
&+ \exp(\lambda:f_3^{tr}:)\exp(\lambda:f_4^{tr}:):f_4^{tr}:\cdots\exp(\lambda:g_3:)\exp(\lambda:g_4:)\cdots \\
&+ \cdots \\
&+ \exp(\lambda:f_3^{tr}:)\exp(\lambda:f_4^{tr}:)\cdots\exp(\lambda:g_3:):g_3:\exp(\lambda:g_4:)\cdots \\
&+ \exp(\lambda:f_3^{tr}:)\exp(\lambda:f_4^{tr}:)\cdots\exp(\lambda:g_3:)\exp(\lambda:g_4:):g_4:\cdots \\
&+ \cdots\ .
\end{aligned} \tag{10.6.27}$$

Consequently the Hamiltonian Lie operator $:-H:$ is given by

$$\begin{aligned}
:-H: &= \mathcal{N}^{-1}\dot{\mathcal{N}} \\
&= \cdots\exp(-\lambda:g_4:)\exp(-\lambda:g_3:)\cdots\times \\
&\quad \exp(-\lambda:f_4^{tr}:):f_3^{tr}:\exp(\lambda:f_4^{tr}:)\cdots\exp(\lambda:g_3:)\exp(\lambda:g_4:)\cdots \\
&+ \cdots\exp(-\lambda:g_4:)\exp(-\lambda:g_3:)\cdots:f_4^{tr}:\cdots\exp(\lambda:g_3:)\exp(\lambda:g_4:)\cdots \\
&+ \cdots \\
&+ \cdots\exp(-\lambda:g_4:):g_3:\exp(\lambda:g_4:)\cdots \\
&+ \cdots:g_4:\cdots \\
&+ \cdots\ .
\end{aligned} \tag{10.6.28}$$

This result can also be written more compactly with the aid of adjoint operators to take the form

$$\begin{aligned}
:-H: &= \cdots\exp(-\lambda\#g_4\#)\exp(-\lambda\#g_3\#)\cdots\exp(-\lambda\#f_4^{tr}\#):f_3^{tr}: \\
&+ \cdots\exp(-\lambda\#g_4\#)\exp(-\lambda\#g_3\#)\cdots:f_4^{tr}: \\
&+ \cdots \\
&+ \cdots\exp(-\lambda\#g_4\#):g_3: \\
&+ \cdots:g_4: \\
&+ \cdots\ .
\end{aligned} \tag{10.6.29}$$

The colons can now be removed from both sides of (6.29) to give the equivalent result

$$\begin{aligned}
-H &= \cdots\exp(-\lambda:g_4:)\exp(-\lambda:g_3:)\cdots\exp(-\lambda:f_4^{tr}:)f_3^{tr} \\
&+ \cdots\exp(-\lambda:g_4:)\exp(-\lambda:g_3:)\cdots f_4^{tr} \\
&+ \cdots \\
&+ \cdots\exp(-\lambda:g_4:)g_3 \\
&+ \cdots g_4 \\
&+ \cdots\ .
\end{aligned} \tag{10.6.30}$$

Finally, equating terms of like degree on both sides of (6.30) yields the results

$$-H_2 = 0, \tag{10.6.31}$$

$$-H_3 = f_3^{tr} + g_3, \tag{10.6.32}$$

$$-H_4 = -\lambda : g_3 : f_3^{tr} + f_4^{tr} + g_4, \tag{10.6.33}$$

$$\begin{aligned} -H_5 &= f_5^{tr} + g_5 - \lambda : f_4^{tr} : f_3^{tr} - \lambda : g_3 : f_4^{tr} \\ &+ (1/2)\lambda^2 : g_3 :^2 f_3^{tr} - \lambda : g_4 : f_3^{tr} - \lambda : g_4 : g_3, \text{ etc.} \end{aligned} \tag{10.6.34}$$

Evidently the h_m in (6.24) can be regarded as the solutions to differential equations of the form (6.14) through (6.20) with H given by (6.31) through (6.34). Also, as a consequence of (6.31), we have the result

$$H_m^{\text{int}} = H_m. \tag{10.6.35}$$

It follows that the h_m satisfy the differential equations

$$\dot{h}_3 = -H_3 = f_3^{tr} + g_3, \tag{10.6.36}$$

$$\begin{aligned} \dot{h}_4 &= -H_4 + (: h_3 : /2)(-H_3) \\ &= -\lambda : g_3 : f_3^{tr} + f_4^{tr} + g_4 + (: h_3 : /2)(f_3^{tr} + g_3), \end{aligned} \tag{10.6.37}$$

$$\begin{aligned} \dot{h}_5 &= -H_5 - (1/6) : h_3 :^2 (-H_3) + : h_4 : (-H_3) \\ &= f_5^{tr} + g_5 - \lambda : f_4^{tr} : f_3^{tr} - \lambda : g_3 : f_4^{tr} + (1/2)\lambda^2 : g_3 :^2 f_3^{tr} - \lambda : g_4 : f_3^{tr} \\ &- \lambda : g_4 : g_3 - (1/6) : h_3 :^2 (f_3^{tr} + g_3) + : h_4 : (f_3^{tr} + g_3), \text{ etc.} \end{aligned} \tag{10.6.38}$$

These equations can now be solved. Equation (6.36) has the immediate solution

$$h_3(\lambda) = \lambda(f_3^{tr} + g_3). \tag{10.6.39}$$

When this solution is substituted into (6.37), the result is that h_4 satisfies the differential equation

$$\dot{h}_4 = -\lambda : g_3 : f_3^{tr} + f_4^{tr} + g_4 \tag{10.6.40}$$

with the solution

$$h_4(\lambda) = \lambda(f_4^{tr} + g_4) - (\lambda^2/2) : g_3 : f_3^{tr}. \tag{10.6.41}$$

Next, with this knowledge of $h_3(\lambda)$ and $h_4(\lambda)$, the equation of motion for h_5 becomes

$$\dot{h}_5 = f_5^{tr} + g_5 - 2\lambda : g_3 : f_4^{tr} + \lambda^2 : g_3 :^2 f_3^{tr} - (\lambda^2/2) : f_3^{tr} :^2 g_3, \tag{10.6.42}$$

with the solution

$$h_5(\lambda) = \lambda(f_5^{tr} + g_5) - \lambda^2 : g_3 : f_4^{tr} + (\lambda^3/3) : g_3 :^2 f_3^{tr} - (\lambda^3/6) : f_3^{tr} :^2 g_3. \tag{10.6.43}$$

The $h_m(\lambda)$ for $m = 6, 7, \cdots$ can be found in an analogous way. We conclude that all the $h_m(\lambda)$ can be computed recursively for any value of m.

Finally, the quantities $h_m(1)$ yield the desired h_m in (6.21). Compare, for example, (8.4.31) through (8.4.33) with the $h_m(1)$ computed from (6.39), (6.41), and (6.43). The virtue of this method for deriving the Lie concatenation formulas is that no knowledge of the BCH series coefficients is required and the results are immediately obtained in Lie form. Only the Taylor coefficients in the *exp* and *iex* functions are needed, and these are known to all orders. And since the equations to be integrated are polynomial in λ, all calculations can be carried out to any desired order by symbolic manipulation.

Exercises

10.6.1.

10.7 Direct Taylor Summation

We now return to the task of computing maps. Suppose the Hamiltonian H is autonomous (time independent) and is analytic in z about the origin $z = 0$. Then it has an expansion in homogeneous polynomials of the form

$$H = \sum_{\ell=1}^{\infty} H_\ell(z). \tag{10.7.1}$$

(Here we have omitted a possible constant term since it has no dynamic effect.) We know from Section 7.4 that in this case the associated transfer map $\mathcal{M}$ can be written formally as

$$\mathcal{M} = \exp(-\tau : H :) \tag{10.7.2}$$

where we have used the short-hand notation

$$\tau = t - t^i. \tag{10.7.3}$$

The purpose of this section, among other things, is to explore what happens when there are singularities in τ.

Let us write

$$z_a^f = \mathcal{M} z_a^i \tag{10.7.4}$$

and make the Taylor expansion

$$z_a^f = k_a + \sum_b R_{ab} z_b^i + \sum_{bc} T_{abc} z_b^i z_c^i + \sum_{bcd} U_{abcd} z_b^i z_c^i z_d^i + \cdots . \tag{10.7.5}$$

We also have the result

$$z_a^f = \exp(-\tau : H :) z_a^i = \sum_{j=0}^{\infty} [(-\tau)^j / j!] : H :^j z_a^i. \tag{10.7.6}$$

Here H is to be regarded as a function of the z^i,

$$H = H(z^i) = H_1(z^i) + H_2(z^i) + H_3(z^i) + \cdots . \tag{10.7.7}$$

If we substitute (7.7) into (7.6), carry out all the indicated Poisson brackets, and then group terms by degree, we will find the Taylor coefficients k, R, T, U, etc. that appear in (7.5). Once the Taylor coefficients are known, there is (according to the Factorization Theorem of Sections 7.6 through 7.8) a standard procedure for finding the homogeneous polynomials f_1, f_2^c, f_2^a, f_3, f_4, $\cdots$ such that $\mathcal{M}$ can be written in the form

$$\mathcal{M} = \exp(: f_1 :) \exp(: f_2^c :) \exp(: f_2^a :) \exp(: f_3 :) \exp(: f_4 :) \cdots . \tag{10.7.8}$$

What we wish to investigate at this point is the convergence of the series (7.6) *in the sense* that it produces *series* for the Taylor coefficients k, R, T, U, etc. Note that this issue is separate from the convergence of the Taylor series (7.5) with regard to the variables z^i.

To facilitate this investigation, it is convenient to employ the basis monomials G_r introduced in Sections 7.3 and 8.3. With the aid of these monomials and the inner product (8.3.32), introduce the infinite dimensional matrices M and H by the rules

$$M_{sr} = \langle G_s, \mathcal{M} G_r \rangle, \tag{10.7.9}$$

$$H_{sr} = \langle G_s, :H: G_r \rangle. \tag{10.7.10}$$

Then, as a result of (8.3.41), the operator relation (7.2) has the equivalent matrix formulation

$$M = \exp(-\tau H) = \sum_{j=0}^{\infty} (\tau^j / j!) H^j. \tag{10.7.11}$$

[Here, to test the reader's mental agility, the symbol H stands not for the Hamiltonian (7.7) but rather for the matrix (7.10).] Moreover, the various Taylor coefficients k, R, T, U, etc. in (7.5) are just matrix elements of the form $\langle G_s, \mathcal{M} G_a^1 \rangle$ where we have used the notation G_a^1 to denote the *linear* functions z_a.

In any practical calculation with power series it is necessary to truncate them at some stage. Operations performed on and with truncated power series will be referred to as *Truncated Power Series Algebra* (TPSA). In this context it is useful to introduce a *projection* operator $\mathcal{P}^D$. Let $m(r)$ denote the degree of the monomial G_r. It is defined by the relation

$$m(r) = \sum (u_i + v_i). \tag{10.7.12}$$

See (7.3.33) and (7.3.34). We now define $\mathcal{P}^D$ to be the *linear* operator with the property

$$\mathcal{P}^D G_r = G_r \text{ if } m(r) \leq D,$$

$$\mathcal{P}^D G_r = 0 \text{ if } m(r) > D. \tag{10.7.13}$$

That is, $\mathcal{P}^D$ retains monomials having degree D or less, and discards those with degree larger than D. In terms of the earlier notation associated with (8.9.68) and (8.9.69), $\mathcal{P}^D$ is just the truncation operator $\mathcal{T}(> D)$. Let θ be a step function given by the rule

$$\theta(x) = 0 \text{ for } x < 0,$$

$$\theta(x) = 1 \text{ for } x \geq 0. \tag{10.7.14}$$

Then we also have the equivalent definition

$$\mathcal{P}^D G_r = \theta(D - m) G_r. \tag{10.7.15}$$

Evidently $\mathcal{P}^D$ has the property

$$(\mathcal{P}^D)^2 = \mathcal{P}^D. \tag{10.7.16}$$

Now let $\mathcal{A}$ be any linear operator. In TPSA this operator is realized by its *truncated* counterpart ${}^D\!\mathcal{A}$ defined by the rule

$$ {}^D\!\mathcal{A} = \mathcal{P}^D \mathcal{A} \mathcal{P}^D. \tag{10.7.17}$$

Following (7.3.33) through (7.3.35), let us also use the modified notation G_r^m for the basis monomials. Consider the vector space V^D spanned by the monomials G_r^0, G_r^1, $\cdots$ G_r^D. From the definition (7.17) we evidently have the result

$$\langle G_r^m,\ {}^D\!\mathcal{A} G_{r'}^{m'} \rangle = 0 \text{ if either } m > D \text{ or } m' > D. \tag{10.7.18}$$

It follows that ${}^D\!\mathcal{A}$ maps V^D into itself, and consequently has a representation as a *finite* dimensional matrix ${}^D\!A$ acting on V^D. Indeed, the matrix ${}^D\!A$ has the entries

$${}^D\!A_{sr} = \langle G_s,\ {}^D\!\mathcal{A} G_r \rangle \text{ with } m(s), m(r) \leq D. \tag{10.7.19}$$

Supppose $\mathcal{A}$, $\mathcal{B}$, and $\mathcal{C}$ are three linear operators related by the equation

$$\mathcal{C} = \mathcal{A}\mathcal{B}. \tag{10.7.20}$$

Then in general one has the inequalities

$${}^D\mathcal{C} \neq\ {}^D\!\mathcal{A}\ {}^D\mathcal{B}, \tag{10.7.21}$$

$${}^D C \neq\ {}^D A\ {}^D B. \tag{10.7.22}$$

However, if either $\mathcal{A}$ or $\mathcal{B}$ commute with $\mathcal{P}^D$, then (7.21) and (7.22) become equalities. Indeed, from (7.16) and the definitions (7.13) we have the result

$${}^D\!\mathcal{A}\ {}^D\mathcal{B} = \mathcal{P}^D \mathcal{A} \mathcal{P}^D \mathcal{P}^D \mathcal{B} P^D = \mathcal{P}^D \mathcal{A} \mathcal{P}^D \mathcal{B} \mathcal{P}^D. \tag{10.7.23}$$

Evidently if one can move the middle factor $\mathcal{P}^D$ either to the left or to the right with impunity, then (7.21) and (7.22) become equalities.

The truncated counterparts of Lie operators are also not derivations. Consider, for example, the case of a 2-dimensional phase space. We have in accord with (5.3.7) the relation

$$: q : p^4 = (: q : p^2)p^2 + p^2 : q : p^2. \tag{10.7.24}$$

Suppose $D = 3$. Then the counterpart of the left side of (7.24) has the value

$$({}^3\!: q :)p^4 = (\mathcal{P}^3 : q : \mathcal{P}^3)p^4 = 0. \tag{10.7.25}$$

On the other hand, the counterpart of the right side of (7.24) is the quantity

$$[({}^3\!: q :)p^2]p^2 + p^2\ ({}^3\!: q :)p^2 = 4p^3. \tag{10.7.26}$$

Thus $({}^3\!: q :)$ is not a derivation. It follows from analogous calculations that no truncated Lie operator of the form $({}^D\!: f_1 :)$ is a derivation.

However, any $({}^D\!: f_\ell :)$ with $\ell \geq 2$ does at least enjoy the property

$$({}^D\!: f_\ell :) = \mathcal{P}^D : f_\ell : \mathcal{P}^D = \mathcal{P}^D : f_\ell : \text{ when } \ell \geq 2. \tag{10.7.27}$$

Let G_r^m be any monomial. From (7.6.16) and (7.15) we find the results

$$\begin{aligned}({}^D\!\!: f_\ell :)G_r^m &= \mathcal{P}^D : f_\ell : \mathcal{P}^D G_r^m = \mathcal{P}^D : f_\ell : \theta(d-m)G_r^m \\ &= \theta(D-m)\mathcal{P}^D \sum_{r'} c_{r'} G_{r'}^{m+\ell-2} \\ &= \theta(D-m)\theta(D+2-\ell-m)\sum_{r'} c_{r'} G_{r'}^{m+\ell-2}, \end{aligned} \tag{10.7.28}$$

$$\mathcal{P}^D : f_\ell : G_r^m = \mathcal{P}^D \sum_{r'} c_{r'} G_{r'}^{m+\ell-2} = \theta(D+2-\ell-m)\sum_{r'} c_{r'} G_{r'}^{m+\ell-2}. \tag{10.7.29}$$

Here the $c_{r'}$ are certain coefficients whose exact values need not concern us. But from (7.14) we conclude that

$$\theta(D-m)\theta(D+2-\ell-m) = \theta(D+2-\ell-m) \text{ for } \ell \geq 2. \tag{10.7.30}$$

Consequently, (7.27) holds when $\ell \geq 2$.

How close does $({}^D\!\!: f_\ell :)$ with $\ell \geq 2$ come to being a derivation? Let g and h be any two polynomials and suppose $\ell \geq 2$. We find from (4.3.7) and (7.7) the result

$$\begin{aligned}({}^D\!\!: f_\ell :)(gh) &= \mathcal{P}^D : f_\ell : (gh) = \mathcal{P}^D[(: f_\ell : g)h + g : f_\ell : h] \\ &= \mathcal{P}^D\{[({}^D\!\!: f_\ell :)g]h + g\ ({}^D\!\!: f_\ell :)h\} \text{ when } \ell \geq 2. \end{aligned} \tag{10.7.31}$$

We see in general that the factor of $\mathcal{P}^D$ cannot be removed from the right side of (7.31), and thus no $({}^D\!\!: f_\ell :)$ is a derivation. Finally, as the counter example (7.24) through (7.26) shows, neither (7.22) nor (7.31) hold when $\ell = 1$.

The stage is now set to study the question of convergence. Consider the operator $\hat{\mathcal{M}}$ defined by the equation

$$\hat{\mathcal{M}} = \exp[-\tau\ ({}^D\!\!: H :)], \tag{10.7.32}$$

which is the truncated analog of (7.2). Let us compute the matrix element $\langle G_s, \hat{\mathcal{M}} G_r\rangle$ with the assumption that

$$m(s), m(r) \leq D. \tag{10.7.33}$$

We find the result

$$\langle G_s, \hat{\mathcal{M}} G_r\rangle = \sum_{j=0}^{\infty} [(-\tau^j/j!]\langle G_s, ({}^D\!\!: H :)^j G_r\rangle. \tag{10.7.34}$$

Let ${}^D H$ be the matrix associated with $({}^D\!\!: H :)$,

$$({}^D H)_{sr} = \langle G_s,\ ({}^D\!\!: H :)G_r\rangle. \tag{10.7.35}$$

With this notation (7.17) takes the form

$$\langle G_s, \hat{\mathcal{M}} G_r\rangle = [\exp(-\tau\ {}^D H)]_{sr}. \tag{10.7.36}$$

Since ${}^D H$ is a finite dimensional matrix, the exponential series for $\exp(-\tau\ {}^D H)$ *converges* for all τ. See Section 3.7. It follows that all the matrix elements $\langle G_s, \hat{\mathcal{M}} G_r\rangle$, and in particular the matrix elements $\langle G_s, \hat{\mathcal{M}} G_a^1 \rangle$, are well defined for all H of the form (7.7) and any τ and any D.

What happens to the matrix elements in the limit $D \to \infty$ when truncation no longer occurs? We need to distinguish the two cases $H_1 = 0$ and $H_1 \neq 0$. Suppose $H_1 = 0$. Then, according to (7.27), $(^D\!: H :)$ has the property

$$(^D\!: H :) = \mathcal{P}^D : H : . \tag{10.7.37}$$

Consequently, from (7.16) and (7.37), $(^D\!: H :)$ also has the property

$$(^D\!: H :)^j = \mathcal{P}^D : H :^j \mathcal{P}^D = \; [^D(: H :^j)]. \tag{10.7.38}$$

Now make use of this property in either (7.32) or its series and matrix element equivalent. Doing so gives the result

$$\hat{\mathcal{M}} = \; ^D\mathcal{M}. \tag{10.7.39}$$

It follows that all matrix elements

$$(^D M)_{rs} = \langle G_r, \; ^D\mathcal{M} G_s \rangle = \langle G_r, \hat{\mathcal{M}} G_s \rangle \tag{10.7.40}$$

are well defined and are independent of D once D is large enough to satisfy (7.33).

In particular, suppose we wish to compute the coefficients in the Taylor series (7.5) through terms of degree D. Then we need the matrix elements $\langle G_s^m, \mathcal{M} G_a^1 \rangle$ for $m \leq D$. We know that all the constant terms k will vanish since we have assumed $H_1 = 0$. Also, all terms $H_\ell(z)$ in (7.1) with $\ell > (D+1)$ may be discarded since, in view of (7.6) and (7.6.16), they make no contribution to the desired terms having degree D and lower. Similarly, if we compute the terms $(: H :^j) z_a^i$ in (7.6) recursively by the relation

$$: H :^{j+1} z_a^i =: H : (: H :^j z_a^i) = [H, : H :^j z_a^i], \tag{10.7.41}$$

then we may discard at each step all those terms that would produce results having degree larger than D. Thus, all operations may be carried out within TPSA. Finally, since we know that the exponential series is convergent, it is only necessary to carry out the Poisson bracket operation (7.41) and the summation in (7.6) for successive values of j until some convergence criterion is met. Of course, all the caveats described in Section 4.1 concerning the use of Taylor series to evaluate the exponential function also apply here. Thus, as described in the next section, we may wish to consider approaches other than direct Taylor summation.

The case $H_1 \neq 0$ is more complicated. In this case there are simple examples for which not even the constant terms k in (7.5) are well defined. Consider the example of two-dimensional phase space and the Hamiltonian

$$\begin{aligned} H &= p^2/2 - (q+q_0)^4/2 + q_0^4/2 = -2qq_0^3 + (p^2/2 - 3q^2q_0^2) - 2q^3q_0 - q^4/2 \\ &= H_1 + H_2 + H_3 + H_4 \end{aligned} \tag{10.7.42}$$

where q_0 is some constant. Assume that

$$q_0 > 0, \tag{10.7.43}$$

and examine the trajectory with the initial conditions

$$t^i = q^i = p^i = 0. \tag{10.7.44}$$

From energy conservation we have the result

$$\dot{q} = [(q + q_0)^4 - q_0^4]^{1/2}, \tag{10.7.45}$$

and hence the time t along the trajectory is given by the integral

$$t(q) = \int_0^q dq'[(q' + q_0)^4 - q_0^4]^{-1/2}. \tag{10.7.46}$$

This integral is well defined and finite for all $q \geq 0$ including $q = +\infty$. That is, the trajectory reaches $q = \infty$ in *finite* time. Moreover, the trajectory also has infinite momentum at this time. Thus both k_1 and k_2 in (7.5) are divergent as τ approaches $t(\infty)$. Put other way, if in this example we set $\tau = t(\infty)$ in (7.36) and then let $D \to \infty$, we will get divergent results for at least some of the matrix elements, including the matrix elements that yield k_1 and k_2. Note that this nonexistence of at least some of the matrix elements of $\mathcal{M}$ is not due to any defect in the method of direct Taylor summation. It is inherent in $\mathcal{M}$, and must occur no matter how $\mathcal{M}$ is computed. We conclude that Hamiltonians for which $H_1 \neq 0$ must be handled with care and on a case by case basis.

Exercises

10.7.1.

10.8 Scaling, Splitting, and Squaring

Let us assume that H is autonomous and that $H_1 = 0$. Then we know that all matrix elements are in principle well defined. However, we also know from Section 4.1 that direct computation of $\exp(-\tau\ {}^D\!H)$ by simply summing the exponential series can be problematic. We therefore wish to explore alternatives.

One approach is to use scaling and squaring. In this section we will try to generalize, for the case of operators, the method used to exponentiate matrices in Section 4.1. The matrix elements corresponding to the Taylor coefficients in (7.5), and in fact all the matrix elements of ${}^D\!M$, can be computed reliably from the exponential series if τ is sufficiently small. Indeed, as described earlier, to compute the Taylor coefficients one simply carries out within TPSA the Poisson brackets indicated in (7.6) for successive values of j until some convergence criterion is met; and if τ is sufficiently small we know that this convergence criterion is met for modest values of j. However, successively squaring the resulting map is not so easy: We might consider computing the full matrix ${}^D\!M$ for a small (scaled) value of τ and then successively squaring the result. The full matrix ${}^D\!M$ has dimension $[S(D, d) + 1] \times [S(D, d) + 1]$, and this number can be very large. (See Section 7.9 and Table 7.2.) Thus, computing and successively squaring it requires considerable effort. Alternatively, one might consider squaring the map using the Taylor form (7.5). In this case one must successively substitute Taylor series into themselves. This process too might be quite time consuming. Yet another approach is to compute the Taylor series for the scaled map, factorize the scaled map, and then successively square the map in the factorized Lie form (7.6.3). This process might be faster.

At this point, and after some thought, one wonders if it might be possible to compute the Lie generators for the scaled map directly without going through the intermediate steps of computing the scaled Taylor map and then factorizing the result. If so, such an approach might both be considerably faster and require less storage. The first part of this section is devoted to describing such a procedure. It is then applied to scaling and squaring.

We know that, as a special case of the previous discussion in Section 10.5, the map (7.2) has the representation

$$\mathcal{M} = \exp(t : -H :) = \cdots \exp(: f_5 :) \exp(: f_4 :) \exp(: f_3 :)\mathcal{R}. \tag{10.8.1}$$

Here we have replaced the symbol τ by t since we will soon need τ for other purposes. We have also assumed $H_1 = 0$. Equation (8.1) may be viewed as a kind of *splitting* formula that writes $\exp(t : -H :)$ as a product of factors having desirable properties. (We will learn more about other splitting formulas in Section 10.10.) As such, it has three advantages: First, (as a consequence of the Factorization Theorem) its form is fixed and potentially exact. See Section 7.6. Second, it can be concatenated easily with other maps of the same form. See Section 8.4. Consequently, it can be squared repeatedly with relative ease. Third, the exact f_ℓ are *entire* (analytic everywhere except at ∞) functions of t, and have rapidly convergent Taylor expansions in t for small t.

We will now describe how to find the Taylor expansions (in t) for the f_ℓ. Let us begin with f_2, which is equivalent to determining $\mathcal{R}$. From (5.18), (5.31), and (5.32) we find the result

$$\mathcal{R} = \mathcal{M}_2 = \exp(: f_2 :) \tag{10.8.2}$$

with

$$f_2(z^i, t) = -tH_2(z^i). \tag{10.8.3}$$

Evidently f_2 is entire in t.

According to the equations of motion (5.60) through (5.66) for the remaining f_ℓ, we need to know the interaction Hamiltonian terms $H_m^{\rm int}$. Following (5.41), they are given by the relations

$$H_m^{\rm int}(z^i, t) = H_m(\mathcal{M}_2 z^i) = \mathcal{M}_2 H_m(z^i) = \exp(t : -H_2 :)H_m(z^i). \tag{10.8.4}$$

We note that because H is assumed to be autonomous, the time dependence of the $H_m^{\rm int}$ comes entirely from the factor $\exp(t : -H_2 :)$. From (8.4) we see that each $H_m^{\rm int}$ has the Taylor expansion

$$H_m^{\rm int} = \sum_{\ell=0}^{\infty} (1/\ell!)(-t)^\ell : H_2 :^\ell H_m. \tag{10.8.5}$$

From (8.4) and (5.25) through (5.35) we know that $H_m^{\rm int}$ can be written as well in the form

$$H_m^{\rm int} = H_m(\mathcal{M}_2 z^i) = H_m(Rz^i) \tag{10.8.6}$$

with

$$R = \exp(tJS). \tag{10.8.7}$$

We know that the matrix exponential function converges and therefore is analytic for all t. Finally, H_m is a polynomial in z^i. It follows that $H_m^{\rm int}$ is entire in t and consequently (8.5) converges for all t.

Let us next compute f_3. From (5.60) and the initial condition $f_3(0) = 0$ we obtain the result

$$f_3 = -\int_0^t dt' H_3^{\rm int}. \tag{10.8.8}$$

This integral can be done using the representation (8.5) to give the series

$$f_3 = \sum_{\ell=1}^{\infty} (1/\ell!)(-t)^\ell : H_2 :^{\ell-1} H_3. \tag{10.8.9}$$

Since the right side of (5.60), namely $H_3^{\rm int}$, is entire in t, it follows from Poincaré's Theorem 1.3.3 that f_3 is entire in t. More simply, we just observe that the integral of an entire function is also an entire function. Either way, we conclude that (8.9) converges for all t.

The computation of f_4 is a bit more involved. From (5.61) and the initial condition $f_4(0) = 0$ we find that f_4 contains two terms:

$$f_4 = -\int_0^t dt' H_4^{\rm int} - (1/2)\int_0^t dt' : f_3 : H_3^{\rm int}. \tag{10.8.10}$$

We will refer to the first term as the *direct* term since it is produced by $H_4^{\rm int}$, which is of the same degree as f_4. The second term will be called a *feed-up* term since it arises from the combined effect of the lower-degree term $H_3^{\rm int}$ and the lower-degree term f_3 (which comes from $H_3^{\rm int}$). Thus we write

$$f_4 = f_4^{\rm d} + f_4^{\rm fu}. \tag{10.8.11}$$

For $f_4^{\rm d}$ we use (8.5) to get a result analogous to that for f_3,

$$f_4^{\rm d} = \sum_{\ell=1}^{\infty} (1/\ell!)(-t)^\ell : H_2 :^{\ell} H_4. \tag{10.8.12}$$

Again we know that $f_4^{\rm d}$ is entire in t and the series (8.12) converges for all t. For the feed-up term we use the series representations (8.5) and (8.9) to get the result

$$\begin{aligned}
f_4^{\rm fu} &= -(1/2)\int_0^t dt' : f_3 : H_3^{\rm int} = -(1/2)\int_0^t dt' [f_3, H_3^{\rm int}] \\
&= -(1/2)\int_0^t dt' \sum_{\ell=1}^{\infty}\sum_{m=1}^{\infty} (1/\ell!)(1/m!)(-t')^{\ell+m} [: H_2^{\ell-1} : H_3, : H_2 :^m H_3] \\
&= (1/2)\sum_{\ell=1}^{\infty}\sum_{m=0}^{\infty} (1/\ell!)(1/m!)[1/(\ell+m+1)](-t)^{\ell+m+1} [: H_2 :^{\ell-1} H_3, : H_2 :^m H_3] \\
&= -(1/12)t^3 [H_3, : H_2 : H_3] + (1/24)t^4 [H_3, : H_2 :^2 H_3] - t^5\{(1/80)[H_3, : H_2 :^3 H_3] \\
&+ (1/120)[: H_2 : H_3, : H_2 :^2 H_3]\} + \cdots .
\end{aligned} \tag{10.8.13}$$

The quantity $f_4^{\rm fu}$ is also entire in t and the series (8.13) converges for all t.

The computation of the remaining f_j is similar. In each case there is a direct term analogous to (8.9) and (8.12). There are also feed-up terms arising from multiple Poisson brackets involving lower degree terms in the Hamiltonian. By contrast, there are no *feed-down* terms. To find a given f_ℓ, it is only necessary to know the $H_{\ell'}$ with $\ell' \leq \ell$. We also observe that all the formulas for the f_ℓ are expressible entirely in terms of Poisson brackets. All formulas involve only operations within the Poisson bracket Lie algebra generated by the H_m. Such results are to be expected in general as a consequence of the BCH theorem. Analogous formulas, but involving instead commutators of vector fields, are to be expected in the non-Hamiltonian case. The coefficients in the various series should be universal. Also, all the series represent entire functions and therefore converge for all values of t. Finally, we note that the rate of convergence of the various series depends only on the properties of $t : H_2 :$ (and hence tH_2), because that is the only term that appears infinitely often in the series.

To fix these ideas more clearly in the mind, we will also consider in some detail the computation of f_5. From (5.62) we find the result

$$f_5 = f_5^{\rm d} + f_5^{\rm fu} \tag{10.8.14}$$

where

$$f_5^{\rm d} = -\int_0^t dt' H_5^{\rm int} \tag{10.8.15}$$

and

$$f_5^{\rm fu} = \int_0^t dt' [: f_3 : (-H_4^{\rm int}) + (1/3) : f_3 :^2 (-H_3^{\rm int})]. \tag{10.8.16}$$

The direct term has the expansion

$$f_5^{\rm d} = \sum_{\ell=1}^{\infty} (1/\ell!)(-t)^\ell : H_2 :^{\ell-1} H_5. \tag{10.8.17}$$

To find the expansion for the feed-up term we insert the previously obtained expressions for $H_3^{\rm int}$, $H_4^{\rm int}$, f_3, and f_4 in (8.16) to obtain the result

$$\begin{aligned}
f_5^{\rm fu} \;&=\; \sum_{\ell=1}^{\infty}\sum_{m=0}^{\infty}(1/\ell!)(1/m!)[1/(\ell+m+1)](-t)^{\ell+m+1}[: H_2 :^{\ell-1} H_3, : H_2 :^m H_4] \\
&-\; (1/3)\sum_{\ell=1}^{\infty}\sum_{m=0}^{\infty}\sum_{n=1}^{\infty}(1/\ell!)(1/m!)(1/n!)[1/(\ell+m+n+1)] \\
&\;\; (-t)^{\ell+m+n+1}[: H_2 :^{\ell-1} H_3, [: H_2 :^m H_3, : H_2 :^{n-1} H_3]] \\
&=\; (1/2)t^2[H_3, H_4] - t^3\{(1/3)[H_3, : H_2 : H_4] + (1/6)[: H_2 : H_3, H_4]\} \\
&+\; t^4\{(-1/24)[H_3, [: H_2 : H_3, H_3]] + (1/8)[H_3, : H_2 :^2 H_4] \\
&+\; (1/8)[: H_2 : H_3, : H_2 : H_4] + (1/24)[: H_2 :^2 H_3, H_4]\} \\
&+\; t^5\{(1/45)[H_3, [: H_2 :^2 H_3, H_3]] - (1/30)[H_3, : H_2 :^3 H_4] \\
&+\; (1/60)[: H_2 : H_3, [: H_2 : H_3, H_3]] - (1/20)[: H_2 : H_3, : H_2 :^2 H_4] \\
&-\; (1/30)[: H_2 :^2 H_3, : H_2, H_4 :] - (1/120)[: H_2 :^3 H_3, H_4]\} + \cdots .
\end{aligned} \tag{10.8.18}$$

At this point we might quote formulas for the f_j for the next few higher values of j and up to some power in t. Instead we observe that, rather than the reverse factorization (8.1) which we write in the form

$$\mathcal{M} = \exp(t : -H :) = \cdots \exp[: f_5(t) :] \exp[: f_4(t) :] \exp[: f_3(t) :]\mathcal{R}(t), \tag{10.8.19}$$

it is often more convenient to have results for the forward factorization

$$\mathcal{M} = \exp(t : -H :) = \mathcal{R}'(t) \exp[: g_3(t) :] \exp[: g_4(t) :] \exp[: g_5(t) :] \cdots . \tag{10.8.20}$$

The relation between the two factorizations is immediate. Suppose we invert both sides of (8.19). Doing so gives the result

$$\exp(t : +H :) = \mathcal{R}^{-1}(t) \exp[- : f_3(t) :] \exp[- : f_4(t) :] \exp[- : f_5(t) :] \cdots . \tag{10.8.21}$$

Next replace t by $-t$ in (8.21) to find the relation

$$\exp(t : -H :) = \mathcal{R}^{-1}(-t) \exp[- : f_3(-t) :] \exp[- : f_4(-t) :] \exp[- : f_5(-t) :] \cdots . \tag{10.8.22}$$

Since the factorization (8.20) is unique, comparison of the first factors on the right sides of (8.20) and (8.22) shows that

$$\mathcal{R}'(t) = \mathcal{R}^{-1}(-t). \tag{10.8.23}$$

But from (8.2) and (8.3) we find that

$$\mathcal{R}^{-1}(-t) = \mathcal{R}(t) \tag{10.8.24}$$

so that

$$\mathcal{R}'(t) = \mathcal{R}(t). \tag{10.8.25}$$

This result is also evident on general grounds. Finally, upon comparing the remaining factors in (8.20) and (8.22), we conclude that

$$g_m(t) = -f_m(-t). \tag{10.8.26}$$

We now quote formulas, obtained by symbolic manipulation, for the first few g_m through terms of order t^5. Again each g_m is the sum of a direct and a feed-up term,

$$g_m = g_m^{\rm d} + g_m^{\rm fu}. \tag{10.8.27}$$

For the direct terms we have in general the formula

$$g_m^{\rm d} = -\sum_{\ell=1}^{\infty} (1/\ell!) t^\ell : H_2 :^{\ell-1} H_m. \tag{10.8.28}$$

For the feed-up terms $g_3^{\rm fu}$ through $g_6^{\rm fu}$ we find, through terms of order t^5, the result

$$g_3^{\rm fu} = 0, \tag{10.8.29}$$

$$\begin{aligned}
g_4^{\rm fu} &= -(1/2)\sum_{\ell=1}^{\infty}\sum_{m=0}^{\infty}(1/\ell!)(1/m!)[1/(\ell+m+1)]t^{\ell+m+1}[:H_2:^{\ell-1}H_3, :H_2:^{m}H_3] \\
&= (1/12)t^3[:H_2:H_3, H_3] + (1/24)t^4[:H_2:^2H_3, H_3] \\
&+ t^5\{(1/80)[:H_2:^3H_3, H_3] + (1/120)[:H_2:^2H_3, :H_2:H_3]\} + \cdots, \qquad (10.8.30)
\end{aligned}$$

$$\begin{aligned}
g_5^{\rm fu} &= -(1/2)t^2[H_3, H_4] - t^3\{(1/3)[H_3, :H_2:H_4] + (1/6)[:H_2:H_3, H_4]\} \\
&- t^4\{(-1/24)[H_3, [:H_2:H_3, H_3]] + (1/8)[H_3, :H_2:^2H_4] \\
&+ (1/8)[:H_2:H_3, :H_2:H_4] + (1/24)[:H_2:^2H_3, H_4]\} \\
&+ t^5\{(1/45)[H_3, [:H_2:^2H_3, H_3]] - (1/30)[H_3, :H_2:^3H_4] \\
&+ (1/60)[:H_2:H_3, [:H_2:H_3, H_3]] - (1/20)[:H_2:H_3, :H_2:^2H_4] \\
&- (1/30)[:H_2:^2H_3, :H_2, H_4:] - (1/120)[:H_2:^3H_3, H_4]\} + \cdots, \qquad (10.8.31)
\end{aligned}$$

$$\begin{aligned}
g_6^{\rm fu} &= -(1/2)t^2[H_3, H_5] \\
&+ t^3\{(-1/6)[H_3, [H_3, H_4]] - (1/3)[H_3, :H_2:H_5] \\
&- (1/3)[H_3, :H_2:H_5] - (1/6)[:H_2:H_3, H_5] \\
&+ (1/12)[:H_2:H_4, H_4]\} \\
&- t^4\{(1/8)[H_3, [H_3, :H_2:H_4]] + (1/6)[H_3, [:H_2:H_3, H_4]] \\
&+ (1/8)[H_3:H_2:^2H_5] - (1/48)[H_4, [:H_2:H_3, H_3]] \\
&+ (1/16)[:H_2:H_3, [H_3, H_4]] + (1/8)[:H_2:H_3, :H_2:H_5] \\
&+ (1/24)[:H_2:^2H_3, H_5] - (1/24)[:H_2:^2H_4, H_4]\} \\
&+ t^5\{(1/80)[H_3, [H_3, [:H_2:H_3, H_3]]] - (1/20)[H_3, [H_3, :H_2:^2H_4]] \\
&- (1/20)[H_3, [:H_2:H_3, :H_2:H_4]] - (1/60)[H_3, [:H_2:^2H_3, H_4]] \\
&- (1/30)[H_3, :H_2:^3H_5] + (1/80)[H_4, [:H_2:^2H_3, H_3]] \\
&- (1/20)[:H_2:H_3, [H_3, :H_2:H_4]] - (1/40)[:H_2:H_3, [:H_2:H_3, H_4]] \\
&- (1/20)[:H_2:H_3, :H_2:^2H_5] + (1/240)[:H_2:H_4, [:H_2:H_3, H_3]] \\
&- (1/60)[:H_2:^2H_3, [H_3, H_4]] - (1/30)[:H_2:^2H_3, :H_2:H_5] \\
&+ (1/20)[:H_2:^2H_4, :H_2:H_4] - (1/120)[:H_2:^3H_3, H_5] \\
&+ (1/180)[:H_2:^3H_4, H_4]\} + \cdots. \qquad (10.8.32)
\end{aligned}$$

These results were obtained using a Mathematica program. See Appendix E.

We have derived the splitting formula (8.1) with the f_m given by (8.9), (8.11) through (8.18), and analogous expressions. Equivalently, we have also derived the splitting formula (8.20) with the g_m given by (8.27) through (8.32) and analogous expressions. How are these formulas to be used? With the aid of scaling and squaring we have the result

$$\begin{aligned}
\mathcal{M} &= \exp(t:-H:) = \{\exp[(t/2^n):-H:]\}^{2^n} \\
&= \{\cdots\{\{\exp[(t/2^n):-H:]\}^2\}^2\cdots\}^2 \ (n \text{ squarings}). \qquad (10.8.33)
\end{aligned}$$

See Section 4.1 and (4.1.6). Now define a quantity τ by writing

$$\tau = t/2^n. \qquad (10.8.34)$$

Next insert, for example, the splitting formula (8.20) into (8.33). Doing so gives the result

$$\begin{aligned}\mathcal{M} &= \exp(t:-H:) = \mathcal{R}(t)\exp[:g_3(t):]\exp[:g_4(t):]\exp[:g_5(t):]\cdots \qquad (10.8.35)\\ &= \{\mathcal{R}(\tau)\exp[:g_3(\tau):]\exp[:g_4(\tau):]\exp[:g_5(\tau):]\cdots\}^{2^n}\\ &= \{\cdots\{\{\mathcal{R}(\tau)\exp[:g_3(\tau):]\exp[:g_4(\tau):]\exp[:g_5(\tau):]\cdots\}^2\}^2\cdots\}^2 \text{ (n squarings).}\end{aligned}$$

Finally, suppose we choose n to be large enough so that τ is sufficiently small that the truncated series (8.28) through (8.32) give accurate results for the $g_m(\tau)$. Then (8.35) gives an accurate result for $\mathcal{M}$.

How large must n be (or, equivalently, how small must τ be) for the truncated series to give accurate results for the $g_m(\tau)$? We have already observed that the convergence of these series depends only on the properties of τH_2. Let us explore what can be said about terms of the form $(\tau:H_2:)^\ell H_m$, which are the common ingredient of all the series. As before we write H_2 in a form analogous to (5.28) except that S is now a constant time-independent matrix. We then find, in analogy to (5.29), the relation

$$:H_2:z_a = -\sum_b (JS)_{ab}z_b. \qquad (10.8.36)$$

Consider the matrix $(-JS)^T$. In general, barring degeneracy, it has $2n$ eigenvectors v^j with eigenvalues λ_j:

$$(-JS)^T v^j = \lambda_j v^j. \qquad (10.8.37)$$

(Here, for the moment, n is the number of degrees of freedom, and *not* the number of squarings.) Define $2n$ first-degree polynomials h_1^j by the rule

$$h_1^j = \sum_a v_a^j z_a. \qquad (10.8.38)$$

In general, again barring degeneracy, the h_1^j will be functionally independent and will span the space of all first-degree polynomials. Let us compute the effect of $:H_2:$ on the h_1^j. From (8.36) through (8.38) we find the result

$$\begin{aligned}:H_2:h_1^j &= \sum_a v_a^j:H_2:z_a = \sum_{a,b} v_a^j(-JS)_{ab}z_b\\ &= \sum_b\{\sum_a[(-JS)^T]_{ba}v_a^j\}z_b = \lambda_j\sum_b v_b^j z_b\\ &= \lambda_j h_1^j. \qquad (10.8.39)\end{aligned}$$

We know from (7.6.14) that the (linear) operator $:H_2:$ maps the space $\mathcal{P}_m$ into itself. (Note that here $\mathcal{P}_m$ denotes a vector space and not a projection operator.) What is its largest eigenvalue when acting on this space? Consider for example, the degree 3 homogeneous polynomials h_3^{ijk} defined by the relation

$$h_3^{ijk} = h_1^i h_1^j h_1^k. \qquad (10.8.40)$$

In general, these polynomials will span the space of third-degree polynomials. Since $: H_2 :$ is a derivation, and in view of (8.39), we find the result

$$\begin{aligned} : H_2 : h_3^{ijk} &= (: H_2 : h_1^i)h_1^j h_1^k + h_1^i(: H_2 : h_1^j)h_1^k + h_1^i h_1^j(: H_2 : h_1^k) \\ &= (\lambda_i + \lambda_j + \lambda_k)h_3^{ijk}. \end{aligned} \quad (10.8.41)$$

Let $\lambda_{\max}$ be the modulus of the eigenvalue with the largest absolute value,

$$\lambda_{\max} = \max_j \; |\lambda_j|. \quad (10.8.42)$$

We conclude from relations of the form (8.41) that the eigenvalues of $: H_2 :$ when acting on $\mathcal{P}_m$ are bounded by the quantity $(m\lambda_{\max})$.

In general, given the matrix $(-JS)^T$, one can compute its eigenvalues. However, this computation requires some work, and often an estimate that requires less computation is sufficient. Let λ_k be the eigenvalue of $(-JS)^T$ having the largest absolute value. Then from (8.39) we have the result

$$\lambda_k v^k = (-JS)^T v^k = (SJ)v^k. \quad (10.8.43)$$

Here we have used the fact that S is symmetric and J is antisymmetric. Now take norms of both sides of (8.43) to get the result

$$\|\lambda_k v^k\| = \|SJv^k\| \leq \|SJ\|\|v^k\|. \quad (10.8.44)$$

The left side of (8.44) can be manipulated using (3.7.8) and (8.42) to give the relation

$$\|\lambda_k v^k\| = |\lambda_k|\|v^k\| = \lambda_{\max}\|v^k\|, \quad (10.8.45)$$

and we conclude upon comparison with (8.44) that $\lambda_{\max}$ has the bound

$$\lambda_{\max} \leq \|SJ\|. \quad (10.8.46)$$

Moreover, we may also write the equation

$$SJ = -JJSJ. \quad (10.8.47)$$

Now take the norm of both sides of (8.47) to get the bound

$$\|SJ\| = \| - JJSJ\| = \|JJSJ\| \leq \|J\|\|JS\|\|J\|. \quad (10.8.48)$$

Suppose the matrix norm $\| \;\|$ to be employed has the property

$$\|J\| = 1, \quad (10.8.49)$$

which is true of the norm (3.7.15). Then (8.46) through (8.49) may be combined to give the bound

$$\lambda_{\max} \leq \|JS\|. \quad (10.8.50)$$

We now have all the tools in hand to examine the convergence of series that involve terms of the form $(\tau : H_2 :)^\ell H_m$. According to the previous discussion the convergence of such series is governed by the size of the terms $(m\tau\lambda_{\rm max})^\ell$ with $\lambda_{\rm max}$ bounded by (8.50). Suppose, for example, we truncate the series (8.28) for $g_m^d(\tau)$ by selecting some N and discarding all terms with $\ell > N$. Let us estimate the error committed in doing so by examining the size of the first neglected term,

$$\text{first neglected term } = -[1/(N+1)!]\tau^{N+1} : H_2 :^N H_m. \tag{10.8.51}$$

We know from our previous discussion that $(: H_2 :^N H_m)$ behaves at worst according to the estimate

$$: H_2 :^N H_m \sim (m\lambda_{\rm max})^N H_m. \tag{10.8.52}$$

Also, we expect from the first term in (8.28) that $g_m^d(\tau)$ itself will be of order (τH_m). Consequently, using (8.51) and (8.52), we should make the comparison

$$\tau H_m \overset{?}{\leftrightarrow} [1/(N+1)!]\tau^{N+1}(m\lambda_{\rm max})^N H_m. \tag{10.8.53}$$

We conclude that the *relative* error in computing $g_m^d(\tau)$, and hence also $\mathcal{M}(t)$, has the estimate

$$\text{relative error } \sim [1/(N+1)!](\tau m\lambda_{\rm max})^N. \tag{10.8.54}$$

Finally, let us define a quantity λ by the rule

$$\lambda = t\lambda_{\rm max}. \tag{10.8.55}$$

By (8.50) it has the estimate

$$\lambda \le \|tJS\|, \tag{10.8.56}$$

and is dimensionless. With the aid of (8.34), (8.54), and (8.55) we see that the relative error can be written in the form

$$\text{relative error } \sim [1/(N+1)!](m\lambda/2^n)^N. \tag{10.8.57}$$

Suppose, for example, we set $N = 5$, limit our attention to the cases $m \le 8$, and select n such that

$$(8\lambda/2^n) < (1/20). \tag{10.8.58}$$

[Note that λ and hence the required n can be computed in advance using (8.58).] Then we find from (8.57) that the relative error has the estimate

$$\text{relative error } \sim (1/6!)(1/20)^5 \simeq 4 \times 10^{-10}. \tag{10.8.59}$$

Although we have only estimated the error due to truncating the series for g_m^d, we expect that the result of truncating the other series at the same N will be comparable as long as (8.58) is satisfied. We conclude from (8.59) that (just as scaling and squaring works well for matrix exponentiation) scaling, splitting, and squaring works well for computing $\mathcal{M}$ in the factorized product forms (8.1) and (8.20). It has high, controllable, and predictable accuracy. Of course, the n required to satisfy a relation of the form (8.58) varies from Hamiltonian to Hamiltonian. However, just as in the matrix case, the n required to achieve some specific accuracy grows only logarithmically with the norm of (tJS), and for any given

Hamiltonian the accuracy increases very rapidly for increasing n. Correspondingly, because the number of required operations is relatively small and no cancellations are required to occur between large terms, problems with round-off error are minimized. Finally, with regard to computational speed, the method of scaling, splitting, and squaring is far faster than numerical integration. (Of course, numerical integration is required in the nonautonomous case.) It is also faster and, as expected, far more reliable than direct use of the Taylor series (7.6). The price that has been paid for this good performance is that one must know the expansions of the form (8.28) through (8.32) as well as concatenation formulas of the form (8.4.31) through (8.4.36). By contrast, the implementation of the Taylor series (7.6) to any order is straightforward.

Exercises

10.8.1. Show that if the matrix norm has the property (8.49), then one has the equation

$$\|JS\| = \|SJ\| = \|S\|. \tag{10.8.60}$$

10.9 Canonical Treatment of Errors

Let $H(z,t)$ be a general, possibly time-dependent, Hamiltonian that is analytic about the origin and consequently has an expansion in homogeneous polynomials in z of the form

$$H(z,t) = \sum_{m=1}^{\infty} H_m(z,t). \tag{10.9.1}$$

(Here we drop a possible z independent term H_0 since it has no effect on the equations of motion.) Moreover, we shall assume that H_1 is *small* so that $z = 0$ is close to being a solution to the equation of motion generated by H. Such Hamiltonians often arise in connection with the description of errors. For example, we will see in Chapter 26 that both mispowered dipole bending magnets and dipole steering magnets are described by Hamiltonians of this form.

Hamiltonians of the form (9.1) with H_1 small can be treated by the method of Section 10.5 and, in the autonomous case, also by the method of Section 10.7. The method of Section 10.5 requires determination of the design trajectory $z^d(t)$, and then provides an expansion about this trajectory. However, since $z = 0$ is nearly a trajectory, we may prefer an expansion of the transfer map $\mathcal{M}$ about $z = 0$. Such an expansion is provided, in the autonomous case, by the method of Section 10.7, but requires the summation of Taylor series for the exponential function. We have seen that the use of such series may be problematic.

The purpose of this section is to develop a method for expanding the transfer map about $z = 0$ under the assumption that H_1 is small. In essence, we will produce a simultaneous expansion both in z and in powers of some parameter that characterizes the smallness of H_1. This method is applicable to both the time dependent and time independent cases.

The method is based on an *enlargement* of $2n$ dimensional phase space to include the extra variables q_{n+1} and p_{n+1}. This is the same enlargement that was used in Section 9.4, and the method based on it will be referred to as a *canonical* treatment of errors. As before, let us use the symbol $\hat{z}$ to denote the coordinates in this enlarged phase space,

$$\hat{z} = (q_1 \cdots q_n, q_{n+1}, p_1 \cdots p_n, p_{n+1}). \tag{10.9.2}$$

Next, modify the Hamiltonian (9.1) to obtain the Hamiltonian $\hat{H}$ defined by the rule

$$\hat{H}(\hat{z}, t) = (q_{n+1})H_1(z, t) + \sum_{m=2}^{\infty} H_m(z, t). \tag{10.9.3}$$

We will see that the transfer map for the Hamiltonian $\hat{H}$, which we will call $\hat{\mathcal{M}}$, can be computed using the methods we have developed previously, and that $\hat{\mathcal{M}}$ contains the information we seek.

We being by noting that $\hat{z} = 0$ is a trajectory for $\hat{H}$, and hence the transfer map $\hat{\mathcal{M}}$ produced by $\hat{H}$ maps the origin of the enlarged phase space into itself. Indeed, with respect to the enlarged phase-space variables, the Hamiltonian $\hat{H}$ has the expansion

$$\hat{H}(\hat{z}, t) = \sum_{m=2}^{\infty} \hat{H}_m(\hat{z}, t) \tag{10.9.4}$$

with

$$\hat{H}_2(\hat{z}, t) = (q_{n+1})H_1(z, t) + H_2(z, t), \tag{10.9.5}$$

$$\hat{H}_m(\hat{z}, t) = H_m(z, t) \text{ for } m > 2. \tag{10.9.6}$$

Observe that this expansion begins with homogeneous polynomials of degree *two*. Correspondingly, the transfer map $\hat{\mathcal{M}}$ can be written in the factored product form

$$\hat{\mathcal{M}} = \hat{\mathcal{R}} \exp(:\hat{f}_3:) \exp(:\hat{f}_4:) \exp(:\hat{f}_5:) \cdots . \tag{10.9.7}$$

Here the $\hat{f}_m$ denote homogeneous polynomials of degree m in the enlarged phase-space variables $\hat{z}$. The map $\hat{\mathcal{M}}$ can be computed in both the time dependent and time independent cases using the method of Section 10.5, and in the time independent case using the methods of Sections 10.7 and 10.8.

By construction $\hat{H}$ is independent of p_{n+1}, and therefore there is the obvious equation of motion

$$\dot{q}_{n+1} = \partial \hat{H}/\partial p_{n+1} = 0. \tag{10.9.8}$$

It follows that $\hat{\mathcal{M}}$ leaves q_{n+1} unchanged,

$$q^f_{n+1} = \hat{\mathcal{M}} q^i_{n+1} = q^i_{n+1}. \tag{10.9.9}$$

But now the reasoning presented in the beginning of Section 9.4 applies. We conclude that $\hat{\mathcal{R}}$ must satisfy the relation

$$\hat{\mathcal{R}} q_{n+1} = q_{n+1}, \tag{10.9.10}$$

and its associated matrix $\hat{R}$ must (for the case $n = 3$) be of the general form (9.4.84). Also, the $\hat{f}_m$ in (9.7) must be independent of p_{n+1},

$$\partial \hat{f}_m/\partial p_{n+1} = 0. \tag{10.9.11}$$

They will depend only on the z^i and q^i_{n+1}. Finally, we see that the relation

$$\hat{z}^f = \hat{\mathcal{M}}\hat{z}^i \tag{10.9.12}$$

provides an expansion of z^f in terms of z^i and q^i_{n+1}, and p^i_{n+1} does not occur in this expansion.

Evidently the size of q^i_{n+1} governs the effect of the term $(q_{n+1})H_1$ in (9.3), and an expansion in powers of q_{n+1} is, in effect, an expansion in terms of powers of H_1. Thus, after some final result for $\hat{\mathcal{M}}$ (or some consequence of $\hat{\mathcal{M}}$) has been obtained as a series in q_{n+1} up to some order, we may set $q_{n+1} = 1$ in this series to obtain a result appropriate to the original Hamiltonian (9.1) when H_1 in this Hamiltonian is treated as a perturbation through the same order.

A simple example helps clarify this approach. Consider the *displaced* one-dimensional harmonic oscillator described by the Hamiltonian

$$H = (p_1^2 + q_1^2)/2 + \delta q_1 \tag{10.9.13}$$

where δ is a small quantity, not to be confused with the δ_a in Section 9.4. It is easily verified that the equations of motion associated with (9.13) have the solution

$$q_1(t) = -\delta + (q_1^i + \delta)\cos t + p_1^i \sin t, \tag{10.9.14}$$

$$p_1(t) = -(q_1^i + \delta)\sin t + p_1^i \cos t, \tag{10.9.15}$$

where the initial time is taken to be $t^i = 0$. According to (9.3) the modified Hamiltonian associated with (9.13) is given by the relation

$$\hat{H} = (p_1^2 + q_1^2)/2 + \delta q_1 q_2. \tag{10.9.16}$$

Since $\hat{H}$ is time independent, and all the $\hat{H}_m$ with $m > 2$ happen to vanish in this simple case, we have the immediate result

$$\hat{\mathcal{M}} = \exp(-t : \hat{H} :) = \exp(-t : \hat{H}_2 :) = \hat{\mathcal{R}}(t). \tag{10.9.17}$$

The map $\hat{\mathcal{R}}(t)$ is in turn described by the matrix $\hat{R}(t)$ given by

$$\hat{R} = \exp(t\hat{J}\hat{S}). \tag{10.9.18}$$

Here we have placed a hat over J to indicate that the 4×4 J is to be used. Also, for convenience, we have used the ordering (9.4.15). Correspondingly, $\hat{J}$ is of the form (3.2.10). With this convention, and according to (5.28), $\hat{S}$ is the matrix

$$\hat{S} = \begin{pmatrix} 1 & 0 & \delta & 0 \\ 0 & 1 & 0 & 0 \\ \delta & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{10.9.19}$$

The exponentiation (9.18) can be carried out to give the result

$$\hat{R} = \begin{pmatrix} \cos t & \sin t & \delta(\cos t - 1) & 0 \\ -\sin t & \cos t & -\delta \sin t & 0 \\ 0 & 0 & 1 & 0 \\ -\delta \sin t & \delta(\cos t - 1) & \delta^2(t - \sin t) & 1 \end{pmatrix}. \tag{10.9.20}$$

Correspondingly, in analogy with (5.27), we find the relations

$$q_1(t) = q_1^i \cos t + p_1^i \sin t + q_2^i \delta(\cos t - 1), \tag{10.9.21}$$

$$p_1(t) = -q_1^i \sin t + p_1^i \cos t - q_2^i \delta \sin t, \tag{10.9.22}$$

$$q_2(t) = q_1^i, \tag{10.9.23}$$

$$p_2(t) = -q_1^i \delta \sin t + p_1^i \delta(\cos t - 1) + q_2^i \delta^2 (t - \sin t) + p_2^i. \tag{10.9.24}$$

We see, as advertised, that (9.21) and (9.22) reduce to (9.14) and (9.15), respectively, when we set $q_2 = 1$. Also, (9.23) is consistent with (9.8) and (9.9). Finally, although of no particular interest for our purposes, (9.24) is consistent with the equation of motion

$$\dot{p}_2 = -\partial \hat{H} / \partial q_2 = -\delta q_1. \tag{10.9.25}$$

In this example we have been able to solve for the map $\hat{\mathcal{M}}$ exactly, and have found that the result for $z(t)$ when q_{n+1} is set to one agrees with the corresponding trajectory, which we were also able to find exactly, for the original problem. For most cases we will only compute $\hat{\mathcal{M}}$ to some order in the phase-space variables including the variable q_{n+1}. In such cases we expect that the correspondingly results for $z(t)$ will be correct through the same order in δ where δ measures the size of H_1.

There is one last observation to be made. In the example just described the computation of $\hat{R}$ was somewhat complicated because it was 4×4, and the information about $p_2(t)$, which was contained in $\hat{R}$, was of no interest. Is there a way of bypassing such complications? In some cases the answer is yes. For the example problem let us rewrite (9.17) in the form

$$\hat{\mathcal{R}}(t) = \exp(: \hat{f}_2 :) \tag{10.9.26}$$

with $\hat{f}_2$ defined by

$$\hat{f}_2 = -t\hat{H}_2 = -t[(p_1^i)^2 + (q_1^i)^2]/2 - t\delta q_1^i q_2^i. \tag{10.9.27}$$

When $\hat{f}_2$ is regarded as a function of q_1^i and p_1^i, which are the dynamical variables of interest, we see that it can be written in the form

$$\hat{f}_2 = f_1^{(2)} + f_2^{(2)} \tag{10.9.28}$$

where $f_1^{(2)}$ is a homogeneous polynomial of degree 1 in the variables of interest,

$$f_1^{(2)} = -t\delta q_2^i q_1^i, \tag{10.9.29}$$

and $f_2^{(2)}$ is a polynomial of degree 2 in these variables,

$$f_2^{(2)} = -t[(p_1^i)^2 + (q_1^i)^2]/2. \tag{10.9.30}$$

Here we have used a subscript on f to indicate degree in the variables of interest, and a superscript to indicate overall degree. This notation is similar to that of Section 9.3 where the subscript served the same purpose and the superscript indicated overall grade. Indeed, at this stage, we may simply view q_2^i as a parameter that plays the same role as ϵ did in Section 9.3.

With the decomposition (9.28) we may rewrite $\hat{\mathcal{M}}$, which we now simply call $\mathcal{M}$ because we are no longer treating q_2 and p_2 as dynamical variables, in the form

$$\mathcal{M} = \exp(: f_1^{(2)} + f_2^{(2)} :). \tag{10.9.31}$$

At this stage we use (9.2.4) to rewrite $\mathcal{M}$ in the form

$$\mathcal{M} = \exp(: f_2 :) \exp(: f_1 :) \tag{10.9.32}$$

where, according to (9.2.7) and (9.2.9),

$$f_2 = f_2^{(2)} = -(t/2)[(p_1^i)^2 + (q_1^i)^2], \tag{10.9.33}$$

$$f_1 = \text{iex}\ (- : f_2^{(2)} :) f_1^{(2)}. \tag{10.9.34}$$

Simple calculation gives the result

$$\begin{aligned} \exp(-\tau : f_2^{(2)} :) f_1^{(2)} &= \exp[(\tau t/2) : (p_1^i)^2 + (q_1^i)^2 :](-t\delta q_2^i q_1^i) \\ &= -t\delta q_2^i \exp[(\tau t/2) : (p_1^i)^2 + (q_1^i)^2 :] q_1^i \\ &= -t\delta q_2^i [q_1^i \cos(t\tau) - p_1^i \sin(t\tau)]. \end{aligned} \tag{10.9.35}$$

Consequently, we find for f_1 the explicit result

$$\begin{aligned} f_1 &= \text{iex}\ (- : f_2^{(2)} :) f_1^{(2)} = \int_0^1 d\tau \exp(-\tau : f_2^{(2)} :) f_1^{(2)} \\ &= -t\delta q_2^i \int_0^1 d\tau [q_1^i \cos(t\tau) - p_1^i \sin(t\tau)] \\ &= -\delta q_2^i [q_1^i \sin t + p_1^i (\cos t - 1)]. \end{aligned} \tag{10.9.36}$$

Here we have used (8.7.9). Let us now find the effect of $\mathcal{M}$, with $\mathcal{M}$ given by (9.32), when it acts on q_1^i and p_1^i. We find for exp(: f_1 :) and exp(: f_2 :) the results

$$\exp(: f_1 :) q_1^i = q_1^i + \delta q_2^i (\cos t - 1), \tag{10.9.37}$$

$$\exp(: f_1 :) p_1^i = p_1^i - \delta q_2^i \sin t, \tag{10.9.38}$$

$$\exp(: f_2 :) q_1^i = q_1^i \cos t + p_1^i \sin t, \tag{10.9.39}$$

$$\exp(: f_2 :) p_1^i = -q_1^i \sin t + p_1^i \cos t. \tag{10.9.40}$$

Consequently we find for $\mathcal{M}$ the net results

$$q_1(t) = \mathcal{M} q_1^i = \delta q_2^i (\cos t - 1) + q_1^i \cos t + p_1^i \sin t, \tag{10.9.41}$$

$$p_1(t) = \mathcal{M} p_1^i = -\delta q_2^i \sin t - q_1^i \sin t + p_1^i \cos t. \tag{10.9.42}$$

Let us compare these results with those of (9.14) and (9.15), which can be written in the form

$$q_1(t) = \delta(\cos t - 1) + q_1^i \cos t + p_1^i \sin t, \tag{10.9.43}$$

$$p_1(t) = -\delta \sin t - q_1^i \sin t + p_1^i \cos t. \tag{10.9.44}$$

We see that (9.41) and (9.43), and (9.42) and (9.44), agree when we set $q_2^i = 1$. Note that, had we wished, we could have set $q_2^i = 1$ at an earlier stage before carrying out the calculations (9.37) through (9.42).

There is a moral to be learned from this last exercise. Quite generally, we see that once $\hat{\mathcal{M}}$ is computed in the form (9.7) with the aid of the auxiliary variable q_{n+1}, then each $\hat{f}_m$ may be decomposed in the form

$$\hat{f}_m = f_m^m(z) + (q_{n+1})f_{m-1}^m(z) + \cdots + (q_{n+1})^m f_0^m. \tag{10.9.45}$$

Here, as in Section 9.4, the superscript m on f_ℓ^m indicates that the quantity is associated with $\hat{f}_m$, and the subscript ℓ indicates that the quantity is homogeneous of degree ℓ in the variables z. After this is done, we may view q_{n+1} as playing the role of ϵ and use the calculus of Section 9.3 to manipulate the $(q_{n+1})^{m-\ell} f_\ell^m$ to produce a map of the form

$$\mathcal{M} = \exp(:f_1:)\mathcal{R}\exp(:f_3:)\exp(:f_4:)\cdots, \tag{10.9.46}$$

and then set $q_{n+1} = 1$ in all the f_m to obtain a final map that involves only the variables z. Better yet, we may simply use the shrinker of Section 9.4 to obtain $\mathcal{M}$ from $\hat{\mathcal{M}}$.

Exercises

10.9.1. Verify that (9.20) is of the form (9.4.46).

10.9.2. The map (9.32), with f_1 and f_2 given by (9.33) and (9.36), is written in reverse factorized form. See Section 7.8. Rewrite the map in forward factorized form. See (9.2.30). Before doing so, set $q_2^i = 1$. Verify that use of the forward factorized map also gives (9.43) and (9.44).

10.11 Symplectic Integration

Symplectic numerical integration methods, like the numerical integration methods described in Chapter 2, seek to compute trajectories accurately through some order in the time step h or with some prescribed over all accuracy. However, they are special in that they are designed for Hamiltonian systems and seek to satisfy the requirement that the resulting transfer map $\mathcal{M}$ between initial and final conditions be exactly (to machine precision) symplectic.

Many aspects of the construction of symplectic integrators involve map-like methods including Zassenhaus formulas. Moreover, for some symplectic integration methods, in the course of computing a trajectory it is also possible to compute in a natural way the transfer map about this trajectory. Thus, symplectic integration and symplectic maps are closely related, and their discussion could logically form part of this chapter. However, the subject is sufficiently vast to deserve a chapter if its own, and will be treated in Chapter 12.

10.12 Taylor Methods and the Complete Variational Equations

The work of the previous sections dealt for the most part with Hamiltonian systems and the representation of their associated *symplectic* transfer maps $\mathcal{M}$ by Lie transformations. In this section we will work with differential equations that are not necessarily Hamiltonian in form. This may occur if the dynamical system under consideration is intrinsically non-Hamiltonian. Also, there is the possibility that the dynamical system does have a Hamiltonian description, but we do not wish to use it. For example, we may want to consider charged-particle motion but do not wish to be concerned with scalar and vector potentials. Rather, we would prefer to work only in terms of electric and magnetic fields $\boldsymbol{E}$ and $\boldsymbol{B}$. One such option is to employ the first-order set of equations (1.6.68) and (1.6.69). Another is to employ a first-order set of equations obtained from the second-order set (1.6.74) by the usual means. Finally, the equations may be Hamiltonian in form, but we do not wish to exploit their Hamiltonian structure. However the equations arise, we will seek *Taylor* representations for their associated transfer maps

Let us recapitulate some of the contents of Section 1.3. Consider any set of m first-order differential equations of the form

$$\dot{z}_a = f_a(z_1, \cdots, z_m; t; \lambda_1, \cdots, \lambda_n), \quad a = 1, \cdots, m. \tag{10.12.1}$$

Here t is the independent variable and the z_a are dependent variables. Unlike the Hamiltonian case, the z_a need not be canonical variables and they need not be even in number. See (1.3.4). The λ_b are possible parameters.

Let the quantities z_a^0 be initial conditions specified at some initial time $t = t^0$,

$$z_a(t^0) = z_a^0. \tag{10.12.2}$$

Then, under mild conditions imposed on the functions f_a that appear on the right side of (12.1) and thereby define the set of differential equations, there exists a *unique* solution

$$z_a(t) = g_a(z_1^0, \cdots, z_m^0; t^0, t; \lambda_1, \cdots, \lambda_n), \quad a = 1, m \tag{10.12.3}$$

of (12.1) with the property

$$z_a(t^0) = g_a(z_1^0, \cdots, z_m^0; t^0, t^0; \lambda_1, \cdots, \lambda_n) = z_a^0, \quad a = 1, m. \tag{10.12.4}$$

Now assume that the functions f_a are analytic (within some domain) in the quantities z_a, the time t, and the parameters λ_b. Then, according to Poincaré's theorem, the solution given by (12.3) will be analytic (again within some domain) in the initial conditions z_a^0, the times t^0 and t, and the parameters λ_b.

If the solution $z_a(t)$ is analytic in the initial conditions z_a^0 and the parameters λ_b, then it is possible to expand it in the form of a Taylor series, with time-dependent coefficients, in the variables z_a^0 and λ_b. The aim of this section is to describe how these Taylor coefficients can be found as solutions to what we will call the *complete variational* equations.

To aid further discussion, it is useful to also rephrase our goal in the context of maps. Suppose we rewrite the set of first-order differential equations (12.1) in the more compact vector form

$$\dot{\boldsymbol{z}} = \boldsymbol{f}(\boldsymbol{z}; t; \boldsymbol{\lambda}). \tag{10.12.5}$$

Then, again using vector notation, their solution can be written in the form

$$\boldsymbol{z}(t) = \boldsymbol{g}(\boldsymbol{z}^0; t^0, t; \boldsymbol{\lambda}). \tag{10.12.6}$$

That is, the quantities $\boldsymbol{z}(t)$ at any time t are uniquely specified by the initial quantities $\boldsymbol{z}^0$ given at the initial time t^0.

We capitalize on this fact by introducing a slightly different notation. First, use t^i instead of t^0 to denote the *initial* time. Similarly use $\boldsymbol{z}^i$ to denote initial conditions by writing

$$\boldsymbol{z}^i = \boldsymbol{z}^0 = \boldsymbol{z}(t^i). \tag{10.12.7}$$

Next, let t^f be some *final* time, and define final conditions $\boldsymbol{z}^f$ by writing

$$\boldsymbol{z}^f = \boldsymbol{z}(t^f). \tag{10.12.8}$$

Then, with this notation, (12.6) can be rewritten in the form

$$\boldsymbol{z}^f = \boldsymbol{g}(\boldsymbol{z}^i; t^i, t^f; \boldsymbol{\lambda}). \tag{10.12.9}$$

We now view (12.9) as a *map* that sends the initial conditions $\boldsymbol{z}^i$ to the final conditions $\boldsymbol{z}^f$. This map will be called the *transfer map* between the times t^i and t^f, and will be denoted by the symbol $\mathcal{M}$. What we have emphasized is that a set of first-order differential equations of the form (12.5) can be integrated to produce a transfer map $\mathcal{M}$. We express the fact that $\mathcal{M}$ sends $\boldsymbol{z}^i$ to $\boldsymbol{z}^f$ in symbols by writing

$$\boldsymbol{z}^f = \mathcal{M}\boldsymbol{z}^i, \tag{10.12.10}$$

Recall the analogous discussion in Section 1.4 We also note that $\mathcal{M}$ is always invertible: Given $\boldsymbol{z}^f$, t^f, and t^i, we can always integrate backward in time from the moment $t = t^f$ to the moment $t = t^i$ and thereby find the initial conditions $\boldsymbol{z}^i$.

In the context of maps, our goal is to find a Taylor representation for $\mathcal{M}$. If parameters are present, we may wish to have an expansion in them as well. Initially, we will seek Taylor expansions of final conditions in terms of initial conditions. Subsequently, we will seek expansions of final conditions in terms of both initial conditions and parameters.

10.12.1 Case of No or Ignored Parameter Dependence

Suppose the equations (12.1) do not depend on any parameters λ_b or we do not wish to make expansions in them. We may then suppress their appearance to rewrite (12.1) in the form

$$\dot{z}_a = f_a(z,t), \quad a = 1, m. \tag{10.12.11}$$

Suppose, as in Section 10.5, that z^d is some given *design* solution to these equations, and we wish to study solutions in the vicinity of this solution. As before, we introduce deviation variables ζ_a by writing

$$z_a = z_a^d + \zeta_a. \tag{10.12.12}$$

Then the equations of motion (12.11) take the form

$$\dot{z}_a^d + \dot{\zeta}_a = f_a(z^d + \zeta, t). \tag{10.12.13}$$

We assume that the right side of (12.11) is analytic about z^d. See Theorem 3.3 of Section 1.3. Then we may write the relation

$$f_a(z^d + \zeta, t) = f_a(z^d, t) + g_a(z^d, t, \zeta) \tag{10.12.14}$$

where each g_a has a Taylor expansion of the form

$$g_a(z^d, t, \zeta) = \sum_r g_a^r(t) G_r(\zeta). \tag{10.12.15}$$

Here the $G_r(\zeta)$ are the various monomials in the variables ζ_b labeled by an *index* r using some convenient labeling scheme. (See, for examples, Tables 12.1 and 12.3. For more detail about monomial labeling schemes, see Section 39.2 and Appendix S.2.1.) And the g_a^r are (generally) time-dependent coefficients that we will call *forcing terms*.[1] By construction, all the monomials occurring in the right side of (12.15) have degree one or greater. We note that the g_a^r are known once $z^d(t)$ is given. By assumption, z^d is a solution of (12.11) and therefore satisfies the relations

$$\dot{z}_a^d = f_a(z^d, t). \tag{10.12.16}$$

It follows that the deviation variables satisfy the equations of motion

$$\dot{\zeta}_a = g_a(z^d, t, \zeta) = \sum_r g_a^r(t) G_r(\zeta). \tag{10.12.17}$$

These equations are evidently generalizations of the usual variational equations (see Exercise 4.6 of Section 1.4), and will be called the *complete variational* equations.

Consider the solution to the complete variational equations with *initial* conditions ζ_b^i specified at some initial time t^i. Under the conditions of Theorem 3.3 in Section 1.3 we expect that this solution will be an analytic function of the initial conditions ζ_b^i. (Here we have used the notation of Section 1.4.) Also, since the right side of (12.17) vanishes when all $\zeta_b = 0$ [all the monomials G_r appearing in (12.17) have degree one or greater], $\zeta(t) = 0$ is

[1] Here and in what follows the quantities g_a are not to be confused with those appearing in (12.3).

a solution to (12.17). It follows that the solution to the complete variational equations has a Taylor expansion of the form

$$\zeta_a(t) = \sum_r h_a^r(t) G_r(\zeta^i) \tag{10.12.18}$$

where the $h_a^r(t)$ are functions to be determined, and again all the monomials that occur have degree one or greater. When the quantities $h_a^r(t)$ are evaluated at some *final* time t^f, (12.18) provides a representation of the transfer map $\mathcal{M}$ about the design orbit in the Taylor form

$$\zeta_a^f = \zeta_a(t^f) = \sum_r h_a^r(t^f) G_r(\zeta^i). \tag{10.12.19}$$

10.12.2 Inclusion of Parameter Dependence

What can be done if we desire to have an expansion in parameters as well? Suppose that there are n such parameters, or that we wish to have expansions in n of them. The work of the previous section can be extended to handle this case by means of a simple trick: View the n parameters as additional *variables*, and "augment" the set of differential equations by additional differential equations that ensure these additional variables remain constant.

In detail, suppose we label the parameters so that those in which we wish to have an expansion are $\lambda_1 \cdots \lambda_n$. Introduce n additional variables $z_{m+1}, \cdots z_\ell$ where $\ell = m + n$ by making the replacements

$$\lambda_b \rightarrow z_{m+b}, \quad b = 1, n. \tag{10.12.20}$$

Next augment the equations (12.1) by n more of the form

$$\dot{z}_a = 0, \quad a = m + 1, \ell. \tag{10.12.21}$$

By this device we can rewrite the equations (12.1) in the form

$$\dot{z}_a = f_a(z, t), \quad a = 1, \ell \tag{10.12.22}$$

with the understanding that

$$f_a = f_a(z; t; \lambda^{\text{rem}}) \quad a = 1, m, \tag{10.12.23}$$

where λ^{rem} denotes the other *remaining* parameters, if any, and

$$f_a = 0, \quad a = m + 1, \ell. \tag{10.12.24}$$

For the first m equations we impose, as before, the initial conditions

$$z_a(t^i) = z_a^i, \quad a = 1, m. \tag{10.12.25}$$

For the remaining equations we impose the initial conditions

$$z_a(t^i) = \lambda_{a-m}, \quad a = m + 1, \ell. \tag{10.12.26}$$

Note that the relations (12.21) then ensure that the z_a for $a > m$ retain these values for all t.

To continue, let $z^d(t)$ be some design solution. Then, by construction, we have the result

$$z_a^d(t) = \lambda_{a-m}^d = \lambda_{a-m}, \quad a = m+1, \ell. \tag{10.12.27}$$

Again introduce deviation variables by writing

$$z_a = z_a^d + \zeta_a \quad a = 1, \ell. \tag{10.12.28}$$

Then the quantities ζ_a for $a > m$ will describe deviations in the parameter values about the values λ_{a-m}^d. Moreover, because we have assumed analyticity in the parameters as well, relations of the forms (12.14) and (12.15) will continue to hold except that the $G_r(\zeta)$ are now the various monomials in the ℓ variables ζ_b. Relations of the forms (12.16) and (12.17) will also hold with the provisos (12.24) and

$$g_a^r(t) = 0, \quad a = m+1, \ell. \tag{10.12.29}$$

Therefore, we will only need to integrate the equations of the forms (12.16) and (12.17) for $a \leq m$. Finally, relations of the form (12.19) will continue to hold for $a \leq m$ supplemented by the relations

$$\zeta_a^f = \zeta_a^i, \quad a = m+1, \ell. \tag{10.12.30}$$

Since the $G_r(\zeta^i)$ now involve ℓ variables, the relations of the form (12.19) will provide an expansion of the final quantities ζ_a^f (for $a \leq m$) in terms of the initial quantities ζ_a^i (for $a \leq m$) and also the parameter deviations ζ_a^i with $a = m+1, \ell$.

10.12.3 Solution of Complete Variational Equations Using Forward Integration

This subsection and Subsection 12.5 describe two methods for the solution of the complete variational equations. This subsection describes the method that employs integration forward in time, and is the conceptually simpler of the two methods.

To determine the functions h_a^r, let us insert the expansion (12.18) into both sides of (12.17). With r'' as a dummy index, the left side becomes the relation

$$\dot{\zeta}_a = \sum_{r''} \dot{h}_a^{r''}(t) G_{r''}(\zeta^i). \tag{10.12.31}$$

For the right side we find the intermediate result

$$\sum_r g_a^r(t) G_r(\zeta) = \sum_r g_a^r(t)\ G_r\!\left(\sum_{r'} h_1^{r'}(t) G_{r'}(\zeta^i), \cdots \sum_{r'} h_m^{r'}(t) G_{r'}(\zeta^i)\right). \tag{10.12.32}$$

However, since the G_r are monomials, there are relations of the form

$$G_r\!\left(\sum_{r'} h_1^{r'}(t) G_{r'}(\zeta^i), \cdots \sum_{r'} h_m^{r'}(t) G_{r'}(\zeta^i)\right) = \sum_{r''} U_r^{r''}(h_n^s) G_{r''}(\zeta^i), \tag{10.12.33}$$

and therefore the right side of (12.17) can be rewritten in the form

$$\sum_r g_a^r(t) G_r(\zeta) = \sum_{r''} \sum_r g_a^r(t) U_r^{r''}(h_n^s) G_{r''}(\zeta^i). \tag{10.12.34}$$

The notation $U_r^{r''}(h_n^s)$ is employed to indicate that these quantities might (at this stage of the argument) depend on all the h_n^s with n ranging from 1 to ℓ, and s ranging over all possible values.

Now, in accord with (12.17), equate the right sides of (12.31) and (12.34) to obtain the relation

$$\sum_{r''} \dot{h}_a^{r''}(t) G_{r''}(\zeta^i) = \sum_{r''} \sum_r g_a^r(t) U_r^{r''}(h_n^s) G_{r''}(\zeta^i). \tag{10.12.35}$$

Since the monomials $G_{r''}(\zeta^i)$ are linearly independent, we must have the result

$$\dot{h}_a^{r''}(t) = \sum_r g_a^r(t) U_r^{r''}(h_n^s). \tag{10.12.36}$$

We have found a set of differential equations that must be satisfied by the h_a^r. Moreover, from (12.18), there is the relation

$$\zeta_a(t^i) = \sum_r h_a^r(t^i) G_r(\zeta^i) = \zeta_a^i. \tag{10.12.37}$$

Thus, all the functions $h_a^r(t)$ have a known value at the initial time t^i, and indeed are mostly initially zero. When the equations (12.36) are integrated *forward* from $t = t^i$ to $t = t^f$ to obtain the quantities $h_a^r(t^f)$, the result is the transfer map $\mathcal{M}$ about the design orbit in the Taylor form (12.19).

Let us now examine the structure of this set of differential equations. A key observation is that the functions $U_r^{r''}(h_n^s)$ are *universal.* That is, as (12.33) indicates, they describe certain *combinatorial* properties of monomials. They depend only on the dimension ℓ of the system under study, and are the *same* for all such systems. As (12.17) shows, what are peculiar to any given system are the forcing terms $g_a^r(t)$.

10.12.4 Application of Forward Integration to the Two-Variable Case

To see what is going on in more detail, it is instructive to work out the first nontrivial case, that with $\ell = 2$. For two variables, all monomials in (ζ_1, ζ_2) are of the form $(\zeta_1)^{j_1}(\zeta_2)^{j_2}$. Here, to simplify notation, we have dropped the superscript i. Table 12.1 below shows a convenient way of labeling such monomials, and for this labeling we write

$$G_r(\zeta) = (\zeta_1)^{j_1}(\zeta_2)^{j_2} \tag{10.12.38}$$

with

$$j_1 = j_1(r) \;\text{ and }\; j_2 = j_2(r) \tag{10.12.39}$$

and $D(r)$ denotes the *degree* of each monomial.

Table 10.12.1: A labeling scheme for monomials through degree three in two variables.

r	j_1	j_2	D
1	1	0	1
2	0	1	1
3	2	0	2
4	1	1	2
5	0	2	2
6	3	0	3
7	2	1	3
8	1	2	3
9	0	3	3

Thus, for example,

$$G_1 = \zeta_1, \tag{10.12.40}$$

$$G_2 = \zeta_2, \tag{10.12.41}$$

$$G_3 = \zeta_1^2, \tag{10.12.42}$$

$$G_4 = \zeta_1\zeta_2, \tag{10.12.43}$$

$$G_5 = \zeta_2^2, \text{ etc.} \tag{10.12.44}$$

Again, for more detail about monomial labeling schemes, see Section 39.2 and Appendix S.2.1.

Let us now compute the first few $U_r^{r''}(h_n^s)$. From (12.33) and (12.40) we find the relation

$$G_1\left(\sum_{r'} h_1^{r'} G_{r'}(\zeta), \sum_{r'} h_2^{r'} G_{r'}(\zeta)\right) = \sum_{r'} h_1^{r'} G_{r'}(\zeta) = \sum_{r''} U_1^{r''} G_{r''}(\zeta). \tag{10.12.45}$$

It follows that there is the result

$$U_1^{r''} = h_1^{r''}. \tag{10.12.46}$$

Similarly, from (12.33) and (12.41), we find the result

$$U_2^{r''} = h_2^{r''}. \tag{10.12.47}$$

From (12.33) and (12.42) we find the relation

$$\begin{aligned} G_3\left(\sum_{r'} h_1^{r'} G_{r'}(\zeta), \sum_{r'} h_2^{r'} G_{r'}(\zeta)\right) &= \left(\sum_{r'} h_1^{r'} G_{r'}(\zeta)\right)^2 \\ &= \sum_{s,t} h_1^s h_1^t G_s(\zeta) G_t(\zeta) = \sum_{r''} U_3^{r''} G_{r''}(\zeta). \end{aligned} \tag{10.12.48}$$

Use of (12.48) and inspection of (12.40) through (12.44) yield the results

$$U_3^1 = 0, \tag{10.12.49}$$

$$U_3^2 = 0, \tag{10.12.50}$$

$$U_3^3 = (h_1^1)^2, \tag{10.12.51}$$

$$U_3^4 = 2h_1^1 h_1^2, \tag{10.12.52}$$

$$U_3^5 = (h_1^2)^2. \tag{10.12.53}$$

From (12.33) and (12.43) we find the relation

$$\begin{aligned} G_4\Bigg(\sum_{r'} h_1^{r'} G_{r'}(\zeta), \sum_{r'} h_2^{r'} G_{r'}(\zeta)\Bigg) &= \Bigg(\sum_{r'} h_1^{r'} G_{r'}(\zeta)\Bigg)\Bigg(\sum_{r'} h_2^{r'} G_{r'}(\zeta)\Bigg) \\ = \sum_{s,t} h_1^s h_2^t G_s(\zeta) G_t(\zeta) &= \sum_{r''} U_4^{r''} G_{r''}(\zeta). \end{aligned} \tag{10.12.54}$$

It follows that there are the results

$$U_4^1 = 0, \tag{10.12.55}$$

$$U_4^2 = 0, \tag{10.12.56}$$

$$U_4^3 = h_1^1 h_2^1, \tag{10.12.57}$$

$$U_4^4 = h_1^1 h_2^2 + h_1^2 h_2^1, \tag{10.12.58}$$

$$U_4^5 = h_1^2 h_2^2. \tag{10.12.59}$$

Finally, from (12.33) and (12.44), we find the results

$$U_5^1 = 0, \tag{10.12.60}$$

$$U_5^2 = 0, \tag{10.12.61}$$

$$U_5^3 = (h_2^1)^2, \tag{10.12.62}$$

$$U_5^4 = 2h_2^1 h_2^2, \tag{10.12.63}$$

$$U_5^5 = (h_2^2)^2. \tag{10.12.64}$$

Two features now become apparent. As in Table 12.1, let $D(r)$ be the *degree* of the monomial with label r. Then, from the examples worked out, and quite generally from (12.33), we see that there is the relation

$$U_r^{r''} = 0 \text{ when } D(r) > D(r''). \tag{10.12.65}$$

It follows that the sum on the right side of (12.36) always terminates. Second, for the arguments h_n^s possibly appearing in $U_r^{r''}(h_n^s)$, we see that there is the relation

$$D(s) \leq D(r''). \tag{10.12.66}$$

It follows, again see (12.36), that the right side of the differential equation for any $h_a^{r''}$ involves only the h_n^s for which (12.66) holds. Therefore, to determine the coefficients $h_a^r(t^f)$ of the Taylor expansion (12.19) through terms of some degree D, it is only necessary to integrate a finite number of equations, and the right sides of these equations involve only the coefficients for this degree and lower.

For example, to continue our discussion of the case of two variables, the equations (12.36) take the form

$$\dot{h}_1^1(t) = \sum_{r=1}^{2} g_1^r(t) U_r^1 = g_1^1(t)h_1^1(t) + g_1^2(t)h_2^1(t), \tag{10.12.67}$$

$$\dot{h}_2^1(t) = \sum_{r=1}^{2} g_2^r(t) U_r^1 = g_2^1(t)h_1^1(t) + g_2^2(t)h_2^1(t), \tag{10.12.68}$$

$$\dot{h}_1^2(t) = \sum_{r=1}^{2} g_1^r(t) U_r^2 = g_1^1(t)h_1^2(t) + g_1^2(t)h_2^2(t), \tag{10.12.69}$$

$$\dot{h}_2^2(t) = \sum_{r=1}^{2} g_2^r(t) U_r^2 = g_2^1(t)h_1^2(t) + g_2^2(t)h_2^2(t), \tag{10.12.70}$$

$$\begin{aligned} \dot{h}_1^3(t) &= \sum_{r=1}^{5} g_1^r(t) U_r^3 \\ &= g_1^1(t)h_1^3(t) + g_1^2(t)h_2^3(t) + g_1^3(t)[h_1^1(t)]^2 \\ &+ g_1^4(t)h_1^1(t)h_2^1(t) + g_1^5(t)[h_2^1(t)]^2, \end{aligned} \tag{10.12.71}$$

$$\begin{aligned} \dot{h}_2^3(t) &= \sum_{r=1}^{5} g_2^r(t) U_r^3 \\ &= g_2^1(t)h_1^3(t) + g_2^2(t)h_2^3(t) + g_2^3(t)[h_1^1(t)]^2 \\ &+ g_2^4(t)h_1^1(t)h_2^1(t) + g_2^5(t)[h_2^1(t)]^2, \end{aligned} \tag{10.12.72}$$

$$\begin{aligned} \dot{h}_1^4(t) &= \sum_{r=1}^{5} g_1^r(t) U_r^4 \\ &= g_1^1(t)h_1^4(t) + g_1^2(t)h_2^4(t) + 2g_1^3(t)h_1^1(t)h_1^2(t) \\ &+ g_1^4(t)[h_1^1(t)h_2^2(t) + h_1^2(t)h_2^1(t)] + 2g_1^5(t)h_2^1(t)h_2^2(t), \end{aligned} \tag{10.12.73}$$

$$\begin{aligned} \dot{h}_2^4(t) &= \sum_{r=1}^{5} g_2^r(t) U_r^4 \\ &= g_2^1(t)h_1^4(t) + g_2^2(t)h_2^4(t) + 2g_2^3(t)h_1^1(t)h_1^2(t) \\ &+ g_2^4(t)[h_1^1(t)h_2^2(t) + h_1^2(t)h_2^1(t)] + 2g_2^5(t)h_2^1(t)h_2^2(t), \end{aligned} \tag{10.12.74}$$

$$\begin{aligned} \dot{h}_1^5(t) &= \sum_{r=1}^{5} g_1^r(t) U_r^5 \\ &= g_1^1(t)h_1^5(t) + g_1^2(t)h_2^5(t) + g_1^3(t)[h_1^2(t)]^2 \\ &+ g_1^4(t)h_1^2(t)h_2^2(t) + g_1^5(t)[h_2^2(t)]^2, \end{aligned} \tag{10.12.75}$$

$$\begin{aligned}\dot{h}_2^5(t) &= \sum_{r=1}^{5} g_2^r(t)U_r^5 \\ &= g_2^1(t)h_1^5(t) + g_2^2(t)h_2^5(t) + g_2^3(t)[h_1^2(t)]^2 \\ &+ g_2^4(t)h_1^2(t)h_2^2(t) + g_2^5(t)[h_2^2(t)]^2, \text{ etc.}\end{aligned} \tag{10.12.76}$$

From (12.37) we have the initial conditions

$$h_a^r(t^i) = \delta_a^r. \tag{10.12.77}$$

We see that if we desire only the degree one terms in the expansion (12.18), then it is only necessary to integrate the equations (12.67) through (12.70) with the initial conditions (12.77). [A moment's reflection shows that, for the case of two variables and no parameters, these are just the (linear) variational equations for the matrix L in Exercise 4.6 of Section 1.4.] We see that if we desire only the degree one and degree two terms in the expansion (12.18), then it is only necessary to integrate the equations (12.67) through (12.76) with the initial conditions (12.77), etc.

10.12.5 Solution of Complete Variational Equations Using Backward Integration

There is another method of determining the h_a^r that is surprising, ingenious, and in some ways superior to that just described. It involves integrating *backward* in time.[2]

Let us rewrite (12.19) in the slightly more explicit form

$$\zeta_a^f = \sum_r h_a^r(t^i, t^f)G_r(\zeta^i) \tag{10.12.78}$$

to indicate that there are two times involved, t^i and t^f. From this perspective, (12.36) is a set of differential equations for the quantities $(\partial/\partial t)h_a^r(t^i, t)$ that is to be integrated and evaluated at $t = t^f$. An alternate procedure is to seek a set of differential equations for the quantities $(\partial/\partial \bar{t})h_a^r(\bar{t}, t^f)$ that is to be integrated and evaluated at $\bar{t} = t^i$.

As a first step in considering this alternative, rewrite (12.78) in the form

$$\zeta_a^f = \sum_r h_a^r(\bar{t}, t^f)G_r(\zeta(\bar{t})). \tag{10.12.79}$$

Now reason as follows: If $\bar{t}$ is varied and at the same time the quantities $\zeta(\bar{t})$ are varied (evolve) so as to remain on the solution to (12.17) having final conditions ζ^f, then the quantities ζ^f must remain *unchanged.* Consequently, there is the differential equation result

$$0 = d\zeta_a^f/d\bar{t} = \sum_r [(\partial/\partial\bar{t})h_a(\bar{t}, t^f)]G_r(\zeta(\bar{t})) + \sum_r h_a^r(\bar{t}, t^f)(d/d\bar{t})G_r(\zeta(\bar{t})). \tag{10.12.80}$$

Let us introduce the notation $\dot{h}_a^r(\bar{t}, t^f)$ for $(\partial/\partial\bar{t})h_a^r(\bar{t}, t^f)$ so that the first term on the right side of (12.80) can be rewritten in the form

$$\sum_r [(\partial/\partial\bar{t})h_a^r(\bar{t}, t^f)]G_r(\zeta) = \sum_r \dot{h}_a^r G_r(\zeta). \tag{10.12.81}$$

[2] To integrate backward numerically, simply replace h by $-h$ where h is the step size. See Chapter 2.

Next, begin working on the second term on the right side of (12.80) by replacing the summation index r by the dummy index r',

$$\sum_r h_a^r(\bar{t}, t^f)(d/d\bar{t})G_r(\zeta(\bar{t})) = \sum_{r'} h_a^{r'}(\bar{t}, t^f)(d/d\bar{t})G_{r'}(\zeta(\bar{t})). \tag{10.12.82}$$

Now carry out the indicated differentiation using the chain rule and the relation (12.17) which describes how the quantities ζ vary along a solution,

$$(d/d\bar{t})G_{r'}(\zeta(\bar{t})) = \sum_b (\partial G_{r'}/\partial\zeta_b)(d\zeta_b/d\bar{t}) = \sum_{br''} (\partial G_{r'}/\partial\zeta_b)g_b^{r''}(\bar{t})G_{r''}(\zeta(\bar{t})). \tag{10.12.83}$$

Watch closely: Since the G_r are simply standard monomials in the ζ, there must be relations of the form

$$[(\partial/\partial\zeta_b)G_{r'}(\zeta)]G_{r''}(\zeta) = \sum_r C_{br'r''}^r G_r(\zeta) \tag{10.12.84}$$

where the $C_{br'r''}^r$ are *universal constant coefficients* that describe certain combinatorial properties of monomials. As a result, the second term on the right side of (12.80) can be written in the form

$$\sum_{r'} h_a^{r'}(\bar{t}, t^f)(d/d\bar{t})G_{r'}(\zeta(\bar{t})) = \sum_r G_r(\zeta) \sum_{br'r''} C_{br'r''}^r g_b^{r''}(\bar{t})h_a^{r'}(\bar{t}, t^f). \tag{10.12.85}$$

Since the monomials G_r are linearly independent, the relations (12.80) through (12.85) imply the result

$$\dot{h}_a^r(\bar{t}, t^f) = -\sum_{br'r''} C_{br'r''}^r g_b^{r''}(\bar{t})h_a^{r'}(\bar{t}, t^f). \tag{10.12.86}$$

This is a set of differential equations for the h_a^r that are to be integrated from $\bar{t} = t^f$ *back* to $\bar{t} = t^i$. Also, evaluating (12.79) for $\bar{t} = t^f$ gives the results

$$\zeta_a^f = \sum_r h_a^r(t^f, t^f)G_r(\zeta_a^f), \tag{10.12.87}$$

from which it follows that (with the usual polynomial labeling) the h_a^r satisfy the final conditions

$$h_a^r(t^f, t^f) = \delta_a^r. \tag{10.12.88}$$

Therefore the solution to (12.86) is uniquely defined. Finally, it is evident from the definition (12.84) that the coefficients $C_{br'r''}^r$ satisfy the relation

$$C_{br'r''}^r = 0 \text{ unless } [D(r') - 1] + D(r'') = D(r). \tag{10.12.89}$$

Consequently, since $D(r'') \geq 1$ in (12.86), it follows from (12.89) that the only $h_a^{r'}$ that occur on the right side of (12.86) are those that satisfy

$$D(r') \leq D(r). \tag{10.12.90}$$

Similarly, the only $g_b^{r''}$ that occur are those that satisfy

$$D(r'') \leq D(r). \tag{10.12.91}$$

Therefore, as before, to determine the coefficients h_a^r of the Taylor expansion (12.19) through terms of some degree D, it is only necessary to integrate a finite number of equations, and the right sides of these equations involve only the coefficients for this degree and lower.

Comparison of the differential equation sets (12.36) and (12.86) shows that the latter has the remarkable property of being *linear* in the unknown quantities h_a^r. This feature means that the evaluation of the right side of (12.86) involves only the retrieval of certain universal constants $C^r_{br'r''}$ and straight-forward multiplication and addition. By contrast, the use of (12.36) requires evaluation of the fairly complicated *nonlinear* functions $U_r^{r''}(h_n^s)$. Finally, it is easier to insure that a numerical integration procedure is working properly for a set of linear differential equations than it is for a nonlinear set.

The only complication in the use of (12.86) is that the equations must be integrated backwards in $\bar{t}$. Correspondingly the equations (12.16) for the design solution must also be integrated backwards since they supply the required quantities g_a^r through use of (12.14) and (12.15). This is no problem if the final quantities $z^d(t^{\text{fin}})$ are known. However if only the initial quantities $z^d(t^{\text{in}})$ are known, then the equations (12.16) for z^d must first be integrated forward in time to find the final quantities $z^d(t^{\text{fin}})$.

10.12.6 The Two-Variable Case Revisited

For clarity, let us also apply this second method to the two-variable case. Table 12.2 shows the nonzero values of $C^r_{br'r''}$ for $r \in [1,5]$ obtained using (12.40) through (12.44) and (12.84). Note that the rules (12.89) hold. Use of this Table shows that in the two-variable case the equations (12.86) take the form

$$\dot{h}_1^1(\bar{t},t^f) = -\ g_1^1(\bar{t})h_1^1(\bar{t},t^f) - g_2^1(\bar{t})h_1^2(\bar{t},t^f), \tag{10.12.92}$$

$$\dot{h}_2^1(\bar{t},t^f) = -\ g_1^1(\bar{t})h_2^1(\bar{t},t^f) - g_2^1(\bar{t})h_2^2(\bar{t},t^f), \tag{10.12.93}$$

$$\dot{h}_1^2(\bar{t},t^f) = -\ g_1^2(\bar{t})h_1^1(\bar{t},t^f) - g_2^2(\bar{t})h_1^2(\bar{t},t^f), \tag{10.12.94}$$

$$\dot{h}_2^2(\bar{t},t^f) = -\ g_1^2(\bar{t})h_2^1(\bar{t},t^f) - g_2^2(\bar{t})h_2^2(\bar{t},t^f), \tag{10.12.95}$$

$$\dot{h}_1^3(\bar{t},t^f) = -\ 2g_1^1(\bar{t})h_1^3(\bar{t},t^f) - g_1^3(\bar{t})h_1^1(\bar{t},t^f) - g_2^1(\bar{t})h_1^4(\bar{t},t^f) - g_2^3(\bar{t})h_1^2(\bar{t},t^f), \tag{10.12.96}$$

$$\dot{h}_2^3(\bar{t},t^f) = -\ 2g_1^1(\bar{t})h_2^3(\bar{t},t^f) - g_1^3(\bar{t})h_2^1(\bar{t},t^f) - g_2^1(\bar{t})h_2^4(\bar{t},t^f) - g_2^3(\bar{t})h_2^2(\bar{t},t^f), \tag{10.12.97}$$

$$\begin{aligned}\dot{h}_1^4(\bar{t},t^f) &= -\ g_1^1(\bar{t})h_1^4(\bar{t},t^f) - 2g_1^2(\bar{t})h_1^3(\bar{t},t^f) - g_1^4(\bar{t})h_1^1(\bar{t},t^f) \\ &-\ 2g_2^1(\bar{t})h_1^5(\bar{t},t^f) - g_2^2(\bar{t})h_1^4(\bar{t},t^f) - g_2^4(\bar{t})h_1^2(\bar{t},t^f),\end{aligned} \tag{10.12.98}$$

$$\begin{aligned}\dot{h}_2^4(\bar{t},t^f) &= -\ g_1^1(\bar{t})h_2^4(\bar{t},t^f) - 2g_1^2(\bar{t})h_2^3(\bar{t},t^f) - g_1^4(\bar{t})h_2^1(\bar{t},t^f) \\ &-\ 2g_2^1(\bar{t})h_2^5(\bar{t},t^f) - g_2^2(\bar{t})h_2^4(\bar{t},t^f) - g_2^4(\bar{t})h_2^2(\bar{t},t^f),\end{aligned} \tag{10.12.99}$$

$$\dot{h}_1^5(\bar{t},t^f) = -\ g_1^2(\bar{t})h_1^4(\bar{t},t^f) - g_1^5(\bar{t})h_1^1(\bar{t},t^f) - 2g_2^2(\bar{t})h_1^5(\bar{t},t^f) - g_2^5(\bar{t})h_1^2(\bar{t},t^f), \tag{10.12.100}$$

$$\dot{h}_2^5(\bar{t},t^f) = -\ g_1^2(\bar{t})h_2^4(\bar{t},t^f) - g_1^5(\bar{t})h_2^1(\bar{t},t^f) - 2g_2^2(\bar{t})h_2^5(\bar{t},t^f) - g_2^5(\bar{t})h_2^2(\bar{t},t^f),\ \text{etc.} \tag{10.12.101}$$

As advertised, the right sides of (12.92) through (12.101) are indeed simpler than those of (12.67) through (12.76).

Table 10.12.2: Nonzero values of $C^r_{br'r''}$ for $r \in [1, 5]$ in the two-variable case.

10.12.7 Application to Duffing's Equation

As an extension of our discussion of the case of two variables (and no parameters), let us apply the results obtained so far to Duffing's equation (1.4.27) described earlier in Section 1.4. Recall that by a suitable change of variables this equation can be brought to the form

$$q'' + 2\beta q' + q + q^3 = -\epsilon \sin \omega\tau. \tag{10.12.102}$$

Here, for notational convenience, a prime denotes $d/d\tau$. For our purposes, particularly for the parameter expansion soon to be made in the next subsection, it is useful to make the further change of variables

$$q = \omega Q, \tag{10.12.103}$$

$$\omega = 1/\sigma, \tag{10.12.104}$$

$$\omega\tau = t. \tag{10.12.105}$$

When this is done, there are the relations

$$q' = \omega^2 \dot{Q} \tag{10.12.106}$$

and

$$q'' = \omega^3 \ddot{Q} \tag{10.12.107}$$

where now a dot denotes d/dt. [Note that the variable t here is different from that in (1.4.27).] Correspondingly, Duffing's equation takes the form

$$\ddot{Q} + 2\beta\sigma\dot{Q} + \sigma^2 Q + Q^3 = -\epsilon\sigma^3 \sin t. \tag{10.12.108}$$

Finally, this equation can be converted to a first-order pair of the form (12.11) by writing

$$Q = z_1, \tag{10.12.109}$$

$$\dot{Q} = z_2. \tag{10.12.110}$$

Doing so gives the system

$$\dot{z}_1 = z_2, \tag{10.12.111}$$

$$\dot{z}_2 = -2\beta\sigma z_2 - \sigma^2 z_1 - z_1^3 - \epsilon\sigma^3 \sin t, \tag{10.12.112}$$

and we see that there are the relations

$$f_1(z,t) = z_2, \tag{10.12.113}$$

$$f_2(z,t) = -2\beta\sigma z_2 - \sigma^2 z_1 - z_1^3 - \epsilon\sigma^3 \sin t. \tag{10.12.114}$$

Now we are ready to carry out the expansions (12.14) and (12.15). We find the results

$$f_1(z^d + \zeta, t) = z_2^d + \zeta_2, \tag{10.12.115}$$

$$\begin{aligned} f_2(z^d + \zeta, t) &= -2\beta\sigma(z_2^d + \zeta_2) - \sigma^2(z_1^d + \zeta_1) - (z_1^d + \zeta_1)^3 - \epsilon\sigma^3 \sin t \\ &= -[2\beta\sigma z_2^d + \sigma^2 z_1^d + (z_1^d)^3 + \epsilon\sigma^3 \sin] - \{[\sigma^2 + 3(z_1^d)^2]\zeta_1 + 2\beta\sigma\zeta_2\} \\ &\quad -3z_1^d\zeta_1^2 - \zeta_1^3. \end{aligned} \tag{10.12.116}$$

Note that the right sides of (12.115) and (12.116) contain only terms of degree 3 and lower in the deviation variables ζ_a. It follows that for Duffing's equation the only nonzero forcing terms are given by the relations

$$g_1^2 = 1, \tag{10.12.117}$$

$$g_2^1 = -\sigma^2 - 3(z_1^d)^2, \tag{10.12.118}$$

$$g_2^2 = -2\beta\sigma, \tag{10.12.119}$$

$$g_2^3 = -3z_1^d, \tag{10.12.120}$$

$$g_2^6 = -1. \tag{10.12.121}$$

And, according to (12.16), the design solution z^d obeys the equations (12.111) and (12.112) with $z = z^d$.

At this point we pause to look particularly at the lowest-degree (linear) variational equations because they have a special simplicity in the Duffing case. Let L be the matrix defined by the relation

$$L = \begin{pmatrix} h_1^1 & h_1^2 \\ h_2^1 & h_2^2 \end{pmatrix} \tag{10.12.122}$$

so that

$$\zeta(t) = L(t)\zeta^i + O[(\zeta^i)^2]. \qquad (10.12.123)$$

See (12.18). Then equations (12.67) through (12.70) are equivalent to the matrix equation

$$\dot{L} = AL \qquad (10.12.124)$$

where A is the matrix

$$A = \begin{pmatrix} g_1^1 & g_1^2 \\ g_2^1 & g_2^2 \end{pmatrix}. \qquad (10.12.125)$$

From (12.125) and (12.117) through (12.121), we find the result

$$\text{tr } A = g_1^1 + g_2^2 = -2\beta\sigma. \qquad (10.12.126)$$

Also, in the Duffing case, we may set $t^i = 0$ and require the initial condition

$$L(0) = I. \qquad (10.12.127)$$

Based on the results of Exercise 1.4.6, we conclude that there is the relation

$$\det L(t) = \exp(-2\beta\sigma t), \qquad (10.12.128)$$

and, in particular, for $t = t^f = 2\pi$ there is the relation

$$\det L(2\pi) = \exp(-4\pi\beta\sigma) = \exp(-4\pi\beta/\omega). \qquad (10.12.129)$$

Thus, for the Duffing equation, we are able to find the determinant of the linear part of the transfer map *analytically.* Note also the remarkable feature that for the Duffing equation the determinant of the linear part of the transfer map does not depend on z^d. The determinant is the *same* for any trajectory.

Returning to our main discussion, suppose, for example, that we specify the values of β, ϵ, and ω, and then integrate the system (12.111) and (12.112) from $t = 0$ to $t = 2\pi$. So doing produces an example of the stroboscopic map $\mathcal{M}$ described in Subsection 1.4.3. Suppose, further, that we require that the design solution z^d be periodic (with period 2π) thus yielding a fixed point of $\mathcal{M}$,

$$z_a^d(2\pi) = z_a^d(0). \qquad (10.12.130)$$

We will see in Chapter 28 that such fixed points exist. Using this $z^d(t)$, we may integrate from $t = t^i = 0$ to $t = t^f = 2\pi$ the equations (12.67) through (12.76), etc., with the g_a^r given by (12.117) through (12.121) and the initial conditions given by (12.77). Alternatively, we may integrate (12.92) though (12.101), etc. from $\bar{t} = t^f = 2\pi$ back to $\bar{t} = t^i = 0$ with the final conditions (12.88). Carrying out either method determines the quantities $h_a^r(0, 2\pi)$, and we see from (12.19) or (12.78) that we have found a Taylor expansion for $\mathcal{M}$ about the *fixed* point $z^d(0)$.

10.12.8 Application to Duffing's Equation Including some Parameter Dependence

Suppose, as described in Subsection 12.2, we wish to include some parameter dependence. Figures 28.8.5 and 28.8.6 in Chapter 28 show, for example, a portion of the Feigenbaum diagram for Duffing's equation as ω is varied. Evidently ω is a parameter and therefore, according to Theorem 3.3 of Section 1.3, it should be possible to Taylor expand the solution to Duffing's equation with respect to ω as well as with respect to the initial conditions. Equivalently, we will seek an expansion of the solution of (12.108) with respect to the parameter σ. See (12.104).

Following the method of Subsection 12.2, we augment the first-order equation set associated with (12.108) by adding the equation

$$\dot{\sigma} = 0. \tag{10.12.131}$$

Then we may view σ as a variable, and (12.131) guarantees that this variable remains a constant. Taken together, (12.108) and (12.131) may be converted to a first-order triplet of the form (12.22) by writing (12.109), (12.110), and

$$\sigma = z_3. \tag{10.12.132}$$

Doing so gives the system

$$\dot{z}_1 = z_2, \tag{10.12.133}$$

$$\dot{z}_2 = -2\beta z_3 z_2 - z_3^2 z_1 - z_1^3 - \epsilon z_3^3 \sin t, \tag{10.12.134}$$

$$\dot{z}_3 = 0, \tag{10.12.135}$$

and we see that there are the relations

$$f_1(z,t) = z_2, \tag{10.12.136}$$

$$f_2(z,t) = -\ 2\beta z_3 z_2 - z_3^2 z_1 - z_1^3 - \epsilon z_3^3 \sin t, \tag{10.12.137}$$

$$f_3(z,t) = 0. \tag{10.12.138}$$

As before, we introduce deviation variables using (12.12) and carry out the steps (12.13) through (12.19). In particular, we write

$$z_3 = z_3^d + \zeta_3 = \sigma^d + \zeta_3. \tag{10.12.139}$$

This time we are working with monomials in the three variables ζ_1, ζ_2, and ζ_3. [That is, a ranges from 1 to 3 in (12.18).] They are conveniently labeled using the indices r given in Table 12.3 below. We see, for example, that if we desire to work with monomials through degree 2, the index r should range from 1 through 9.

With regard to the expansions (12.14) and (12.15), we find the results

$$f_1(z^d + \zeta, t) = z_2^d + \zeta_2, \tag{10.12.140}$$

Table 10.12.3: A labeling scheme for monomials through degree three in three variables.

r	j_1	j_2	j_3	D
1	1	0	0	1
2	0	1	0	1
3	0	0	1	1
4	2	0	0	2
5	1	1	0	2
6	1	0	1	2
7	0	2	0	2
8	0	1	1	2
9	0	0	2	2
10	3	0	0	3
11	2	1	0	3
12	2	0	1	3
13	1	2	0	3
14	1	1	1	3
15	1	0	2	3
16	0	3	0	3
17	0	2	1	3
18	0	1	2	3
19	0	0	3	3

$$\begin{aligned} f_2(z^d+\zeta,t) &= -\ 2\beta(z_3^d+\zeta_3)(z_2^d+\zeta_2)-(z_3^d+\zeta_3)^2(z_1^d+\zeta_1) \\ &\quad -(z_1^d+\zeta_1)^3-\epsilon(z_3^d+\zeta_3)^3\sin t \\ &= [-2\beta z_2^d z_3^d - z_1^d(z_3^d)^2-(z_1^d)^3-\epsilon(z_3^d)^3\sin t] \\ &\quad -[3(z_1^d)^2+(z_3^d)^2]\zeta_1-2\beta z_3^d\zeta_2-[2\beta z_2^d+2z_1^d z_3^d+3\epsilon(z_3^d)^2\sin t]\zeta_3 \\ &\quad -2\beta\zeta_2\zeta_3-(z_1^d+3\epsilon z_3^d)\zeta_3^2-z_3^d\zeta_1\zeta_2-3z_1^d\zeta_1^2 \\ &\quad -\zeta_1^3-\zeta_1\zeta_3^2-\epsilon(\sin t)\zeta_3^3. \end{aligned} \tag{10.12.141}$$

$$f_3(z^d+\zeta,t)=0. \tag{10.12.142}$$

Note the right sides of (12.140) through (12.142) are at most cubic in the deviation variables ζ_a. Therefore, from Table 12.3, we see that the index r for the g_a^r should range from 1 through 19. It follows that for Duffing's equation (with σ parameter expansion) the *only* nonzero forcing terms are given by the relations

$$g_1^2=1, \tag{10.12.143}$$

$$g_2^1=-3(z_1^d)^2-(z_3^d)^2, \tag{10.12.144}$$

$$g_2^2=-2\beta z_3^d, \tag{10.12.145}$$

$$g_2^3=-2\beta z_2^d-2z_1^d z_3^d-3\epsilon(z_3^d)^2\sin t, \tag{10.12.146}$$

$$g_2^4 = -3z_1^d, \tag{10.12.147}$$

$$g_2^6 = -2z_3^d, \tag{10.12.148}$$

$$g_2^8 = -2\beta, \tag{10.12.149}$$

$$g_2^9 = -z_1^d - 3\epsilon z_3^d \sin t, \tag{10.12.150}$$

$$g_2^{10} = -1, \tag{10.12.151}$$

$$g_2^{15} = -1, \tag{10.12.152}$$

$$g_2^{19} = -\epsilon \sin t. \tag{10.12.153}$$

If we choose to use forward integration, and again restrict our attention to monomials through degree 2, the relevant $U_r^{r''}(h_n^s)$ are given by the relations

$$U_1^{r''} = h_1^{r''}, \tag{10.12.154}$$

$$U_2^{r''} = h_2^{r''}, \tag{10.12.155}$$

$$U_3^{r''} = h_3^{r''}, \tag{10.12.156}$$

$$U_4^r = 0 \text{ for } r \leq 3, \tag{10.12.157}$$

$$U_4^4 = (h_1^1)^2, \tag{10.12.158}$$

$$U_4^5 = 2h_1^1 h_1^2, \tag{10.12.159}$$

$$U_4^6 = 2h_1^1 h_1^3, \tag{10.12.160}$$

$$U_4^7 = (h_1^2)^2, \tag{10.12.161}$$

$$U_4^8 = 2h_1^2 h_1^3, \tag{10.12.162}$$

$$U_4^9 = (h_1^3)^2, \tag{10.12.163}$$

$$U_5^r = 0 \text{ for } r \leq 3, \tag{10.12.164}$$

$$U_5^4 = h_1^1 h_2^1, \tag{10.12.165}$$

$$U_5^5 = h_1^1 h_2^2 + h_1^2 h_2^1, \tag{10.12.166}$$

$$U_5^6 = h_1^3 h_2^1 + h_1^1 h_2^3, \tag{10.12.167}$$

$$U_5^7 = h_1^2 h_2^2, \tag{10.12.168}$$

$$U_5^8 = h_1^3 h_2^2 + h_1^2 h_2^3, \tag{10.12.169}$$

$$U_5^9 = h_1^3 h_2^3, \tag{10.12.170}$$

$$U_6^r = 0 \text{ for } r \leq 3, \tag{10.12.171}$$

$$U_6^4 = h_1^1 h_3^1, \tag{10.12.172}$$

$$U_6^5 = h_1^1 h_3^2 + h_1^2 h_3^1, \tag{10.12.173}$$

$$U_6^6 = h_1^3 h_3^1 + h_1^1 h_3^3, \tag{10.12.174}$$

$$U_6^7 = h_1^2 h_3^2, \tag{10.12.175}$$

$$U_6^8 = h_1^2 h_3^3 + h_1^3 h_3^2, \tag{10.12.176}$$

$$U_6^9 = h_1^3 h_3^3, \tag{10.12.177}$$

$$U_7^r = 0 \text{ for } r \leq 3, \tag{10.12.178}$$

$$U_7^4 = (h_1^2)^2, \tag{10.12.179}$$

$$U_7^5 = 2h_2^1 h_2^2, \tag{10.12.180}$$

$$U_7^6 = 2h_2^1 h_2^3, \tag{10.12.181}$$

$$U_7^7 = (h_2^2)^2, \tag{10.12.182}$$

$$U_7^8 = 2h_2^2 h_2^3, \tag{10.12.183}$$

$$U_7^9 = (h_2^3)^2, \tag{10.12.184}$$

$$U_8^r = 0 \text{ for } r \leq 3, \tag{10.12.185}$$

$$U_8^4 = h_2^1 h_3^1, \tag{10.12.186}$$

$$U_8^5 = h_2^1 h_3^2 + h_2^2 h_3^1, \tag{10.12.187}$$

$$U_8^6 = h_2^3 h_3^1 + h_2^1 h_3^3, \tag{10.12.188}$$

$$U_8^7 = h_2^2 h_3^2, \tag{10.12.189}$$

$$U_8^8 = h_2^2 h_3^3 + h_2^3 h_3^2, \tag{10.12.190}$$

$$U_8^9 = h_2^3 h_3^3, \tag{10.12.191}$$

$$U_9^r = 0 \text{ for } r \leq 3, \tag{10.12.192}$$

$$U_9^4 = (h_3^1)^2, \tag{10.12.193}$$

$$U_9^5 = 2h_3^1 h_3^2, \tag{10.12.194}$$

$$U_9^6 = 2h_3^1 h_3^3, \tag{10.12.195}$$

$$U_9^7 = (h_3^2)^2, \tag{10.12.196}$$

$$U_9^8 = 2h_3^2 h_3^3, \tag{10.12.197}$$

$$U_9^9 = (h_3^3)^2. \tag{10.12.198}$$

As before, the rules (12.65) and (12.66) hold.

The relevant equations for the h_a^r become

$$\dot{h}_a^{r''} = \sum_{r=1}^{3} g_a^r U_r^{r''} \text{ for } r'', a \in [1,3], \tag{10.12.199}$$

$$\dot{h}_a^{r''} = \sum_{r=1}^{9} g_a^r U_r^{r''} \text{ for } r'' \in [4,9] \text{ and } a \in [1,3]. \tag{10.12.200}$$

The initial conditions are

$$h_a^r(t^i) = \delta_a^r \text{ for } a \in [1,3] \text{ and } r \in [1,9]. \tag{10.12.201}$$

Note that because of (12.135) and (12.201) we can actually restrict a in the differential equations (12.199) and (12.200) for the $h_a^{r''}$ to the values $a = 1$ and $a = 2$ since we have the relations

$$h_3^r(t) = \delta_3^r \text{ for all } t. \tag{10.12.202}$$

For the use of backward integration in the three-variable case, Table 12.4 gives the nonzero values of $C_{br'r''}^r$ for $r \in [1, 9]$. In this method the equations (12.86) are to be integrated from $\bar{t} = t^{\text{fin}}$ back to $\bar{t} = t^{\text{in}}$ with the final conditions (12.88). From these equations, and the information about the $g_b^{r''}$ given by (12.143) through (12.153), it is not immediately obvious that there is the relation

$$h_3^r(\bar{t}, t^f) = \delta_3^r \text{ for all } \bar{t}, \tag{10.12.203}$$

which is consistent with (12.202). (And perhaps this is one minor drawback of this method.) However inspection of Table 12.4 for the cases $b = 1$ and $b = 2$ [the possibility $b = 3$ need not be considered because, as can be checked, $g_3^r = 0$ for all r] reveals there is no nonzero coefficient with $r' = 3$. Therefore, $\dot{h}_3^r(\bar{t}, t^f) = 0$ is the solution to (12.86) and (12.88) with $a = 3$ for the $g_b^{r''}$ in question. Correspondingly, as before, only the equations (12.86) with $a = 1$ and $a = 2$ need be integrated.

For further detail including numerical examples, see Section 29.12.

Table 10.12.4: Nonzero values of $C^{r}_{br'r''}$ for $r \in [1, 9]$ in the three-variable case.

10.12.9 Taylor Methods for the Hamiltonian Case

Suppose the equations of motion (12.1) arise from some Hamiltonian H. Then we may introduce deviation variables ζ as in Section 10.5, and employ the Hamiltonian $H^{\text{new}}(\zeta, t)$ of (5.4) to find the evolution of the variables ζ. Expand H^{new} in terms of the monomials $G_{r''}$ by writing

$$H^{\text{new}}(\zeta, t) = \sum_{r''} H^{r''}(t) G_{r''}(\zeta). \tag{10.12.204}$$

According to (5.4), all the $G_{r''}$ have degree two or greater. From Hamilton's equations of motion we have the result

$$\dot{\zeta}_a = [\zeta_a, H^{\text{new}}] = \sum_{r''} H^{r''}(t)[\zeta_a, G_{r''}]. \tag{10.12.205}$$

Since the monomials G_r form a basis, there is an expansion of the form

$$[\zeta_a, G_{r''}] = \sum_r E^r_{ar''} G_r \tag{10.12.206}$$

where the $E^r_{ar''}$ are universal coefficients that again describe certain combinatorial properties of monomials. With the aid of these coefficients (12.205) can be rewritten in the form

$$\dot{\zeta}_a = \sum_r (\sum_{r''} H^{r''} E^r_{ar''}) G_r. \tag{10.12.207}$$

Comparison of (12.17) and (12.207) gives the result

$$g^r_a(t) = \sum_{r''} E^r_{ar''} H^{r''}(t). \tag{10.12.208}$$

This result for the g^r_a may now be used to find the h^r_a in (12.19) by employing either forward or backward integration.

For the method of backward integration there is a further simplification. In its derivation we had to compute the quantities $(d/d\bar{t})G_{r'}(\zeta(\bar{t}))$. See (12.83). In the Hamiltonian case this quantity is given by the rule

$$(d/d\bar{t})G_{r'}(\zeta(\bar{t})) = [G_{r'}, H^{\text{new}}]. \tag{10.12.209}$$

See (1.7.4). Next insert the expansion (12.204) into (12.209) to find the result

$$(d/d\bar{t})G_{r'}(\zeta(\bar{t})) = \sum_{r''} H^{r''}(\bar{t})[G_{r'}, G_{r''}]. \tag{10.12.210}$$

Again, there are universal coefficients $F^{r}_{r'r''}$ describing certain monomial combinatorial properties such that

$$[G_{r'}, G_{r''}] = \sum_{r} F^{r}_{r'r''} G_r. \tag{10.12.211}$$

Note that as a consequence of (7.6.14) there is the restriction

$$F^{r}_{r'r''} = 0 \text{ unless } D(r') + D(r'') - 2 = D(r). \tag{10.12.212}$$

As a result of (12.210) and (12.211) we may write the relation

$$(d/d\bar{t})G_{r'}(\zeta(\bar{t}) = \sum_{r} \left(\sum_{r''} F^{r}_{r'r''} H^{r''}(\bar{t}) \right) G_r. \tag{10.12.213}$$

As a last step combine (12.80) through (12.82) and (12.213) to get the result

$$\dot{h}^{r}_{a}(\bar{t}, t^f) = -\sum_{r'r''} F^{r}_{r'r''} H^{r''}(\bar{t}) h^{r'}_{a}(\bar{t}, t^f). \tag{10.12.214}$$

These equations are the Hamiltonian analog of the general equations (12.86). As before, they are to be integrated from $\bar{t} = t^f$ back to $\bar{t} = t^i$ with the final conditions (12.88).

Let us compare the method just described for Taylor maps in the Hamiltonian case and that for factored product maps given in Section 10.5. Inspection of the equations (5.60) through (5.66) for the Lie generators show that they become ever more complicated with increasing order. By contrast, the equations (12.214) for the Taylor coefficients can be found easily to any desired order since the coefficients $F^{r}_{r'r''}$, which describe the monomial Poisson bracket results (12.211), can be obtained easily using Truncated Power Series Algebra. See Section 39.8. The price that must be paid for this ease of programming and computing to any desired order is the need to integrate many more differential equations. The numbers of equations that must be integrated in the Taylor and Lie methods are the same as those required to specify a map in Taylor or factored product Lie form, respectively. See Table 7.10.2.

Of course, no matter how a Taylor map is computed, if it arises from Hamiltonian equations it will be symplectic. And we know from the factorization Theorem of Section 7.6 that once a symplectic map is known in Taylor form, it can be rewritten in the factored product Lie form (7.6.3).

Exercises

10.12.1. Verify the entries in Table 12.2.

10.12.2. Consider the differential equation

$$\dot{x} = tx^2 \tag{10.12.215}$$

with the initial condition x^i at the initial time t^i. Verify that a particular solution is given by $x^d = 0$, and is the solution with $x(t^i) = 0$. Show that it has the general solution

$$x^f = x^i/\{1 - (x^i/2)[(t^f)^2 - (t^i)^2]\}. \tag{10.12.216}$$

Find the first few terms in the Taylor expansion of x^f in powers of x^i. This expansion is, in essence, an expansion about the solution x^d. Also compute the Taylor expansion of x^f in powers of x^i using both the methods of forward and backward integration. Verify that all your results agree.

10.12.3. Verify the derivation of (12.214).

10.12.4. Let $(\eta_1, \eta_2, \cdots \eta_{2n})$ be $2n$ "dummy" variables. Define functions $Z_a(\bar{t}, t^f; \eta)$ by the rule

$$Z_a(\bar{t}, t^f; \eta) = \sum_r h_a^r(\bar{t}, t^f) G_r(\eta), \tag{10.12.217}$$

which can also be written in the equivalent form

$$Z_a(\bar{t}, t^f; \eta) = \sum_{r'} h_a^{r'}(\bar{t}, t^f) G_{r'}(\eta). \tag{10.12.218}$$

Also define a function $H^{\text{new}}(\bar{t}, \eta)$ by the rule

$$H^{\text{new}}(\bar{t}, \eta) = \sum_{r''} H^{r''}(\bar{t}) G_{r''}(\eta). \tag{10.12.219}$$

Using (12.218), (12.219), (12.211), and (12.214) show that

$$[Z_a, H^{\text{new}}]_\eta = \sum_r \left(\sum_{r'r''} h_a^{r'} H^{r''} F_{r'r''}^r \right) G_r = -\sum_r \dot{h}_a^r(\bar{t}, t^f) G_r(\eta). \tag{10.12.220}$$

Hence, show that (12.114) is equivalent to the differential equation

$$\partial Z_a/\partial \bar{t} = -[Z_a, H^{\text{new}}]_\eta. \tag{10.12.221}$$

10.12.5. Suppose the complete variational equations (12.17) happen to be autonomous. That is, the functions g_a^r do not depend on time. In the Hamiltonian case assume, equivalently, that the H^r do not depend on time. This will be the case for idealized beam-line elements. See Chapters 13 and 14. In the case of equation (12.86), define quantities $K_{rr'}$ by the rule

$$K_{rr'} = \sum_{br''} C_{br'r''}^r g_b^{r''}. \tag{10.12.222}$$

They will be time independent since, by hypothesis, the $g_b^{r''}$ are time independent. In the case of equation (12.214), define quantities $K_{rr'}$ by the rule

$$K_{rr'} = \sum_{r''} F^r_{r'r''} H^{r''}. \tag{10.12.223}$$

They too will be time independent if the $H^{r''}$ are. Show that in either case, equation (12.86) or equation (12.214), there is the common result

$$\dot{h}^r_a = -\sum_{r'} K_{rr'} h^{r'}_a \tag{10.12.224}$$

which, when written in vector form, becomes the vector-matrix equation

$$\dot{h}_a = -K h_a. \tag{10.12.225}$$

Verify that (12.225) has the solution

$$h_a(\bar{t}, t^f) = e^{-(\bar{t}-t^f)K} h_a(t^f, t^f), \tag{10.12.226}$$

and consequently there is the result

$$h_a(t^i, t^f) = e^{-(t^i-t^f)K} h_a(t^f, t^f). \tag{10.12.227}$$

Also, according to (12.88), the vectors $h_a(t^f, t^f)$ are given by the relation

$$h^r_a(t^f, t^f) = \delta^r_a. \tag{10.12.228}$$

Thus, the Taylor map can be found explicitly in the autonomous case in terms of the matrix $\exp[-(t^i - t^f)K]$. This matrix can be computed using the scaling and squaring method of Section 4.1. Compare the results above for the Hamiltonian case with those found in Section 10.7, and in particular that of (7.11). Hint: For simplicity consider the two-variable case and suppose H^{new} consists of only an H_2 and an H_3.

Chapter 11

Geometric/Structure-Preserving Integration: Integration on Manifolds

Overview

The subject of *geometric integration*, also sometimes called *structure-preserving integration*, deals both with the construction of numerical integrators on manifolds and with the construction of numerical integrators that respect various group properties. This chapter provides an introduction to the subject of numerical integration on manifolds, mostly by way of three examples: rigid body motion, spin and qubits, and motion of a charged particle in a static magnetic field. Symplectic integration, the main topic of the next chapter, is a special case of geometric integration that respects a particular group property.[1]

Suppose a set of first-order ordinary differential equations is formulated in terms of coordinates in some ambient space and suppose it is known that, when these equations are integrated exactly, some class of trajectories is confined to a lower dimensional manifold in the ambient space, often a manifold associated with some group. If these same equations are integrated numerically with the aid of some integrator that is locally accurate through terms of order h^m one may expect, unless the integrator has special properties, that trajectories will deviate, at each integration step, from this lower dimensional manifold by terms of order h^{m+1}. In this context, a geometric numerical integrator is an integrator that, even though it may make local errors of order h^{m+1}, is guaranteed to produce trajectories that remain on the desired manifold, perhaps exactly to machine precision, or at least to substantially higher order in h. The construction and study of such numerical integrators is the subject of numerical integration on manifolds.[2]

Again suppose a set of first-order ordinary differential equations is formulated in terms of coordinates, call them z, in some ambient space. Let t^i and t^f be initial and final times. Now suppose it is known that the relation/map between $z^i = z(t^i)$ and $z^f = z(t^f)$ for

[1] Although for brevity we will not do so, for precision we should use the terms geometric *numerical* integration and, by association, symplectic *numerical* integration. Strictly speaking, this distinction is necessary because the term *geometric integration* can also refer to the extension of the integration procedures of ordinary calculus to integration over manifolds based on the use of differential forms.

[2] From this perspective numerical integrators that preserve integrals of motion, such as energy and angular momentum, are special instances of geometric integrators.

variable z^i, arising from exactly integrating initial conditions from $t = t^i$ to $t = t^f$, belongs to some group G that acts on the ambient space. What happens if these same equations are integrated numerically with the aid of some integrator that is locally accurate through terms of order h^m? Let t^b be the time at the *beginning* of some integration step. We may expect, unless the integrator has special properties, that the relation/map between $z(t^b)$ and $z(t^b+h)$ will differ from an element of G by terms of order h^{m+1}. In this context, a geometric integrator is an integrator with the property that, even though it may make local errors of order h^{m+1}, the relation/map between $z(t^b)$ and $z(t^b+h)$, for each integration step, is a map that belongs to G, perhaps exactly to machine precision, or at least to substantially higher order in h. Since for such a geometric integrator the maps for all successive integration steps belong to G, their product will also belong to G, and thus the map relating $z(t^i)$ and $z(t^f)$ will also belong to G.[3] In the Hamiltonian case, the ambient space is phase space, the group G is the group of all symplectic maps, and a symplectic numerical integrator is an integrator designed to produce a relation between z^i and z^f that is a symplectic map.

11.1 Numerical Integration on Manifolds: Rigid-Body Motion

As a first example of integration on manifolds, we will consider the problem of determining the motion of a rigid body with one point fixed and subject to an external torque $\boldsymbol{N}$ about the fixed point. We begin with the *kinematics* of rigid-body motion, and then follow with the *dynamics* of rigid-body motion.[4] Subsequent discussion treats various formulations of the equations of motion and various methods for their numerical integration.

11.1.1 Angular Velocity and Rigid-Body Kinematics

To describe rigid-body *kinematics*, suppose $\boldsymbol{e}_1$, $\boldsymbol{e}_2$, $\boldsymbol{e}_3$ is an orthonormal right-hand triad of vectors that is fixed in space, and suppose $\boldsymbol{f}_1(t)$, $\boldsymbol{f}_2(t)$, $\boldsymbol{f}_3(t)$ is an orthonormal right-hand triad of vectors that is fixed in the body.[5] The $\boldsymbol{f}_j(t)$ will generally be time dependent because the body is expected to rotate, and they will be taken to have the initial values

$$\boldsymbol{f}_j(t^0) = \boldsymbol{e}_j. \tag{11.1.1}$$

Since the $\boldsymbol{e}_j$ and the $\boldsymbol{f}_j(t)$ are both orthonormal basis sets, there is a unique *orthogonal* matrix $R(t)$ such that

$$\boldsymbol{f}_j(t) = R(t)\boldsymbol{e}_j. \tag{11.1.2}$$

[3] Note that unlike the case of Chapter 10, we do not seek here, at least primarily, to compute the transfer map $\mathcal{M}$ that relates $z(t^i)$ and $z(t^f)$. Rather, we seek trajectories but require that, were all trajectories to be considered, the relation between z^i and z^f for all possible initial conditions z^i would be a map that belongs to G.

[4] The kinematic equations are the analog of the single-particle equations $\boldsymbol{v} = d\boldsymbol{r}/dt$ or $d\boldsymbol{r}/dt = \boldsymbol{v}$, and the dynamic equations are the analog of the equations $d\boldsymbol{v}/dt = \boldsymbol{F}/m$.

[5] We require that the space-fixed and body-fixed triads have the fixed point of the body as their common origin.

See Section 3.6.3. In view of (1.1) there is the relation

$$R(t^0) = I \tag{11.1.3}$$

and therefore, by continuity, $R(t) \in SO(3, \mathbb{R})$.

Let $(\omega_1^{bf}, \omega_2^{bf}, \omega_3^{bf})$ be the *components* of the *angular velocity* in the *body-fixed* frame. They are *defined* by the rules

$$\omega_j^{bf}(t) = -\boldsymbol{f}_k(t) \cdot \dot{\boldsymbol{f}}_\ell(t) \tag{11.1.4}$$

where j, k, ℓ is any cyclic permutation of $1, 2, 3$. Some implications of this definition of angular velocity are explored in Exercise 1.1. Here we examine how the $\omega_j^{bf}(t)$ are related to $R(t)$. From (1.2) there are the relations

$$\dot{\boldsymbol{f}}_\ell(t) = \dot{R}(t)\boldsymbol{e}_\ell, \tag{11.1.5}$$

and therefore (1.4) can be rewritten in the form

$$\omega_j^{bf}(t) = -[R(t)\boldsymbol{e}_k] \cdot [\dot{R}(t)\boldsymbol{e}_\ell] = -\boldsymbol{e}_k \cdot [R^T(t)\dot{R}(t)\boldsymbol{e}_\ell] = -\boldsymbol{e}_k \cdot [R^{-1}(t)\dot{R}(t)\boldsymbol{e}_\ell]. \tag{11.1.6}$$

Define a matrix $A(t)$ by the rule

$$A(t) = R^{-1}(t)\dot{R}(t) = R^T(t)\dot{R}(t). \tag{11.1.7}$$

With its use, (1.6) can be written in the yet more compact form

$$\omega_j^{bf}(t) = -\boldsymbol{e}_k \cdot A(t)\boldsymbol{e}_\ell. \tag{11.1.8}$$

What can be said about the matrix $A(t)$? From the orthogonality condition

$$R^T(t)R(t) = I \tag{11.1.9}$$

we conclude that

$$\dot{R}^T(t)R(t) + R^T(t)\dot{R}(t) = 0; \tag{11.1.10}$$

and from (1.7) we conclude that

$$A^T(t) = \dot{R}^T(t)R(t). \tag{11.1.11}$$

See Exercise 1.1. It follows from (1.10) that $A(t)$ is antisymmetric,

$$A^T(t) + A(t) = 0, \tag{11.1.12}$$

and therefore can be written in the form

$$A(t) = a_1(t)L^1 + a_2(t)L^2 + a_3(t)L^3 = \boldsymbol{a} \cdot \boldsymbol{L} \tag{11.1.13}$$

where the coefficients $a_j(t)$ are to be determined. Here we have used the notation of Exercise 3.7.30. Now insert (1.13) into (1.8). Computation using the properties of the L^j gives the results

$$a_j(t) = \omega_j^{bf}(t). \tag{11.1.14}$$

For example,

$$\begin{aligned}\omega_1^{bf} &= -\boldsymbol{e}_2 \cdot A\boldsymbol{e}_3 = -\boldsymbol{e}_2 \cdot [(\boldsymbol{a} \cdot \boldsymbol{L})\boldsymbol{e}_3] = -\boldsymbol{e}_2 \cdot (\boldsymbol{a} \times \boldsymbol{e}_3) \\ &= \boldsymbol{e}_2 \cdot (\boldsymbol{e}_3 \times \boldsymbol{a}) = (\boldsymbol{e}_2 \times \boldsymbol{e}_3) \cdot \boldsymbol{a} = \boldsymbol{e}_1 \cdot \boldsymbol{a} = a_1. \end{aligned} \tag{11.1.15}$$

To complete the discussion of rigid-body kinematics, rewrite (1.7) in the form

$$\dot{R} = RA \tag{11.1.16}$$

and introduce the notation

$$A = a_1 L^1 + a_2 L^2 + a_3 L^3 = \omega_1^{bf} L^1 + \omega_2^{bf} L^2 + \omega_3^{bf} L^3 = \boldsymbol{\omega}^{bf} \cdot \boldsymbol{L}. \tag{11.1.17}$$

By substituting (1.17) into (1.16) we find for $R(t)$ the *kinematic* differential equation of motion

$$\dot{R} = R\, \boldsymbol{\omega}^{bf} \cdot \boldsymbol{L}. \tag{11.1.18}$$

Note that, since R is 3×3, the matrix differential equation (1.18) amounts to nine first-order differential equations. Also note, in passing, that $\boldsymbol{\omega}^{bf} \cdot \boldsymbol{L} \in so(3, \mathbb{R})$.

11.1.2 Angular Velocity and Rigid-Body Dynamics

We now turn to the *dynamics* of rigid-body motion. Suppose the body-fixed frame is oriented in the body in such a way that the moment of inertia tensor is diagonal with diagonal entries I_1, I_2, I_3. (Caution! We will also continue to use, as we have already done, the symbol I without a subscript to denote the 3×3 identity matrix.) Then, from the work of Euler, we know that there are the *dynamic* equations of motion

$$\dot{\omega}_1^{bf} = N_1^{bf}/I_1 + \omega_2^{bf}\omega_3^{bf}(I_2 - I_3)/I_1, \tag{11.1.19}$$

$$\dot{\omega}_2^{bf} = N_2^{bf}/I_2 + \omega_3^{bf}\omega_1^{bf}(I_3 - I_1)/I_2, \tag{11.1.20}$$

$$\dot{\omega}_3^{bf} = N_3^{bf}/I_3 + \omega_1^{bf}\omega_2^{bf}(I_1 - I_2)/I_3. \tag{11.1.21}$$

Here the $N_j^{bf}(R, \boldsymbol{\omega^{bf}}, t)$ are the components of $\boldsymbol{N}$ in the body-fixed frame.[6]

11.1.3 Problem of Integrating the Combined Kinematic and Dynamic Equations

Taking both the kinematic and dynamic equations into account, our task is to integrate the nine kinematic differential equations (1.18) and the three dynamic differential equations (1.19) through (1.21) given, at time t^i, some initial orientation $R(t^i)$ and some initial angular velocity $\boldsymbol{\omega}^{bf}(t^i)$. In this context, the ambient space is $9 + 3 = 12$ dimensional.

But now we see that there is a computational problem. We know that R must be an orthogonal matrix. See (1.9). Also, it easily verified that *exact* integration of the matrix

[6] Note that we have allowed the possibility that $\boldsymbol{N}$ is $\boldsymbol{\omega}^{bf}$ dependent, and therefore have gone beyond a Lagrangian/Hamiltonian formulation in allowing for the possibility of dissipative forces.

differential equations (1.18), no matter how $\boldsymbol{\omega}^{bf}$ depends on the time t, maintains the orthogonality condition (1.9) if the initial matrix $R(t^i)$ is orthogonal. See Exercise 1.2. Thus we know that, although R has nine entries, it must lie on the 3-dimensional manifold $SO(3,\mathbb{R})$. However, if some *numerical* integration method is used that is locally accurate only through terms of order h^m, then we expect that the orthogonality condition (1.9) will also be maintained only through terms of order h^m. Thus, in the course of numerical integration, R may be expected to move off the manifold $SO(3,\mathbb{R})$. Moreover, if R is not orthogonal, then the quantities $N_j^{bf}(R,\boldsymbol{\omega}^{bf},t)$ required in (1.19) through (1.21) are not defined since they are only physically specified when R is orthogonal.[7]

11.1.4 Solution by Projection

What to do? One approach is to orthogonalize the R provided after or during the course of each integration step, whenever an orthogonal R is needed to compute the N_j^{bf} or the actual orientation of the body. The orthogonalization can be done, for example, using any of the methods of Section 3.6.4 and Exercise 4.5.7. This process of orthogonalization is an example of a general problem: Given a submanifold embedded in some larger manifold (or ambient space), and given an element in the larger manifold, how does one find a related element in the submanifold, and what is the optional choice for such an element? In the nomenclature of geometric integration, the process for determining such an element is called *projection*.[8]

11.1.5 Solution by Parameterization: Euler Angles

Another approach is to parameterize R in such a way that it is guaranteed to be orthogonal. For example, suppose we employ the Euler parameterization (3.7.207). Then use of (1.18), rewritten in the form

$$\boldsymbol{\omega}^{bf}\cdot\boldsymbol{L} = R^{-1}\dot{R}, \tag{11.1.22}$$

gives the relations

$$\omega_1^{bf} = -\dot{\phi}\sin\theta\cos\psi + \dot{\theta}\sin\psi, \tag{11.1.23}$$

$$\omega_2^{bf} = \dot{\phi}\sin\theta\sin\psi + \dot{\theta}\cos\psi, \tag{11.1.24}$$

$$\omega_3^{bf} = \dot{\phi}\cos\theta + \dot{\psi}, \tag{11.1.25}$$

[7] Note that a similar problem arises in the numerical integration of (10.4.28) with the initial condition (10.4.29). Although the ambient space is $(2n)^2$ dimensional, the solution of (10.4.28) is required to originate and remain in the $n(2n+1)$ dimensional submanifold $Sp(2n,\mathbb{R})$.

[8] For the problem at hand we need some projection $E^9 \rightarrow SO(3,\mathbb{R})$ where E^9 denotes 9-dimensional Euclidean space. Recall also the problem of matrix symplectification, projections $E^{(2n)^2} \rightarrow Sp(2n,\mathbb{R})$, treated in Subsection 3.6.5 and Chapter 4. Observe that all the integration methods of Chapter 2 require the evaluation of the right side $\boldsymbol{f}$ at intermediate points, and generally these points will not be on the desired manifold, but only nearby. Therefore $\boldsymbol{f}$ may not even be defined at these points unless $\boldsymbol{f}$ can be extrapolated off the manifold to nearby points in the ambient space. Alternatively, the intermediate points can be projected from the ambient space onto the manifold, and $\boldsymbol{f}$ is then computed at these projected intermediate points. In either case one has to ensure that extrapolation or projection does not spoil the desired accuracy of the integration method.

from which it follows that

$$\dot{\phi} = (1/\sin\theta)(\omega_2^{bf}\sin\psi - \omega_1^{bf}\cos\psi), \tag{11.1.26}$$

$$\dot{\theta} = \omega_1^{bf}\sin\psi + \omega_2^{bf}\cos\psi, \tag{11.1.27}$$

$$\dot{\psi} = \omega_3^{bf} + (\cot\theta)(\omega_1^{bf}\cos\psi - \omega_2\sin\psi). \tag{11.1.28}$$

See Exercise 1.3. In terms of Euler angles, our task is to integrate the equations (1.26) through (1.28) and (1.19) through (1.21) where now

$$N_j^{bf} = N_j^{bf}(\phi,\theta,\psi,\dot{\phi},\dot{\theta},\dot{\psi},t). \tag{11.1.29}$$

11.1.6 Problem of Kinematic Singularities

Have we achieved our goal? Only in a fashion. It is true that equations (1.26) through (1.28) and (1.19) through (1.21) constitute a set of six first-order equations of motion, which is what we expect for a system with three degrees of freedom. Also, $R(\phi,\theta,\psi)$ is guaranteed to be orthogonal no matter how inaccurately the equations of motion are numerically integrated. However, note that the factor $(1/\sin\theta)$ in (1.26) and the factor $(\cot\theta)$ in (1.28) become *singular* when $\theta = 0$ or $\theta = \pi$. Therefore these equations are unsuitable for numerical integration whenever $\theta \simeq 0$ or $\theta \simeq \pi$. The singularity at $\theta = 0$ is particularly alarming because it means that Euler angles do not provide a good coordinate patch in the vicinity $R \simeq I$.

Now there is nothing *a priori* to prevent $\theta \simeq 0$ or $\theta \simeq \pi$ from happening over the course of a rigid body's motion. (For example, a top is allowed to be vertical or inverted.) These singularities are *kinematic* in the sense that they are an artifact of our choice of coordinate system, and are not intrinsic to the motion of the system being considered. (See Exercise 8.2.11.) However, it can be shown from topological considerations that singularities of this type must arise no mater how R is parameterized if only three parameters are used. A global three-variable and singularity-free parameterization of $SO(3,\mathbb{R})$ is impossible. Consequently, if only three variables are used, it is necessary to change coordinate patches whenever a singularity of the coordinate system in current use is approached.[9] This complication might appear to make it difficult to write a robust three-variable numerical integration procedure that would apply for all possible rigid-body motions.[10] However, we will eventually entertain the possibility of changing the coordinate system frequently, and perhaps at every integration step.

[9] Moreover, even if a trajectory does not pass directly through a kinematic singularity, the presence of a singularity still affects the integration of nearby trajectories because numerical integration is based on the assumption of analyticity and the use of Taylor series, and nearby singularities affect the convergence of Taylor series.

[10] We also remark that the kind of problem we have encountered here is expected to occur quite generally whenever one seeks to numerically integrate trajectories that are known, and hence required, to lie within some group manifold. Because group manifolds do not generally have the topology of Euclidean space, there is generally no global singularity-free coordinate system that can be used.

11.1.7 Quaternions to the Rescue

Our ancestors have discovered that, for rigid-body motion, this troublesome singularity problem can be overcome in an optimum way by the use of (unit) quaternion parameters $w = (w_0, w_1, w_2, w_3)$. Again see Exercise 8.2.11. Note that there are now four parameters, rather then three as in the Euler-angle case, and they are related by the constraint

$$w \cdot w = \sum_{j=0}^{3} w_j^2 = 1. \tag{11.1.30}$$

Quaternion parameters and $SO(3,\mathbb{R})$ matrices are connected by (8.2.73). Quaternion and angle-axis parameters are connected by the relations

$$w_0 = \cos(\theta/2), \tag{11.1.31}$$

$$\boldsymbol{w} = -\boldsymbol{n}\sin(\theta/2). \tag{11.1.32}$$

Quaternion and Euler-angle parameters are connected by the relations

$$w_0 = \cos(\theta/2)\cos[(1/2)(\phi+\psi)], \tag{11.1.33}$$

$$w_1 = -\sin(\theta/2)\sin[(1/2)(-\phi+\psi)], \tag{11.1.34}$$

$$w_2 = -\sin(\theta/2)\cos[(1/2)(-\phi+\psi)], \tag{11.1.35}$$

$$w_3 = -\cos(\theta/2)\sin[(1/2)(\phi+\psi)]. \tag{11.1.36}$$

See Exercise 1.4.

More to the point for our purposes, the angular velocities are given in terms of quaternion parameters by the relations

$$\omega_1^{bf} = 2(w_1\dot{w}_0 - w_0\dot{w}_1 + w_3\dot{w}_2 - w_2\dot{w}_3), \tag{11.1.37}$$

$$\omega_2^{bf} = 2(w_2\dot{w}_0 - w_0\dot{w}_2 + w_1\dot{w}_3 - w_3\dot{w}_1), \tag{11.1.38}$$

$$\omega_3^{bf} = 2(w_3\dot{w}_0 - w_0\dot{w}_3 + w_2\dot{w}_1 - w_1\dot{w}_2). \tag{11.1.39}$$

See Exercise 1.5. To these relations we add the further relation

$$0 = -\sum_{j=0}^{3} w_j\dot{w}_j, \tag{11.1.40}$$

which follows from differentiating (1.30). Together the equations (1.37) through (1.40) can be written in the vector/matrix form

$$\begin{pmatrix} 0 \\ \omega_1^{bf}/2 \\ \omega_2^{bf}/2 \\ \omega_3^{bf}/2 \end{pmatrix} = \begin{pmatrix} -w_0 & -w_1 & -w_2 & -w_3 \\ w_1 & -w_0 & w_3 & -w_2 \\ w_2 & -w_3 & -w_0 & w_1 \\ w_3 & w_2 & -w_1 & -w_0 \end{pmatrix} \begin{pmatrix} \dot{w}_0 \\ \dot{w}_1 \\ \dot{w}_2 \\ \dot{w}_3 \end{pmatrix}. \tag{11.1.41}$$

Remarkably, the 4 × 4 matrix on the right side of (1.41) is orthogonal! See Exercise 1.6. Consequently (1.41) can be inverted easily to give the relation

$$\begin{pmatrix} \dot{w}_0 \\ \dot{w}_1 \\ \dot{w}_2 \\ \dot{w}_3 \end{pmatrix} = \begin{pmatrix} -w_0 & w_1 & w_2 & w_3 \\ -w_1 & -w_0 & -w_3 & w_2 \\ -w_2 & w_3 & -w_0 & -w_1 \\ -w_3 & -w_2 & w_1 & -w_0 \end{pmatrix} \begin{pmatrix} 0 \\ \omega_1^{bf}/2 \\ \omega_2^{bf}/2 \\ \omega_3^{bf}/2 \end{pmatrix}. \tag{11.1.42}$$

Taking components of (1.42) yields the four kinematic equations of motion

$$\dot{w}_0 = (1/2)(\omega_1^{bf} w_1 + \omega_2^{bf} w_2 + \omega_3^{bf} w_3), \tag{11.1.43}$$

$$\dot{w}_1 = (1/2)(-\omega_1^{bf} w_0 - \omega_2^{bf} w_3 + \omega_3^{bf} w_2), \tag{11.1.44}$$

$$\dot{w}_2 = (1/2)(\omega_1^{bf} w_3 - \omega_2^{bf} w_0 - \omega_3^{bf} w_1), \tag{11.1.45}$$

$$\dot{w}_3 = (1/2)(-\omega_1^{bf} w_2 + \omega_2^{bf} w_1 - \omega_3^{bf} w_0). \tag{11.1.46}$$

It is these four kinematic equations, along with the three dynamic equations (1.19) through (1.21), that are to be integrated. Note that equations (1.43) through (1.46) are singularity free. Indeed, they are *linear* in the w_j. They are therefore ideal for numerical integration. For further elaboration on this point, see the discussion at the end of Exercise 1.13.

It is easily verified that exact integration of the differential equations (1.43) through (1.46) preserves the unit sphere condition (1.30) if this condition is satisfied at some initial time t^i. See Exercise 1.8. However, if we are integrating the equations of motion numerically by some routine that is only exact through order h^m, we may expect that the condition (1.30) will be violated by terms of order h^{m+1} at each integration step. That is, instead of remaining on the unit sphere S^3, w will become a general point in the ambient four-dimensional space E^4. One simple procedure to overcome this problem is to repeatedly project, by simple scaling, $w \in E^4$ back onto the unit sphere S^3 any time a unit w is required to compute $R(w)$. So doing requires little computational overhead.

11.1.8 Modification of the Quaternion Kinematic Equations of Motion

Another procedure is to modify the kinematic equations of motion. Define an *error* quantity ϵ that measures the departure of w from S^3 by the rule

$$\epsilon = 1 - w \cdot w. \tag{11.1.47}$$

Replace equations (1.43) through (1.46) by the modified equations

$$\dot{w}_0 = (1/2)(\omega_1^{bf} w_1 + \omega_2^{bf} w_2 + \omega_3^{bf} w_3) + k\epsilon w_0, \tag{11.1.48}$$

$$\dot{w}_1 = (1/2)(-\omega_1^{bf} w_0 - \omega_2^{bf} w_3 + \omega_3^{bf} w_2) + k\epsilon w_1, \tag{11.1.49}$$

$$\dot{w}_2 = (1/2)(\omega_1^{bf} w_3 - \omega_2^{bf} w_0 - \omega_3^{bf} w_1) + k\epsilon w_2, \tag{11.1.50}$$

$$\dot{w}_3 = (1/2)(-\omega_1^{bf} w_2 + \omega_2^{bf} w_1 - \omega_3^{bf} w_0) + k\epsilon w_3, \tag{11.1.51}$$

where k is some constant satisfying $k > 0$. Evidently the modified equations have the same solutions as the original equations as long as $\epsilon = 0$. But, if for some reason $\epsilon \neq 0$, the modified equations *drive* ϵ to 0 if k is positive! Again see Exercise 1.8. Thus, even when integrated numerically, the modified equations (1.48) through (1.51) along with (1.19) through (1.21) provide a satisfactory description of rigid body motion, and are commonly used for this purpose in applications that range from inertial guidance (including space craft orientation/control) through robotics to virtual reality.

11.1.9 Local Coordinate Patches

So far, in the case of rigid-body motion, we have been able to finesse the problem of maintaining the manifold condition (1.9) either by some projection $E^9 \rightarrow SO(3, \mathbb{R})$ or the use of a remarkable coordinate system, namely quaternions, and the simpler projection $E^3 \rightarrow S^3$ by scaling, or by modification of the quaternion kinematic equations of motion. Are there other approaches, and in particular are there approaches that are also applicable in a more general context?

One procedure is to introduce a local coordinate patch at each integration step. Suppose, for a given integration step, we write

$$R(t) = R^b R^v(t). \tag{11.1.52}$$

Here

$$R^b = R(t^b) \tag{11.1.53}$$

where t^b is the time at the *beginning* of the integration step, and R^v is a *variable* rotation matrix near the identity with the property

$$R^v(t^b) = I. \tag{11.1.54}$$

From (1.52) we have the relation

$$\dot{R} = R^b \dot{R}^v, \tag{11.1.55}$$

and substituting this result and (1.52) into (1.18) yields the relation

$$\dot{R}^v = R^v\, \boldsymbol{\omega}^{bf} \cdot \boldsymbol{L}. \tag{11.1.56}$$

We wish to integrate (1.56) to find $R^v(t^b + h)$ starting with the initial condition (1.54). Then, having done so, we have from (1.52) the result

$$R(t^b + h) = R^b R^v(t^b + h). \tag{11.1.57}$$

Note that in view of (1.54) what is needed in any given instance, if parameters are to be employed, is a local coordinate patch in the vicinity of the identity.

11.1.10 Canonical Coordinates of the Second Kind: Tait-Bryan Angles

In the case of $SO(3,\mathbb{R})$, how can we parameterize R^v near the identity? One possibility is to employ canonical coordinates of the second kind (see Section 7.9) to write, for example, the Ansatz

$$R^v(\lambda) = \exp(\lambda_1 L^1)\exp(\lambda_2 L^2)\exp(\lambda_3 L^3) \tag{11.1.58}$$

with the quantities λ_j being parameters. [In the context of rigid-body motion, the quantities λ_j in (1.58) are called *Tait-Bryan* or *Cardan* angles.] Unlike the Euler-angle parameterization, application of the BCH formula shows that such parameterizations are well defined for R^v near I and the λ_j near 0 since all three L^j are employed.[11]

For these coordinates use of (1.22) yields the relations

$$\omega_1^{bf} = \dot\lambda_1\cos(\lambda_2)\cos(\lambda_3) + \dot\lambda_2\sin(\lambda_3), \tag{11.1.59}$$

$$\omega_2^{bf} = -\dot\lambda_1\cos(\lambda_2)\sin(\lambda_3) + \dot\lambda_2\cos(\lambda_3), \tag{11.1.60}$$

$$\omega_3^{bf} = \dot\lambda_1\sin(\lambda_2) + \dot\lambda_3. \tag{11.1.61}$$

And inverting the relations (1.59) through (1.61) yields the kinematic equations of motion

$$\dot\lambda_1 = [1/\cos(\lambda_2)][\omega_1^{bf}\cos(\lambda_3) - \omega_2^{bf}\sin(\lambda_3)], \tag{11.1.62}$$

$$\dot\lambda_2 = \omega_1^{bf}\sin(\lambda_3) + \omega_2^{bf}\cos(\lambda_3), \tag{11.1.63}$$

$$\dot\lambda_3 = \omega_3^{bf} - \tan(\lambda_2)[\omega_1^{bf}\cos(\lambda_3) - \omega_2^{bf}\sin(\lambda_3)]. \tag{11.1.64}$$

See Exercise 1.9. In terms of these coordinates our task is to integrate the equations (1.62) through (1.64) and (1.19) through (1.21) where now

$$N_j^{bf} = N_j^{bf}(\lambda_1,\lambda_2,\lambda_3,\dot\lambda_1,\dot\lambda_2,\dot\lambda_3,t). \tag{11.1.65}$$

Observe, as anticipated, that the equations of motion are nonsingular for small λ_j. However they are singular when $\lambda_2 = \pm\pi/2$. (For the source of these singularities, again see Exercise 1.9.) Thus, like the case for Euler angles, these coordinates cannot be used globally.

11.1.11 Canonical Coordinates of the First Kind: Angle-Axis Parameters

Alternatively, inspired by the angle-axis parameterization (3.7.199), another possibility is to introduce parameters $\lambda_1, \lambda_2, \lambda_3$ and make the Ansatz

$$R^v(\lambda) = \exp(\lambda_1 L^1 + \lambda_2 L^2 + \lambda_3 L^3) = \exp(\boldsymbol{\lambda}\cdot\boldsymbol{L}). \tag{11.1.66}$$

[11] Canonical coordinates of the first and second kind are both well defined near the origin for any finite-dimensional Lie group. However, we know that in some cases canonical coordinates of the first kind cannot be set up globally. See Section 3.8. The global status of canonical coordinates of the second kind is less clear. In general there is a global polar decomposition, which amounts to a hybrid of canonical coordinates of the first and second kinds.

That is, we have expressed $R^v \in SO(3,\mathbb{R})$ and near the identity in terms of elements in the Lie algebra $so(3,\mathbb{R})$; and we have parameterized the Lie algebra. Since the map between group elements near the identity and Lie elements near the origin is well defined, we know that this parameterization is well defined for R^v near I and the λ_j near 0. As described in Section 7.9, this parameterization amounts to using canonical coordinates of the first kind.

This parameterization yields the remarkably symmetric looking kinematic equations of motion

$$\dot{\boldsymbol{\lambda}} = \boldsymbol{\omega}^{bf} + (1/2)(\boldsymbol{\lambda} \times \boldsymbol{\omega}^{bf}) + [(\boldsymbol{\lambda} \cdot \boldsymbol{\omega}^{bf})\boldsymbol{\lambda} - (\boldsymbol{\lambda} \cdot \boldsymbol{\lambda})\boldsymbol{\omega}^{bf}]\{1/|\boldsymbol{\lambda}|^2 - [1/(2|\boldsymbol{\lambda}|)]\cot(|\boldsymbol{\lambda}|/2)\}. \tag{11.1.67}$$

See Exercise 1.10. For the inverse relation that expresses $\boldsymbol{\omega}^{bf}$ in terms of $\boldsymbol{\lambda}$ and $\dot{\boldsymbol{\lambda}}$, see Exercise 1.11.

Observe, again as anticipated, that the equations of motion are nonsingular for small λ_j, namely when $|\boldsymbol{\lambda}| < 2\pi$. But they are singular when $|\boldsymbol{\lambda}| = 2\pi$. We expect this singularity to occur because we see from (3.7.188) and (3.7.202) that the individual components of $\boldsymbol{n}$ are not defined in terms of v or R when $\theta = |\boldsymbol{\lambda}| = 2\pi$.

We reiterate that even when coordinates can be set up globally, as in the case of $SO(3,\mathbb{R})$ using either Euler angles or angle-axis parameters, there may still be singularities in the equations of motion because at some points the inverse map from the group to the Lie algebra may not be well defined. We have seen an example of this problem in the case of Euler angles. Every element of $SO(3,\mathbb{R})$ can be written in Euler form, but at $\theta = 0$ and $\theta = \pi$ the inverse map is not well defined. The same is true for angle-axis parameters. Every element of $SO(3,\mathbb{R})$ can be written in angle-axis form, but at $\theta = 2\pi$ the inverse map is not well defined.

11.1.12 Cayley Parameters

Quadratic groups, including $SO(3,\mathbb{R})$ and $SU(2)$, can also be parameterized near the identity in terms of Cayley parameters. When Cayley parameters are used for $SO(3,\mathbb{R})$ or $SU(2)$, call them μ_j, the task is to find differential equations that specify the $\dot{\mu}_j$ in terms of the μ_j and ω^{bf}.

We first consider the case of $SO(3,\mathbb{R})$ and employ the Cayley parameterization

$$R^v(\boldsymbol{\mu}) = (I + \boldsymbol{\mu} \cdot \boldsymbol{L})(I - \boldsymbol{\mu} \cdot \boldsymbol{L})^{-1}. \tag{11.1.68}$$

For this parameterization it can be shown that there are the kinematic equations of motion

$$\dot{\boldsymbol{\mu}} = (1/2)[\boldsymbol{\omega}^{bf} + (\boldsymbol{\mu} \times \boldsymbol{\omega}^{bf}) + (\boldsymbol{\mu} \cdot \boldsymbol{\omega}^{bf})\boldsymbol{\mu}]. \tag{11.1.69}$$

See Exercise 1.13.

Next consider the case of $SU(2)$ and employ the Cayley parameterization

$$u^v(\boldsymbol{\mu}) = (I + \boldsymbol{\mu} \cdot \boldsymbol{K})(I - \boldsymbol{\mu} \cdot \boldsymbol{K})^{-1}. \tag{11.1.70}$$

Here we have again used the notation of Exercise 3.7.30. In this case there are the kinematic equations of motion

$$\dot{\boldsymbol{\mu}} = (1/2)[\boldsymbol{\omega}^{bf} + (\boldsymbol{\mu} \times \boldsymbol{\omega}^{bf}) + (1/2)(\boldsymbol{\mu} \cdot \boldsymbol{\omega}^{bf})\boldsymbol{\mu} - (1/4)(\boldsymbol{\mu} \cdot \boldsymbol{\mu})\boldsymbol{\omega}^{bf}]. \tag{11.1.71}$$

Again see Exercise 1.13.

What can be said about the singularity structure of the kinematic equations of motion (1.69) and (1.71)? Strangely enough, both sets appear to be singularity free! However, this appearance is deceptive because both sets of kinematic equations of motion are singular in $\boldsymbol{\mu}$ at infinity, and there is the possibility that this singularity can be encountered in *finite* time. Yet again see Exercise 1.13.

11.1.13 Summary of Integration Using Local Coordinates

Upon employing (1.58) or (1.66) in (1.56) we can find first-order differential equations that, analogous to the relations (1.26) through (1.28), specify $\dot{\lambda}_1, \dot{\lambda}_2, \dot{\lambda}_3$ in terms of the λ_j and ω_j^{bf}. Moreover, these equations will be singularity free in the neighborhood the origin in λ space. What we have done is to convert the group-space differential equation (1.56) into a set of differential equations for the parameters λ_j. These equations, with the initial conditions

$$\lambda_j(t^b) = 0, \tag{11.1.72}$$

see (1.54), can be integrated numerically for one integration step using any convenient method to find the quantities $\lambda_j(t^b + h)$. If h is sufficiently small, the $\lambda(t)$ for $t \in [t^b, t^b + h]$ will remain small, and the differential equations specifying the $\dot{\lambda}_j$ will remain singularity free over the course of integration. Once the quantities $\lambda_j(t^b + h)$ have been found, $R(t^b + h)$ is given, depending on what type of canonical parameterization has been employed, by either (1.58) or (1.66).

As a modification of this procedure, one may integrate for k steps to find $\lambda_j(t^b + kh)$ and subsequently $R(t^b + kh)$. What is required then is continual checking that the λ_j have not come too close to singular values.

Evidently generalizations of the methods just described can in principle be employed for any Lie group. The difficulties encountered lie only in determining the equations that specify the $\dot{\lambda}_j$, see for example Exercises 1.9 and 1.10, and in evaluating the exponentials that occur with the use of (1.58) or (1.66). Assuming these exponentials can be evaluated accurately, the result for $R^v(t^b + h)$ will lie on the group manifold to high accuracy even though the $\lambda_j(t^b + h)$ are only exact through terms of order h^m. Finally, we must assume that the group multiplications involved in (1.57) can also be carried out with high accuracy.

Similarly, with the use of Cayley parameters, the difficulties lie only in determining the equations that specify the $\dot{\mu}_j$ [see for example (1.69) and (1.71)], and in carrying out the matrix inversions and multiplications that occur with the use of a Cayley representation [see (1.68) and (1.70)]. Assuming these inversions and multiplications can be evaluated accurately, the results for $R^v(t^b + h)$ or $u^v(t^b + h)$ will lie on the associated group manifold to high accuracy even though the $\mu_j(t^b + h)$ are only exact through terms of order h^m. Finally, we must again assume that the group multiplications involved in (1.57), for example, can also be carried out with high accuracy.

11.1.14 Integration in the Lie Algebra: Exponential Representation

With a suitable translation of the origin in time, the differential equation (1.56) with the initial condition (1.54) is a special case of the general differential equation of the form

$$\dot{M}(t) = M(t)A(t) \tag{11.1.73}$$

with the initial condition

$$M(0) = I, \tag{11.1.74}$$

and our goal is to find $M(h)$. Here $M(t)$ is expected to belong to some Lie group G and is near the identity for small t; and $A(t)$ belongs to the Lie algebra of G, which we denote by $\mathcal{L}(G)$. See Appendix C. In particular, we wish to obtain $M(h)$ by numerical means with a possible local error of order h^{m+1} and, despite this possible error, we want to guarantee that $M(h)$ is in G.

Since $M(t)$ is near the identity, we may write

$$M(t) = \exp[B(t)] \tag{11.1.75}$$

where $B(t)$ is in $\mathcal{L}(G)$ and is small (near the origin). If we can find $B(h)$ with a local error of order h^{m+1} and if, despite this possible error, we can assure that $B(h)$ is in $\mathcal{L}(G)$, then we know that $M(h) = \exp[B(h)]$ will have the desired local accuracy and is guaranteed to be in G. We will now see that a suitable $B(h)$ can be found by converting the differential equation (1.73), a *group* differential equation for the group elements $M(t)$ in terms of the group elements $M(t)$ and the Lie elements $A(t)$, into a *Lie* differential equation for the Lie elements $B(t)$ in terms of the Lie elements $B(t)$ and the Lie elements $A(t)$.

Before proceeding further, here is a chance to learn some terminology: Thinking geometrically, we may view $M(t)$ as a path in G, and we may view $B(t)$ as a path in $\mathcal{L}(G)$. In this context, the path $B(t)$ is said to be a *lift* of the path $M(t)$. That is, we may view $\mathcal{L}(G)$, the Lie algebra of G, as lying "above" the group G. Correspondingly, we may say that the path $B(t)$ is obtained by "lifting" the path $M(t)$ in the group G up to a path in $\mathcal{L}(G)$. Upon solving (1.75) for B in terms of M, we have the relation

$$B(t) = \log[M(t)], \tag{11.1.76}$$

and we see that the lift in question is accomplished by the logarithmic function. Conversely, in view of (1.75), the exponential function "lowers" the path $B(t)$ in $\mathcal{L}(G)$ down to the path $M(t)$ in the group G.

Let us continue. Given the differential equation (1.73) for the path $M(t)$, what is the associated differential equation for the path $B(t)$? The relation (1.75) can be differentiated to yield the result

$$\dot{M}(t) = M(t)\,\mathrm{iex}[-\#B(t)\#]\dot{B}(t). \tag{11.1.77}$$

See (*) in Appendix C. Also, in view of (1.73), the relation (1.77) can be rewritten in the form

$$\mathrm{iex}[-\#B(t)\#]\dot{B}(t) = A(t). \tag{11.1.78}$$

Finally, as in Section 10.3, the relation (1.78) can be inverted to become

$$\dot{B}(t) = \{\mathrm{iex}[-\#B(t)\#]\}^{-1}A(t). \tag{11.1.79}$$

We have obtained a (somewhat fearsome looking) differential equation for B in terms of B and A. Our task is to integrate this equation from $t = 0$ to $t = h$ with, in view of (1.74), the initial condition

$$B(0) = 0. \tag{11.1.80}$$

What can we make of (1.79)? The function $[\mathrm{iex}(-w)]^{-1}$ has an expansion of the form

$$[\mathrm{iex}(-w)]^{-1} = \sum_{\ell=0}^{\infty} b_\ell w^\ell \tag{11.1.81}$$

where the coefficients b_ℓ are known. Again see Appendix C. Correspondingly, the differential equation (1.79) is equivalent to the equation

$$\begin{aligned}\dot{B}(t) &= \sum_{\ell=0}^{\infty} b_\ell [\#B(t)\#]^\ell A(t)\\ &= \{b_0 + b_1[\#B(t)\#] + b_2[\#B(t)\#]^2 + \cdots\}A(t)\\ &= b_0A(t) + b_1\{B(t), A(t)\} + b_2\{B(t), \{B(t), A(t)\}\} + \cdots . \end{aligned}\tag{11.1.82}$$

In general, all terms in the expansion (1.82) need to be retained. That is, in general, we need to sum the series (1.82) which, in the general case, can be a formidable task.[12]

However, suppose we only wish to obtain $B(h)$ through some order in h. From the Magnus expansion, see Section 10.3, we know that $B(t)$ is of order h for $t \in [0, h]$. It follows that the term $b_\ell[\#B(t)\#]^\ell A(t)$ is of order h^ℓ and therefore contributes a term of order $h^{\ell+1}$ to $B(h)$. Suppose we truncate the series (1.82) beyond $\ell = n$ with n even. Then the size of the first omitted term will be of order h^{n+3}.[13] The result is the replacement of the differential equation (1.82) with the truncated equation

$$\begin{aligned}\dot{B}(t) &= \sum_{\ell=0}^{\ell=n} b_\ell [\#B(t)\#]^\ell A(t)\\ &= b_0A(t) + b_1\{B(t), A(t)\} + b_2\{B(t), \{B(t), A(t)\}\} + \cdots\\ &\quad + b_n\{B(t), \{B(t), \{\cdots\{B(t), A(t)\}\cdots\}\}\}, \end{aligned}\tag{11.1.83}$$

and the understanding is that this truncated equation is to be integrated only over the interval $t \in [0, h]$. Then the $B(h)$ so obtained will be correct through order h^m with $m = n + 2$. We have obtained a tractable problem. We have also been introduced to a new idea: the equation of motion to be integrated may be *modified* depending on the desired local accuracy for the integrated result.

[12] Exercise 1.10 shows, in effect, how this summation can be done for the cases of the Lie algebras $su(2)$ and $so(3, \mathbb{R})$.

[13] Examination of the b_ℓ, see Appendix C, reveals (save for $b_1 = 1/2$) that they all vanish for odd ℓ.

Still it might appear that, even with all our efforts, not much has been accomplished. We will soon see that progress has indeed been made. First, let us perform a sanity check on the results obtained so far. Suppose that $B(t) \in \mathcal{L}(G)$. From the definition

$$\dot{B}(t) = \lim_{\epsilon \to 0} [B(t+\epsilon) - B(t)]/\epsilon \tag{11.1.84}$$

we see that only vector space operations are involved in the calculation of $\dot{B}(t)$, and therefore $\dot{B}(t)$, which appears on the left side of (1.83), must also be in $\mathcal{L}(G)$. But is the right side of (1.83) in $\mathcal{L}(G)$? We know that $A(t)$ is in $\mathcal{L}(G)$. Also, all the rest of the right side of (1.83) involves sums of commutators of $B(t)$ with $A(t)$. By definition, $\mathcal{L}(G)$ is closed under addition and commutation. Therefore the right side of (1.83) is also in $\mathcal{L}(G)$. We conclude (1.83) is sane at least to the extent that both sides are in $\mathcal{L}(G)$.

But now we make a key observation: Suppose (1.83) is integrated by some numerical integrator to find $B(t)$. Examination of the various numerical integration schemes (for example all those discussed in Chapter 2) reveals that they all involve just *linear* combinations of the right side of the differential equation in question evaluated at various times and coordinate values. We know, by definition, that $\mathcal{L}(G)$ is closed under addition. Therefore, if the right side of the differential equation is known to be in $\mathcal{L}(G)$ at all evaluation points, then the result of numerically integrating such an equation is guaranteed to be in $\mathcal{L}(G)$. Since we have verified that the right side of (1.83) is in $\mathcal{L}(G)$, it follows that the $B(t)$ obtained by numerical integration, whatever the accuracy of the method, is guaranteed to be in $\mathcal{L}(G)$. Finally, if we wish to obtain $B(h)$ with an accuracy of some desired order in h, we may truncate (1.82) to obtain (1.83) with a known accuracy, and then integrate (1.83) using any integrator whose order equals or exceeds the accuracy of (1.83).

In summary, where conveniently feasible, integration in the Lie algebra is advantageous compared to integration in the group because numerical integration schemes, no matter their accuracy, generally preserve Lie algebraic structure.[14] Put another way, suppose the matrices A and B are $k \times k$. Then (1.83) is a differential equation in an ambient k^2 dimensional space. Numerical integration of (1.83) by any of the standard methods produces a sequence of points in this ambient space corresponding to the times t^n. We have seen that if the initial point is in the subspace $\mathcal{L}(G)$, then all subsequent points will also be in $\mathcal{L}(G)$. In our case, the initial point is given by (1.80), and is obviously in $\mathcal{L}(G)$. Therefore all subsequent points will also be in $\mathcal{L}(G)$.[15]

11.1.15 Integration in the Lie Algebra: Cayley Representation

We have used the exponential and logarithmic functions to relate G and $\mathcal{L}(G)$. For quadratic groups, which are often of interest, one may also use a Cayley representation to provide a

[14] Note that the work of Subsection 10.4.2 essentially employs a hybrid of canonical coordinates of the first and second kinds for the the nonlinear part of a symplectic map and formulates differential equations in the Lie algebra. The work of Section 10.3 and Subsection 10.4.3 also formulates differential equations in the Lie algebra.

[15] In the context of the exponential representation and in the case of finite-dimensional groups, the strategy of integrating in the Lie algebra and making the truncation (1.83) was pioneered by *Munthe-Kaas*; and the use of Runge-Kutta in this setting is often referred to as *RKMK* integration.

map between group elements near the identity and Lie algebra elements near the origin. That is, lowering and lifting can be done using the Cayley transformation and its inverse. See Section 3.12. Where possible, employing this approach yields a Lie algebraic differential equation analogous to (1.82), but with the advantage that only three terms appear on the right side. Therefore, *no* truncation is required. See Exercise 1.12.

We again seek to integrate equations of the form (1.73) with the initial condition (1.74) where now $M(t)$ is expected to belong to some quadratic Lie group G, and $A(t)$ belongs to its associated Lie algebra. What we again desire is a way of numerically integrating (1.73) that guarantees $M(t)$ is in G even though the numerical solution may be locally exact only through terms of order h^m.

When M belongs to a quadratic group G, we may employ the Cayley parameterization

$$M = (I + V)(I - V)^{-1}, \tag{11.1.85}$$

where V is in the Lie algebra of G. The challenge now is is to find the equation of motion for V. In Exercise 1.12 you will show that the desired result is the equation of motion

$$\dot{V} = (1/2)(A + \{V, A\} - VAV). \tag{11.1.86}$$

Note that, in contrast to (1.82) whose right side contains an infinite number of terms, the right side of (1.86) contains only three terms. Therefore no truncation is necessary and, unlike the case of $B(t)$, the accuracy to which $V(t)$ is calculated depends only on the method of integration.

Is this result sane? For a quadratic group G we know that V is in the Lie algebra. By an argument identical to that made in Subsection 1.14 for the case of $\dot{B}(t)$, it follows that $\dot{V}(t)$ must also be in the Lie algebra of G. But is the right side of (1.86) in the Lie algebra of G? Evidently, since A is in the Lie algebra of G, the first two terms on the right side of (1.86) are in the Lie algebra of G. What about the third term VAV? It can be shown that for a quadratic group the quantity VAV is also in the Lie algebra of G. Again see Exercise 1.12. Therefore (1.86) is sane at least to the extent that both its sides are in the Lie algebra of G.

Suppose (1.86) is integrated by some numerical integrator to find $V(t)$ under the assumption that V is initially in the Lie algebra of G. We repeat the key observation of Subsection 1.14: Examination of the usual numerical integration schemes, see Chapter 2, reveals that they all involve just linear combinations of the right side of the differential equation in question evaluated at various times and coordinate values. Therefore, if the right side is known to be in the Lie algebra of G for all evaluation points, then the result of numerically integrating such an equation is guaranteed to be in the Lie algebra of G, no matter what the local accuracy of the integrator or the step size employed. Since we have verified that the right side of (1.86) is in the Lie algebra of G, it follows that $V(t)$ will be in the Lie algebra of G if it is initially in the Lie algebra of G. Finally, since $V(t)$ is in the Lie algebra of G, it follows that $M(t)$ given by (1.85) is in G.

We have achieved our goal of, in effect, numerically integrating (1.73) in such a way that $M(t)$ is guaranteed to be in G. All that is required is accurate matrix multiplication in the calculation of the right side of (1.86) and accurate matrix inversion and multiplication in the evaluation of (1.85). Note, however, that this procedure cannot be carried out globally since the Cayley parameterization (1.85) cannot be made globally. It may therefore be necessary to change coordinate systems (by left or right group translation) from time to time during the course of a numerical integration in order to stay clear of the singularities associated with any given Cayley parametrization.[16]

11.1.16 Parameterization of G and $\mathcal{L}(G)$

To reiterate a point, if the matrices M or B are $k \times k$, then equations of the kind (1.73) or (1.82) involve k^2 variables. By contrast, the group G, and correspondingly its Lie algebra $\mathcal{L}(G)$, generally have much smaller dimension. Therefore it may be advantageous to parameterize the group or Lie algebra and to convert the differential equations for the group or Lie algebra into (usually) far fewer differential equations for the parameters. This is what was done for the case of $SO(3,\mathbb{R})$ by the use of quaternion parameters, the use of Tait-Bryan angles, and the use of angle-axis parameters.

By the introduction of a basis it is also possible to parameterize the Lie elements that occur in a Cayley formulation. That is, we parameterize the A and V appearing in (1.86). Again, as illustrated in Subsection 1.12, the result is (usually) far fewer equations that need to be integrated. See also Exercise 1.13.

11.1.17 Quaternions Revisited

We close this subsection by remarking that, in the case of $SO(3,\mathbb{R})$ and in the context of local coordinates, there is a still better approach, which again uses quaternions: Namely, suppose we again write (1.56) but now parameterize R^v in terms of quaternions. In this case the relations(1.43) through (1.46) will continue to hold and, in view of (1.54), there will be the initial conditions

$$w_0(t^b) = 1, \tag{11.1.87}$$

$$w_j(t^b) = 0 \text{ for } j = 1,2,3. \tag{11.1.88}$$

Also, if h is sufficiently small, the w_j for $j = 1,2,3$ will remain small over the course of a single integration step. We may therefore enforce the condition (1.30) by writing

$$w_0 = [1 - (w_1^2 + w_2^2 + w_3^2)]^{1/2} \tag{11.1.89}$$

and insert this result into (1.44) through (1.46). So doing gives the modified equations of motion

$$\dot{w}_1 = (1/2)\{-\omega_1^{bf}[1 - (w_1^2 + w_2^2 + w_3^2)]^{1/2} - \omega_2^{bf} w_3 + \omega_3^{bf} w_2\}, \tag{11.1.90}$$

$$\dot{w}_2 = (1/2)\{\omega_1^{bf} w_3 - \omega_2^{bf}[1 - (w_1^2 + w_2^2 + w_3^2)]^{1/2} - \omega_3^{bf} w_1\}, \tag{11.1.91}$$

$$\dot{w}_3 = (1/2)\{-\omega_1^{bf} w_2 + \omega_2^{bf} w_1 - \omega_3^{bf}[1 - (w_1^2 + w_2^2 + w_3^2)]^{1/2}\}. \tag{11.1.92}$$

These three kinematic equations, whose right sides depend only on (w_1, w_2, w_3) and on $(\omega_1^{bf}, \omega_2^{bf}, \omega_3^{bf})$, along with the three dynamic equations (1.19) through (1.21), are to be

[16] It might appear the the right side of (1.86) is singularity free. However, it is singular at infinity, and this singularity can be reached in finite time. See the discussion in Exercise 1.13.

integrated over the interval $t \in [t^b, t^b + h]$. (And any kind of integrator can be used.) Whenever w_0 is needed, it is to be computed from (1.89). Note that in view of (8.2.73), no exponentials need be computed to find $R^v(t)$. Also, the kinematic equations are mostly linear and involve, at worst, the calculation of a square root. Moreover, if desired, the equivalent of matrix multiplication in $SO(3, \mathbb{R})$ can be carried out at the quaternion level where the operations are computationally simpler. See (5.10.24) and Exercises 8.2.10 and 8.2.11. For all these reasons, relatively few floating-point operations are needed to carry out an integration step. Finally, although the quaternion parameters (w_1, w_2, w_3) may only be computed with a local error of order h^{m+1}, the resulting matrix $R_v(t^b+h)$ will be orthogonal to a very high accuracy limited only by roundoff error.

Exercises

11.1.1. The purpose of this exercise is to explore some of the consequences of the definition of angular velocity given in Subsection 1.1. The first task is a bit of housekeeping. In deriving (1.10) through (1.12) it was tacitly assumed that

$$[(d/dt)R]^T = (d/dt)(R^T). \tag{11.1.93}$$

That is, the operations of differentiating and transposing commute. Verify that this is so for any matrix.

Now move on to the main task. The *components* $\omega_j^{bf}(t)$ of the angular velocity in the *body-fixed* frame are defined by the rule (1.4). Accordingly, define the angular velocity *vector* $\boldsymbol{\omega}(t)$ by the rule

$$\boldsymbol{\omega}(t) = \sum_j \omega_j^{bf}(t)\boldsymbol{f}_j(t). \tag{11.1.94}$$

Let us compute the vector $\boldsymbol{\omega} \times \boldsymbol{f}_1$. Verify the chain of relations

$$\begin{aligned}
\boldsymbol{\omega} \times \boldsymbol{f}_1 &= \omega_2^{bf}\boldsymbol{f}_2 \times \boldsymbol{f}_1 + \omega_3^{bf}\boldsymbol{f}_3 \times \boldsymbol{f}_1 = -\omega_2^{bf}\boldsymbol{f}_3 + \omega_3^{bf}\boldsymbol{f}_2 \\
&= (\boldsymbol{f}_3 \cdot \dot{\boldsymbol{f}}_1)\boldsymbol{f}_3 - (\boldsymbol{f}_1 \cdot \dot{\boldsymbol{f}}_2)\boldsymbol{f}_2 \\
&= (\boldsymbol{f}_3 \cdot \dot{\boldsymbol{f}}_1)\boldsymbol{f}_3 + (\boldsymbol{f}_2 \cdot \dot{\boldsymbol{f}}_1)\boldsymbol{f}_2 + (\boldsymbol{f}_1 \cdot \dot{\boldsymbol{f}}_1)\boldsymbol{f}_1 \\
&= \dot{\boldsymbol{f}}_1.
\end{aligned} \tag{11.1.95}$$

Here we have used the fact

$$\boldsymbol{f}_1 \cdot \boldsymbol{f}_2 = 0 \tag{11.1.96}$$

from which it follows that

$$\dot{\boldsymbol{f}}_1 \cdot \boldsymbol{f}_2 + \boldsymbol{f}_1 \cdot \dot{\boldsymbol{f}}_2 = 0, \tag{11.1.97}$$

and the fact

$$\boldsymbol{f}_1 \cdot \boldsymbol{f}_1 = 1 \tag{11.1.98}$$

from which it follows that

$$\boldsymbol{f}_1 \cdot \dot{\boldsymbol{f}}_1 = 0. \tag{11.1.99}$$

It is easily checked that there are two more relations like (1.95), and that they together give the general equations of motion

$$\dot{\boldsymbol{f}}_j(t) = \boldsymbol{\omega}(t) \times \boldsymbol{f}_j(t). \tag{11.1.100}$$

Verify from (1.100) that

$$\boldsymbol{f}_j \times \dot{\boldsymbol{f}}_j = \boldsymbol{f}_j \times (\boldsymbol{\omega} \times \boldsymbol{f}_j) = \boldsymbol{\omega} - (\boldsymbol{\omega} \cdot \boldsymbol{f}_j)\boldsymbol{f}_j, \tag{11.1.101}$$

and therefore

$$\sum_j \boldsymbol{f}_j \times \dot{\boldsymbol{f}}_j = 3\boldsymbol{\omega} - \sum_j (\boldsymbol{\omega} \cdot \boldsymbol{f}_j)\boldsymbol{f}_j = 3\boldsymbol{\omega} - \boldsymbol{\omega} = 2\boldsymbol{\omega}. \tag{11.1.102}$$

Conclude that $\boldsymbol{\omega}$ is also given by the relation

$$\boldsymbol{\omega} = (1/2) \sum_j \boldsymbol{f}_j \times \dot{\boldsymbol{f}}_j. \tag{11.1.103}$$

Moreover, suppose $\boldsymbol{v}(t)$ is any vector that is “fixed” in the body. That is, suppose $\boldsymbol{v}(t)$ has an expansion of the form

$$\boldsymbol{v}(t) = \sum_j v_j \boldsymbol{f}_j(t) \tag{11.1.104}$$

where the components v_j are *constant* numbers. Show that it follows from (1.100) that $\boldsymbol{v}$ obeys the equation of motion

$$\dot{\boldsymbol{v}}(t) = \boldsymbol{\omega}(t) \times \boldsymbol{v}(t). \tag{11.1.105}$$

Let us compute the $\omega_j^{bf}(t)$ for a special case. Suppose $R(t)$ is of the form

$$R(t) = \exp[\theta(t)\boldsymbol{n} \cdot \boldsymbol{L}] \tag{11.1.106}$$

where $\boldsymbol{n}$ is a constant vector. Verify that

$$\dot{R}(t) = \exp[\theta(t)\boldsymbol{n} \cdot \boldsymbol{L}]\ \dot{\theta}(t)\boldsymbol{n} \cdot \boldsymbol{L}. \tag{11.1.107}$$

Show, from (1.22), that in this case

$$\omega_j^{bf}(t) = \dot{\theta}(t)n_j. \tag{11.1.108}$$

This special case illustrates why the name *angular velocity* is appropriate.

What can be said more generally? Suppose $R(t)$ is a time-dependent matrix in $SO(3,\mathbb{R})$. Show that

$$\begin{aligned} R(t+dt) &= R(t) + \dot{R}(t)dt + O[(dt)^2] = R(t)[I + R^{-1}(t)\dot{R}(t)dt] + O[(dt)^2] \\ &= R(t)[I + (dt)\boldsymbol{\omega}^{bf}(t) \cdot \boldsymbol{L}] + O[(dt)^2] \\ &= R(t)\exp[(dt)\boldsymbol{\omega}^{bf}(t) \cdot \boldsymbol{L}] + O[(dt)^2]. \end{aligned} \tag{11.1.109}$$

You have shown that, through terms of order dt, $R(t+dt)$ is gotten from $R(t)$ by translating $R(t)$ on the right with the near-identity element $\exp[(dt)\boldsymbol{\omega}^{bf}(t) \cdot \boldsymbol{L}]$.

Can $R(t+dt)$ and $R(t)$ instead be related by translating $R(t)$ on the left with a near-identity element? Show that the answer is *yes*. Verify the manipulations

$$\begin{aligned} R(t+dt) &= R(t)+\dot{R}(t)dt+O[(dt)^2]=[I+dt\dot{R}(t)R^{-1}(t)]R(t)+O[(dt)^2] \\ &= \{I+dtR(t)[R^{-1}(t)\dot{R}(t)]R^{-1}(t)\}R(t)+O[(dt)^2] \\ &= \{I+dtR(t)[\boldsymbol{\omega}^{bf}(t)\cdot\boldsymbol{L}]R^{-1}(t)\}R(t)+O[(dt)^2]. \end{aligned} \tag{11.1.110}$$

Next verify that

$$R(t)[\boldsymbol{\omega}^{bf}(t)\cdot\boldsymbol{L}]R^{-1}(t)=\boldsymbol{\omega}^{sf}(t)\cdot\boldsymbol{L} \tag{11.1.111}$$

where $\boldsymbol{\omega}^{sf}(t)$ is defined by the relation

$$\boldsymbol{\omega}^{sf}(t)=R(t)\boldsymbol{\omega}^{bf}(t). \tag{11.1.112}$$

See (8.2.59). Combine (1.110) through (1.112) to get the result

$$\begin{aligned} R(t+dt) &= \{I+dtR(t)[\boldsymbol{\omega}^{bf}(t)\cdot\boldsymbol{L}]R^{-1}(t)\}R(t)+O[(dt)^2] \\ &= \{I+dt\boldsymbol{\omega}^{sf}(t)\cdot\boldsymbol{L}\}R(t)+O[(dt)^2] \\ &= \exp[(dt)\boldsymbol{\omega}^{sf}(t)\cdot\boldsymbol{L}]R(t)+O[(dt)^2]. \end{aligned} \tag{11.1.113}$$

You have shown that, through terms of order dt, $R(t+dt)$ is gotten from $R(t)$ by translating $R(t)$ on the left with the near-identity element $\exp[(dt)\boldsymbol{\omega}^{sf}(t)\cdot\boldsymbol{L}]$. Verify also that (1.113) implies the relation

$$\boldsymbol{\omega}^{sf}(t)\cdot\boldsymbol{L}=\dot{R}(t)R^{-1}(t), \tag{11.1.114}$$

which is to be compared with (1.22).

According to (1.112), the quantities we have called ω_j^{sf} are related to the ω_j^{bf} by the rule

$$\omega_j^{sf}=\sum_k R_{jk}\omega_k^{bf}. \tag{11.1.115}$$

What is their significance? Recall the angular velocity vector $\boldsymbol{\omega}(t)$ defined by (1.94). Rewrite this definition using the dummy index k to obtain the equivalent definition

$$\boldsymbol{\omega}(t)=\sum_k \omega_k^{bf}(t)\boldsymbol{f}_k(t). \tag{11.1.116}$$

Since the *space-fixed* vectors $\boldsymbol{e}_j$ form a basis, we may make the expansion

$$\boldsymbol{\omega}(t)=\sum_j[\boldsymbol{e}_j\cdot\boldsymbol{\omega}(t)]\boldsymbol{e}_j. \tag{11.1.117}$$

Use the representation (1.116) to compute the expansion coefficients $[\boldsymbol{e}_j\cdot\boldsymbol{\omega}(t)]$. Verify that so doing gives the result

$$\begin{aligned} \boldsymbol{e}_j\cdot\boldsymbol{\omega}(t) &= \sum_k \omega_k^{bf}(t)[\boldsymbol{e}_j\cdot\boldsymbol{f}_k(t)]=\sum_k \omega_k^{bf}(t)\{\boldsymbol{e}_j\cdot[R(t)\boldsymbol{e}_k(t)]\} \\ &= \sum_k \omega_k^{bf}(t)R_{jk}(t)=\sum_k R_{jk}(t)\omega_k^{bf}(t)=\omega_j^{sf}(t), \end{aligned} \tag{11.1.118}$$

where use has been made of (1.2) and (1.115). By putting everything together, show that (1.117) can be rewritten in the form

$$\boldsymbol{\omega}(t) = \sum_j \omega_j^{sf}(t)\boldsymbol{e}_j. \tag{11.1.119}$$

We conclude that the quantities $\omega_j^{sf}(t)$ are the *space-fixed* components of the angular velocity vector $\boldsymbol{\omega}(t)$.

Finally show, for the special case (1.106), that

$$\omega_j^{sf}(t) = \omega_j^{bf}(t). \tag{11.1.120}$$

11.1.2. The purpose of this exercise is to show that the matrix differential equation (1.18) preserves the orthogonality condition (1.9), and conversely.

Begin with the converse. We already know from the orthogonality assumption (1.9) that the matrix $(R^{-1}\dot{R})$ must be antisymmetric. See (1.12). Therefore for orthogonal 3×3 matrices a relation of the form (1.18) must hold.

Now prove the main assertion. Show, by taking transposes, that (1.18) implies the relation

$$(d/dt)R^T = -\boldsymbol{\omega}^{bf} \cdot \boldsymbol{L}\ R^T. \tag{11.1.121}$$

Next show that there is the relation

$$(d/dt)(RR^T) = [(d/dt)R]R^T + R(d/dt)R^T = R(\boldsymbol{\omega}^{bf} \cdot \boldsymbol{L})R^T - R(\boldsymbol{\omega}^{bf} \cdot \boldsymbol{L})R^T = 0. \tag{11.1.122}$$

Here use has been made of (1.18) and (1.121). Assume that R is orthogonal at the initial time t^i,

$$R(t^i)R(t^i)^T = I = R^T(t^i)R(t^i). \tag{11.1.123}$$

Verify that the solution to the differential equation (1.122) with the initial condition (1.123) is

$$R(t)R(t)^T = I = R^T(t)R(t). \tag{11.1.124}$$

You have shown that (1.18) preserves orthogonality.

11.1.3. The purpose of this exercise is to derive equations (1.23) through (1.28), the expressions for the ω_j^{bf} in terms of Euler angles. Recall the Euler-angle parameterization (3.7.207),

$$R(t) = \exp[\phi(t)L^3]\exp[\theta(t)L^2]\exp[\psi(t)L^3]. \tag{11.1.125}$$

According to (1.22), we must compute the quantities ω_j^{bf} defined by the relation

$$\boldsymbol{\omega}^{bf} \cdot \boldsymbol{L} = R^{-1}\dot{R}. \tag{11.1.126}$$

Verify that R^{-1} is given by the relation

$$R^{-1} = \exp(-\psi L^3)\exp(-\theta L^2)\exp(-\phi L^3). \tag{11.1.127}$$

Show that $\dot{R}$ is given by the relation

$$\begin{aligned}\dot{R} &= \dot{\phi}L^3\exp(\phi L^3)\exp(\theta L^2)\exp(\psi L^3)\\ &+ \exp(\phi L^3)\dot{\theta}L^2\exp(\theta L^2)\exp(\psi L^3)\\ &+ \exp(\phi L^3)\exp(\theta L^2)\exp(\psi L^3)\dot{\psi}L^3.\end{aligned} \tag{11.1.128}$$

Now begins the fun. Verify that $R^{-1}\dot{R}$ is given by the seemingly hopeless expression

$$\begin{aligned}R^{-1}\dot{R} &= \exp(-\psi L^3)\exp(-\theta L^2)\exp(-\phi L^3)\dot{\phi}L^3\exp(\phi L^3)\exp(\theta L^2)\exp(\psi L^3)\\ &+ \exp(-\psi L^3)\exp(-\theta L^2)\exp(-\phi L^3)\exp(\phi L^3)\dot{\theta}L^2\exp(\theta L^2)\exp(\psi L^3)\\ &+ \exp(-\psi L^3)\exp(-\theta L^2)\exp(-\phi L^3)\exp(\phi L^3)\exp(\theta L^2)\exp(\psi L^3)\dot{\psi}L^3.\end{aligned} \tag{11.1.129}$$

Simplify each of the three lines in (1.129) so that they become

$$\begin{aligned}&\exp(-\psi L^3)\exp(-\theta L^2)\exp(-\phi L^3)\dot{\phi}L^3\exp(\phi L^3)\exp(\theta L^2)\exp(\psi L^3)\\ &= \dot{\phi}\exp(-\psi L^3)\exp(-\theta L^2)L^3\exp(\theta L^2)\exp(\psi L^3),\end{aligned} \tag{11.1.130}$$

$$\begin{aligned}&\exp(-\psi L^3)\exp(-\theta L^2)\exp(-\phi L^3)\exp(\phi L^3)\dot{\theta}L^2\exp(\theta L^2)\exp(\psi L^3)\\ &= \dot{\theta}\exp(-\psi L^3)L^2\exp(\psi L^3),\end{aligned} \tag{11.1.131}$$

$$\begin{aligned}&\exp(-\psi L^3)\exp(-\theta L^2)\exp(-\phi L^3)\exp(\phi L^3)\exp(\theta L^2)\exp(\psi L^3)\dot{\psi}L^3\\ &= \dot{\psi}L^3.\end{aligned} \tag{11.1.132}$$

Line (1.132) is as simple as we could desire. The next more complicated line is (1.131). Show, using the machinery of Exercise 8.2.10, that

$$\exp(-\psi L^3)L^2\exp(\psi L^3) = \cos(\psi)L^2 + \sin(\psi)L^1. \tag{11.1.133}$$

Thus, the right side of (1.131) becomes

$$\dot{\theta}[\cos(\psi)L^2 + \sin(\psi)L^1]. \tag{11.1.134}$$

Finally, work on line (1.130). Show that

$$\exp(-\theta L^2)L^3\exp(\theta L^2) = \cos(\theta)L^3 - \sin(\theta)L^1. \tag{11.1.135}$$

Next show that

$$\begin{aligned}&\exp(-\psi L^3)[\cos(\theta)L^3 - \sin(\theta)L^1]\exp(\psi L^3)\\ &= \cos(\theta)L^3 - \sin(\theta)\exp(-\psi L^3)L^1\exp(\psi L^3)\\ &= \cos(\theta)L^3 - \sin(\theta)[\cos(\psi)L^1 - \sin(\psi)L^2].\end{aligned} \tag{11.1.136}$$

By combining (1.135) and (1.136), verify that

$$\begin{aligned}&\exp(-\psi L^3)\exp(-\theta L^2)L^3\exp(\theta L^2)\exp(\psi L^3)\\&=\cos(\theta)L^3-\sin(\theta)[\cos(\psi)L^1-\sin(\psi)L^2].\end{aligned}\tag{11.1.137}$$

Thus, the right side of (1.130) becomes

$$\dot{\phi}\{\cos(\theta)L^3-\sin(\theta)[\cos(\psi)L^1-\sin(\psi)L^2]\}.\tag{11.1.138}$$

All the necessary ingredients are at hand. By combining (1.129) through (1.138), show that

$$\begin{aligned}R^{-1}\dot{R} &= \dot{\phi}\{\cos(\theta)L^3-\sin(\theta)[\cos(\psi)L^1-\sin(\psi)L^2]\}\\&+ \dot{\theta}[\cos(\psi)L^2+\sin(\psi)L^1]\\&+ \dot{\psi}L^3\\&= (-\dot{\phi}\sin\theta\cos\psi+\dot{\theta}\sin\psi)L^1\\&+ (\dot{\phi}\sin\theta\sin\psi+\dot{\theta}\cos\psi)L^2\\&+ (\dot{\phi}\cos\theta+\dot{\psi})L^3.\end{aligned}\tag{11.1.139}$$

Verify, upon equating coefficients of the L^j in (1.126) and (1.139), that the relations (1.23) through (1.25) follow. Finally, verify that inverting the relations (1.23) through (1.25) yields the relations (1.26) through (1.28).

11.1.4. The purpose of this exercise is to derive equations (1.31) and (1.32), the relation between quaternion and angle-axis parameters, and equations (1.33) through (1.36), the relation between quaternion and Euler-angle parameters. For this purpose, it is convenient to exploit the homomorphism between $SO(3,\mathbb{R})$ and $SU(2)$. Review Exercises 3.7.30, 5.10.13, 8.2.10, and 8.2.11.

Suppose $u \in SU(2)$ is parameterized in terms of angle-axis parameters by writing

$$u=\exp(\theta\boldsymbol{n}\cdot\boldsymbol{K})=I\cos(\theta/2)+2(\boldsymbol{n}\cdot\boldsymbol{K})\sin(\theta/2).\tag{11.1.140}$$

See (3.7.186) and (3.7.188). Suppose that u is also parameterized in terms of unit quaternion matrices by writing

$$u(w)=w_0\sigma^0+i\boldsymbol{w}\cdot\boldsymbol{\sigma}.\tag{11.1.141}$$

Equate (1.140) and (1.141) and employ the relations

$$I=\sigma^0,\tag{11.1.142}$$

$$\boldsymbol{K}=(-i/2)\boldsymbol{\sigma}.\tag{11.1.143}$$

Use the linear independence of the matrices σ^0 through σ^3 to verify (1.31) and (1.32).

Next suppose $u \in SU(2)$ is parameterized in terms of Euler angles as in (3.7.195) in Exercise 3.7.30. Verify that there is the decomposition

$$u(\phi,\theta,\psi) = \begin{pmatrix} \cos(\theta/2)\exp[-(i/2)(\phi+\psi)] & -\sin(\theta/2)\exp[(i/2)(-\phi+\psi)] \\ \sin(\theta/2)\exp[-(i/2)(-\phi+\psi)] & \cos(\theta/2)\exp[(i/2)(\phi+\psi)] \end{pmatrix}$$
$$= \cos(\theta/2)\cos[(1/2)(\phi+\psi)]\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} - i\sin(\theta/2)\sin[(1/2)(-\phi+\psi)]\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$
$$-i\sin(\theta/2)\cos[(1/2)(-\phi+\psi)]\begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix} - i\cos(\theta/2)\sin[(1/2)(\phi+\psi)]\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{11.1.144}$$

Thus, using the definition of the Pauli matrices, verify that

$$\begin{aligned} u &= \sigma^0\{\cos(\theta/2)\cos[(1/2)(\phi+\psi)]\} \\ &- i\sigma^1\{\sin(\theta/2)\sin[(1/2)(-\phi+\psi)]\} \\ &- i\sigma^2\{\sin(\theta/2)\cos[(1/2)(-\phi+\psi)]\} \\ &- i\sigma^3\{\cos(\theta/2)\sin[(1/2)(\phi+\psi)]\}. \end{aligned} \tag{11.1.145}$$

Finally, verify that comparison of (1.141) and (1.145), and use of the linear independence of the matrices σ^0 through σ^3, yields (1.33) through (1.36).

11.1.5. The purpose of this exercise is to derive equations (1.37) through (1.39), the expressions for the angular velocities ω_j^{bf} in terms of quaternion parameters. Surprisingly, this task turns out to be computationally simpler than the Euler-angle case of Exercise 1.3. Review Exercise 1.4 above for notation.

The relation (1.22) specifies the ω_j^{bf} in terms of $SO(3,\mathbb{R})$ quantities. Based on the homomorphism between $SO(3,\mathbb{R})$ and $SU(2)$ (see Exercises 3.7.30, 5.10.13, 8.2.10, and 8.2.11), verify that there is an associated $SU(2)$ relation given by the formula

$$u^{-1}\dot{u} = \omega_1^{bf}K^1 + \omega_2^{bf}K^2 + \omega_3^{bf}K^3 = \boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}. \tag{11.1.146}$$

Indeed, suppose u is parameterized in terms of Euler angles by writing

$$u(t) = \exp[\phi(t)K^3]\exp[\theta(t)K^2]\exp[\psi(t)K^3]. \tag{11.1.147}$$

See (3.7.194). Show that then use of (1.147) in (1.146) reproduces the results of Exercise 1.3.

Instead, we will parameterize u in terms of unit quaternion matrices by writing (1.141). Then we have the results

$$u^{-1} = u^\dagger = w_0\sigma^0 - i\boldsymbol{w}\cdot\boldsymbol{\sigma} \tag{11.1.148}$$

and

$$\dot{u}(w) = \dot{w}_0\sigma^0 + i\dot{\boldsymbol{w}}\cdot\boldsymbol{\sigma}. \tag{11.1.149}$$

Verify that carrying out the required multiplication $u^{-1}\dot{u}$ yields the intermediate result

$$\begin{aligned} u^{-1}\dot{u} &= [w_0\sigma^0 - i\boldsymbol{w}\cdot\boldsymbol{\sigma}][\dot{w}_0\sigma^0 + i\dot{\boldsymbol{w}}\cdot\boldsymbol{\sigma}] \\ &= w_0\dot{w}_0\sigma^0 + iw_0\dot{\boldsymbol{w}}\cdot\boldsymbol{\sigma} - i\dot{w}_0\boldsymbol{w}\cdot\boldsymbol{\sigma} + (\boldsymbol{w}\cdot\boldsymbol{\sigma})(\dot{\boldsymbol{w}}\cdot\boldsymbol{\sigma}). \end{aligned} \tag{11.1.150}$$

Now use (5.7.44) to write

$$(\boldsymbol{w}\cdot\boldsymbol{\sigma})(\dot{\boldsymbol{w}}\cdot\boldsymbol{\sigma}) = (\boldsymbol{w}\cdot\dot{\boldsymbol{w}})\sigma^0 + i(\boldsymbol{w}\times\dot{\boldsymbol{w}})\cdot\boldsymbol{\sigma}. \tag{11.1.151}$$

Substitute (1.151) into (1.150) to yield the next intermediate result

$$u^{-1}\dot{u} = (w_0\dot{w}_0 + \boldsymbol{w}\cdot\dot{\boldsymbol{w}})\sigma^0 + i(w_0\dot{\boldsymbol{w}} - \dot{w}_0\boldsymbol{w} + \boldsymbol{w}\times\dot{\boldsymbol{w}})\cdot\boldsymbol{\sigma}. \tag{11.1.152}$$

But in view of (1.40), which follows from the requirement that u be a unit quaternion, the first term on the right of (1.152) vanishes, and (1.152) therefore becomes

$$u^{-1}\dot{u} = i(w_0\dot{\boldsymbol{w}} - \dot{w}_0\boldsymbol{w} + \boldsymbol{w}\times\dot{\boldsymbol{w}})\cdot\boldsymbol{\sigma}. \tag{11.1.153}$$

There is also the result (1.143), and therefore (1.153) can be written as

$$u^{-1}\dot{u} = -2(w_0\dot{\boldsymbol{w}} - \dot{w}_0\boldsymbol{w} + \boldsymbol{w}\times\dot{\boldsymbol{w}})\cdot\boldsymbol{K}. \tag{11.1.154}$$

Upon comparing (1.146) and (1.154), show that

$$\omega_j^{bf} = -2(w_0\dot{\boldsymbol{w}} - \dot{w}_0\boldsymbol{w} + \boldsymbol{w}\times\dot{\boldsymbol{w}})\cdot\boldsymbol{e}_j. \tag{11.1.155}$$

Verify that (1.37) through (1.39) are equivalent to (1.155).

11.1.6. The purpose of this exercise is to verify that the 4×4 matrices appearing in (1.41) and (1.42) are orthogonal. Suppose $(w_0, w_1, w_2, w_3)^T$ is a unit four vector. That is, suppose (1.30) is satisfied. Consider the mapping of this four vector into the space of 4×4 matrices given by the rule

$$\begin{pmatrix} w_0 \\ w_1 \\ w_2 \\ w_3 \end{pmatrix} \rightarrow M(w) = \begin{pmatrix} w_0 & -w_1 & -w_2 & -w_3 \\ w_1 & w_0 & w_3 & -w_2 \\ w_2 & -w_3 & w_0 & w_1 \\ w_3 & w_2 & -w_1 & w_0 \end{pmatrix}. \tag{11.1.156}$$

Verify that all the columns of M are unit vectors. Verify that all the columns of M are mutually orthogonal. It follows that M is an orthogonal matrix,

$$M^T M = I. \tag{11.1.157}$$

Verify that the matrices appearing in (1.41) and (1.42) are $-M^T$ and $-M$, and hence both are also orthogonal.

11.1.7. Intrigued by the remarkable mapping (1.156), this exercise is devoted to a further exploration of what is going on. We will learn that what is involved is a mapping of a pair of unit quaternions into $SO(4,\mathbb{R})$.

Show that since M is orthogonal, it must satisfy

$$\det M = \pm 1. \tag{11.1.158}$$

Let e_0 be the unit vector

$$e_0 = (1,0,0,0)^T. \tag{11.1.159}$$

Verify that

$$M(e_0) = I, \tag{11.1.160}$$

and therefore

$$\det M(e_0) = +1. \tag{11.1.161}$$

Show that any unit vector $w \in S^3$ is connected to e_0 by a continuous path in S^3. [Hint: Show, for example, that $SO(4,\mathbb{R})$ acts transitively on S^3.] Verify that the mapping (1.156) is continuous. Show that it follows, by continuity, that

$$\det M(w) = +1, \tag{11.1.162}$$

and therefore $M(w) \in SO(4,\mathbb{R})$. That is, (1.156) produces a map

$$S^3 \to SO(4,\mathbb{R}). \tag{11.1.163}$$

Can all elements of $SO(4,\mathbb{R})$ be written in the form $M(w)$? No, because $w \in S^3$ involves three parameters, and we know that $SO(4,\mathbb{R})$ is six dimensional. What elements in $SO(4,\mathbb{R})$ can be written in the form $M(w)$? Let's see. Define three matrices D^1, D^2, D^3 by the rules

$$D^1 = \begin{pmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix}, \tag{11.1.164}$$

$$D^2 = \begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}, \tag{11.1.165}$$

$$D^3 = \begin{pmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}. \tag{11.1.166}$$

Verify the relation

$$M(w) = w_0 I + w_1 D^1 + w_2 D^2 + w_3 D^3. \tag{11.1.167}$$

Show that the matrices D^j satisfy the relations

$$(D^j)^2 = -I, \tag{11.1.168}$$

$$D^1D^2 = -D^2D^1 = -D^3, \tag{11.1.169}$$

$$D^2D^3 = -D^3D^2 = -D^1, \tag{11.1.170}$$

$$D^3D^1 = -D^1D^3 = -D^2. \tag{11.1.171}$$

By employing these relations, show that

$$M(w)M(w') = M(w'') \tag{11.1.172}$$

with

$$\begin{aligned} w_0'' &= w_0w_0' - w_1w_1' - w_2w_2' - w_3w_3', \\ w_1'' &= w_0w_1' + w_0'w_1 - w_2w_3' + w_3w_2', \\ w_2'' &= w_0w_2' + w_0'w_2 - w_3w_1' + w_1w_3', \\ w_3'' &= w_0w_3' + w_0'w_3 - w_1w_2' + w_2w_1', \end{aligned} \tag{11.1.173}$$

which, with the notation $\boldsymbol{w} = (w_1, w_2, w_3)$, can be written more compactly in the form

$$w_0'' = w_0w_0' - \boldsymbol{w} \cdot \boldsymbol{w}', \tag{11.1.174}$$

$$\boldsymbol{w}'' = w_0\boldsymbol{w}' + w_0'\boldsymbol{w} - \boldsymbol{w} \times \boldsymbol{w}'. \tag{11.1.175}$$

Show that if $w \in S^3$ and $w' \in S^3$, then $w'' \in S^3$. Show also that

$$M(w + w') = M(w) + M(w'). \tag{11.1.176}$$

Observe that the relations (1.174) and (1.175) are exactly those for quaternion matrix multiplication. See Section 5.10.4 and Exercise 5.10.15. Verify that there is the correspondence

$$\begin{aligned} I &\leftrightarrow e, \\ -D^1 &\leftrightarrow j, \\ -D^2 &\leftrightarrow, k \\ -D^3 &\leftrightarrow \ell. \end{aligned} \tag{11.1.177}$$

That is, the 4×4 matrices $I, -D^1, -D^2, -D^3$ provide a representation for quaternion algebra. Observe that, unlike the 2×2 representation given by the complex matrices in (5.10.64), these 4×4 matrices are all real.

Verify that the D^j are antisymmetric,

$$(D^j)^T = -D^j. \tag{11.1.178}$$

Verify that

$$[M(w)]^T = M(w^*) \tag{11.1.179}$$

with the definitions

$$w_0^* = w_0, \quad w_1^* = -w_1, \quad w_2^* = -w_2, \quad w_3^* = -w_3. \tag{11.1.180}$$

Verify that

$$(w^*)^* = w. \tag{11.1.181}$$

Verify that $w^* \in S^3$ if $w \in S^3$, and verify the relation

$$M(w^*) = [M(w)]^{-1}. \tag{11.1.182}$$

Thus, verify that the $M(w)$ for $w \in S^3$ form a group.

Finally, what elements in $SO(4,\mathbb{R})$ can be written in the form $M(w)$? We know from Exercise 5.10.13 that unit quaternions form a group that is isomorphic to $SU(2)$. We also know from Exercises 4.4.19 and 4.3.20 that $so(4,\mathbb{R})$ is the direct sum of two commuting $su(2)$ Lie algebras. From these same exercises we know that the H^j generate the $SU(2)$ associated with one of these $su(2)$ Lie algebras. Verify from (4.3.152) and (1.161) through (1.163) that there is the relation

$$D^j = -2H^j. \tag{11.1.183}$$

Show that it follows that the elements in $SO(4,\mathbb{R})$ that can be written in the form $M(w)$ are those that belong to the $SU(2)$ subgroup generated by the H^j. Verify, in the terminology of Exercises 4.3.19 and 4.3.20, that these are all elements of the form $\exp(\boldsymbol{t}\cdot\boldsymbol{H})$. Find the relation between $w \in S^3$ and $\boldsymbol{t}$. Lastly verify that, as expected from the work of Exercise 4.3.19, that all $M(w)$ with $w \in S^3$ are also symplectic with respect to the J of (4.3.65).

But wait, as they say in infomercials, there's more! As just stated, we know from Exercises 4.3.19 and 4.3.20 that $SO(4,\mathbb{R})$ is the direct product of two commuting $SU(2)$ subgroups, and we know from Exercise 5.10.13 that any $SU(2)$ has an associated unit quaternion equivalent. Therefore, there should be *two* unit quaternions associated with $SO(4,\mathbb{R})$. How can the second unit quaternion be found/employed?

Motivated by (1.183), we might define matrices E^j by the rule

$$E^j \overset{?}{=} -2G^j \tag{11.1.184}$$

with the G^j given by (4.3.151). This is a workable possibility. However, a choice that yields more aesthetic results is to make the definitions

$$\begin{aligned} E^1 &= 2G^3, \\ E^2 &= -2G^2, \\ E^3 &= -2G^1. \end{aligned} \tag{11.1.185}$$

The E^j have the explicit form

$$E^1 = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix}, \tag{11.1.186}$$

$$E^2 = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \\ -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}, \tag{11.1.187}$$

$$E^3 = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}. \tag{11.1.188}$$

Form the matrix $N(w)$ by the rule

$$N(w) = w_0 I + w_1 E^1 + w_2 E^2 + w_3 E^3. \tag{11.1.189}$$

Verify that $N(w)$ has the explicit form

$$N(w) = \begin{pmatrix} w_0 & w_1 & w_2 & w_3 \\ -w_1 & w_0 & w_3 & -w_2 \\ -w_2 & -w_3 & w_0 & w_1 \\ -w_3 & w_2 & -w_1 & w_0 \end{pmatrix}. \tag{11.1.190}$$

Check that the columns of $N(w)$ are mutually orthogonal and, if $w \in S^3$, are also unit vectors. It follows that $N(w)$ is an orthogonal matrix if $w \in S^3$. Check that

$$N(e_0) = I, \tag{11.1.191}$$

and therefore show, as was done for $M(w)$, that $N(w) \in SO(4, \mathbb{R})$. Thus the correspondence

$$\begin{pmatrix} w_0 \\ w_1 \\ w_2 \\ w_3 \end{pmatrix} \rightarrow N(w) = \begin{pmatrix} w_0 & w_1 & w_2 & w_3 \\ -w_1 & w_0 & w_3 & -w_2 \\ -w_2 & -w_3 & w_0 & w_1 \\ -w_3 & w_2 & -w_1 & w_0 \end{pmatrix} \tag{11.1.192}$$

also provides a mapping

$$S^3 \rightarrow SO(4, \mathbb{R}). \tag{11.1.193}$$

Review the relations (1.168) through (1.182). Show that there are completely analogous relations for the E^j and $N(w)$. Among other things, the 4×4 matrices $I, -E^1, -E^2, -E^3$ also provide a representation for quaternion algebra. Also verify that $M(w')$ and $N(w)$ commute.

Finally, in analogy with (4.3.166) and (4.3.174), define a matrix $O(w, w')$ by the rule

$$O(w, w') = N(w)M(w'). \tag{11.1.194}$$

Call the pair $(w, w') = S^3 \times S^3$ a double three-sphere. The relation (1.194) provides a two-to-one mapping of the double three-sphere into $SO(4, \mathbb{R})$,

$$S^3 \times S^3 \rightarrow SO(4, \mathbb{R}). \tag{11.1.195}$$

11.1.8. The purpose of this exercise is to determine the behavior of $w \cdot w$ when w evolves as in equations (1.42) or in equations (1.48) through (1.51), and to explore the nature of these equations. Let Ω be the vector

$$\Omega = \begin{pmatrix} 0 \\ \omega_1^{bf}/2 \\ \omega_2^{bf}/2 \\ \omega_3^{bf}/2 \end{pmatrix}. \tag{11.1.196}$$

Verify that the equations (1.48) through (1.51) can be written in the compact form

$$\dot{w} = -M(w)\Omega + k\epsilon w \tag{11.1.197}$$

with $M(w)$ defined by (1.156). It follows that

$$(w, \dot{w}) = -(w, M(w)\Omega) + k\epsilon(w, w). \tag{11.1.198}$$

Verify that

$$M^T(w)w = e_0 \tag{11.1.199}$$

with e_0 given by (1.159). Next verify that

$$(w, M(w)\Omega) = (M^T(w)w, \Omega) = (e_0, \Omega) = 0. \tag{11.1.200}$$

It follows that

$$(1/2)(d/dt)(w, w) = (w, \dot{w}) = k\epsilon(w, w), \tag{11.1.201}$$

and therefore $w \cdot w$ is conserved if $k = 0$, which is the case for the equations of motion (1.42). In particular, if $w \cdot w = 1$ initially, it will remain so.

What about the evolution of $w \cdot w$ when $k \neq 0$? Verify that

$$\dot{\epsilon} = -2(w, \dot{w}). \tag{11.1.202}$$

Show that, consequently, (1.201) and (1.202) together yield the relation

$$\dot{\epsilon} = -2k\epsilon(1 - \epsilon). \tag{11.1.203}$$

Verify that (1.203) has the implicit solution

$$\epsilon(t)/[1 - \epsilon(t)] = [\epsilon_0/(1 - \epsilon_0)] \exp[-2k(t - t_0)] \tag{11.1.204}$$

where

$$\epsilon_0 = \epsilon(t_0). \tag{11.1.205}$$

To solve (1.204) explicitly for $\epsilon(t)$, let

$$r(t) = [\epsilon_0/(1 - \epsilon_0)] \exp[-2k(t - t_0)]. \tag{11.1.206}$$

Show that

$$\epsilon(t) = r(t)/[1 + r(t)]. \tag{11.1.207}$$

Evidently, for $k > 0$, $\epsilon(t) \to 0$ as $t \to +\infty$, essentially exponentially. Correspondingly, $w \cdot w \to 1$ as $t \to +\infty$.

There is an alternate way of looking at the equations (1.43) through (1.46) or (1.47) through (1.51) that emphasizes linearity in w. Let $A(\boldsymbol{\omega}^{bf})$ be the matrix defined by the rule

$$A(\boldsymbol{\omega}^{bf}) = (1/2) \begin{pmatrix} 0 & \omega_1^{bf} & \omega_2^{bf} & \omega_3^{bf} \\ -\omega_1^{bf} & 0 & \omega_3^{bf} & -\omega_2^{bf} \\ -\omega_2^{bf} & -\omega_3^{bf} & 0 & \omega_1^{bf} \\ -\omega_3^{bf} & \omega_2^{bf} & -\omega_1^{bf} & 0 \end{pmatrix}. \tag{11.1.208}$$

Show that (1.43) through (1.46) can be written in the vector/matrix form

$$\dot{w} = A(\boldsymbol{\omega}^{bf})w. \tag{11.1.209}$$

Verify that A is antisymmetric, and therefore it immediately follows from (1.209) that

$$(w, \dot{w}) = (w, Aw) = 0. \tag{11.1.210}$$

Similarly, show that (1.48) through (1.51) can be written in the form

$$\dot{w} = A(\boldsymbol{\omega}^{bf})w + k\epsilon w. \tag{11.1.211}$$

In this case, it follows directly from (1.211) and the antisymmetry of A that

$$(w, \dot{w}) = (w, Aw) + k\epsilon(w, w) = k\epsilon(w, w), \tag{11.1.212}$$

as before.

11.1.9. The aim of the this exercise is to find the ω_j^{bf} corresponding to the Tait-Bryan angle parameterization (1.58). The tools for this purpose will be very similar to those employed in Exercise 1.3, which you should review. Our discussion begins with the key relation

$$(R^v)^{-1}\dot{R}^v = \boldsymbol{\omega}^{bf} \cdot \boldsymbol{L}. \tag{11.1.213}$$

Show that this relation follows from (1.56).

For R^v given by (1.58), verify that

$$(R^v)^{-1} = \exp(-\lambda_3 L^3)\exp(-\lambda_2 L^2)\exp(-\lambda_1 L^1) \tag{11.1.214}$$

and

$$\begin{aligned}\dot{R}^v &= \dot{\lambda}_1 L^1 \exp(\lambda_1 L^1)\exp(\lambda_2 L^2)\exp(\lambda_3 L^3)\\ &+ \exp(\lambda_1 L^1)\dot{\lambda}_2 L^2 \exp(\lambda_2 L^2)\exp(\lambda_3 L^3)\\ &+ \exp(\lambda_1 L^1)\exp(\lambda_2 L^2)\exp(\lambda_3 L^3)\dot{\lambda}_3 L^3.\end{aligned} \tag{11.1.215}$$

Next verify that $(R^v)^{-1}\dot{R}^v$ is given by the expression

$$\begin{aligned}(R^v)^{-1}\dot{R}^v &= \exp(-\lambda_3 L^3)\exp(-\lambda_2 L^2)\exp(-\lambda_1 L^1)\dot{\lambda}_1 L^1 \exp(\lambda_1 L^1)\exp(\lambda_2 L^2)\exp(\lambda_3 L^3)\\ &+ \exp(-\lambda_3 L^3)\exp(-\lambda_2 L^2)\exp(-\lambda_1 L^1)\exp(\lambda_1 L^1)\dot{\lambda}_2 L^2 \exp(\lambda_2 L^2)\exp(\lambda_3 L^3)\\ &+ \exp(-\lambda_3 L^3)\exp(-\lambda_2 L^2)\exp(-\lambda_1 L^1)\exp(\lambda_1 L^1)\exp(\lambda_2 L^2)\exp(\lambda_3 L^3)\dot{\lambda}_3 L^3.\end{aligned} \tag{11.1.216}$$

Simplify each of the three lines in (1.216) so that they become

$$\begin{aligned}&\exp(-\lambda_3 L^3)\exp(-\lambda_2 L^2)\exp(-\lambda_1 L^1)\dot{\lambda}_1 L^1 \exp(\lambda_1 L^1)\exp(\lambda_2 L^2)\exp(\lambda_3 L^3)\\ &\qquad = \dot{\lambda}_1 \exp(-\lambda_3 L^3)\exp(-\lambda_2 L^2) L^1 \exp(\lambda_2 L^2)\exp(\lambda_3 L^3),\end{aligned} \tag{11.1.217}$$

$$\begin{aligned}&\exp(-\lambda_3 L^3)\exp(-\lambda_2 L^2)\exp(-\lambda_1 L^1)\exp(\lambda_1 L^1)\dot{\lambda}_2 L^2\exp(\lambda_2 L^2)\exp(\lambda_3 L^3)\\&\qquad = \dot{\lambda}_2\exp(-\lambda_3 L^3)L^2\exp(\lambda_3 L^3),\end{aligned} \tag{11.1.218}$$

$$\begin{aligned}&\exp(-\lambda_3 L^3)\exp(-\lambda_2 L^2)\exp(-\lambda_1 L^1)\exp(\lambda_1 L^1)\exp(\lambda_2 L^2)\exp(\lambda_3 L^3)\dot{\lambda}_3 L^3\\&\qquad = \dot{\lambda}_3 L^3.\end{aligned} \tag{11.1.219}$$

Line (1.219) is as simple as we could desire. The next more complicated line is (1.218). Show, using the machinery of Exercise 8.2.10, that

$$\exp(-\lambda_3 L^3)L^2\exp(\lambda_3 L^3) = \cos(\lambda_3)L^2 + \sin(\lambda_3)L^1. \tag{11.1.220}$$

Thus, the right side of (1.218) becomes

$$\dot{\lambda}_2[\cos(\lambda_3)L^2 + \sin(\lambda_3)L^1]. \tag{11.1.221}$$

Finally, work on line (1.217). Show that

$$\exp(-\lambda_2 L^2)L^1\exp(\lambda_2 L^2) = \cos(\lambda_2)L^1 + \sin(\lambda_2)L^3. \tag{11.1.222}$$

Next show that

$$\begin{aligned}&\exp(-\lambda_3 L^3)[\cos(\lambda_2)L^1 + \sin(\lambda_2)L^3]\exp(\lambda_3 L^3)\\&= \sin(\lambda_2)L^3 + \cos(\lambda_2)\exp(-\lambda_3 L^3)L^1\exp(\lambda_3 L^3)\\&= \sin(\lambda_2)L^3 + \cos(\lambda_2)[\cos(\lambda_3)L^1 - \sin(\lambda_3)L^2].\end{aligned} \tag{11.1.223}$$

By combining (1.222) and (1.223), verify that

$$\begin{aligned}&\exp(-\lambda_3 L^3)\exp(-\lambda_2 L^2)L^1\exp(\lambda_2 L^2)\exp(\lambda_3 L^3)\\&= \sin(\lambda_2)L^3 + \cos(\lambda_2)[\cos(\lambda_3)L^1 - \sin(\lambda_3)L^2].\end{aligned} \tag{11.1.224}$$

Thus, the right side of (1.217) becomes

$$\dot{\lambda}_1\{\sin(\lambda_2)L^3 + \cos(\lambda_2)[\cos(\lambda_3)L^1 - \sin(\lambda_3)L^2]\}. \tag{11.1.225}$$

Now we have everything we need. By combining (1.216) through (1.225), show that

$$\begin{aligned}(R^v)^{-1}\dot{R}^v &= \dot{\lambda}_1\{\sin(\lambda_2)L^3 + \cos(\lambda_2)[\cos(\lambda_3)L^1 - \sin(\lambda_3)L^2]\}\\&+ \dot{\lambda}_2[\cos(\lambda_3)L^2 + \sin(\lambda_3)L^1]\\&+ \dot{\lambda}_3 L^3\\&= [\dot{\lambda}_1\cos(\lambda_2)\cos(\lambda_3) + \dot{\lambda}_2\sin(\lambda_3)]L^1\\&+ [-\dot{\lambda}_1\cos(\lambda_2)\sin(\lambda_3) + \dot{\lambda}_2\cos(\lambda_3)]L^2\\&+ [\dot{\lambda}_1\sin(\lambda_2) + \dot{\lambda}_3]L^3.\end{aligned} \tag{11.1.226}$$

Verify, upon equating coefficients of the L^j in (1.213) and (1.226), that there are the relations

$$\omega_1^{bf} = \dot{\lambda}_1 \cos(\lambda_2)\cos(\lambda_3) + \dot{\lambda}_2 \sin(\lambda_3), \tag{11.1.227}$$

$$\omega_2^{bf} = -\dot{\lambda}_1 \cos(\lambda_2)\sin(\lambda_3) + \dot{\lambda}_2 \cos(\lambda_3), \tag{11.1.228}$$

$$\omega_3^{bf} = \dot{\lambda}_1 \sin(\lambda_2) + \dot{\lambda}_3. \tag{11.1.229}$$

Finally, verify that inverting the relations (1.227) through (1.229) yields the equations of motion

$$\dot{\lambda}_1 = [1/\cos(\lambda_2)][\omega_1^{bf}\cos(\lambda_3) - \omega_2^{bf}\sin(\lambda_3)], \tag{11.1.230}$$

$$\dot{\lambda}_2 = \omega_1^{bf}\sin(\lambda_3) + \omega_2^{bf}\cos(\lambda_3), \tag{11.1.231}$$

$$\dot{\lambda}_3 = \omega_3^{bf} - \tan(\lambda_2)[\omega_1^{bf}\cos(\lambda_3) - \omega_2^{bf}\sin(\lambda_3)]. \tag{11.1.232}$$

Verify that these equations of motion are nonsingular for small λ_j. Note, however, that there are singularities when $\lambda_2 = \pm\pi/2$. What causes these singularities? Show that

$$\begin{aligned}
&\exp(\lambda_1 L^1)\exp[(\pi/2)L^2]\exp(\lambda_3 L^3)\\
&= \exp(\lambda_1 L^1)\exp[(\pi/2)L^2]\exp(\lambda_3 L^3)\exp[-(\pi/2)L^2]\exp[(\pi/2)L^2]\\
&= \exp(\lambda_1 L^1)\exp(\lambda_3 L^1)\exp[(\pi/2)L^2]\\
&= \exp[(\lambda_1 + \lambda_3)L^1]\exp[(\pi/2)L^2],
\end{aligned} \tag{11.1.233}$$

$$\begin{aligned}
&\exp(\lambda_1 L^1)\exp[-(\pi/2)L^2]\exp(\lambda_3 L^3)\\
&= \exp(\lambda_1 L^1)\exp[(-\pi/2)L^2]\exp(\lambda_3 L^3)\exp[(\pi/2)L^2]\exp[-(\pi/2)L^2]\\
&= \exp(\lambda_1 L^1)\exp(-\lambda_3 L^1)\exp[-(\pi/2)L^2]\\
&= \exp[(\lambda_1 - \lambda_3)L^1]\exp[-(\pi/2)L^2].
\end{aligned} \tag{11.1.234}$$

Verify that only the combination $(\lambda_1 + \lambda_3)$ is well defined when $\lambda_2 = \pi/2$, and only the combination $(\lambda_1 - \lambda_3)$ is well defined when $\lambda_2 = -\pi/2$. Therefore the parameterization (1.58) fails when $\lambda_2 = \pm\pi/2$.

11.1.10. The aim of this exercise, which is not easy, is to find the $\dot{\lambda}_j$ in terms of the ω_j^{bf} for the angle-axis parameterization (1.66). Although not essential, it is convenient for this purpose to use the $SU(2)$ version (1.146) of the $SO(3,\mathbb{R})$ relation (1.22). In analogy to (1.66), begin by writing

$$u(\boldsymbol{\lambda}) = \exp(\boldsymbol{\lambda}\cdot\boldsymbol{K}). \tag{11.1.235}$$

From the rule for differentiating the exponential function there is the result

$$(d/dt)u = u\ \mathrm{iex}(-\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)(d/dt)(\boldsymbol{\lambda}\cdot\boldsymbol{K}), \tag{11.1.236}$$

which can be rewritten in the form

$$\dot{u} = u\ \mathrm{iex}(-\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)(\dot{\boldsymbol{\lambda}}\cdot\boldsymbol{K}). \tag{11.1.237}$$

See Appendix C. Combine (1.146) and (1.237) to show that

$$\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K} = \mathrm{iex}(-\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)(\dot{\boldsymbol{\lambda}}\cdot\boldsymbol{K}). \tag{11.1.238}$$

Now for some daring steps. Show that, as in Section 10.3, the relation (1.238) can be inverted to become

$$\begin{aligned}\dot{\boldsymbol{\lambda}}\cdot\boldsymbol{K} &= [\mathrm{iex}(-\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)]^{-1}(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})\\ &= [I+(1/2)\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#+(1/12)(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^2+\cdots](\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})\\ &= (\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})+(1/2)\{(\boldsymbol{\lambda}\cdot\boldsymbol{K}),(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})\}\\ &\quad +(1/12)\{(\boldsymbol{\lambda}\cdot\boldsymbol{K}),\{(\boldsymbol{\lambda}\cdot\boldsymbol{K}),(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})\}\}+\cdots. \qquad (11.1.239)\end{aligned}$$

The result (1.239) is quite general in the sense that analogous results hold for any Lie group. For the specific case of $SU(2)$ we will seek to explicitly sum the series (1.239).

From Appendix C we know that there is the expansion

$$[\mathrm{iex}(-\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)]^{-1}=\sum_{m=0}^{\infty}b_m(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^m. \qquad (11.1.240)$$

Verify that insertion of (1.240) into (1.239) gives the result

$$\begin{aligned}\dot{\boldsymbol{\lambda}}\cdot\boldsymbol{K} &= [\sum_{m=0}^{\infty}b_m(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^m](\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})\\ &= b_0(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})+b_1(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})\\ &\quad +b_2(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^2(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})+b_3(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^3(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})\\ &\quad +b_4(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^4(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})+b_5(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^5(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})+\cdots. \qquad (11.1.241)\end{aligned}$$

Now evaluate the terms appearing in (1.241). Show that there are the results

$$(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})=\{\boldsymbol{\lambda}\cdot\boldsymbol{K},\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}\}=(\boldsymbol{\lambda}\times\boldsymbol{\omega}^{bf})\cdot\boldsymbol{K}, \qquad (11.1.242)$$

$$\begin{aligned}(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^2(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}) &= \{\boldsymbol{\lambda}\cdot\boldsymbol{K},(\boldsymbol{\lambda}\times\boldsymbol{\omega}^{bf})\cdot\boldsymbol{K}\}=[\boldsymbol{\lambda}\times(\boldsymbol{\lambda}\times\boldsymbol{\omega}^{bf})]\cdot\boldsymbol{K}\\ &= (\boldsymbol{\lambda}\cdot\boldsymbol{\omega}^{bf})(\boldsymbol{\lambda}\cdot\boldsymbol{K})-(\boldsymbol{\lambda}\cdot\boldsymbol{\lambda})(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}), \qquad (11.1.243)\end{aligned}$$

$$\begin{aligned}(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^3(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}) &= (\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^2(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})\\ &= -(\boldsymbol{\lambda}\cdot\boldsymbol{\lambda})\{\boldsymbol{\lambda}\cdot\boldsymbol{K},\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}\}\\ &= -(\boldsymbol{\lambda}\cdot\boldsymbol{\lambda})(\boldsymbol{\lambda}\times\boldsymbol{\omega}^{bf})\cdot\boldsymbol{K}\\ &= (i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda})(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}), \qquad (11.1.244)\end{aligned}$$

$$\begin{aligned}(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^4(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}) &= (\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^3(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})\\ &= (\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)(-1)(\boldsymbol{\lambda}\cdot\boldsymbol{\lambda})(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})\\ &= (i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda})(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^2(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}),\ \text{etc.} \qquad (11.1.245)\end{aligned}$$

Note the similarity of (3.7.201) and (1.244).

Verify that putting everything together gives the net result

$$\begin{aligned}
&[\sum_{m=0}^{\infty} b_m(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^m](\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}) = b_0(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})\\
&+b_1(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}) + b_3(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^3(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}) + \cdots\\
&+b_2(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^2(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}) + b_4(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^4(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}) + \cdots\\
&= b_0(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})\\
&+[(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})][b_1 + b_3(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda}) + b_5(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda})^2\cdots]\\
&+[(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^2(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})][b_2 + b_4(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda}) + b_6(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda})^2\cdots]\\
&= b_0(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})\\
&+[(\boldsymbol{\lambda}\times\boldsymbol{\omega}^{bf})\cdot\boldsymbol{K}][b_1 + b_3(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda}) + b_5(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda})^2\cdots]\\
&+[(\boldsymbol{\lambda}\cdot\boldsymbol{\omega}^{bf})(\boldsymbol{\lambda}\cdot\boldsymbol{K}) - (\boldsymbol{\lambda}\cdot\boldsymbol{\lambda})(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})][b_2 + b_4(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda}) + b_6(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda})^2\cdots].
\end{aligned} \tag{11.1.246}$$

Also verify that combining (1.241) and the last result in (1.246) gives the relation

$$\begin{aligned}
&\dot{\boldsymbol{\lambda}} = b_0\boldsymbol{\omega}^{bf}\\
&+(\boldsymbol{\lambda}\times\boldsymbol{\omega}^{bf})[b_1 + b_3(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda}) + b_5(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda})^2\cdots]\\
&+[(\boldsymbol{\lambda}\cdot\boldsymbol{\omega}^{bf})\boldsymbol{\lambda} - (\boldsymbol{\lambda}\cdot\boldsymbol{\lambda})\boldsymbol{\omega}^{bf}][b_2 + b_4(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda}) + b_6(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda})^2\cdots].
\end{aligned} \tag{11.1.247}$$

What remains to be done is to sum the series in (1.247). Begin by defining a quantity w by the rule

$$w = \sqrt{(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda})} = i|\boldsymbol{\lambda}|. \tag{11.1.248}$$

With this definition we have the relations

$$[b_1 + b_3(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda}) + b_5(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda})^2\cdots] = (1/w)\sum_{\text{odd } m} b_m w^m, \tag{11.1.249}$$

$$[b_2 + b_4(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda}) + b_6(i\boldsymbol{\lambda}\cdot i\boldsymbol{\lambda})^2\cdots] = (1/w^2)\sum_{\text{even } m>0} b_m w^m. \tag{11.1.250}$$

We also know, see Appendix C, that

$$\sum_{m=0}^{\infty} b_m w^m = w/[1-\exp(-w)], \tag{11.1.251}$$

from which it follows that

$$\sum_{m>0} b_m w^m = w/[1-\exp(-w)] - 1. \tag{11.1.252}$$

(Here we have used the result $b_0 = 1$, which you should check.) Verify the identity

$$\begin{aligned}
w/[1-\exp(-w)] &= w\exp(w/2)/[\exp(w/2)-\exp(-w/2)]\\
&= (w/2)[\cosh(w/2)+\sinh(w/2)]/\sinh(w/2)\\
&= w/2 + (w/2)\coth(w/2).
\end{aligned} \tag{11.1.253}$$

Use this identity to show that

$$\sum_{m>0} b_m w^m = [w/2] + [(w/2)\coth(w/2) - 1]. \tag{11.1.254}$$

From (1.254), by equating odd and even parts, show that

$$\sum_{\text{odd } m} b_m w^m = w/2, \tag{11.1.255}$$

$$\sum_{\text{even } m>0} b_m w^m = (w/2)\coth(w/2) - 1. \tag{11.1.256}$$

Use these results to show that

$$(1/w) \sum_{\text{odd } m} b_m w^m = 1/2, \tag{11.1.257}$$

$$(1/w^2) \sum_{\text{even } m>0} b_m w^m = [1/(2w)]\coth(w/2) - 1/w^2. \tag{11.1.258}$$

Verify that employing (1.248) in (1.258) yields the result

$$(1/w^2) \sum_{\text{even } m>0} b_m w^m = 1/|\boldsymbol{\lambda}|^2 - [1/(2|\boldsymbol{\lambda}|)]\cot(|\boldsymbol{\lambda}|/2). \tag{11.1.259}$$

At last, verify the final (and amazing) result

$$\dot{\boldsymbol{\lambda}} = \boldsymbol{\omega}^{bf} + (1/2)(\boldsymbol{\lambda} \times \boldsymbol{\omega}^{bf}) + [(\boldsymbol{\lambda} \cdot \boldsymbol{\omega}^{bf})\boldsymbol{\lambda} - (\boldsymbol{\lambda} \cdot \boldsymbol{\lambda})\boldsymbol{\omega}^{bf}]\{1/|\boldsymbol{\lambda}|^2 - [1/(2|\boldsymbol{\lambda}|)]\cot(|\boldsymbol{\lambda}|/2)\}. \tag{11.1.260}$$

Check that wherever $|\boldsymbol{\lambda}|$ appears in (1.260), it appears as an *even* power. Therefore, there is no overall ambiguity in (1.260) despite the sign ambiguity present in the definition (1.248). Show, moreover, that the right side of (1.260) is *analytic* in the components of $\boldsymbol{\lambda}$ for $|\boldsymbol{\lambda}| < 2\pi$, but is singular when $|\boldsymbol{\lambda}| = 2\pi$. As stated earlier, we expect this singularity to occur because we see from (3.7.188) and (3.7.202) that the individual components of $\boldsymbol{n}$ are not defined in terms of v or R when $\theta = |\boldsymbol{\lambda}| = 2\pi$.

There is another way of writing (1.260) that is of interest. Define a function $f(\boldsymbol{\lambda})$ by the rule

$$f(\boldsymbol{\lambda}) = 1/|\boldsymbol{\lambda}|^2 - [1/(2|\boldsymbol{\lambda}|)]\cot(|\boldsymbol{\lambda}|/2). \tag{11.1.261}$$

Verify that $f(\boldsymbol{\lambda})$ is even in $|\boldsymbol{\lambda}|$, is analytic in the components of $\boldsymbol{\lambda}$ for $|\boldsymbol{\lambda}| < 2\pi$, and is singular when $|\boldsymbol{\lambda}| = 2\pi$. Define a 3×3 matrix $M(\boldsymbol{\lambda})$ by the rule

$$M(\boldsymbol{\lambda}) = I + (1/2)(\boldsymbol{\lambda} \cdot \boldsymbol{L}) + f(\boldsymbol{\lambda})(\boldsymbol{\lambda} \cdot \boldsymbol{L})^2. \tag{11.1.262}$$

Verify that (1.260) can also be written in the form

$$\dot{\boldsymbol{\lambda}} = M(\boldsymbol{\lambda})\boldsymbol{\omega}^{bf}, \tag{11.1.263}$$

which highlights linearity in $\boldsymbol{\omega}^{bf}$ and the role of the matrix $\boldsymbol{\lambda} \cdot \boldsymbol{L}$.

11.1.11. Review Exercise 1.10. It found the $\dot{\lambda}_j$ in terms of the ω_j^{bf} for the parameterization (1.66). For some purposes it is useful to also find the ω_j^{bf} in terms of the $\dot{\lambda}_j$. That is the aim of this exercise.

There are at least two ways to proceed. The first begins with the relation (1.238) and makes an expansion of the form

$$\text{iex}(-\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)=\sum_{m=0}^{\infty}d_m(\#\boldsymbol{\lambda}\cdot\boldsymbol{K}\#)^m. \tag{11.1.264}$$

This expansion is then manipulated, in the spirit of Exercise 1.10, to find and sum expansions that specify the ω_j^{bf} in terms of the $\dot{\lambda}_j$.

A second way exploits more of what we already know from Exercise 1.10. Suppose we could invert the matrix $M(\boldsymbol{\lambda})$ given in (1.262). Then we could rewrite (1.263) in the form

$$\boldsymbol{\omega}^{bf}=[M(\boldsymbol{\lambda})]^{-1}\dot{\boldsymbol{\lambda}}, \tag{11.1.265}$$

and we would have found the ω_j^{bf} in terms of the $\dot{\lambda}_j$.

We now proceed to construct $[M(\boldsymbol{\lambda})]^{-1}$. Let $N(\boldsymbol{\lambda})$ be a 3×3 matrix of the form

$$N(\boldsymbol{\lambda})=I+a(\boldsymbol{\lambda})(\boldsymbol{\lambda}\cdot\boldsymbol{L})+b(\boldsymbol{\lambda})(\boldsymbol{\lambda}\cdot\boldsymbol{L})^2 \tag{11.1.266}$$

where $a(\boldsymbol{\lambda})$ and $(\boldsymbol{\lambda})$ are coefficients to be determined. Next form the product of $M(\boldsymbol{\lambda})$ and $N(\boldsymbol{\lambda})$. Verify that so doing yields the result

$$\begin{aligned} MN &= I+(1/2)(\boldsymbol{\lambda}\cdot\boldsymbol{L})+f(\boldsymbol{\lambda}\cdot\boldsymbol{L})^2\\ &+ a(\boldsymbol{\lambda}\cdot\boldsymbol{L})+(1/2)a(\boldsymbol{\lambda}\cdot\boldsymbol{L})^2+af(\boldsymbol{\lambda}\cdot\boldsymbol{L})^3\\ &+ b(\boldsymbol{\lambda}\cdot\boldsymbol{L})^2+(1/2)b(\boldsymbol{\lambda}\cdot\boldsymbol{L})^3+bf(\boldsymbol{\lambda}\cdot\boldsymbol{L})^4. \end{aligned} \tag{11.1.267}$$

Verify the property

$$(\boldsymbol{\lambda}\cdot\boldsymbol{L})^3=-|\boldsymbol{\lambda}|^2\boldsymbol{\lambda}\cdot\boldsymbol{L}, \tag{11.1.268}$$

and employ it in (1.267) to achieve the net result

$$\begin{aligned} & MN=I+(1/2)(\boldsymbol{\lambda}\cdot\boldsymbol{L})+f(\boldsymbol{\lambda}\cdot\boldsymbol{L})^2\\ + \quad & a(\boldsymbol{\lambda}\cdot\boldsymbol{L})+(1/2)a(\boldsymbol{\lambda}\cdot\boldsymbol{L})^2-|\boldsymbol{\lambda}|^2af(\boldsymbol{\lambda}\cdot\boldsymbol{L})\\ + \quad & b(\boldsymbol{\lambda}\cdot\boldsymbol{L})^2-|\boldsymbol{\lambda}|^2(1/2)b(\boldsymbol{\lambda}\cdot\boldsymbol{L})-|\boldsymbol{\lambda}|^2bf(\boldsymbol{\lambda}\cdot\boldsymbol{L})^2\\ = \quad & I+[(1/2)+a-|\boldsymbol{\lambda}|^2af-|\boldsymbol{\lambda}|^2(1/2)b](\boldsymbol{\lambda}\cdot\boldsymbol{L})\\ + \quad & [f+(1/2)a+b-|\boldsymbol{\lambda}|^2bf](\boldsymbol{\lambda}\cdot\boldsymbol{L})^2. \end{aligned} \tag{11.1.269}$$

Suppose we can arrange that the coefficients of $(\boldsymbol{\lambda}\cdot\boldsymbol{L})$ and $(\boldsymbol{\lambda}\cdot\boldsymbol{L})^2$ in the net result (1.269) vanish. So doing requires the conditions

$$(1/2)+a-|\boldsymbol{\lambda}|^2af-|\boldsymbol{\lambda}|^2(1/2)b=0 \tag{11.1.270}$$

and

$$f + (1/2)a + b - |\boldsymbol{\lambda}|^2 bf = 0. \tag{11.1.271}$$

If these conditions are met, it follows that $MN = I$, and therefore

$$N(\boldsymbol{\lambda}) = [M(\boldsymbol{\lambda})]^{-1}. \tag{11.1.272}$$

Verify that the linear equations (1.270)and (1.271) can be written in the standard form

$$(1 - |\boldsymbol{\lambda}|^2 f)a - (|\boldsymbol{\lambda}|^2/2)b = -1/2, \tag{11.1.273}$$

$$(1/2)a + (1 - |\boldsymbol{\lambda}|^2 f)b = -f. \tag{11.1.274}$$

Show from the definition (1.261) of f that

$$(1 - |\boldsymbol{\lambda}|^2 f) = (|\boldsymbol{\lambda}|/2)\cot(|\boldsymbol{\lambda}|/2). \tag{11.1.275}$$

Show that (1.273) and (1.274) have the solution

$$a = -(2/|\boldsymbol{\lambda}|^2)\sin^2(|\boldsymbol{\lambda}|/2), \tag{11.1.276}$$

$$b = (1/|\boldsymbol{\lambda}|^2)[1 - (1/|\boldsymbol{\lambda}|)\sin(|\boldsymbol{\lambda}|)]. \tag{11.1.277}$$

Evaluate $a(0)$ and $b(0)$ and verify that both $a(\boldsymbol{\lambda})$ and $b(\boldsymbol{\lambda})$ are analytic in the components of $\boldsymbol{\lambda}$ everywhere except at ∞.

11.1.12. The aim of this exercise is to explore the use of Cayley transforms and parameterizations for the purpose of integration on manifolds. Review Section 3.12 and Exercises 3.12.1, 3.12.5, and 3.12.6 to recall the subject of Cayley transforms for quadratic groups G. We will begin with the general case. Then in a following exercise, we will study in more detail the cases of $SO(3, \mathbb{R})$ and $SU(2)$, which are more tractable. Specifically, in this exercise we will study equations of motion of the form

$$\dot{M}(t) = M(t)A(t) \tag{11.1.278}$$

where $M(t)$ is expected to belong to some quadratic Lie group G and $A(t)$ belongs to its associated Lie algebra. What we seek is a way of numerically integrating (1.278) that guarantees $M(t)$ is in G even though the numerical solution may be locally exact only through terms of order h^m.

We could also study the related equations of motion of the form

$$\dot{N}(t) = \bar{A}(t)N(t) \tag{11.1.279}$$

but, as will be seen from some of the work of Exercise 2.7, this case is equivalent to the case (1.278) under the substitutions $N = M^{-1}$ and $\bar{A} = -A$.

From Appendix C we know in general that exact integration of (1.278) assures that $M(t)$ is in G. Here, before going further, your first task is to provide a simple proof of this fact in the case of quadratic groups.

Begin with the converse claim. Let $M(t)$ be some path in matrix space. By Taylor's theorem there is the result

$$M(t+dt)=M(t)+dt\dot{M}(t)+O[(dt)^2]. \tag{11.1.280}$$

Define a matrix $A(t)$ by the rule

$$A(t)=M^{-1}(t)\dot{M}(t). \tag{11.1.281}$$

Verify that (1.278) follows from (1.281). What remains is to determine the properties of $A(t)$.

For $M(t)$ to belong to a quadratic group G it must satisfy a relation of the form

$$M^T(t)LM(t)=L. \tag{11.1.282}$$

See Exercise 3.12.5. From (1.282) verify that

$$M^T(t+dt)LM(t+dt)=L. \tag{11.1.283}$$

Since $M(t)$ and $M(t+dt)$ are nearby matrices, it follows that the product $M^{-1}(t)M(t+dt)$ must be near the identity. Indeed, verify that we may write

$$\begin{aligned} M^{-1}(t)M(t+dt) &= M^{-1}(t)[M(t)+dt\dot{M}(t)]+O[(dt)^2] \\ &= I+dtM^{-1}(t)\dot{M}(t)+O[(dt)^2] \\ &= I+dtA(t)+O[(dt)^2] \\ &= \exp[dtA(t)]+O[(dt)^2]. \end{aligned} \tag{11.1.284}$$

Rewrite (1.284) in the form

$$M(t+dt)=M(t)\exp[dtA(t)]+O[(dt)^2]. \tag{11.1.285}$$

Show that employing this relation in (1.283) and equating powers of dt yields the condition

$$A^T(t)L+LA(t)=0, \tag{11.1.286}$$

which demonstrates that $A(t)$ belongs to the Lie algebra of G.

Next consider the direct claim. Suppose that $M(t)$ satisfies (1.278) and that $A(t)$ satisfies (1.286). Assume also that at some time t^0 there is the relation

$$M^T(t^0)LM(t^0)=L. \tag{11.1.287}$$

Such will be the case, in particular, if $M(t^0)$=I. Your task is to show that then (1.282) must hold for all t.

Begin by showing that (1.287) can be rewritten in the form

$$[M^{-1}(t^0)]^TL[M^{-1}(t^0)]=L. \tag{11.1.288}$$

Next, from the identity

$$M^{-1}(t)M(t)=I \tag{11.1.289}$$

and (1.278), show that

$$(d/dt)[M^{-1}(t)] = -A(t)M^{-1}(t). \tag{11.1.290}$$

As a further step show that

$$\begin{aligned}(d/dt)[(M^{-1})^T LM^{-1}] &= \{(d/dt)[(M^{-1})^T]\}LM^{-1} + (M^{-1})^T L(d/dt)(M^{-1}) \\ &= [(d/dt)(M^{-1})]^T LM^{-1} + (M^{-1})^T L(d/dt)(M^{-1}) \\ &= [-AM^{-1}]^T LM^{-1} + (M^{-1})^T L[-AM^{-1}] \\ &= -(M^{-1})^T[A^T L + LA]M^{-1} = 0. \end{aligned} \tag{11.1.291}$$

Verify that the unique solution to the differential equation (1.291) with the initial condition (1.288) is the relation

$$[M^{-1}(t)]^T L[M^{-1}(t)] = L. \tag{11.1.292}$$

Finally, show that (1.282) follows from (1.292).

With this background work out of the way, the main task of this exercise is to consider use of the Cayley parameterization. Specifically, for M we employ the Cayley parameterization

$$M = (I+V)(I-V)^{-1}, \tag{11.1.293}$$

see (3.12.36), and your task is to find the equation of motion for V. In particular, you are to show how this may be done starting from (1.278) rewritten as(1.281).

Begin by writing M in the form

$$M = BC \tag{11.1.294}$$

where

$$B = I + V \tag{11.1.295}$$

and

$$C = D^{-1} \tag{11.1.296}$$

with

$$D = I - V. \tag{11.1.297}$$

Show that the product differentiation rule yields the result

$$\dot{M} = \dot{B}C + B\dot{C}. \tag{11.1.298}$$

Simple calculation with (1.295) yields the result

$$\dot{B} = \dot{V}. \tag{11.1.299}$$

The calculation of $\dot{C}$ is more involved. Show from (1.296) and the product differentiation rule that

$$CD = I, \tag{11.1.300}$$

$$\dot{C}D + C\dot{D} = 0, \tag{11.1.301}$$

and therefore

$$\dot{C} = -C\dot{D}C. \tag{11.1.302}$$

Show that use of (1.297) gives the result

$$\dot{D} = -\dot{V}, \tag{11.1.303}$$

and therefore

$$\dot{C} = C\dot{V}C. \tag{11.1.304}$$

Verify that combining the results obtained so far gives the next conclusion

$$\dot{M} = \dot{V}C + BC\dot{V}C. \tag{11.1.305}$$

Manipulate some more. Verify the steps

$$\begin{aligned}\dot{M} &= \dot{V}C + BC\dot{V}C = C^{-1}C\dot{V}C + BC\dot{V}C = (C^{-1} + B)C\dot{V}C \\ &= (D + B)C\dot{V}C = [(I - V) + (I + V)]C\dot{V}C = 2C\dot{V}C.\end{aligned} \tag{11.1.306}$$

According to (1.281) what is needed is the quantity $M^{-1}\dot{M}$. Show that

$$M^{-1} = C^{-1}B^{-1} \tag{11.1.307}$$

and therefore

$$M^{-1}\dot{M} = 2C^{-1}B^{-1}C\dot{V}C. \tag{11.1.308}$$

Verify that B and C commute and therefore B^{-1} and C^{-1} commute. It follows that

$$C^{-1}B^{-1}C = B^{-1}C^{-1}C = B^{-1} \tag{11.1.309}$$

so that

$$M^{-1}\dot{M} = 2C^{-1}B^{-1}C\dot{V}C = 2B^{-1}\dot{V}C, \tag{11.1.310}$$

from which we conclude, with the aid of (1.281), that

$$A = 2B^{-1}\dot{V}C. \tag{11.1.311}$$

Solve (1.311) for $\dot{V}$ to yield the result

$$\dot{V} = (1/2)BAC^{-1} = (1/2)(I + V)A(I - V) = (1/2)(A + VA - AV - VAV), \tag{11.1.312}$$

which can be written as

$$\dot{V} = (1/2)(A + \{V, A\} - VAV). \tag{11.1.313}$$

You have found $\dot{V}$ in terms of A. Note that, in contrast to (1.82) whose right side contains an infinite number of terms, the right side of (1.313) contains only three terms.

Is this result sane? For a quadratic group G we know that V is in the Lie algebra. From the definition

$$\dot{V}(t) = \lim_{\epsilon \to 0}[V(t + \epsilon) - V(t)]/\epsilon \tag{11.1.314}$$

we see that only vector space operations are involved in the calculation of $\dot{V}(t)$, and therefore $\dot{V}(t)$ must also be in the Lie algebra of G. But is the right side of (1.313) in the Lie algebra of G? Evidently, since A is in the Lie algebra of G, the first two terms on the right side of (1.313) are in the Lie algebra of G. What about the third term VAV? According to Exercise 3.12.4 the condition for A and V to be in the Lie algebra of G is that

$$L^{-1}A^T L = -A, \tag{11.1.315}$$

$$L^{-1}V^T L = -V. \tag{11.1.316}$$

See (3.12.34). Verify it follows by matrix manipulation that

$$L^{-1}(VAV)^T L = -VAV, \tag{11.1.317}$$

and therefore VAV is also in the Lie algebra of G. Therefore (1.313) is sane at least to the extent that both its sides are in the Lie algebra of G.

To return to the main discussion, suppose (1.313) is integrated by some numerical integrator to find $V(t)$ under the assumption that V is initially in the Lie algebra of G. We repeat the key observation of Subsection 1.14: Examination of the usual numerical integration schemes, see Chapter 2, reveals that they all involve just linear combinations of the right side of the differential equation in question evaluated at various times and coordinate values. Therefore, if the right side is known to be in the Lie algebra of G for all evaluation points, then the result of numerically integrating such an equation is guaranteed to be in the Lie algebra of G, no matter what the local accuracy of the integrator or the step size employed. Since we have verified that the right side of (1.313) is in the Lie algebra of G, it follows that $V(t)$ will be in the Lie algebra of G if it is initially in the Lie algebra of G. Finally, since $V(t)$ is in the Lie algebra of G, it follows that $M(t)$ given by (1.293) is in G.

We have achieved our goal of, in effect, numerically integrating (1.278) in such a way that $M(t)$ is guaranteed to be in G. Note, however, that this procedure cannot be carried out globally since the Cayley parameterization (1.293) cannot be made globally. It may therefore be necessary to change coordinate systems (by left or right group translation) from time to time during the course of a numerical integration in order to stay clear of the singularities associated with any given Cayley parametrization.

Although we have achieved our goal, there is still one undesirable feature of our procedure. Namely, if A and V are $k \times k$ matrices, then the integration of (1.313) involves the integration of k^2 equations. Generally the group G has dimension considerably less than k^2. What we would like is a way of parameterizing the Lie algebra of G and a procedure that only involves the integration of differential equations for these parameters. In the next exercise we will illustrate such a procedure for the cases of $SO(3,\mathbb{R})$ and $SU(2)$ where the necessary operations can be carried out relatively easily.

We close this exercise with a small variation. Suppose the relations (1.293) through (1.307) remain in force, but the task is to find

$$\bar{A} = \dot{M}M^{-1} \tag{11.1.318}$$

rather than (1.281). Verify, using (1.306) and (1.307), that

$$\dot{M}M^{-1} = 2C\dot{V}CC^{-1}B^{-1} = 2C\dot{V}B^{-1}. \tag{11.1.319}$$

Show that solving (1.319) for $\dot{V}$ with the aid of (1.318) yields the result

$$\begin{aligned} \dot{V} &= (1/2)C^{-1}\bar{A}B = (1/2)D\bar{A}B = (1/2)I - V)\bar{A}(I+V) \\ &= (1/2)(\bar{A} - \{V, \bar{A}\} - V\bar{A}V). \end{aligned} \tag{11.1.320}$$

This result will be of use in Subsection 2.9.

11.1.13. The aim of this exercise is to apply the methods of the previous exercise to the cases of $SO(3, \mathbb{R})$ and $SU(2)$ including parameterization of the associated Lie algebras. In the case of $SO(3, \mathbb{R})$ we seek to integrate the equation

$$\dot{R} = R\, \boldsymbol{\omega}^{bf} \cdot \boldsymbol{L}. \tag{11.1.321}$$

Recall (1.18). And in the case of $SU(2)$ we seek to integrate (1.146) rewritten in the form

$$\dot{u} = u\, \boldsymbol{\omega}^{bf} \cdot \boldsymbol{K}. \tag{11.1.322}$$

In these two cases we write the Cayley parameterizations

$$R(\boldsymbol{\mu}) = (I + \boldsymbol{\mu} \cdot \boldsymbol{L})(I - \boldsymbol{\mu} \cdot \boldsymbol{L})^{-1} \tag{11.1.323}$$

and

$$u(\boldsymbol{\mu}) = (I + \boldsymbol{\mu} \cdot \boldsymbol{K})(I - \boldsymbol{\mu} \cdot \boldsymbol{K})^{-1}. \tag{11.1.324}$$

What you are to find is the relation between $\dot{\boldsymbol{\mu}}$ and $\boldsymbol{\omega}^{bf}$ for these two cases. At this point you should review Exercise 1.12 if you have not previously studied it.

For the case of $SO(3, \mathbb{R})$ compare (1.321) with (1.278) and compare (1.323) with (1.293). Show that in this case there are the correspondences

$$A = \boldsymbol{\omega}^{bf} \cdot \boldsymbol{L}, \tag{11.1.325}$$

$$V = \boldsymbol{\mu} \cdot \boldsymbol{L},\ \dot{V} = \dot{\boldsymbol{\mu}} \cdot \boldsymbol{L}. \tag{11.1.326}$$

For the case of $SU(2)$ compare (1.322) with (1.278) and compare (1.324) with (1.293). Show that in this case there are the correspondences

$$A = \boldsymbol{\omega}^{bf} \cdot \boldsymbol{K}, \tag{11.1.327}$$

$$V = \boldsymbol{\mu} \cdot \boldsymbol{K},\ \dot{V} = \dot{\boldsymbol{\mu}} \cdot \boldsymbol{K}. \tag{11.1.328}$$

What remains is to insert these results into (1.313) and to work out the consequences. Begin with the case of $SO(3, \mathbb{R})$. Show that use of (1.325) and (1.326) in (1.313) yields the result

$$\dot{\boldsymbol{\mu}} \cdot \boldsymbol{L} = (1/2)[\boldsymbol{\omega}^{bf} \cdot \boldsymbol{L} + \{\boldsymbol{\mu} \cdot \boldsymbol{L}, \boldsymbol{\omega}^{bf} \cdot \boldsymbol{L}\} - (\boldsymbol{\mu} \cdot \boldsymbol{L})(\boldsymbol{\omega}^{bf} \cdot \boldsymbol{L})(\boldsymbol{\mu} \cdot \boldsymbol{L})]. \tag{11.1.329}$$

Next manipulate the terms appearing on the right side of this equation. The commutator term is easy. It has the value

$$\{\boldsymbol{\mu} \cdot \boldsymbol{L}, \boldsymbol{\omega}^{bf} \cdot \boldsymbol{L}\} = (\boldsymbol{\mu} \times \boldsymbol{\omega}^{bf}) \cdot \boldsymbol{L}. \tag{11.1.330}$$

See (3.7.183). The evaluation of

$$(\boldsymbol{\mu}\cdot\boldsymbol{L})(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{L})(\boldsymbol{\mu}\cdot\boldsymbol{L}) = \ ? \tag{11.1.331}$$

is more tedious. By using the 3×3 matrix form for each of the factors in (1.331), multiplying out the matrices, and rewriting the result in the form $\boldsymbol{c}\cdot\boldsymbol{L}$, show that

$$(\boldsymbol{\mu}\cdot\boldsymbol{L})(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{L})(\boldsymbol{\mu}\cdot\boldsymbol{L}) = -(\boldsymbol{\mu}\cdot\boldsymbol{\omega}^{bf})(\boldsymbol{\mu}\cdot\boldsymbol{L}). \tag{11.1.332}$$

Verify that combining (1.329) through (1.332) gives the result

$$\dot{\boldsymbol{\mu}}\cdot\boldsymbol{L} = (1/2)[\boldsymbol{\omega}^{bf} + (\boldsymbol{\mu}\times\boldsymbol{\omega}^{bf}) + (\boldsymbol{\mu}\cdot\boldsymbol{\omega}^{bf})\boldsymbol{\mu}]\cdot\boldsymbol{L}. \tag{11.1.333}$$

From this result it follows that there are the equations of motion

$$\dot{\boldsymbol{\mu}} = (1/2)[\boldsymbol{\omega}^{bf} + (\boldsymbol{\mu}\times\boldsymbol{\omega}^{bf}) + (\boldsymbol{\mu}\cdot\boldsymbol{\omega}^{bf})\boldsymbol{\mu}]. \tag{11.1.334}$$

We have achieved the desired goal for the case of $SO(3,\mathbb{R})$. Note that, since R is 3×3 real, the integration of (1.321), and its Cayley counterpart (1.313), involves 9 real differential equations. By contrast, the integration of (1.334) involves only 3 real differential equations. Although (1.313) and its integration preserves lie algebraic structure, it does not exploit this structure. By contrast, based on the introduction of a basis, (1.334) exploits Lie algebraic structure. And, of course, if local errors of order h^{m+1} arise in the numerical integration of (1.334), the resulting $R(\boldsymbol{\mu})$ is still guaranteed to be in $SO(3,\mathbb{R})$ because of the Ansatz (1.323).

The case of $SU(2)$ requires more calculations, but these calculations involve only results already known. Verify that inserting (1.327) and (1.328) into (1.313) yields the relation

$$\dot{\boldsymbol{\mu}}\cdot\boldsymbol{K} = (1/2)[\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K} + \{\boldsymbol{\mu}\cdot\boldsymbol{K},\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}\} - (\boldsymbol{\mu}\cdot\boldsymbol{K})(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})(\boldsymbol{\mu}\cdot\boldsymbol{K})]. \tag{11.1.335}$$

Now manipulate the terms in (1.335) using known results. Recall that

$$\{\boldsymbol{\mu}\cdot\boldsymbol{K},\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}\} = (\boldsymbol{\mu}\times\boldsymbol{\omega}^{bf})\cdot\boldsymbol{K}. \tag{11.1.336}$$

See (3.7.182). Next recall that

$$(\boldsymbol{\mu}\cdot\boldsymbol{K})(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K}) = -(1/4)(\boldsymbol{\mu}\cdot\boldsymbol{\omega}^{bf})I + (1/2)(\boldsymbol{\mu}\times\boldsymbol{\omega}^{bf})\cdot\boldsymbol{K}. \tag{11.1.337}$$

See (3.7.176). It follows that

$$(\boldsymbol{\mu}\cdot\boldsymbol{K})(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})(\boldsymbol{\mu}\cdot\boldsymbol{K}) = -(1/4)(\boldsymbol{\mu}\cdot\boldsymbol{\omega}^{bf})(\boldsymbol{\mu}\cdot\boldsymbol{K}) + (1/2)[(\boldsymbol{\mu}\times\boldsymbol{\omega}^{bf})\cdot\boldsymbol{K}](\boldsymbol{\mu}\cdot\boldsymbol{K}). \tag{11.1.338}$$

Verify that

$$\begin{aligned}[(\boldsymbol{\mu}\times\boldsymbol{\omega}^{bf})\cdot\boldsymbol{K}](\boldsymbol{\mu}\cdot\boldsymbol{K}) &= -(1/4)[(\boldsymbol{\mu}\times\boldsymbol{\omega}^{bf})\cdot\boldsymbol{\mu}]I + (1/2)[(\boldsymbol{\mu}\times\boldsymbol{\omega}^{bf})\times\boldsymbol{\mu}]\cdot\boldsymbol{K}\\ &= 0 - (1/2)[\boldsymbol{\mu}\times(\boldsymbol{\mu}\times\boldsymbol{\omega}^{bf})]\cdot\boldsymbol{K} = -(1/2)[(\boldsymbol{\mu}\cdot\boldsymbol{\omega}^{bf})\boldsymbol{\mu} - (\boldsymbol{\mu}\cdot\boldsymbol{\mu})\boldsymbol{\omega}^{bf}]\cdot\boldsymbol{K},\end{aligned} \tag{11.1.339}$$

and that, consequently,

$$\begin{aligned}&(\boldsymbol{\mu}\cdot\boldsymbol{K})(\boldsymbol{\omega}^{bf}\cdot\boldsymbol{K})(\boldsymbol{\mu}\cdot\boldsymbol{K})\\&=-(1/4)(\boldsymbol{\mu}\cdot\boldsymbol{\omega}^{bf})(\boldsymbol{\mu}\cdot\boldsymbol{K})-(1/4)[(\boldsymbol{\mu}\cdot\boldsymbol{\omega}^{bf})\boldsymbol{\mu}-(\boldsymbol{\mu}\cdot\boldsymbol{\mu})\boldsymbol{\omega}^{bf}]\cdot\boldsymbol{K}\\&=[-(1/2)(\boldsymbol{\mu}\cdot\boldsymbol{\omega}^{bf})\boldsymbol{\mu}+(1/4)(\boldsymbol{\mu}\cdot\boldsymbol{\mu})\boldsymbol{\omega}^{bf}]\cdot\boldsymbol{K}.\end{aligned}\tag{11.1.340}$$

Verify that combining (1.335) through (1.340) gives the result

$$\dot{\boldsymbol{\mu}}\cdot\boldsymbol{K}=(1/2)[\boldsymbol{\omega}^{bf}+(\boldsymbol{\mu}\times\boldsymbol{\omega}^{bf})+(1/2)(\boldsymbol{\mu}\cdot\boldsymbol{\omega}^{bf})\boldsymbol{\mu}-(1/4)(\boldsymbol{\mu}\cdot\boldsymbol{\mu})\boldsymbol{\omega}^{bf}]\cdot\boldsymbol{K}.\tag{11.1.341}$$

From this result it follows that there are the equations of motion

$$\dot{\boldsymbol{\mu}}=(1/2)[\boldsymbol{\omega}^{bf}+(\boldsymbol{\mu}\times\boldsymbol{\omega}^{bf})+(1/2)(\boldsymbol{\mu}\cdot\boldsymbol{\omega}^{bf})\boldsymbol{\mu}-(1/4)(\boldsymbol{\mu}\cdot\boldsymbol{\mu})\boldsymbol{\omega}^{bf}].\tag{11.1.342}$$

We have achieved our goal for the case of $SU(2)$. Note that, since u is 2×2 complex, the integration of (1.322), and its Cayley counterpart, involves 8 real differential equations. By contrast, the integration of (1.342) again involves only 3 real differential equations. And, again, if local errors of order h^{m+1} arise in the numerical integration of (1.342), the resulting $u(\boldsymbol{\mu})$ is still guaranteed to be in $SU(2)$ because of the Ansatz (1.324).

What can be said about the singularity structure of Cayley parameterization? Evidently (1.293) is singular when

$$\det(I-V)=0,\tag{11.1.343}$$

that is, when V has +1 as an eigenvalue. Also, (1.311) can be rewritten in the form

$$A=2(I+V)^{-1}\dot{V}(I-V)^{-1}\tag{11.1.344}$$

so that the relation between A and $\dot{V}$ is singular when

$$\det(I+V)=0\ \text{ and }\ \det(I-V)=0.\tag{11.1.345}$$

Strangely enough, the general equation of motion (1.313), and the specific $SO(3,\mathbb{R})$ and $SU(2)$ equations of motion (1.334) and (1.342), appear to be singularity free. This appearance is deceptive, because, for example, (1.334) and (1.342) *are* singular in $\boldsymbol{\mu}$ at infinity, and there is the possibility that this singularity can be encountered in *finite* time.

To realize this possible singularity in the case of $SO(3,\mathbb{R})$, suppose that

$$\omega_j^{bf}=\Omega\delta_{j3},\tag{11.1.346}$$

where Ω is a constant, and make the Ansatz

$$\mu_j=f(t)\delta_{j3}\tag{11.1.347}$$

where f satisfies the initial condition

$$f(0)=0,\tag{11.1.348}$$

but is otherwise to be determined. Show that putting this Ansatz into the equation of motion (1.334) yields the result

$$\dot{f} = (1/2)\Omega(1 + f^2). \tag{11.1.349}$$

Show that the solution to (1.349) with the initial condition (1.348) is

$$f = \tan(\Omega t/2). \tag{11.1.350}$$

Review Exercise 3.12.6. Show that the corresponding $\boldsymbol{\lambda}$ is given by

$$\lambda_j = \Omega t \delta_{j3} \tag{11.1.351}$$

and therefore R is given by

$$R = \exp(\Omega t L^3). \tag{11.1.352}$$

See (3.12.61). Observe that (1.350), and hence (1.347), are singular when $\Omega t = \pi$ and therefore when $|\boldsymbol{\lambda}| = \pi$ which, according to Exercise 3.12.6, is the expected condition for singularity in the case of $SO(3, \mathbb{R})$.

To realize this possible singularity in the case of $SU(2)$, suppose that (1.346) through (1.348) continue to hold. Show that putting this Ansatz into (1.342) yields the differential equation

$$\dot{f} = (\Omega/2)(1 + f^2/4), \tag{11.1.353}$$

and that this equation has the solution

$$f = 2\tan(\Omega t/4). \tag{11.1.354}$$

Show that the corresponding $\boldsymbol{\lambda}$ is again given by

$$\lambda_j = \Omega t \delta_{j3} \tag{11.1.355}$$

and therefore u is given by

$$u = \exp(\Omega t K^3). \tag{11.1.356}$$

See (3.12.73). Observe that (1.354), and hence (1.347), are singular when $\Omega t = 2\pi$ and therefore when $|\boldsymbol{\lambda}| = 2\pi$ which, according to Exercise 3.12.6, is the expected condition for singularity in the case of $SU(2)$.

At this point you, the observant reader, might object that the quaternion parameter equations of motion (1.43) through (1.46), which were lauded as being wonderful, are also singular in the components of w at infinity. They are indeed singular at infinity, but this singularity cannot be reached in *real* time because these equations preserve the condition $w \cdot w = 1$. This singularity can be reached in *complex* time, but because the equations of motion are *linear* in w, the time must be *infinite* complex. Therefore, for quaternion parameterization, there are no singularities in finite time, real or complex.

11.2 Numerical Integration on Manifolds: Spin and Qubits

As a second example of integration on manifolds, we consider an equation that occurs in several contexts. Let $\boldsymbol{s}(t)$ be a time-dependent 3-dimensional vector that evolves according to the rule

$$d\boldsymbol{s}/dt = \bar{\boldsymbol{\omega}}(t) \times \boldsymbol{s} \tag{11.2.1}$$

where $\bar{\boldsymbol{\omega}}(t)$ is some other specified, possibly time dependent, 3-dimensional vector. This equation is called the *Bloch* equation in the context of nuclear magnetic resonance (NMR or MRI) and electron spin resonance (ESR), and the *Bargmann-Michel-Telegdi* (BMT or *Thomas*-BMT or *Thomas-Frenkel*-BMT) equation in the context of determining the evolution of a particle's spin polarization vector as it traverses some accelerator or beam line. It also occurs in the context of rigid-body motion. See (1.105) in Exercise 1.1. Finally, it is relevant to the general quantum mechanical treatment of two level systems (qubits), and therefore plays a prominent role in quantum information theory and quantum computation. See Exercises 2.15 and 2.16. Note also that the equation of motion (1.6.112) can be written as

$$d\boldsymbol{v}/dt = [-(q/m^*)\boldsymbol{B}] \times \boldsymbol{v}, \tag{11.2.2}$$

which also appears to be of the form (2.1). See Section 3 for further discussion of this observation.

Suppose our task is to find $\boldsymbol{s}(t)$ given $\bar{\boldsymbol{\omega}}(t)$ and the initial vector

$$\boldsymbol{s}^0 = \boldsymbol{s}(t^0) \tag{11.2.3}$$

at time t^0.[17] It is easily verified that the equations of motion (2.1) preserve $\boldsymbol{s} \cdot \boldsymbol{s}$. Define a quantity s^* by the rule

$$s^* = \sqrt{\boldsymbol{s}^0 \cdot \boldsymbol{s}^0}, \tag{11.2.4}$$

and let S^{2*} denote the two-sphere of radius s^* imbedded in the ambient space E^3. With this notation, we may say that the equations of motion (2.1) preserve S^{2*}, and are equations of motion on the manifold S^{2*} embedded in the ambient space E^3. Note also that the equations of motion (2.1) are *linear*. Therefore, for many applications, there is no loss in generality in taking $\boldsymbol{s}^0$ to be a unit vector: $\boldsymbol{s}^0 \in S^2$ where, as usual, S^2 denotes the unit two-sphere ($s^* = 1$). Solutions corresponding to initial conditions that are not unit vectors can be obtained by simple scaling of the solutions corresponding to unit-vector initial conditions. Therefore, unless specifically specified otherwise, we will work with the S^2 case. However, where useful, we will treat explicitly the general S^{2*} case.

Our task is to integrate (2.1) numerically in such a way that, even if local errors of order h^{m+1} are made, the solution is guaranteed to be in S^2. One procedure for so doing is to employ any of the standard methods of Chapter 2 for one step at a time (thereby making local errors of order h^{m+1}) and to then project after each step the resulting $\boldsymbol{s}$ back onto S^2 by simple scaling. Alternatively, we may consider other approaches that parameterize S^2 or exploit other features of the problem. The purpose of this section is to describe several such approaches.

[17] For a discussion of the inverse problem, namely given $\boldsymbol{s}(t)$ find $\bar{\boldsymbol{\omega}}(t)$, see Exercise 2.1.

11.2.1 Constrained Cartesian Coordinates Are Not Global

In Cartesian coordinates (2.1) yields the three coupled linear equations

$$\dot{s}_1 = \bar{\omega}_2 s_3 - \bar{\omega}_3 s_2, \tag{11.2.5}$$

$$\dot{s}_2 = \bar{\omega}_3 s_1 - \bar{\omega}_1 s_3, \tag{11.2.6}$$

$$\dot{s}_3 = \bar{\omega}_1 s_2 - \bar{\omega}_2 s_1. \tag{11.2.7}$$

To recapitulate, if they are integrated numerically by a method that makes local errors of order h^{m+1}, the quantity $\boldsymbol{s} \cdot \boldsymbol{s}$ will generally be locally preserved only through terms of order h^m. If we wish to preserve the condition $\boldsymbol{s} \in S^2$ to machine precision, one simple procedure is to project $\boldsymbol{s} \in E^3$ back onto S^2 by simple scaling after each integration step.

Another procedure, assuming $\boldsymbol{s}^0 \in S^2$, is to enforce the condition $\boldsymbol{s} \in S^2$ by making the definition

$$s_1 = +(1 - s_2^2 - s_3^2)^{1/2} \tag{11.2.8}$$

and inserting this definition/constraint into the equations (2.6) and (2.7) to yield the equations of motion

$$\dot{s}_2 = \bar{\omega}_3 (1 - s_2^2 - s_3^2)^{1/2} - \bar{\omega}_1 s_3, \tag{11.2.9}$$

$$\dot{s}_3 = \bar{\omega}_1 s_2 - \bar{\omega}_2 (1 - s_2^2 - s_3^2)^{1/2}. \tag{11.2.10}$$

In essence, we have parameterized S^2 by the coordinates s_2 and s_3. If $\boldsymbol{s}$ is initially in the front hemisphere, $s_1 > 0$, these equations for s_2 and s_3 can be integrated as long as $(s_2^2 + s_3^2) < 1$. However, they become singular if $\boldsymbol{s}$ crosses the plane $s_1 = 0$ (which divides the front and rear hemispheres), as is certainly mathematically/physically possible, and they therefore cannot be generally used to produce a global solution.

11.2.2 Polar-Angle Coordinates Are Not Global

Yet another possibility is to parameterize $\boldsymbol{s} \in S^2$ by the use of polar-angle coordinates θ and ϕ. Make the Ansatz

$$s_1 = \sin(\theta)\cos(\phi), \tag{11.2.11}$$

$$s_2 = \sin(\theta)\sin(\phi), \tag{11.2.12}$$

$$s_3 = \cos(\theta). \tag{11.2.13}$$

This Ansatz guarantees $\boldsymbol{s} \in S^2$. From (2.11) through (2.13) we find the relations

$$\dot{s}_1 = \dot{\theta}\cos(\theta)\cos(\phi) - \dot{\phi}\sin(\theta)\sin(\phi), \tag{11.2.14}$$

$$\dot{s}_2 = \dot{\theta}\cos(\theta)\sin(\phi) + \dot{\phi}\sin(\theta)\cos(\phi), \tag{11.2.15}$$

$$\dot{s}_3 = -\dot{\theta}\sin(\theta). \tag{11.2.16}$$

Solving these relations for $\dot{\theta}$ and $\dot{\phi}$ yields the results

$$\dot{\theta} = -[1/\sin(\theta)]\dot{s}_3, \tag{11.2.17}$$

$$\dot{\phi} = -[1/\sin(\theta)][\dot{s}_1 \sin(\phi) - \dot{s}_2 \cos(\phi)]. \tag{11.2.18}$$

Finally, combining (2.5) through (2.7) and (2.11) through (2.13) with (2.17) and (2.18) yields the equations of motion

$$\dot{\theta} = -\bar{\omega}_1 \sin(\phi) + \bar{\omega}_2 \cos(\phi), \tag{11.2.19}$$

$$\dot{\phi} = \bar{\omega}_3 - [\cos(\theta)/\sin(\theta)][\bar{\omega}_1 \cos(\phi) + \bar{\omega}_2 \sin(\phi)]. \tag{11.2.20}$$

Observe that (2.20) is singular at the poles $\theta = 0$ and $\theta = \pi$. (Note that ϕ is ill defined at the poles, and consequently these singularities are to be expected). Therefore these equations are also not suitable for finding global solutions.

11.2.3 Local Tangent-Space Coordinates

One way to insure that a numerical trajectory will remain on an invariant manifold is to introduce local coordinates in the ambient space at some point on the manifold, locally parameterize the manifold, formulate differential equations for these parameters, and finally numerically integrate the differential equations for the parameters. By so doing, even if single-step errors of order h^{m+1} occur in the parameters over the process of integration, the resulting trajectory is guaranteed to remain on the manifold. We will illustrate this process for the equation of motion (2.1) and, for future use, we will explicitly treat the general case S^{2*}.

Let $\boldsymbol{s}^b$ be some point on the the manifold S^{2*} at the *beginning* of an integration step to be initiated at time t^b. Parameterize points in the ambient space and in the vicinity of $\boldsymbol{s}^b$ by writing

$$\boldsymbol{s}(t) = \boldsymbol{s}^b + \boldsymbol{s}^v(t) \tag{11.2.21}$$

where $\boldsymbol{s}^v(t)$ is a *variable* vector with the property

$$\boldsymbol{s}^v(t^b) = 0. \tag{11.2.22}$$

Next work to insure that $\boldsymbol{s}(t)$ remains on S^{2*} as t varies. Let $\boldsymbol{e}_1$, $\boldsymbol{e}_2$, $\boldsymbol{e}_3$ be a fixed right-hand triad of orthonormal vectors. Construct a second right-hand triad of orthonormal vectors $\boldsymbol{f}_1$, $\boldsymbol{f}_2$, $\boldsymbol{f}_3$ associated with $\boldsymbol{s}^b$ as follows: Begin by defining

$$\boldsymbol{f}_1 = \boldsymbol{s}^b/s^*. \tag{11.2.23}$$

Next examine the quantities $\boldsymbol{e}_j \cdot \boldsymbol{f}_1$ and select the $\boldsymbol{e}_j$ for which $\boldsymbol{e}_j \cdot \boldsymbol{f}_1$ has the least magnitude. This will the $\boldsymbol{e}_j$ that is most nearly perpendicular to $\boldsymbol{s}^b$. Use this $\boldsymbol{e}_j$, call it $\boldsymbol{e}_k$, to define the unit vector

$$\boldsymbol{f}_2 = (\boldsymbol{e}_k \times \boldsymbol{f}_1)/|\boldsymbol{e}_k \times \boldsymbol{f}_1|. \tag{11.2.24}$$

By construction $\boldsymbol{f}_2$ is perpendicular to $\boldsymbol{f}_1$,

$$\boldsymbol{f}_1 \cdot \boldsymbol{f}_2 = 0. \tag{11.2.25}$$

Finally, define the unit vector $\boldsymbol{f}_3$ by the rule

$$\boldsymbol{f}_3 = \boldsymbol{f}_1 \times \boldsymbol{f}_2. \tag{11.2.26}$$

Continue on by expressing $\boldsymbol{s}^v(t)$ in the form

$$\boldsymbol{s}^v(t) = s_1^{vf}(t)\boldsymbol{f}_1 + s_2^{vf}(t)\boldsymbol{f}_2 + s_3^{vf}(t)\boldsymbol{f}_3. \tag{11.2.27}$$

Here the superscript f reminds us that the $\boldsymbol{f}_j$ have been employed as a basis. That is, the s_j^{vf} are the components of $\boldsymbol{s}^v$ with respect to the $\boldsymbol{f}_j$ basis. By construction, vectors of the form

$$\boldsymbol{s}^{tan} = \boldsymbol{s}^b + s_2^{vf}\boldsymbol{f}_2 + s_3^{vf}\boldsymbol{f}_3 \tag{11.2.28}$$

comprise the *tangent* space to S^{2*} at $\boldsymbol{s}^b$; and we may view s_2^{vf} and s_3^{vf} as being tangent-space coordinates. Combining (2.21) and (2.27) gives the result

$$\boldsymbol{s}(t) = [s^* + s_1^{vf}(t)]\boldsymbol{f}_1 + s_2^{vf}(t)\boldsymbol{f}_2 + s_3^{vf}(t)\boldsymbol{f}_3. \tag{11.2.29}$$

Now enforce the condition that $\boldsymbol{s}(t)$ lie in S^{2^*}. So doing gives the relation

$$[s^* + s_1^{vf}(t)]^2 + [s_2^{vf}(t)]^2 + [s_3^{vf}(t)]^2 = (s^*)^2, \tag{11.2.30}$$

from which it follows that

$$s_1^{vf}(t) = \{(s^*)^2 - [s_2^{vf}(t)]^2 - [s_3^{vf}(t)]^2\}^{1/2} - s^*. \tag{11.2.31}$$

We see that in the vicinity of $\boldsymbol{s}^b$ the manifold S^{2*} can be parameterized by s_2^{vf} and s_3^{vf} providing (2.31) is used to specify s_1^{vf}.

What remains is to find equations of motion for s_2^{vf} and s_3^{vf}. The first step is to expand $\bar{\boldsymbol{\omega}}(t)$ in terms of the $\boldsymbol{f}_j$ by writing

$$\bar{\boldsymbol{\omega}}(t) = \sum_j [\bar{\boldsymbol{\omega}}(t)\cdot\boldsymbol{f}_j]\boldsymbol{f}_j = \sum_j \bar{\omega}_j^f(t)\boldsymbol{f}_j \tag{11.2.32}$$

where we have made the definition

$$\bar{\omega}_j^f(t) = \bar{\boldsymbol{\omega}}(t)\cdot\boldsymbol{f}_j \tag{11.2.33}$$

and again the superscript f reminds us that the $\boldsymbol{f}_j$ has been employed as a basis. Use of (2.29) gives for the left side of (2.1) the result

$$d\boldsymbol{s}(t)/dt = \dot{s}_1^{vf}(t)\boldsymbol{f}_1 + \dot{s}_2^{vf}(t)\boldsymbol{f}_2 + \dot{s}_3^{vf}(t)\boldsymbol{f}_3. \tag{11.2.34}$$

Use of (2.29) and (2.32) gives for the right side side of (2.1) the result

$$\begin{aligned}\bar{\boldsymbol{\omega}}(t)\times\boldsymbol{s} &= [\bar{\omega}_2^f(t)s_3^{vf}(t) - \bar{\omega}_3^f(t)s_2^{vf}(t)]\boldsymbol{f}_1\\ &+ \{\bar{\omega}_3^f(t)[s^* + s_1^{vf}(t)] - \bar{\omega}_1^f(t)s_3^{vf}(t)\}\boldsymbol{f}_2\\ &+ \{\bar{\omega}_1^f(t)s_2^{vf}(t) - \bar{\omega}_2^f(t)[s^* + s_1^{vf}(t)]\}\boldsymbol{f}_3.\end{aligned} \tag{11.2.35}$$

Now equate the second and third components of (2.34) and (2.35) to find the relations

$$\dot{s}_2^{vf}(t) = \bar{\omega}_3^f(t)[s^* + s_1^{vf}(t)] - \bar{\omega}_1^f(t)s_3^{vf}(t), \tag{11.2.36}$$

$$\dot{s}_3^{vf}(t) = \bar{\omega}_1^f(t)s_2^{vf}(t) - \bar{\omega}_2^f(t)[s^* + s_1^{vf}(t)]. \tag{11.2.37}$$

Finally, employing (2.31) in (2.36) and (2.37) yields the equations of motion

$$\dot{s}_2^{vf}(t) = \bar{\omega}_3^f(t)\{(s^*)^2 - [s_2^{vf}(t)]^2 - [s_3^{vf}(t)]^2\}^{1/2} - \bar{\omega}_1^f(t)s_3^{vf}(t), \tag{11.2.38}$$

$$\dot{s}_3^{vf}(t) = \bar{\omega}_1^f(t)s_2^{vf}(t) - \bar{\omega}_2^f(t)\{(s^*)^2 - [s_2^{vf}(t)]^2 - [s_3^{vf}(t)]^2\}^{1/2}. \tag{11.2.39}$$

It is these equations that are to be numerically integrated from the time t^b to the time $t^b + h$ (or perhaps $t^b + kh$) starting with the initial conditions $s_2^{vf}(t^b) = s_3^{vf}(t^b) = 0$.[18] Then, once $\boldsymbol{s}^v(t^b + h)$ [or perhaps $\boldsymbol{s}^v(t^b + kh)$] has been obtained, $\boldsymbol{s}(t^b + h)$ [or perhaps $\boldsymbol{s}(t^b + kh)$] is given by (2.21).[19] At this point, the whole process just described is repeated as often as desired. That is, the vectors $\boldsymbol{f}_j$ are reconstructed based on the most recently obtained $\boldsymbol{s}$, etc.

We close this subsection by noting that, as was the case with constrained Cartesian coordinates and polar-angle coordinates, there are only *two* equations to be integrated, namely (2.38) and (2.39), whereas working in the ambient space E^3 as in (2.5) through (2.7) required the integration of *three* equations.

11.2.4 Exploiting Connection with Rigid-Body Kinematics

We next consider approaches related to those used in the rigid-body case. Suppose we seek the general solution of (2.1). Observe, with the aid of the matrices L^j, that (2.1) can be written in the form

$$d\boldsymbol{s}/dt = (\bar{\boldsymbol{\omega}} \cdot \boldsymbol{L})\boldsymbol{s}. \tag{11.2.40}$$

Recall (3.7.200). Also, since (2.1) is linear, we may make the general Ansatz

$$\boldsymbol{s}(t) = S(t)\boldsymbol{s}^0 \tag{11.2.41}$$

where S is a 3×3 matrix to be determined. Now insert (2.41) into (2.40) to find the relation

$$\dot{S}(t)\boldsymbol{s}^0 = (\bar{\boldsymbol{\omega}} \cdot \boldsymbol{L})S(t)\boldsymbol{s}^0. \tag{11.2.42}$$

Since we wish $\boldsymbol{s}^0$ to be an arbitrary unit vector and (2.42) is linear, the relation (2.42) is equivalent to the matrix differential equation

$$\dot{S}(t) = (\bar{\boldsymbol{\omega}} \cdot \boldsymbol{L})S(t), \tag{11.2.43}$$

and from (2.3) and (2.41) we find the initial condition

$$S(t^0) = I. \tag{11.2.44}$$

In summary, solving (2.43) with the initial condition (2.44) provides the general solution to (2.1). This approach has the advantage that once $S(t)$ has been found, $\boldsymbol{s}(t)$ can be found

[18] Observe that the equations of motion (2.38) and (2.39) agree with the equations of motion (2.9) and (2.10) in the case where the $\boldsymbol{f}_j$ agree with the $\boldsymbol{e}_j$ and $s^* = 1$, which is a nice check of our work.

[19] If $k > 1$ is attempted, one must monitor $[(s_2^v)^2 + (s_3^v)^2]$ to ensure that the square root singularity in (2.31) is not approached too closely.

for *all* initial conditions $\boldsymbol{s}^0$ by the easy computation (2.41). In essence, $S(t)$ is the transfer map associated with the differential equation (2.1). By contrast, if (2.5) through (2.7), or (2.9) and (2.10), or (2.19) and (2.20), or (2.38) and (2.39) are employed, these differential equations must be integrated afresh for each different initial $\boldsymbol{s}^0$.

At this point we observe that (2.43) and (1.18) are quite similar. Indeed, suppose we pass back and forth between matrices R and S by the rule

$$R = S^{-1} \text{ or } S = R^{-1}, \tag{11.2.45}$$

from which it follows that

$$R(t^0) = I. \tag{11.2.46}$$

Then it can be shown from (2.43) that there is the relation

$$\dot{R} = R(\boldsymbol{\omega}^{bf} \cdot \boldsymbol{L}) \tag{11.2.47}$$

with

$$\boldsymbol{\omega}^{bf} = -\bar{\boldsymbol{\omega}}. \tag{11.2.48}$$

See Exercise 2.7.

We know that R is orthogonal and therefore, from (2.45), we conclude that S is also orthogonal. We also observe that in the orthogonal case the relation (2.45) is equivalent to the computationally simpler relation

$$R = S^T \text{ or } S = R^T. \tag{11.2.49}$$

We see that all the machinery developed for and the conclusions drawn about rigid body motion in Section 1 are also applicable here.

11.2.5 What Just Happened? Generalizations

In the last subsection we saw that the problem of determining the path $\boldsymbol{s}(t)$ in the manifold S^2 and satisfying the *manifold* differential equation (2.1) [or, equivalently (2.40)] with the initial condition (2.3) was converted into finding a path $S(t)$ in the group $SO(3,\mathbb{R})$ that satisfied the *group* differential equation (2.43) with the initial condition (2.44). We also observe that the group $SO(3,\mathbb{R})$ acts *transitively* on the manifold S^2. (Evidently any point in S^2 can be rotated into any other point in S^2.) Therefore S^2 is a homogeneous space with respect to the group $SO(3,\mathbb{R})$, and is in fact isomorphic to the coset space $SO(3,\mathbb{R})/SO(2,\mathbb{R})$. Recall the discussion of homogeneous spaces in Subsections 5.12.3 through 5.12.5.

Observe moreover that (2.41) is a relation that sends the path $S(t)$ in the group $SO(3,\mathbb{R})$ to the path $\boldsymbol{s}(t)$ in the manifold S^2. The path $S(t)$ begins at the identity, see (2.44), and the path $\boldsymbol{s}(t)$ begins at $\boldsymbol{s}^0$. In the language of manifold theory, the relation (2.41) is said to *push forward* the path $S(t) \in SO(3,\mathbb{R})$ to produce the path $\boldsymbol{s}(t) \in S^2$.[20] Correspondingly, the group differential equation (2.43) is the *pullback* to $SO(3,\mathbb{R})$ of the S^2 manifold differential equation (2.1). Finally, since $SO(3,\mathbb{R})$ acts on and *preserves* S^2, we are guaranteed that $\boldsymbol{s}(t)$ will be in S^2 if $S(t)$ is in $SO(3,\mathbb{R})$. Therefore a numerical integrator that preserves

[20] Put another way, $\boldsymbol{s}(t)$ is the orbit of $\boldsymbol{s}^0$ under the action of the $SO(3,\mathbb{R})$ group elements $S(t)$.

the $SO(3,\mathbb{R})$ group manifold for any group differential equation automatically produces a pushed-forward path that is guaranteed to lie in the S^2 manifold.

It should now be evident that this strategy has some general applicability. Suppose we are given a manifold, call it Γ, perhaps embedded in some larger ambient space, and a first-order differential equation for a path, call it $\gamma(t)$, that from the differential equation and the initial condition γ^0 can be shown to lie in Γ. Suppose we can find a group, call it $\mathcal{G}$, such that $\mathcal{G}$ acts transitively on Γ so that Γ is a homogeneous space with respect to $\mathcal{G}$. Introduce the notation $G(t)$ to denote a path in $\mathcal{G}$ with the beginning point

$$G(t^0) = I. \tag{11.2.50}$$

Then this path in $\mathcal{G}$ may be pushed forward to produce a path $\gamma(t)$ in Γ. In a notation analogous to that of Subsection 5.12.4, we write

$$\gamma(t) = T_{G(t)}(\gamma^0) \tag{11.2.51}$$

where T_G describes the action of $\mathcal{G}$ on Γ. With some suitable parameterization of $\mathcal{G}$, perhaps involving an embedding in an ambient space of its own, the differential equation for $\gamma(t)$ can be pulled back to produce a group differential equation for $G(t)$. And if this group differential equation can be integrated numerically in such a way that the group manifold is preserved, say either by parameterizing $\mathcal{G}$ or its Lie algebra or by integrating in its Lie algebra, then the $\gamma(t)$ given by (2.51) will be (locally) accurate through terms of order h^m and is guaranteed to lie in Γ. Thus, whatever means can be found to integrate group differential equations numerically in such a way that the group manifold is preserved, by the same means one has found a procedure to numerically integrate in a manifold preserving way all differential equations defined on the homogeneous spaces associated with $\mathcal{G}$.

11.2.6 Exploiting an Important Simplification: Lie Taylor Factorization and Lie Taylor Runge Kutta

We observe that there is one way in which the context for (2.43) is simpler than that for (1.18). Namely, in (2.43) $\bar{\boldsymbol{\omega}}$ is assumed to be a *given* function of t *independent* of S whereas in (1.18) $\boldsymbol{\omega}^{bf}$ must be determined dynamically from the Euler equations (1.19) through (1.21) which themselves may depend on R. This simplification can be used to good advantage in integrating (2.43) numerically. Of course, since $S(t)$ is orthogonal when computed exactly, we will want a numerical integrator that guarantees this property for the numerical solution. In this subsection we will see how this simplification can be exploited to perform what we call *Lie Taylor factorization*, and in so doing we will produce in effect a special kind of Runge Kutta that we will call *Lie Taylor Runge Kutta*.

Subsequently, in the next two subsections, we will explore how this requirement that $\bar{\boldsymbol{\omega}}(t)$ be known in advance can be relaxed in the context of two other special forms of Runge Kutta that we will call *factored Lie Runge Kutta* and *Magnus Lie Runge Kutta*. A final subsection revisits the use of integration in the Lie algebra.

For the purposes of this subsection it is convenient to capitalize on the homomorphism between $SO(3,\mathbb{R})$ and $SU(2)$. Let u be the 2×2 matrix that satisfies the differential equation

$$\dot{u}(t) = (\bar{\boldsymbol{\omega}} \cdot \boldsymbol{K})u(t) \tag{11.2.52}$$

with the initial condition

$$u(t^0) = I. \tag{11.2.53}$$

By the results of Section 1.3, $u(t)$ is uniquely defined. Also, it can be shown that $u(t)$ is in $SU(2)$ for all t. See Exercise 2.4. Next, use the homomorphism between $SO(3,\mathbb{R})$ and $SU(2)$ to define $S(t)$ by the rule

$$S_{\alpha\beta}(t) = S_{\alpha\beta}[u(t)] = (1/2)\mathrm{tr}[u^\dagger(t)\sigma^\alpha u(t)\sigma^\beta]. \tag{11.2.54}$$

See (8.2.54). Then it can be shown that $S(t)$ satisfies (2.43) with the initial condition (2.44). See Exercise 2.5.[21]

Since u is a 2×2 complex matrix, it lives in the ambient space $\mathbb{C}^4 = E^8$. However, we know that u is also in $SU(2)$ for all t. Therefore (2.52) is an equation of motion on the three-dimensional manifold $SU(2)$ imbedded in the ambient space E^8. Based on the assumption that $\bar{\boldsymbol{\omega}}$ is a given function of t, what we seek is a method, beyond those already described, for numerically integrating (2.52) in such a way that u is guaranteed to remain in $SU(2)$.[22] Such a method is presented below.

In the language of Section 2.6, let H be the duration of a meso integration step, and suppose H is divided into M micro steps each of duration $h = H/M$. Let t^b be the time at which a meso step is to be initiated so that we wish to integrate from t^b to $t^b + H$. We also suppose that

$$u^b = u(t^b) \tag{11.2.55}$$

is known and is an element of $SU(2)$.

Introduce a relative time τ by the rule

$$t = t^b + \tau \tag{11.2.56}$$

so that, in terms of τ, we wish to integrate from $\tau = \tau^0 = 0$ to $\tau = \tau^M = H$. Also, define a quantity $\hat{\boldsymbol{\omega}}(\tau)$ by the rule

$$\hat{\boldsymbol{\omega}}(\tau) = \bar{\boldsymbol{\omega}}(t^b + \tau). \tag{11.2.57}$$

In the spirit of (1.52), write

$$u(t) = u^v(t)u^b \tag{11.2.58}$$

with u^v being a variable matrix near the identity satisfying

$$u^v(t^b) = I. \tag{11.2.59}$$

[21] Why *can* we move from $SO(3,\mathbb{R})$ matrices to $SU(2)$ matrices? It can be shown that the solution to any matrix differential equation of the forms $dM/dt = AM$ or $dM/dt = MA$ is governed by the Lie algebra generated by the $A(t)$ at different times. See the paper by *E. Wichmann* cited in the Bibliography for Chapter 10. See also Section 10.3 and Appendix C. We may therefore use any set of matrices that obey the Lie algebra in question. In our case this Lie algebra is $so(3,\mathbb{R})$ or, equivalently, $su(2)$. Why *should* we move from $SO(3,\mathbb{R})$ to $SU(2)$? It is computationally advantageous to use the matrices that have the lowest dimension. In this case, the matrices with lowest dimension that satisfy $su(2)$ commutation rules are the K^j.

[22] By methods "already described" we mean that u, like R, can be parameterized in terms of Euler or Tait-Bryan angles or angle-axis or quaternion or Cayley parameters, or can be integrated in its Lie algebra; and so doing produces equations of motion analogous to those for rigid-body motion.

Finally, define a variable matrix $\hat{u}^v(\tau)$ by the rule

$$\hat{u}^v(\tau) = u^v(t^b + \tau). \tag{11.2.60}$$

It then follows from (2.52), (2.53), and (2.55) through (2.60) that $\hat{u}^v(\tau)$ obeys the equation of motion

$$d\hat{u}^v(\tau)/d\tau = [\hat{\boldsymbol{\omega}}(\tau) \cdot \boldsymbol{K}]\hat{u}^v(\tau) \tag{11.2.61}$$

with the initial condition

$$\hat{u}^v(0) = I. \tag{11.2.62}$$

Suppose the $M+1$ vectors $\hat{\boldsymbol{\omega}}^n$ are given with

$$\hat{\boldsymbol{\omega}}^n = \hat{\boldsymbol{\omega}}(\tau^{(n)}) \tag{11.2.63}$$

and

$$\tau^{(n)} = nh \;\text{ for }\; n = 0, 1, \cdots M. \tag{11.2.64}$$

We want to use this information to find a numerical approximation to $\hat{u}^v(H)$ that is both accurate and exactly in $SU(2)$. How to proceed? First use the $M+1$ vectors $\hat{\boldsymbol{\omega}}^n$ to produce a polynomial *fit* to $\hat{\boldsymbol{\omega}}(\tau)$ of the form

$$\hat{\boldsymbol{\omega}}^{\text{fit}}(\tau) = \sum_{m=0}^{M} \boldsymbol{c}_m \tau^m. \tag{11.2.65}$$

Here we have introduced the notation $\tau^{(n)}$ to denote the n^{th} sampling point and the notation τ^m to denote the m^{th} power of τ. We also remark that some sampling procedure other than equal spacing could be used to obtain the expansion (2.65). All we need for present purposes are the expansion coefficients $\boldsymbol{c}_m$ in (2.65), and need not specify how they are to be obtained.

Next, assume that $\hat{u}^v(\tau)$ has a *factorized Taylor* approximation of the form

$$\hat{u}^v(\tau) \simeq \hat{u}^{v\text{fac}}(\tau) = \exp(\tau^{M+1}\boldsymbol{d}_M \cdot \boldsymbol{K})\exp(\tau^M \boldsymbol{d}_{M-1} \cdot \boldsymbol{K}) \cdots \exp(\tau \boldsymbol{d}_0 \cdot \boldsymbol{K}). \tag{11.2.66}$$

Note that this Ansatz satisfies the relation

$$\hat{u}^{v\text{fac}}(0) = I, \tag{11.2.67}$$

as is desirable in view of (2.62).[23] Finally, insert (2.65) and (2.66) into (2.61) to yield the approximate relation

$$d\hat{u}^{v\text{fac}}(\tau)/d\tau = [\hat{\boldsymbol{\omega}}^{\text{fit}}(\tau) \cdot \boldsymbol{K}]\hat{u}^{v\text{fac}}(\tau), \tag{11.2.68}$$

which can also be written in the form

$$[d\hat{u}^{v\text{fac}}(\tau)/d\tau][\hat{u}^{v\text{fac}}(\tau)]^{-1} = \hat{\boldsymbol{\omega}}^{\text{fit}}(\tau) \cdot \boldsymbol{K}. \tag{11.2.69}$$

[23] The justification for the Ansatz (2.66) is as follows: Under the assumption that $\hat{\boldsymbol{\omega}}(\tau)$ is analytic in τ, the solution $\hat{u}^v(\tau)$ to (2.61) will be analytic in τ. See Section 1.3. It follows that the logarithm of $\hat{u}^v(\tau)$, the $su(2)$ element corresponding to $\hat{u}^v(\tau)$, can be expanded as a power series in τ assuming $\hat{u}^v(\tau)$ is near the origin, which it is for small τ. See Subsection 3.7.1. Finally, we may pass from a power series in the exponent to a product of exponentials with the aid of the BCH series, thereby yielding the factorization (2.66).

The strategy now is to equate powers of τ on both sides of (2.69) to determine the vectors $\boldsymbol{d}_n$ in terms of the vectors $\boldsymbol{c}_m$.

As an example, let us see how this procedure plays out for the case $M = 3$. Then there are the results

$$\hat{\boldsymbol{\omega}}^{\text{fit}}(\tau) = \boldsymbol{c}_0 + \boldsymbol{c}_1\tau + \boldsymbol{c}_2\tau^2 + \boldsymbol{c}_3\tau^3, \tag{11.2.70}$$

$$\hat{u}^{v\text{fac}}(\tau) = \exp(\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(\tau\boldsymbol{d}_0\cdot\boldsymbol{K}), \tag{11.2.71}$$

$$[\hat{u}^{v\text{fac}}(\tau)]^{-1} = \exp(-\tau\boldsymbol{d}_0\cdot\boldsymbol{K})\exp(-\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(-\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(-\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K}), \tag{11.2.72}$$

$$\begin{aligned}
d\hat{u}^{v\text{fac}}(\tau)/d\tau \;=\;& \exp(\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})(\boldsymbol{d}_0\cdot\boldsymbol{K})\exp(\tau\boldsymbol{d}_0\cdot\boldsymbol{K})\\
+\;& \exp(\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})(2\tau\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(\tau\boldsymbol{d}_0\cdot\boldsymbol{K})\\
+\;& \exp(\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})(3\tau^2\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(\tau\boldsymbol{d}_0\cdot\boldsymbol{K}).\\
+\;& (4\tau^3\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(\tau\boldsymbol{d}_0\cdot\boldsymbol{K}).
\end{aligned} \tag{11.2.73}$$

Next, in view of (2.69), combine (2.72) and (2.73) to yield the result

$$\begin{aligned}
&[d\hat{u}^{v\text{fac}}(\tau)/d\tau][\hat{u}^{v\text{fac}}(\tau)]^{-1} =\\
&\exp(\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})(\boldsymbol{d}_0\cdot\boldsymbol{K})\exp(\tau\boldsymbol{d}_0\cdot\boldsymbol{K})\times\\
&\exp(-\tau\boldsymbol{d}_0\cdot\boldsymbol{K})\exp(-\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(-\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(-\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\\
&+\exp(\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})(2\tau\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(\tau\boldsymbol{d}_0\cdot\boldsymbol{K})\times\\
&\exp(-\tau\boldsymbol{d}_0\cdot\boldsymbol{K})\exp(-\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(-\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(-\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\\
&+\exp(\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})(3\tau^2\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(\tau\boldsymbol{d}_0\cdot\boldsymbol{K})\times\\
&\exp(-\tau\boldsymbol{d}_0\cdot\boldsymbol{K})\exp(-\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(-\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(-\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\\
&+(4\tau^3\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(\tau\boldsymbol{d}_0\cdot\boldsymbol{K})\times\\
&\exp(-\tau\boldsymbol{d}_0\cdot\boldsymbol{K})\exp(-\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(-\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(-\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K}).
\end{aligned} \tag{11.2.74}$$

After cancellations of various factors in (2.74) against their inverses, (2.74) simplifies to become

$$\begin{aligned}
&[d\hat{u}^{v\text{fac}}(\tau)/d\tau][\hat{u}^{v\text{fac}}(\tau)]^{-1} =\\
&\exp(\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})(\boldsymbol{d}_0\cdot\boldsymbol{K})\times\\
&\exp(-\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(-\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(-\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\\
&+\exp(\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})(2\tau\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(-\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(-\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\\
&+\exp(\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})(3\tau^2\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(-\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\\
&+(4\tau^3\boldsymbol{d}_3\cdot\boldsymbol{K}).
\end{aligned} \tag{11.2.75}$$

Now expand the various terms on the right side of (2.75) as power series in τ through terms of order τ^3. The first term becomes

$$\begin{aligned}
&\exp(\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})(\boldsymbol{d}_0\cdot\boldsymbol{K})\times\\
&\exp(-\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(-\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(-\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K}) =\\
&\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})(\boldsymbol{d}_0\cdot\boldsymbol{K})\exp(-\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(-\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K}) + O(\tau^4).
\end{aligned} \tag{11.2.76}$$

Observe that

$$\begin{aligned}\exp(\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})(\boldsymbol{d}_0\cdot\boldsymbol{K})\exp(-\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K}) &= \boldsymbol{d}_0\cdot\boldsymbol{K}+\tau^2\{\boldsymbol{d}_1\cdot\boldsymbol{K}),\boldsymbol{d}_0\cdot\boldsymbol{K}\}+O(\tau^4)\\ &= \boldsymbol{d}_0\cdot\boldsymbol{K}+\tau^2(\boldsymbol{d}_1\times\boldsymbol{d}_0)\cdot\boldsymbol{K}+O(\tau^4).\end{aligned}\tag{11.2.77}$$

See (3.7.182) and (8.2.5). It follows that

$$\begin{aligned}&\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})(\boldsymbol{d}_0\cdot\boldsymbol{K})\exp(-\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(-\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})=\\ &\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})(\boldsymbol{d}_0\cdot\boldsymbol{K})\exp(-\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})+\tau^2(\boldsymbol{d}_1\times\boldsymbol{d}_0)\cdot\boldsymbol{K}+O(\tau^4)=\\ &\boldsymbol{d}_0\cdot\boldsymbol{K}+\tau^3\{\boldsymbol{d}_2\cdot\boldsymbol{K}),\boldsymbol{d}_0\cdot\boldsymbol{K}\}+\tau^2(\boldsymbol{d}_1\times\boldsymbol{d}_0)\cdot\boldsymbol{K}+O(\tau^4)=\\ &\boldsymbol{d}_0\cdot\boldsymbol{K}+\tau^3(\boldsymbol{d}_2\times\boldsymbol{d}_0)\cdot\boldsymbol{K}+\tau^2(\boldsymbol{d}_1\times\boldsymbol{d}_0)\cdot\boldsymbol{K}+O(\tau^4).\end{aligned}\tag{11.2.78}$$

The net result is that the first term has the expansion

$$\begin{aligned}&\exp(\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})(\boldsymbol{d}_0\cdot\boldsymbol{K})\times\\ &\exp(-\tau^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(-\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(-\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})=\\ &\boldsymbol{d}_0\cdot\boldsymbol{K}+\tau^2(\boldsymbol{d}_1\times\boldsymbol{d}_0)\cdot\boldsymbol{K}+\tau^3(\boldsymbol{d}_2\times\boldsymbol{d}_0)\cdot\boldsymbol{K}+O(\tau^4).\end{aligned}\tag{11.2.79}$$

What remains is to expand the second and third terms. The second term has the expansion

$$\begin{aligned}&\exp(\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})(2\tau\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(-\tau^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(-\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})=\\ &2\tau\boldsymbol{d}_1\cdot\boldsymbol{K}+O(\tau^4).\end{aligned}\tag{11.2.80}$$

The third term has the expansion

$$\exp(\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})(3\tau^2\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(-\tau^4\boldsymbol{d}_3\cdot\boldsymbol{K})=3\tau^2\boldsymbol{d}_2\cdot\boldsymbol{K}+O(\tau^4).\tag{11.2.81}$$

The fourth term, $4\tau^3\boldsymbol{d}_3\cdot\boldsymbol{K}$, is already as simple as possible.

Now gather all the terms together. The result, as a power series in τ, is that (2.75) becomes

$$\begin{aligned}&[d\hat{u}^{v\mathrm{fac}}(\tau)/d\tau][\hat{u}^{v\mathrm{fac}}(\tau)]^{-1}=\\ &\boldsymbol{d}_0\cdot\boldsymbol{K}+2\tau\boldsymbol{d}_1\cdot\boldsymbol{K}+\tau^2[3\boldsymbol{d}_2+(\boldsymbol{d}_1\times\boldsymbol{d}_0)]\cdot\boldsymbol{K}+\tau^3[4\boldsymbol{d}_3+(\boldsymbol{d}_2\times\boldsymbol{d}_0)]\cdot\boldsymbol{K}+O(\tau^4).\end{aligned}\tag{11.2.82}$$

We are ready to equate powers of τ on both sides of (2.69). So doing yields the relations

$$\boldsymbol{d}_0=\boldsymbol{c}_0,\tag{11.2.83}$$

$$2\boldsymbol{d}_1=\boldsymbol{c}_1,\tag{11.2.84}$$

$$3\boldsymbol{d}_2 + (\boldsymbol{d}_1 \times \boldsymbol{d}_0) = \boldsymbol{c}_2, \tag{11.2.85}$$

$$4\boldsymbol{d}_3 + (\boldsymbol{d}_2 \times \boldsymbol{d}_0) = \boldsymbol{c}_3; \tag{11.2.86}$$

and these relations have the solution

$$\boldsymbol{d}_0 = \boldsymbol{c}_0, \tag{11.2.87}$$

$$\boldsymbol{d}_1 = \boldsymbol{c}_1/2, \tag{11.2.88}$$

$$\boldsymbol{d}_2 = (1/3)\boldsymbol{c}_2 + (1/6)(\boldsymbol{c_0} \times \boldsymbol{c}_1), \tag{11.2.89}$$

$$\boldsymbol{d}_3 = (1/4)\boldsymbol{c}_3 + (1/12)(\boldsymbol{c_0} \times \boldsymbol{c}_2) + (1/24)[\boldsymbol{c_0} \times (\boldsymbol{c_0} \times \boldsymbol{c}_1)]. \tag{11.2.90}$$

In the case $M = 3$ we have found the approximation

$$\hat{u}^v(H) \simeq \hat{u}^{v\text{fac}}(H) = \exp(H^4\boldsymbol{d}_3 \cdot \boldsymbol{K})\exp(H^3\boldsymbol{d}_2 \cdot \boldsymbol{K})\exp(H^2\boldsymbol{d}_1 \cdot \boldsymbol{K})\exp(H\boldsymbol{d}_0 \cdot \boldsymbol{K}) \tag{11.2.91}$$

with the coefficients $\boldsymbol{d}_0$ through $\boldsymbol{d}_3$ given by (2.87) through (2.90). And in general we have the result

$$\hat{u}^v(H) \simeq \hat{u}^{v\text{fac}}(H) = \cdots \exp(H^{n+1}\boldsymbol{d}_n \cdot \boldsymbol{K})\exp(H^n\boldsymbol{d}_{n-1} \cdot \boldsymbol{K}) \cdots \exp(H\boldsymbol{d}_0 \cdot \boldsymbol{K}). \tag{11.2.92}$$

What can be said about the error in this approximation? We begin by observing that any given $\boldsymbol{d}_n$ depends only on the $\boldsymbol{c}_m$ with $m \leq n$, and is independent of M as long as $M \geq n$. Also if we use $(M + 1)$ sampling points to find $(M + 1)$ values of $\hat{\boldsymbol{\omega}}$, and use these values to compute $\boldsymbol{c}_0$ through $\boldsymbol{c}_M$, then we can find $\boldsymbol{d}_0$ through $\boldsymbol{d}_M$ using relations of the kind (2.87) through (2.90). With this information we can compute $\hat{u}^v(H)$ given by

$$\hat{u}^v(H) \simeq \hat{u}^{v\text{fac}}(H) = \exp(H^{M+1}\boldsymbol{d}_M \cdot \boldsymbol{K})\exp(H^M\boldsymbol{d}_{M-1} \cdot \boldsymbol{K}) \cdots \exp(H\boldsymbol{d}_0 \cdot \boldsymbol{K}), \tag{11.2.93}$$

which is locally accurate through terms of order H^{M+1}, and exactly in $SU(2)$. In effect, we have produced a special kind of Runge Kutta that we will call *Lie Taylor Runge Kutta*. Indeed, in the terminology of Runge-Kutta integration, we may think of $(M + 1)$ as being the number of stages. Thus, the local accuracy of $\hat{u}^v(H)$ equals the number of stages. Comparison of this result with the entries of Table 2.3.1 shows that this performance of Lie Taylor Runge Kutta equals or exceeds that of ordinary explicit Runge-Kutta; and reference to (T.166) and (T.169) shows that Lie Taylor Runge Kutta has one order lower accuracy than Newton Cotes for odd values of $M + 1$, and equal accuracy for even values of $M + 1$.[24]

There is one other observation that is worth consideration. In determining the $\boldsymbol{c}_0$ through $\boldsymbol{c}_M$ there is no need for the sampling points to lie within the interval of meso-step integration as was done in (2.64). Suppose, for example, that we wish to integrate from the time $t = t^0$ to the time $t = t^0 + T$ using N meso steps each of duration

$$H = T/N. \tag{11.2.94}$$

[24] Note that here we are demanding more than the integration of an equation of the form (T.157) since in this instance the right side of (2.52) depends on u as well as t.

Also suppose that over the *full* interval $t \in [t^0, t^0 + T]$ the vector function $\bar{\boldsymbol{\omega}}(t)$ can be well fit by a polynomial of degree M in t with vector coefficients. Under this assumption, the coefficients of this polynomial can be obtained by evaluating $\bar{\boldsymbol{\omega}}(t)$ at $(M+1)$ sampling points. Use this global polynomial to form the local expansion (2.65) for each meso-step integration, and use a relation of the form (2.93) to find the result for each meso-step integration. Then the local error for each meso step is of order H^{M+2}, and the global error in integrating from the time $t = t^0$ to the time $t = t^0 + T$ is given by

$$\text{global error} \approx NH^{M+2} = N(T/N)^{M+2} = T(T/N)^{M+1}. \tag{11.2.95}$$

We see that the global *integration* error can be made arbitrarily small by increasing N (and, correspondingly, decreasing H) *without* changing the number of sampling points $(M + 1)$. Put another way, for sufficiently large N, the full global error is *only* the error associated with making the global polynomial fit to $\bar{\boldsymbol{\omega}}(t)$ in the full interval $t \in [t^0, t^0 + T]$. The goodness of this polynomial fit in turn depends only on the analytic properties of $\bar{\boldsymbol{\omega}}(t)$. In particular, a good fit is easiest to achieve when $\bar{\boldsymbol{\omega}}(t)$ does not vary too rapidly over the interval $[t^0, t^0 + T]$.[25] Finally, we may truncate (2.93) at M' with $M' < M$ and still achieve convergence, but at the slower rate of

$$\text{global error} \approx NH^{M'+2} = N(T/N)^{M'+2} = T(T/N)^{M'+1}. \tag{11.2.96}$$

In this case we only need to work out formulas for the $\boldsymbol{d}_n$ with $n \leq M'$

Where applicable, employing the ideas just described should result in a substantial savings in computer time because only $(M + 1)$ evaluations of $\bar{\boldsymbol{\omega}}(t)$ are required for the full integration run.

11.2.7 Factored Lie Runge Kutta

Purpose, Motivation, and Plan

The purpose of this subsection is to describe a special form of Runge Kutta designed to preserve group properties. We will see that for integrating equations of the form (2.43), unlike Lie Taylor Runge Kutta, it does not require the values of $\bar{\boldsymbol{\omega}}(t)$ in advance.

By way of motivation, suppose we seek to integrate (2.43) by the simplest Runge-Kutta method, namely the crude Euler method of Section 2.2. Doing so yields the stepping formula

$$S^{n+1} = S^n + h\dot{S}^n = S^n + h[\bar{\boldsymbol{\omega}}(t^n) \cdot \boldsymbol{L}]S^n = \{I + h[\bar{\boldsymbol{\omega}}(t^n) \cdot \boldsymbol{L}]\}S^n. \tag{11.2.97}$$

Observe that $\{I + h[\bar{\boldsymbol{\omega}}(t^n) \cdot \boldsymbol{L}]\}$ is generally not an orthogonal matrix. Consequently, S^{n+1} will generally not be orthogonal even if S^n is. Consider, instead, the modified stepping formula

$$S^{n+1} = \exp[h\bar{\boldsymbol{\omega}}(t^n) \cdot \boldsymbol{L}]S^n. \tag{11.2.98}$$

As can be seen by expanding $\exp[h\bar{\boldsymbol{\omega}}(t^n) \cdot \boldsymbol{L}]$ in powers of h, (2.98) and (2.97) agree through terms of order h. Therefore, use of (2.98) provides an integration algorithm that is of the

[25] More precisely, $\bar{\boldsymbol{\omega}}(t)$ needs to be analytic in the complex t plane in a disk of radius $T/2$ and centered on $t = t^0 + T/2$.

same order as the Euler method (2.97). However the algorithm (2.98), even though (like Euler) it makes local errors of order h^2, preserves $SO(3,\mathbb{R})$ exactly because $\exp[h\bar{\boldsymbol{\omega}}(t^n)\cdot\boldsymbol{L}]$ is orthogonal.

The relation (2.98) provides an example of what we call a *factored Lie Runge-Kutta* algorithm designed to preserve some group, in this case $SO(3,\mathbb{R})$.[26] We now discuss the possibility of finding such algorithms that are of order h^m with $m > 1$.

The equation (2.43) is a special case of a more general equation, and some results are known about factored Lie Runge Kutta for this more general equation. Our plan is to discuss this more general equation, and then apply the known results for the more general equation to the special case (2.43).

Factored Lie Runge Kutta

Let G be some Lie group of $n\times n$ matrices, and let Y denote matrices in G. Next assume that there is some $n\times n$ matrix function $A(Y,t)$ such that $A(Y,t)$ is in the Lie algebra of G for all $Y\in G$ and all t. Let t^0 be some initial time and let Y^0 be some initial matrix in G. Consider the matrix differential equation

$$\dot{Y}(t) = A(Y,t)Y(t). \tag{11.2.99}$$

Then it can be shown that the solution to (2.99) lies in G for all time.[27] See Exercise 2.8. Comparison of (2.43) and (2.99) shows that (2.43) is a special case of (2.99) with S playing the role of Y and $[\bar{\boldsymbol{\omega}}(t)\cdot\boldsymbol{L}]$ playing the role of $A(Y,t)$:

$$S \leftrightarrow Y, \tag{11.2.100}$$

$$[\bar{\boldsymbol{\omega}}(t)\cdot\boldsymbol{L}] \leftrightarrow A(Y,t). \tag{11.2.101}$$

Note that for the special case (2.43) the matrices $A(Y,t)$ are in fact *independent* of Y.

Crouch, *Grossman*, and others have developed factored Lie Runge-Kutta algorithms for the numerical integration of (2.99). These algorithms are constructed in such a way that, although they may make local errors of order h^{m+1}, $Y(t)$ is guaranteed to lie in G to machine precision and evaluations of $A(Y,t)$ are required only for matrices Y in G.

Applying crude Euler to (2.99) produces the stepping rule

$$Y^{n+1} = Y^n + h\dot{Y}^n = [I + hA(Y^n,t^n)]Y^n \tag{11.2.102}$$

which, to the same order in h, can be rewritten in the exponential form

$$Y^{n+1} = \{\exp[hA(Y^n,t^n)]\}Y^n. \tag{11.2.103}$$

Suppose $Y^n\in G$. Then, by assumption, $A(Y^n,t^n)$ is in the Lie algebra of G, from which it follows that $\{\exp[hA(Y^n,t^n)]\}\in G$, and therefore $Y^{n+1}\in G$. The stepping rule (2.103) preserves G.

[26] The significance of the adjective *factored* will become apparent subsequently. See (2.113).

[27] Note that there is a consistency consideration here. If the solution $Y(t)$ were to leave G even though the initial matrix Y^0 is in G, then $A(Y,t)$ could become undefined.

Consider a single-stage Butcher tableau of the form

$$\begin{array}{c|c} c_1 & a_{11} \\ \hline & b_1 \end{array} \ . \tag{11.2.104}$$

It describes crude Euler when $c_1 = a_{11} = 0$ and $b_1 = 1$. See Exercise 2.3.3. Define quantities Y_1^n and K_1 by the rules

$$Y_1^n = Y^n, \tag{11.2.105}$$

$$K_1 = A(Y_1^n, t^n + hc_1) = A(Y_1^n, t^n) = A(Y^n, t^n), \tag{11.2.106}$$

Then we see that (2.103) can be written in the form

$$Y^{n+1} = \exp(hb_1 K_1)Y^n. \tag{11.2.107}$$

Thus, there is a correspondence between (2.103) and the Butcher tableau for crude Euler.

Next consider a two-stage Butcher tableau of the form

$$\begin{array}{c|cc} c_1 & 0 & 0 \\ c_2 & a_{21} & 0 \\ \hline & b_1 & b_2 \end{array} \ . \tag{11.2.108}$$

Note that the matrix a is strictly lower triangular, and therefore the associated Runge-Kutta method is explicit, as is the single-stage method specified by (2.104) when $a_{11} = 0$. Also, we continue to enforce the consistency condition (2.3.16) so that, in fact, $c_1 = 0$. Corresponding to the Butcher tableau (2.108), consider the following rule for stepping from Y^n to Y^{n+1}:

$$Y_1^n = Y^n, \tag{11.2.109}$$

$$K_1 = A(Y_1^n, t^n + hc_1) = A(Y_1^n, t^n) = A(Y^n, t^n), \tag{11.2.110}$$

$$Y_2^n = [\exp(ha_{21}K_1)]Y^n, \tag{11.2.111}$$

$$K_2 = A(Y_2^n, t^n + hc_2), \tag{11.2.112}$$

$$Y^{n+1} = [\exp(hb_2K_2)\exp(hb_1K_1)]Y^n. \tag{11.2.113}$$

Observe that the term appearing in square brackets on the right side of (2.113) is *factored* into a product of group elements, each in exponential form.

Let us examine the ingredients in this rule. Assuming $Y^n \in G$, we see from (2.109) that $Y_1^n \in G$. Next, we see from (2.110) that K_1 is in the Lie algebra of G. Now look at (2.111). Since K_1 is in the Lie algebra, $[\exp(ha_{21}K_1)]$ is in G, and therefore $Y_2^n \in G$. With regard to (2.112), we see that the arguments of A are in its domain of definition, and therefore K_2 is well defined and in the Lie algebra of G. Finally, examination of (2.113) shows that $Y^{n+1} \in G$. Our goal has at least been partially achieved: Starting from $Y^0 \in G$, we have produced a sequence of matrices Y^1, Y^2, $\cdots$, all of which are in G to machine precision.

What about the error associated with this rule? It can be shown that this algorithm is locally correct through terms of order h^2 (local error of order h^3) if the coefficients a, b, and c satisfy the consistency condition (2.3.16) and the order conditions (2.3.42), and (2.3.43). Thus, in the case of explicit one and two-stage methods, the order conditions on the Butcher tableau and the local accuracy for factored Lie Runge-Kutta are the same as those for the *ordinary* Runge-Kutta methods of Chapter 2.

To continue our discussion, consider a three-stage explicit Butcher tableau of the form

$$\begin{array}{c|ccc} c_1 & 0 & 0 & 0 \\ c_2 & a_{21} & 0 & 0 \\ c_3 & a_{31} & a_{32} & 0 \\ \hline & b_1 & b_2 & b_3 \end{array} \tag{11.2.114}$$

Corresponding to the Butcher tableau (2.114), we make the following rule for stepping from Y^n to Y^{n+1}:

$$Y_1^n = Y^n, \tag{11.2.115}$$

$$K_1 = A(Y_1^n, t^n + hc_1) = A(Y_1^n, t^n) = A(Y^n, t^n), \tag{11.2.116}$$

$$Y_2^n = [\exp(ha_{21}K_1)]Y^n, \tag{11.2.117}$$

$$K_2 = A(Y_2^n, t^n + hc_2), \tag{11.2.118}$$

$$Y_3^n = [\exp(ha_{32}K_2)][\exp(ha_{31}K_1)]Y^n, \tag{11.2.119}$$

$$K_3 = A(Y_3^n, t^n + hc_3), \tag{11.2.120}$$

$$Y^{n+1} = \exp(hb_3K_3)\exp(hb_2K_2)\exp(hb_1K_1)Y^n. \tag{11.2.121}$$

Again we see that the Y_j^n are in G, the arguments of A are in its domain of definition, and consequently the K_j are well defined and in the Lie algebra of G. And examination of (2.121) shows that therefore $Y^{n+1} \in G$. We conclude that our goal has again at least been partially achieved.

What about the error associated with this rule? It can be shown that this algorithm is locally correct through terms of order h^3 (local error of order h^4) if the Butcher tableau satisfies the consistency condition (2.3.16), the order conditions (2.3.42) through (2.3.45), and the *additional* order condition

Additional Order 3:

$$\sum_i b_i^2 c_i + 2\sum_{i<j} b_i c_i b_j = 1/3. \tag{11.2.122}$$

We know that the consistency condition (2.3.16) and the order conditions (2.3.42) through (2.3.45) are necessary and sufficient for the three-stage explicit ordinary Runge-Kutta methods of Chapter 2 to be locally accurate through terms of order h^3. Because of the additional order condition (2.122), more is required for the case of factored Lie Runge Kutta to achieve a local accuracy through terms of order h^3. Fortunately, there are three-stage explicit Butcher tableaux that meet the requirements (2.3.16), (2.3.42) through (2.3.45), *and* (2.122). Two such Butcher tableaux, found by Crouch and Grossman, are given below:

$$\begin{array}{c|ccc} 0 & 0 & 0 & 0 \\ -1/24 & -1/24 & 0 & 0 \\ 17/24 & 161/24 & -6 & 0 \\ \hline & 1 & -2/3 & 2/3 \end{array}\;, \tag{11.2.123}$$

$$\begin{array}{c|ccc}
0 & 0 & 0 & 0 \\
3/4 & 3/4 & 0 & 0 \\
17/24 & 119/216 & 17/108 & 0 \\
\hline
 & 13/51 & -2/3 & 24/17
\end{array}\;. \tag{11.2.124}$$

Note the curious feature that use of Butcher tableau (2.123) entails the evaluation of A *outside* the temporal interval $[t^n, t^n + h]$, the interval over which integration is being performed, because for this tableau $c_2 < 0$.

At this point we are prepared to state the general recipe for factored Lie Runge-Kutta methods. We have already discussed the cases of $s = 1$ or $s = 2$ or $s = 3$ stages. Consider a Butcher tableau with s stages with $s > 3$ and again suppose that the matrix a is strictly lower triangular. Use this tableau to make the following stepping rule: For $1 \leq j \leq 3$ define, as before, Y_j^n and K_j by the rules (2.115) through (2.120). And for $4 \leq j \leq s$ make the definitions

$$Y_j^n = \exp(ha_{j,j-1}K_{j-1})\exp(ha_{j,j-2}K_{j-2}) \cdot \ldots \cdot \exp(ha_{j,1}K_1)Y^n, \tag{11.2.125}$$

$$K_j = A(Y_j^n, t^n + hc_j). \tag{11.2.126}$$

Finally, step from Y^n to Y^{n+1} using the rule

$$Y^{n+1} = \exp(hb_sK_s)\exp(hb_{s-1}K_{s-1}) \cdot \ldots \cdot \exp(hb_1K_1)Y^n. \tag{11.2.127}$$

What can be said about the error in this case? For an optimum choice of coefficients, how many stages are required to achieve order m? That is, what is the analog of Table 2.3.1 for the case of factored Lie Runge-Kutta methods? This is a difficult question. For factored Lie Runge-Kutta and for $m \geq 3$, compared to the ordinary Runge-Kutta methods of Chapter 2, there are many more conditions that the entries in the Butcher tableau must meet to achieve order m. For example, to achieve $m = 4$ there are 5 more order conditions for factored Lie Runge Kutta compared to ordinary Runge-Kutta. And, unlike ordinary Runge Kutta, it is impossible with only 4 stages to satisfy all the factored Lie Runge-Kutta order conditions required to achieve $m = 4$. At least $s = 5$ stages are required for factored Lie Runge Kutta to achieve order $m = 4$, some 5-stage Butcher tableaux with this property have been obtained by *Owren and Marthinsen*, and they have published one of them. Finally, It is believed that the minimum number of stages required for factored Lie Runge Kutta to achieve an order m with $m > 4$ grows rapidly with increasing m.

Application of Factored Lie Runge Kutta

As described at the beginning of this subsection, our goal is to find higher-order versions of (2.98). This is now easily done based on what we have learned of factored Lie Runge Kutta. From (2.101) and (2.126) we see for the case of (2.43) that we may write

$$K_j \leftrightarrow \bar{\boldsymbol{\omega}}(t^n + hc_j) \cdot \boldsymbol{L}. \tag{11.2.128}$$

And, using (2.127), we see that there is the stepping rule

$$\begin{aligned} S^{n+1} \;\; = \;\; & \exp[hb_s\bar{\boldsymbol{\omega}}(t^n + hc_s) \cdot \boldsymbol{L}]\exp[hb_{s-1}\bar{\boldsymbol{\omega}}(t^n + hc_{s-1}) \cdot \boldsymbol{L}] \times \\ & \ldots \times \exp[hb_1\bar{\boldsymbol{\omega}}(t^n + hc_1) \cdot \boldsymbol{L}]S^n. \end{aligned} \tag{11.2.129}$$

We have achieved our objective. Given an s-stage factored Lie Runge-Kutta method of order m, (2.129) provides a stepping rule that may make local errors of order h^{m+1}, but is guaranteed to preserve $SO(3,\mathbb{R})$ to machine precision.

For example, based on the Butcher tableau (2.124), there is the third-order (but exactly orthogonality-preserving) stepping rule

$$\begin{aligned} S^{n+1} &= \exp\{(24/17)h\bar{\boldsymbol{\omega}}[t^n+(17/24)h]\cdot\boldsymbol{L}\}\exp\{-(2/3)h\bar{\boldsymbol{\omega}}[t^n+(3/4)h]\cdot\boldsymbol{L}\}\times \\ &\quad \exp\{(13/51)h\bar{\boldsymbol{\omega}}[t^n]\cdot\boldsymbol{L}\}S^n. \end{aligned} \tag{11.2.130}$$

We close this subsection with two comments. The first is based on the observation that the Butcher tableau for a factored Lie Runge-Kutta method can also be used as a Butcher tableau for an ordinary Runge Kutta method. This result follows because the order conditions for factored Lie Runge Kutta contain as a subset all the order conditions for ordinary Runge Kutta. Therefore if a factored Lie Runge-Kutta method is used to track particle spin, which amounts to use of the rule (2.129) to track particle spin, then the same algorithm (the same Butcher tableau) could be used for an ordinary Runge-Kutta routine to compute the particle trajectory. In this way, the same times (t^n+hc_j) would occur in both the spin and particle trajectory routines, thus facilitating the computation of the required quantities $\bar{\boldsymbol{\omega}}(t^n+hc_j)$.

There is a corollary to this observation. In the previous subsection $\bar{\boldsymbol{\omega}}(t)$ was assumed to be a *given* function of t. With the use of factored Lie Runge Kutta this assumption is no longer necessary since there is no need with this method for an explicit fit of the form (2.65) with known coefficients. All that is required at each step are the sampling-point values $\bar{\boldsymbol{\omega}}(t^n+hc_j)$. This is true even if the $\bar{\boldsymbol{\omega}}(t^n+hc_j)$ need be determined dynamically.

At this point it is tempting to imagine that this approach could be applied to the case of spin if there were spin-orbit coupling (Stern-Gerlach effect) so that the equations of motion for the particle trajectory could be visualized as depending on S as well as the particle's position and momentum. However, there are quantum-mechanical reasons why this approach is not applicable.

The Stern-Gerlach effect is an example of *quantum entanglement*. Conceptually, and in a fully quantum treatment, when entering a Stern-Gerlach apparatus a single particle (assumed to have spin 1/2) is described by an initial state vector that is the tensor product of a spin state eigenvector (an eigenvector with eigenvalue $+1$ for $\boldsymbol{n}\cdot\boldsymbol{\sigma}$ for some specified unit vector $\boldsymbol{n}$) and an orbital state vector for a wave packet well localized (consistent within the uncertainty principle) both in position and momentum about some initial point z^i in phase space. After passing through the Stern-Gerlach apparatus the particle is no longer described by a product state vector. That is, the outgoing final quantum state vector *cannot* be written in tensor product form. Rather, it is described by a superposition of two vectors, each expressible in tensor product form. The first vector has a spin state that is an eigenvector with eigenvalue $+1$ for $\boldsymbol{m}\cdot\boldsymbol{\sigma}$ for some specified unit vector $\boldsymbol{m}$ that is determined by the orientation of the Stern-Gerlach apparatus, and an orbital part consisting of a well localized packet about some final point z^{f+}. The second vector has a spin state that is an eigenvector of $\boldsymbol{m}\cdot\boldsymbol{\sigma}$ with eigenvalue -1 and an orbital part consisting of a well localized packet about some final point z^{f-}. Moreover, if the Stern-Gerlach experiment is a success, the points z^{f+} and z^{f-} are sufficiently separated and the associated wave packets sufficiently localized so that there is little overlap between them. Finally, there is a definite phase relation between the two vectors. This state of affairs has no classical analog, and therefore cannot be treated classically.

We also remark that the Stern-Gerlach experiment, which is intended to separate a (single) beam of particles (with different particles characterized by different initial vectors $\boldsymbol{n}$) into two well-separated beams with the first consisting of particles in spin eigenstates characterized by $\boldsymbol{m}$ and the second consisting of particles in spin eigenstates characterized by $-\boldsymbol{m}$, may not necessarily be possible for all kinds of particles. The original Stern-Gerlach experiment was performed with silver atoms that are both *heavy* and were *neutral* (not ionized). There is an argument, due to Bohr and generalized by others, to the effect that it is not possible to magnetically separate a beam, consisting of particles with various spin orientations, into two beams with specified polarizations if the particles are *charged* and too light, or have too small a magnetic moment. For example, it is argued that it is not possible to achieve a Stern-Gerlach effect with electrons.

The essence of the argument, which is semiclassical, is as follows: Particles that are both charged and have a magnetic moment experience two forces when they move in a magnetic field, a Lorentz force due to the field itself and a Stern-Gerlach force due to field inhomogeneities. Since the magnetic field must be divergence free, desirable inhomogeneity (inhomogeneity transverse to the beam direction and in the direction of the main field) employed to produce a Stern-Gerlach force must lead to undesirable inhomogeneity in the other transverse direction. This undesirable field inhomogeneity leads to an undesirable Lorentz force that tends to spread the beam. Therefore the beam must be made small so that only small field variations are actually encountered by particles in the beam. But then, by the quantum uncertainty principle, there will be a corresponding spread in velocity space. This spread in velocity space again leads to an uncertainty in the Lorentz force. It may happen, if the particle mass is too small (thereby leading to a very large spread in velocity space and a corresponding large uncertainty in the Lorentz force) or if the magnetic moment is too small, that the uncertainty in the Lorentz force exceeds the Stern-Gerlach force. The net effect then (if the argument is to be believed) is that only a single final beam is produced whose spread due to the quantum-related uncertainty in the Lorentz force exceeds the splitting expected from the Stern-Gerlach force, thereby washing out any anticipated Stern-Gerlach effect.

The moral to be drawn from these considerations is that a full quantum treatment is required to find reliably the complete effect of an inhomogeneous magnetic field on a beam of particles that are charged and possibly too light or have too small a magnetic moment. See the references to the Stern-Gerlach effect at the end of this chapter.[28]

Although the Stern-Gerlach effect cannot be treated classically, there is a classical problem that is somewhat analogous, namely that of rigid-body motion, for which factored Lie Runge Kutta can be used to good advantage. As described earlier, in the case of rigid-body motion there is the complication that the $\boldsymbol{\omega}^{bf}$ must be determined dynamically from the Euler equations (1.19) through (1.21), which themselves may depend on R. This complication

[28] In fact, the semiclassical arguments that are used to describe the Stern-Gerlach effect even in the case of a neutral beam are suspect because they do not include beam spreading due to the uncertainty principle, the Stern-Gerlach force in the other transverse direction due to the undesirable field inhomogeneity, and the precession of the magnetic moment in the main field. See Exercise 2.17.

causes no problem if both the kinematic equations (1.18) and the dynamic equations (1.19) through (1.21) are integrated using the same factored Lie Runge-Kutta Butcher tableau. In fact, all that is really required is that both the kinematic equations (1.18) and the dynamic equations (1.19) through (1.21) be integrated using Runge-Kutta Butcher tableaux that have the same sampling times, i.e. the same vector c. However, it is important to recognize that the integration method(s) must be capable, as factored Lie Runge Kutta is, of producing the intermediate values Y_j^n so that values of R are available when needed in the various Runge-Kutta stages.

The second comment is that the $s = 5$ and $m = 4$ factored Lie Runge-Kutta Butcher tableau published by Owren and Marthinsen has for its b and c entries the values

$$b_1 = (1 + \kappa + \kappa^2)/(2\kappa + 2\kappa^2), \tag{11.2.131}$$

$$b_2 = 0, \tag{11.2.132}$$

$$b_3 = -(1 + 2\kappa + \kappa^2)/(12 + 6\kappa + 6\kappa^2), \tag{11.2.133}$$

$$b_4 = -1/(2\kappa + 2\kappa^2), \tag{11.2.134}$$

$$b_5 = b_1 = (1 + \kappa + \kappa^2)/(2\kappa + 2\kappa^2), \tag{11.2.135}$$

$$c_1 = 0, \tag{11.2.136}$$

$$c_2 = 3/2, \tag{11.2.137}$$

$$c_3 = 2/3 + \kappa/3 + \kappa^2/6 \simeq * \cdots, \tag{11.2.138}$$

$$c_4 = 1/3 - \kappa/3 - \kappa^2/6 \simeq - * \cdots, \tag{11.2.139}$$

$$c_5 = 1, \tag{11.2.140}$$

where

$$\kappa = 2^{1/3}. \tag{11.2.141}$$

Note that $b_2 = 0$. Thus, when (2.129) is used in this case as a stand-alone formula, it is effectively a *four* stage ($s = 4$) $m = 4$ formula. Observe, however, that $c_3 > 1$. Therefore use of this Butcher tableau involves an evaluation of $\bar{\boldsymbol{\omega}}(t)$ outside the interval $[t^n, t^n + h]$. One might also worry that $c_2 > 1$, which also leads to t values outside $[t^n, t^n + h]$. But, since $b_2 = 0$, this is not a concern. Finally, observe that $c_4 < 0$, so a second evaluation of $\bar{\boldsymbol{\omega}}(t)$ outside the interval $[t^n, t^n + h]$ is also required.

11.2.8 Magnus Lie Runge Kutta

The use of factored Lie Runge Kutta is not particularly attractive for our purposes because only relatively low-order results are available and because sometimes some evaluation points lie outside the interval $[t^n, t^{n+1}]$. But factored Lie Runge Kutta is designed to handle the case (2.99) for which A is allowed to depend on Y. What happens if we relax this requirement, and consider *only* equations of the simpler form

$$\dot{Y}(t) = A(t)Y(t)? \tag{11.2.142}$$

Note that, in view of (2.101), our problem of particular interest, namely (2.61), is of this simpler form.[29] We will learn that for the case (2.142) there are far more attractive results.

Our approach will be to *combine* all the exponents in the Lie Taylor factorization (2.93) to write $\hat{u}^{v\mathrm{fac}}(H)$ in *single-exponent* form. For example, in the case $M = 3$, suppose we write

$$\begin{aligned} \hat{u}^{v}(H) &\simeq \hat{u}^{v\mathrm{fac}}(H) = \exp(H^4\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(H^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(H^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(H\boldsymbol{d}_0\cdot\boldsymbol{K}) \\ &\simeq \exp[G(H)] \end{aligned} \tag{11.2.143}$$

where

$$G(H) = H^4\boldsymbol{e}_3\cdot\boldsymbol{K} + H^3\boldsymbol{e}_2\cdot\boldsymbol{K} + H^2\boldsymbol{e}_1\cdot\boldsymbol{K} + H\boldsymbol{e}_0\cdot\boldsymbol{K}. \tag{11.2.144}$$

Since the use of a single-exponent representation is in the spirit of the Magnus equations and our results will eventually be cast in Runge-Kutta form, we will refer to this procedure as *Magnus Lie Runge Kutta.* Indeed, the quantities $\boldsymbol{e}_n$ could be found in terms of the $\boldsymbol{c}_m$ by integrating the Magnus equations. See Section 10.3. Equivalently, they could be found by making temporal Taylor expansions of equations of the forms (1.67) or (1.83) and equating like powers of t.

Alternatively, since we already know the $\boldsymbol{d}_n$, as a first step we can convert the left side of (2.143) to the right side of (2.143) using the BCH formula (3.7.41). So doing will provide the $\boldsymbol{e}_n$ in terms of the $\boldsymbol{d}_m$. Also, according to (2.87) through (2.90), the $\boldsymbol{d}_m$ are already known in terms of the $\boldsymbol{c}_\ell$. Therefore, in a second step, we can find the $\boldsymbol{e}_n$ in terms of the $\boldsymbol{c}_m$ by simple algebraic substitution. We will now carry out this task.

Begin by observing that

$$\exp(H^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(H\boldsymbol{d}_0\cdot\boldsymbol{K}) \simeq \exp(E) \tag{11.2.145}$$

with

$$\begin{aligned} E &= H^2\boldsymbol{d}_1\cdot\boldsymbol{K} + H\boldsymbol{d}_0\cdot\boldsymbol{K} + (1/2)H^3\{\boldsymbol{d}_1\cdot\boldsymbol{K}, \boldsymbol{d}_0\cdot\boldsymbol{K}\} \\ &\quad +(1/12)H^4\{\boldsymbol{d}_0\cdot\boldsymbol{K}, \{\boldsymbol{d}_0\cdot\boldsymbol{K}, \boldsymbol{d}_1\cdot\boldsymbol{K}\}\} \\ &= H\boldsymbol{d}_0\cdot\boldsymbol{K} + H^2\boldsymbol{d}_1\cdot\boldsymbol{K} + (1/2)H^3\{\boldsymbol{d}_1\cdot\boldsymbol{K}, \boldsymbol{d}_0\cdot\boldsymbol{K}\} \\ &\quad +(1/12)H^4\{\boldsymbol{d}_0\cdot\boldsymbol{K}, \{\boldsymbol{d}_0\cdot\boldsymbol{K}, \boldsymbol{d}_1\cdot\boldsymbol{K}\}\} \\ &= H\boldsymbol{d}_0\cdot\boldsymbol{K} + H^2\boldsymbol{d}_1\cdot\boldsymbol{K} + (1/2)H^3(\boldsymbol{d}_1\times\boldsymbol{d}_0)\cdot\boldsymbol{K} \\ &\quad +(1/12)H^4[\boldsymbol{d}_0\times(\boldsymbol{d}_0\times\boldsymbol{d}_1)]\cdot\boldsymbol{K}. \end{aligned} \tag{11.2.146}$$

Next we find that

$$\begin{aligned} &\exp(H^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(H^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(H\boldsymbol{d}_0\cdot\boldsymbol{K}) \simeq \\ &\qquad \exp(H^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(E) = \exp(F) \end{aligned} \tag{11.2.147}$$

[29] Note also that (10.4.28) is of this form.

with

$$\begin{aligned} F \simeq H^3\boldsymbol{d}_2\cdot\boldsymbol{K} + E + (1/2)\{H^3\boldsymbol{d}_2\cdot\boldsymbol{K}, E\} \simeq \\ H^3\boldsymbol{d}_2\cdot\boldsymbol{K} + E + (1/2)H^4\{\boldsymbol{d}_2\cdot\boldsymbol{K}, \boldsymbol{d}_0\cdot\boldsymbol{K}\} = \\ H^3\boldsymbol{d}_2\cdot\boldsymbol{K} + E + (1/2)H^4(\boldsymbol{d}_2\times\boldsymbol{d}_0)\cdot\boldsymbol{K} = \\ H\boldsymbol{d}_0\cdot\boldsymbol{K} + H^2\boldsymbol{d}_1\cdot\boldsymbol{K} + H^3[\boldsymbol{d}_2\cdot\boldsymbol{K} + (1/2)(\boldsymbol{d}_1\times\boldsymbol{d}_0)\cdot\boldsymbol{K}] \\ +H^4\{(1/2)(\boldsymbol{d}_2\times\boldsymbol{d}_0)\cdot\boldsymbol{K} + (1/12)[\boldsymbol{d}_0\times(\boldsymbol{d}_0\times\boldsymbol{d}_1)]\cdot\boldsymbol{K}\}. \end{aligned} \tag{11.2.148}$$

Finally, we see that

$$\begin{aligned} \exp(H^4\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(H^3\boldsymbol{d}_2\cdot\boldsymbol{K})\exp(H^2\boldsymbol{d}_1\cdot\boldsymbol{K})\exp(H\boldsymbol{d}_0\cdot\boldsymbol{K}) \simeq \\ \exp(H^4\boldsymbol{d}_3\cdot\boldsymbol{K})\exp(F) = \exp(G) \end{aligned} \tag{11.2.149}$$

with

$$G \simeq H^4\boldsymbol{d}_3\cdot\boldsymbol{K} + F. \tag{11.2.150}$$

The net result, through terms of order H^4, is that

$$\begin{aligned} G = H\boldsymbol{d}_0\cdot\boldsymbol{K} + H^2\boldsymbol{d}_1\cdot\boldsymbol{K} + H^3[\boldsymbol{d}_2\cdot\boldsymbol{K} + (1/2)(\boldsymbol{d}_1\times\boldsymbol{d}_0)\cdot\boldsymbol{K}] \\ +H^4\{\boldsymbol{d}_3\cdot\boldsymbol{K} + (1/2)(\boldsymbol{d}_2\times\boldsymbol{d}_0)\cdot\boldsymbol{K} + (1/12)[\boldsymbol{d}_0\times(\boldsymbol{d}_0\times\boldsymbol{d}_1)]\cdot\boldsymbol{K}\}. \end{aligned} \tag{11.2.151}$$

Upon comparing (2.144) and (2.151), we conclude that there are the relations

$$\boldsymbol{e}_0 = \boldsymbol{d}_0, \tag{11.2.152}$$

$$\boldsymbol{e}_1 = \boldsymbol{d}_1, \tag{11.2.153}$$

$$\boldsymbol{e}_2 = \boldsymbol{d}_2 + (1/2)(\boldsymbol{d}_1\times\boldsymbol{d}_0), \tag{11.2.154}$$

$$\boldsymbol{e}_3 = \boldsymbol{d}_3 + (1/2)(\boldsymbol{d}_2\times\boldsymbol{d}_0) + (1/12)[\boldsymbol{d}_0\times(\boldsymbol{d}_0\times\boldsymbol{d}_1)]. \tag{11.2.155}$$

The first step is complete. To finish our task, we employ the relations (2.87) through (2.90) in the relations (2.152) through (2.155) to find the results

$$\boldsymbol{e}_0 = \boldsymbol{c}_0, \tag{11.2.156}$$

$$\boldsymbol{e}_1 = \boldsymbol{c}_1/2, \tag{11.2.157}$$

$$\boldsymbol{e}_2 = (1/3)\boldsymbol{c}_2 - (1/12)(\boldsymbol{c}_0\times\boldsymbol{c}_1), \tag{11.2.158}$$

$$\boldsymbol{e}_3 = (1/4)\boldsymbol{c}_3 - (1/12)(\boldsymbol{c}_0\times\boldsymbol{c}_2). \tag{11.2.159}$$

Remarkably, although there are double cross products in the intermediate results (2.90) and (2.155), there is (due to cancelations) no double cross product in the final results (2.156) through (2.159).

And there is a further remarkable result. Define a vector $\boldsymbol{\Omega}$ by the rule

$$\boldsymbol{\Omega}(H) = H\boldsymbol{e}_0 + H^2\boldsymbol{e}_1 + H^3\boldsymbol{e}_2 + H^4\boldsymbol{e}_3 \tag{11.2.160}$$

so that G can be written the form

$$G(H) = \boldsymbol{\Omega}(H)\cdot\boldsymbol{K}. \tag{11.2.161}$$

By (2.156) through (2.159) we may also write

$$\begin{aligned}\boldsymbol{\Omega}(H) \;&=\; H\boldsymbol{c}_0 + (1/2)H^2\boldsymbol{c}_1 + (1/3)H^3\boldsymbol{c}_2 + (1/4)H^4\boldsymbol{c}_3 \\ &\quad -(1/12)H^3(\boldsymbol{c}_0 \times \boldsymbol{c}_1) - (1/12)H^4(\boldsymbol{c}_0 \times \boldsymbol{c}_2).\end{aligned} \tag{11.2.162}$$

Next, in accord with the stipulation that $M = 3$, define a vector $\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau)$ by the rule

$$\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau) = \sum_{m=0}^{3} \boldsymbol{c}_m \tau^m = \boldsymbol{c}_0 + \boldsymbol{c}_1\tau + \boldsymbol{c}_2\tau^2 + \boldsymbol{c}_3\tau^3, \tag{11.2.163}$$

which is the $M = 3$ version of (2.65). Observe that

$$\int_0^H \hat{\boldsymbol{\omega}}^{\rm fit3}(\tau)\, d\tau = H\boldsymbol{c}_0 + (1/2)H^2\boldsymbol{c}_1 + (1/3)H^3\boldsymbol{c}_2 + (1/4)H^4\boldsymbol{c}_3, \tag{11.2.164}$$

and that the right side of (2.164) also appears on the right side of right (2.162). Therefore we many rewrite (2.162) in the form

$$\boldsymbol{\Omega}(H) \;=\; \int_0^H \hat{\boldsymbol{\omega}}^{\rm fit3}(\tau)\, d\tau - (1/12)H^3(\boldsymbol{c}_0 \times \boldsymbol{c}_1) - (1/12)H^4(\boldsymbol{c}_0 \times \boldsymbol{c}_2). \tag{11.2.165}$$

Enter Legendre Gauss

The occurrence of the integral (2.164) suggests the application of quadrature formulas. Suppose we define two sampling times τ_i by the rule

$$(\tau_1, \tau_2) = (Hx_1, Hx_2) \tag{11.2.166}$$

where x_1 and x_2 are the $k = 2$ Legendre-Gauss sampling points. See (T.1.29). Then, since $k = 2$ Legendre Gauss has $\ell_{\max} = 3$, see (T.1.11), there is the relation

$$\int_0^H \hat{\boldsymbol{\omega}}^{\rm fit3}(\tau)\, d\tau = (H/2)[\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_1) + \hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_2)]. \tag{11.2.167}$$

See (T.1.72).

Also, it can be verified that there is the result

$$\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_1) \times \hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_2) = (1/\sqrt{3})[H(\boldsymbol{c}_0 \times \boldsymbol{c}_1) + H^2(\boldsymbol{c}_0 \times \boldsymbol{c}_2)] + O(H^3). \tag{11.2.168}$$

See Exercise 2.12. It follows that

$$\begin{aligned}-(\sqrt{3}/12)H^2[\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_1) \times \hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_2)] = \\ -(1/12)[H^3(\boldsymbol{c}_0 \times \boldsymbol{c}_1) + H^4(\boldsymbol{c}_0 \times \boldsymbol{c}_2)] + O(H^5).\end{aligned} \tag{11.2.169}$$

Comparison of (2.165) with (2.167) and (2.169) now reveals that, through terms of order H^4, there is the even more remarkable result

$$\boldsymbol{\Omega}(H) = (H/2)[\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_1) + \hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_2)] - (\sqrt{3}/12)H^2[\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_1) \times \hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_2)]. \tag{11.2.170}$$

The ingredients for computing $\boldsymbol{\Omega}(H)$ through terms of order H^4 can be obtained by computing the value of $\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau)$ at just *two* sampling points! By contrast, the utilization of $M = 3$ Lie Taylor factorization requires the evaluation of $\hat{\boldsymbol{\omega}}(\tau)$ at $M + 1 = 4$ sampling points.

Let us summarize what has been accomplished. From (2.143) and (2.161) we have the result

$$\hat{u}^v(H) = \exp[G(H)] = \exp[\boldsymbol{\Omega}(H) \cdot \boldsymbol{K}] \tag{11.2.171}$$

where, through terms of order H^4, $\boldsymbol{\Omega}(H)$ is given by (2.170). Upon making in (2.170) the substitution

$$\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_i) \simeq \hat{\boldsymbol{\omega}}(\tau_i) \tag{11.2.172}$$

we obtain, in effect, a *two*-stage *explicit fourth*-order Runge Kutta method for computing $\hat{u}^v(H)$ with the *guarantee* that $\hat{u}^v(H)$ is *exactly* in $SU(2)$. Note that order 4 is the highest order that can be obtained even for the simplest problem of $k = 2$ quadrature of ordinary functions. Again see (T.1.72).

At this point we make two remarks. The first is that (2.164), the first term in (2.165), is what might be expected if the quantities $\hat{\boldsymbol{\omega}}(\tau) \cdot \boldsymbol{K}$ at various times τ all commuted. It is the analog of the term (10.3.17) in the Magnus expansion. Correspondingly (2.169), the remaining terms in (2.165), takes into account the possibility that the quantities $\hat{\boldsymbol{\omega}}(\tau) \cdot \boldsymbol{K}$ at various times may not all commute. It is the analog of the term (10.3.19) in the Magnus expansion.

The second remark is that if (2.170) through (2.172) are to be used to track particle spin, then Gauss4 could be used to compute the particle trajectory. See the Butcher tableau (2.3.19). This is possible because both algorithms would then use the common sampling times $t^n + \tau_1$ and $t^n + \tau_2$, and Gauss4 is a *collocation* method so that the results at each stage produce accurate values for the orbit and hence accurate values for $\hat{\boldsymbol{\omega}}$ at the sampling times. See Exercise 2.3.12. Moreover Gauss4, when applied to Hamiltonian systems, has the further important property of being symplectic. See Section *.

Enter Newton Cotes

With the idea of quadrature still in mind, we recall from Table T.1.1 that $k = 3$ Newton Cotes also has $\ell_{\rm max} = 3$. Suppose we now define three sampling times τ_i by the rule

$$(\tau_1, \tau_2, \tau_3) = (Hx_1, Hx_2, Hx_3) \tag{11.2.173}$$

where x_1, x_2, and x_3 are the $k = 3$ Newton-Cotes sampling points. See (T.1.15). Then we have the relation

$$\int_0^H \hat{\boldsymbol{\omega}}^{\rm fit3}(\tau)\, d\tau = (H/6)[\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_1) + 4\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_2) + \hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_3)]. \tag{11.2.174}$$

See (T.1.16) and (T.1.66). Also, there is the result

$$\begin{aligned} \hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_1) \times \hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_3) &= \hat{\boldsymbol{\omega}}^{\rm fit3}(0) \times \hat{\boldsymbol{\omega}}^{\rm fit3}(H) \\ &= \boldsymbol{c}_0 \times [\boldsymbol{c}_0 + \boldsymbol{c}_1 H + \boldsymbol{c}_2 H^2 + \boldsymbol{c}_3 H^3] \\ &= H(\boldsymbol{c}_0 \times \boldsymbol{c}_1) + H^2(\boldsymbol{c}_0 \times \boldsymbol{c}_2) + O(H^3). \end{aligned} \tag{11.2.175}$$

It follows that

$$-(1/12)H^2[\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_1)\times\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_3)] = -(1/12)[H^3(\boldsymbol{c}_0\times\boldsymbol{c}_1)+H^4(\boldsymbol{c}_0\times\boldsymbol{c}_2)]+O(H^5). \tag{11.2.176}$$

Comparison of (2.165) with (2.174) and (2.176) reveals that, through terms of order H^4, there is also the result

$$\begin{aligned}\boldsymbol{\Omega}(H) &= (H/6)[\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_1)+4\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_2)+\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_3)]\\ &- (1/12)H^2[\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_1)\times\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_3)].\end{aligned} \tag{11.2.177}$$

The ingredients for computing $\boldsymbol{\Omega}(H)$ through terms of order H^4 can be obtained by computing the value of $\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau)$ at the three sampling times (2.173). Moreover, we observe that these sampling times are the same as those for classic RK4. See the Butcher tableau (2.3.14). It follows that use of (2.171), (2.172), and (2.177) are ideal for tracking particle spin when the particle trajectory is computed using classic RK4 equipped with *dense output*. See Section 2.3.4. The dense output feature would be used to provide values for the coordinates and hence the $\hat{\boldsymbol{\omega}}$ at the times τ_i, and since classic RK4 (although not a collocation method) employs the same sampling times, these interpolated values are expected to be especially accurate.

One can also evaluate the integral on the left side of (2.174) using $k = 4$ Newton Cotes, which also has $\ell_{\rm max} = 3$. See (T.1.20) through (T.1.22) and Table T.1.1. So doing produces a $k = 4$ formula for $\boldsymbol{\Omega}(H)$ that involves four sampling times τ_i given by the rule

$$(\tau_1,\tau_2,\tau_3,\tau_4) = (Hx_1,Hx_2,Hx_3,Hx_4) \tag{11.2.178}$$

where the x_i are the $k = 4$ Newton-Cotes sampling points. See (T.1.20). Use of these sampling points gives, through terms of order H^4, the relation

$$\begin{aligned}\boldsymbol{\Omega}(H) &= (H/8)[\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_1)+3\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_2)+3\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_3)+\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_4)]\\ &- (1/12)H^2[\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_1)\times\hat{\boldsymbol{\omega}}^{\rm fit3}(\tau_4)].\end{aligned} \tag{11.2.179}$$

And, in this case, one can use for trajectory integration the explicit RK4 version given by the Butcher tableau (2.3.15), again equipped with dense output, since this RK4 (although again not a collocation method) has the same sampling times τ_1 through τ_4.

We close this subsection with two final remarks. The first remark is that the results we have just found for spin readily generalize to all equations of the form (2.142). Suppose we seek to integrate (2.142) using a stepping rule of the form

$$Y^{n+1} = Y(t^n+H) = \exp(G_n)Y^n. \tag{11.2.180}$$

Then it can be shown, for example and in analogy with (2.170), that through terms of order H^4 there is the rule

$$G_n = (H/2)[A(t^n+\tau_1)+A(t^n+\tau_2)] - (\sqrt{3}/12)H^2\{A(t^n+\tau_1),A(t^n+\tau_2)\}. \tag{11.2.181}$$

There are also rules analogous to (2.177) and (2.179).

The second remark is that there is a systematic procedure for finding the coefficients of the expansion of $G(H)$ in powers of H in terms of the Taylor expansion of $A(t)$ in powers of t, which we have just done for $M \leq 3$, and some specific results are known for the next few orders including the cases $M \leq 6$. See the paper of *Blanes*, *Casas*, and *Ros* listed under the references to Magnus Lie Runge Kutta in the Bibliography at the end of this chapter. When translated to the context of spin tracking, they provide higher-order generalizations of (2.170), (2.177), and (2.179). For example, a three-stage sixth-order generalization of (2.170) could be constructed that could be used in conjunction with Gauss6.

11.2.9 Integration in the Lie Algebra Revisited

In the previous Subsection 2.8 we studied the integration of the equation of motion

$$\dot{Y}(t) = A(t)Y(t). \tag{11.2.182}$$

We also mentioned earlier, and you will prove in Exercise 2.7, that one can work equally well with an equation of motion having the form

$$\dot{M}(t) = M(t)A(t). \tag{11.2.183}$$

Moreover, from the work of Subsections 1.14 and 1.15 , we know how to integrate (2.183) in its Lie algebra. It follows that we also know how to integrate (2.182) in its Lie algebra. The purpose of this subsection is to study how a generalization of (2.182), namely an equation of motion of the form

$$\dot{Y}(t) = A(Y,t)Y(t), \tag{11.2.184}$$

can be integrated in its Lie algebra.[30] In so doing we will describe an alternative to factored Lie Runge Kutta. Recall Subsection 2.7 and (2.99).

For the purposes of Runge Kutta it is sufficient to describe how to take one step. In the spirit of Subsection 2.6, let t^b be the time at which an integration step is to be initiated so that we wish to integrate from t^b to $t^b + h$. We also suppose that

$$Y^b = Y(t^b) \tag{11.2.185}$$

is known and is an element of the group in question. Write

$$Y(t) = Y^v(t)Y^b \tag{11.2.186}$$

with Y^v being a variable matrix near the identity satisfying

$$Y^v(t^b) = I. \tag{11.2.187}$$

Then it follows from (2.184) and (2.186) that $Y^v(t)$ obeys the equation of motion

$$\dot{Y}^v(t) = A(Y^vY^b, t)Y^v(t) \tag{11.2.188}$$

with the initial condition (2.187).

[30] See Exercise 2.14 for the treatment of a related problem equivalent to the generalization of (2.183).

Next introduce a relative time τ by the rule

$$t = t^b + \tau. \tag{11.2.189}$$

Also, define quantities $\hat{Y}^v$ and $\hat{A}$ by the rules

$$\hat{Y}^v(\tau) = Y^v(t^b + \tau), \tag{11.2.190}$$

$$\hat{A}(\hat{Y}^v, \tau) = A[Y^v(t^b + \tau)Y^b, t^b + \tau] = A[\hat{Y}^v(\tau)Y^b, t^b + \tau]. \tag{11.2.191}$$

It follows from these definitions and (2.188) that $\hat{Y}^v(\tau)$ obeys the equation of motion

$$d\hat{Y}^v(\tau)/d\tau = \hat{A}(\hat{Y}^v, \tau)\hat{Y}^v(\tau) \tag{11.2.192}$$

with the initial condition

$$\hat{Y}^v(0) = I. \tag{11.2.193}$$

Our task is to integrate (2.192) from $\tau = 0$ to $\tau = h$ in such a way that $\hat{Y}^v(h)$ is accurate through terms of order h^m, has possible errors of order h^{m+1}, but is still exactly in the group in question, or at least is in the group through terms of substantially higher order than h^m.

Integration in the Lie Algebra: Exponential Representation

Begin by making the exponential Ansatz

$$\hat{Y}^v(\tau) = \exp[\Omega(\tau)]. \tag{11.2.194}$$

The relation (2.194) can be differentiated and manipulated to yield the result

$$[d\hat{Y}^v(\tau)/d\tau][\hat{Y}^v(\tau)]^{-1} = \text{iex}(\#\Omega\#)(d\Omega/d\tau). \tag{11.2.195}$$

See (*) in Appendix C. Also, the equation of motion (2.192) can be rewritten in the form

$$[d\hat{Y}^v(\tau)/d\tau][\hat{Y}^v(\tau)]^{-1} = \hat{A}(\hat{Y}^v, \tau). \tag{11.2.196}$$

Comparison of (2.195) and (2.196) and use of (2.194) give the result

$$\text{iex}(\#\Omega\#)(d\Omega/d\tau) = \hat{A}[\exp(\Omega), \tau]. \tag{11.2.197}$$

Finally, solving (2.197) for $d\Omega/d\tau$ yields the equation of motion

$$d\Omega/d\tau = [\text{iex}(\#\Omega\#)]^{-1}\hat{A}[\exp(\Omega), \tau]; \tag{11.2.198}$$

and use of (2.193) and (2.194) gives the initial condition

$$\Omega(0) = 0. \tag{11.2.199}$$

The function $[\text{iex}(w)]^{-1}$ has an expansion of the form

$$[\text{iex}(w)]^{-1} = \sum_{\ell=0}^{\infty} c_\ell w^\ell \tag{11.2.200}$$

with $c_0 = 1$, $c_1 = -1/2$, $c_2 = 1/12$, and $c_\ell = b_\ell$ for $\ell > 1$. Again see Appendix C. With the aid of this expansion, (2.198) becomes

$$d\Omega/d\tau = \sum_{\ell=0}^{\infty} c_\ell [\#\Omega(\tau)\#]^\ell \hat{A}[\exp(\Omega), \tau]. \tag{11.2.201}$$

As in the work of Subsection 1.14, the sum in (2.201) can be truncated beyond an even number n to obtain a result that is correct through order h^m with $m = n + 2$. Thus, to this accuracy, the equation to be solved is

$$\begin{aligned} d\Omega/d\tau &= \sum_{\ell=0}^{\ell=n} c_\ell [\#\Omega(\tau)\#]^\ell \hat{A}[\exp(\Omega), \tau] \\ &= c_0 \hat{A}[\exp(\Omega), \tau] + c_1\{\Omega(\tau), \hat{A}[\exp(\Omega), \tau]\} \\ &\quad + c_2\{\Omega(\tau), \{\Omega(\tau), \hat{A}[\exp(\Omega), \tau]\}\} + \cdots \\ &\quad + c_n\{\Omega(\tau), \{\Omega(\tau), \{\cdots\{\Omega(\tau), \hat{A}[\exp(\Omega), \tau]\}\cdots\}\}\}, \end{aligned} \tag{11.2.202}$$

and the understanding is that this truncated equation is to be integrated only over the interval $\tau \in [0, h]$.

For the sake of pedagogy, let us work out a specific case in detail. Suppose we take $n = 2$, in which case we expect a local accuracy through terms of order h^4. Then (2.202) becomes

$$\begin{aligned} d\Omega/d\tau &= \hat{A}[\exp(\Omega), \tau] - (1/2)\{\Omega(\tau), \hat{A}[\exp(\Omega), \tau]\} \\ &\quad + (1/12)\{\Omega(\tau), \{\Omega(\tau), \hat{A}[\exp(\Omega), \tau]\}\}. \end{aligned} \tag{11.2.203}$$

Correspondingly, we will use classic RK4 for integration. To do so, and to conform to previous notation, it is convenient to write (2.203) in the form

$$d\Omega/d\tau = f(\Omega, \tau) \tag{11.2.204}$$

where

$$\begin{aligned} f(\Omega, \tau) &= \hat{A}[\exp(\Omega), \tau] - (1/2)\{\Omega, \hat{A}[\exp(\Omega), \tau]\} \\ &\quad + (1/12)\{\Omega, \{\Omega, \hat{A}[\exp(\Omega), \tau]\}\}. \end{aligned} \tag{11.2.205}$$

For the first stage of classic RK4, in this instance, and adopting a notation analogous to that of (2.3.8) through (2.3.10), we have the results

$$\tau_1 = 0, \tag{11.2.206}$$

$$\Omega_1 = 0, \tag{11.2.207}$$

$$K_1 = f(\Omega_1, \tau_1) = f(0, 0) = \hat{A}[I, 0]. \tag{11.2.208}$$

See (2.201) and (2.3.9), and note that according to (2.3.14) the first row in the Butcher tableau for classic RK4 vanishes. For the second stage there are the results

$$\tau_2 = h/2, \tag{11.2.209}$$

$$\Omega_2 = (h/2)K_1, \tag{11.2.210}$$

$$\begin{aligned} K_2 &= f(\Omega_2, \tau_2) \\ &= \hat{A}[\exp(\Omega_2), h/2] - (1/2)\{\Omega_2, \hat{A}[\exp(\Omega_2), h/2]\} \\ &\quad +(1/12)\{\Omega_2, \{\Omega_2, \hat{A}[\exp(\Omega_2), h/2]\}\}. \end{aligned} \tag{11.2.211}$$

For the third stage there are the results

$$\tau_3 = h/2, \tag{11.2.212}$$

$$\Omega_3 = (h/2)K_2, \tag{11.2.213}$$

$$\begin{aligned} K_3 &= f(\Omega_3, \tau_3) \\ &= \hat{A}[\exp(\Omega_3), h/2] - (1/2)\{\Omega_3, \hat{A}[\exp(\Omega_3), h/2]\} \\ &\quad +(1/12)\{\Omega_3, \{\Omega_3, \hat{A}[\exp(\Omega_3), h/2]\}\}. \end{aligned} \tag{11.2.214}$$

For the fourth stage there are the results

$$\tau_4 = h, \tag{11.2.215}$$

$$\Omega_4 = hK_3, \tag{11.2.216}$$

$$\begin{aligned} K_4 &= f(\Omega_4, \tau_4) \\ &= \hat{A}[\exp(\Omega_4), h] - (1/2)\{\Omega_4, \hat{A}[\exp(\Omega_4), h]\} \\ &\quad +(1/12)\{\Omega_4, \{\Omega_4, \hat{A}[\exp(\Omega_4), h]\}\}. \end{aligned} \tag{11.2.217}$$

The net result of the full RK4 step is that

$$\Omega(h) = (h/6)K_1 + (h/3)K_2 + (h/3)K_3 + (h/6)K_4. \tag{11.2.218}$$

See (2.3.11).

Finally, from (2.194), we find that, through terms of order h^4,

$$\hat{Y}^v(h) = \exp[\Omega(h)]. \tag{11.2.219}$$

Also, from the definitions (2.186), (2.189), and (2.190), we have the relation

$$Y(t^b + h) = Y^v(t^b + h)Y^b = \hat{Y}^v(h)Y^b. \tag{11.2.220}$$

Therefore, upon setting $t^b = t^n$ and making the identification

$$Y^b = Y^n, \tag{11.2.221}$$

we obtain the stepping rule

$$Y^{n+1} = \exp[\Omega(h)]Y^n. \tag{11.2.222}$$

Let us reflect on what has been accomplished. Let G be the group in question and let $\mathcal{L}(G)$ be its Lie algebra. From (2.207) we see that $\Omega_1 \in \mathcal{L}(G)$. Also, since $I \in G$, we see from (2.208) that $\hat{A}$ is evaluated in its domain, and therefore $K_1 \in \mathcal{L}(G)$. Next look at the second stage results. By (2.210), $\Omega_2 \in \mathcal{L}(G)$ since $K_1 \in \mathcal{L}(G)$. Also, since $\Omega_2 \in \mathcal{L}(G)$, there is the result that $\exp(\Omega_2) \in G$ and therefore again $\hat{A}$ is evaluated in its domain. See the right side of (2.211). It follows that all the ingredients in the right side of (2.211) are in $\mathcal{L}(G)$. Moreover they are combined there in such a way that the full right side of (2.211) is in $\mathcal{L}(G)$, and therefore $K_2 \in \mathcal{L}(G)$. Evidently analogous results hold for all the stages so that $\hat{A}$ is always evaluated in its domain and all the K_j are in $\mathcal{L}(G)$. Therefore, by (2.218), $\Omega(h) \in \mathcal{L}(G)$ from which it follows that $\exp[\Omega(h)] \in G$. And from (2.222) we conclude that $Y^{n+1} \in G$ if $Y^n \in G$. Despite generally having made local errors of order h^5, arising both from the truncation of (2.201) and the use of RK4, we have preserved G to machine precision.

Finally we note that, contrary to appearances, the relation (2.222) between Y^{n+1} and Y^n is generally *not* linear. This is the case because generally $\Omega(h)$ depends on Y^n. See the far right side of (2.191) and recall (2.221).

Integration in the Lie Algebra: Cayley Representation

Suppose G is a quadratic group. The results (2.185) through (2.193), since they are general, continue to hold. But if G is a quadratic group, then we may also make, in place of (2.194), the Ansatz

$$\hat{Y}^v(\tau) = \mathrm{cay}[V(\tau)], \tag{11.2.223}$$

where

$$\mathrm{cay}(V) = (I+V)(I-V)^{-1}. \tag{11.2.224}$$

Note that here the definition of $\mathrm{cay}(V)$ given by (2.224) differs by a sign from that given in (3.12.45). Again V will be in $\mathcal{L}(G)$ if $\hat{Y}^v$ is in G, and conversely.

From (2.223) and (2.224) it follows that

$$[d\hat{Y}^v(\tau)/d\tau][\hat{Y}^v(\tau)]^{-1} = 2C(dV/d\tau)B^{-1}, \tag{11.2.225}$$

where B and C are given in terms of V by the relations (1.295) through (1.297). See the calculations at the end of Exercise 1.12. Recall also that (2.192) can be rewritten in the form (2.196). Combining (2.196) and (2.225) gives the relation

$$2C(dV/d\tau)B^{-1} = \hat{A}[\mathrm{cay}(V), \tau]. \tag{11.2.226}$$

Finally, solving (2.226) for $dV/d\tau$ yields the equation of motion

$$dV/d\tau = (1/2)\hat{A}[\mathrm{cay}(V), \tau] - (1/2)\{V, \hat{A}[\mathrm{cay}(V), \tau]\} - (1/2)V\hat{A}[\mathrm{cay}(V), \tau]V. \tag{11.2.227}$$

See (1.320) at the end of Exercise 1.12. And use of (2.193) and (2.223) gives the initial condition

$$V(0) = 0. \tag{11.2.228}$$

Note that the right side of (2.227), unlike (2.201), involves only a finite number of terms, namely three, and therefore in this case no truncation is required.

Because no truncation of the equation of motion has occurred, the only source of error in this case is that associated with numerical integration. Suppose we write (2.227) in the form

$$dV/d\tau = f(V,\tau) \tag{11.2.229}$$

where

$$f(V,\tau) = (1/2)\hat{A}[\mathrm{cay}(V),\tau] - (1/2)\{V,\hat{A}[\mathrm{cay}(V),\tau]\} - (1/2)V\hat{A}[\mathrm{cay}(V),\tau]V. \tag{11.2.230}$$

And suppose for purposes of illustration that we again use classic RK4 for integration. For the first stage of classic RK4, and again adopting a notation analogous to that of (2.3.8) through (2.3.10), we now have the results

$$\tau_1 = 0, \tag{11.2.231}$$

$$V_1 = 0, \tag{11.2.232}$$

$$K_1 = f(V_1,\tau_1) = f(0,0) = (1/2)\hat{A}[I,0]. \tag{11.2.233}$$

See (2.228). For the second stage there are the results

$$\tau_2 = h/2, \tag{11.2.234}$$

$$V_2 = (h/2)K_1, \tag{11.2.235}$$

$$\begin{aligned} K_2 &= f(V_2,\tau_2) \\ &= (1/2)\hat{A}[\mathrm{cay}(V_2),h/2] - (1/2)\{V_2,\hat{A}[\mathrm{cay}(V_2),h/2]\} \\ &\quad -(1/2)V_2\hat{A}[\mathrm{cay}(V_2),h/2]V_2. \end{aligned} \tag{11.2.236}$$

For the third stage there are the results

$$\tau_3 = h/2, \tag{11.2.237}$$

$$V_3 = (h/2)K_2, \tag{11.2.238}$$

$$\begin{aligned} K_3 &= f(V_3,\tau_3) \\ &= (1/2)\hat{A}[\mathrm{cay}(V_3),h/2] - (1/2)\{V_3,\hat{A}[\mathrm{cay}(V_3),h/2]\} \\ &\quad -(1/2)V_3\hat{A}[\mathrm{cay}(V_3),h/2]V_3. \end{aligned} \tag{11.2.239}$$

For the fourth stage there are the results

$$\tau_4 = h, \tag{11.2.240}$$

$$V_4 = hK_3, \tag{11.2.241}$$

$$\begin{aligned} K_4 &= f(V_4,\tau_4) \\ &= (1/2)\hat{A}[\mathrm{cay}(V_4),h] - (1/2)\{V_4,\hat{A}[\mathrm{cay}(V_4),h]\} \\ &\quad -(1/2)V_4\hat{A}[\mathrm{cay}(V_4),h]V_4. \end{aligned} \tag{11.2.242}$$

The net result of the full RK4 step is that

$$V(h) = (h/6)K_1 + (h/3)K_2 + (h/3)K_3 + (h/6)K_4. \tag{11.2.243}$$

Finally, from (2.223), we find that, through terms of order h^4,

$$\hat{Y}^v(h) = \text{cay}[V(h)]. \tag{11.2.244}$$

Look again at the relations (2.220) and (2.221). Combining them with (2.244) yields the stepping rule

$$Y^{n+1} = \text{cay}[V(h)]Y^n. \tag{11.2.245}$$

Let us again reflect on what has been accomplished. Let G be the group in question and let $\mathcal{L}(G)$ be its Lie algebra. From (2.232) we see that $V_1 \in \mathcal{L}(G)$. Also, since $I \in G$, we see from (2.233) that $\hat{A}$ is evaluated in its domain, and therefore $K_1 \in \mathcal{L}(G)$. Next look at the second stage results. By (2.235), $V_2 \in \mathcal{L}(G)$ since $K_1 \in \mathcal{L}(G)$. Also, since $V_2 \in \mathcal{L}(G)$, there is the result that $\text{cay}(V_2) \in G$ and therefore again $\hat{A}$ is evaluated in its domain. See the right side of (2.236). It follows that all the ingredients in the right side of (2.236) are in $\mathcal{L}(G)$. Moreover they are combined there in such a way that the full right side of (2.236) is in $\mathcal{L}(G)$, and therefore $K_2 \in \mathcal{L}(G)$. Recall the discussion in Exercise 1.12. Evidently analogous results hold for all the stages so that $\hat{A}$ is always evaluated in its domain and all the K_j are in $\mathcal{L}(G)$. Therefore, by (2.243), $V(h) \in \mathcal{L}(G)$ from which it follows that $\text{cay}[V(h)] \in G$. And from (2.245) we conclude that $Y^{n+1} \in G$ if $Y^n \in G$. Despite generally having made local errors of order h^5 arising from the use of RK4, we have preserved G to machine precision.

Finally we note again that, contrary to appearances, the relation (2.245) between Y^{n+1} and Y^n is generally *not* linear. This is the case because generally $V(h)$ depends on Y^n. Again see the far right side of (2.191) and recall (2.221).

Exercises

11.2.1. Much of Section 2 discussed the problem of finding $\boldsymbol{s}(t)$ given $\bar{\boldsymbol{\omega}}(t)$, the equation of motion (2.1), and the initial condition (2.3). The aim of this exercise is to treat the inverse *control theory* problem: given $\boldsymbol{s}(t)$, can one find an $\bar{\boldsymbol{\omega}}(t)$ such that solving (2.1) yields $\boldsymbol{s}(t)$? Stated geometrically, given a path in S^2, is there an $\bar{\boldsymbol{\omega}}(t)$ such that solving (2.1) yields this path? You are to show that the answer to this question is *yes*, and that there are in fact many such $\bar{\boldsymbol{\omega}}(t)$. Then you are to show that a knowledge of *two* paths suffices to define $\bar{\boldsymbol{\omega}}(t)$ uniquely.[31] Treatment of the two-path case employs some of the machinery of Exercise 1.1, which you should review.

Begin by showing that, since by assumption $\boldsymbol{s}(t) \in S^2$, there is the condition

$$\boldsymbol{s}(t) \cdot \dot{\boldsymbol{s}}(t) = 0. \tag{11.2.246}$$

Next show that (2.1) can be rewritten in the forms

$$d\boldsymbol{s}/dt = \bar{\boldsymbol{\omega}}(t) \times \boldsymbol{s} = -\boldsymbol{s} \times \bar{\boldsymbol{\omega}}(t) = -[\boldsymbol{s}(t) \cdot \boldsymbol{L}]\bar{\boldsymbol{\omega}}(t), \tag{11.2.247}$$

[31] The idea of considering two paths, as well as the relation (1.103), were suggested by Sateesh Mane.

$$[\boldsymbol{s}(t)\cdot\boldsymbol{L}]\bar{\boldsymbol{\omega}}(t) = -\dot{\boldsymbol{s}}(t). \tag{11.2.248}$$

According to (2.248), given $\boldsymbol{s}(t)$ and $\dot{\boldsymbol{s}}(t)$, we seek to find a vector $\bar{\boldsymbol{\omega}}(t)$ such that the vector/matrix equation (2.248) is satisfied.

Evidently, at any moment t', there are three possibilities:

$$\boldsymbol{s}(t') \in S^2 \text{ and } \boldsymbol{s}(t') = +\boldsymbol{e}_3, \tag{11.2.249}$$

$$\boldsymbol{s}(t') \in S^2 \text{ and } \boldsymbol{s}(t') = -\boldsymbol{e}_3, \tag{11.2.250}$$

$$\boldsymbol{s}(t') \in S^2 \text{ and } \boldsymbol{s}(t') \neq \pm\boldsymbol{e}_3. \tag{11.2.251}$$

First consider the nongeneric possibilities (2.249) and (2.250). Verify that then the relation (2.248) becomes

$$\pm\, L^3\bar{\boldsymbol{\omega}}(t') = -\dot{\boldsymbol{s}}(t'). \tag{11.2.252}$$

Write out $\bar{\boldsymbol{\omega}}(t')$ and $\dot{\boldsymbol{s}}(t')$ in component form,

$$\bar{\boldsymbol{\omega}}(t') = \begin{pmatrix} \bar{\omega}_1(t') \\ \bar{\omega}_2(t') \\ \bar{\omega}_3(t') \end{pmatrix}, \tag{11.2.253}$$

$$\dot{\boldsymbol{s}}(t') = \begin{pmatrix} \dot{s}_1(t') \\ \dot{s}_2(t') \\ 0 \end{pmatrix}. \tag{11.2.254}$$

Here, in writing (2.254), we have used the fact $\dot{s}_3(t') = 0$ which follows from (2.249), (2.250), and the condition (2.246). Show that

$$L^3\bar{\boldsymbol{\omega}}(t') = \begin{pmatrix} -\bar{\omega}_2(t') \\ \bar{\omega}_1(t') \\ 0 \end{pmatrix}. \tag{11.2.255}$$

Therefore verify (2.252) is satisfied in the possibilities (2.249) and (2.250) providing that (respectively)

$$\bar{\omega}_1(t') = \mp\dot{s}_2(t'), \tag{11.2.256}$$

$$\bar{\omega}_2(t') = \pm\dot{s}_1(t'), \tag{11.2.257}$$

$$\bar{\omega}_3(t') = \text{anything}. \tag{11.2.258}$$

What remains is the generic possibility (2.251). For this possibility parameterize $\boldsymbol{s}(t') \in S^2$ in terms of polar angle coordinates as in (2.11) through (2.13), and verify that both $\theta(t')$ and $\phi(t')$ are well defined. Show that, in terms of the Euler angle parameterization (3.7.207), the rotation $R(\phi,\theta,0)$ relates $\boldsymbol{s}(t') \in S^2$ and $\boldsymbol{e}_3$ by the equation

$$\boldsymbol{s}(t') = R[\phi(t'),\theta(t'),0]\boldsymbol{e}_3. \tag{11.2.259}$$

See (3.7.208). Next verify that

$$RL^3R^{-1} = R(\boldsymbol{e}_3\cdot\boldsymbol{L})R^{-1} = [(R\boldsymbol{e}_3)\cdot\boldsymbol{L}] = \boldsymbol{s}(t')\cdot\boldsymbol{L}. \tag{11.2.260}$$

Recall (8.2.59). Show that inserting this result into (2.248) yields, at the generic moment $t = t'$, the relation

$$[RL^3R^{-1}]\bar{\boldsymbol{\omega}}(t') = -\dot{\boldsymbol{s}}(t') \tag{11.2.261}$$

from which it follows that

$$L^3[R^{-1}\bar{\boldsymbol{\omega}}(t')] = -R^{-1}\dot{\boldsymbol{s}}(t'). \tag{11.2.262}$$

Introduce the notation

$$\boldsymbol{u} = R^{-1}\bar{\boldsymbol{\omega}}(t'), \tag{11.2.263}$$

$$\boldsymbol{v} = R^{-1}\dot{\boldsymbol{s}}(t'), \tag{11.2.264}$$

so that (2.262) becomes

$$L^3\boldsymbol{u} = -\boldsymbol{v}. \tag{11.2.265}$$

Verify also that

$$\boldsymbol{e}_3 \cdot \boldsymbol{v} = [R^{-1}\boldsymbol{s}] \cdot [R^{-1}\dot{\boldsymbol{s}}] = \boldsymbol{s} \cdot \dot{\boldsymbol{s}} = 0. \tag{11.2.266}$$

Here we have used the orthogonality of R. Consequently, verify that we may write

$$\boldsymbol{u} = \begin{pmatrix} u_1 \\ u_2 \\ u_3 \end{pmatrix}, \tag{11.2.267}$$

$$\boldsymbol{v} = \begin{pmatrix} v_1 \\ v_2 \\ 0 \end{pmatrix}. \tag{11.2.268}$$

We are back to the first case we considered, and conclude that

$$u_1 = -v_2, \tag{11.2.269}$$

$$u_2 = v_1, \tag{11.2.270}$$

$$u_3 = \text{anything}. \tag{11.2.271}$$

Verify that (2.269) through (2.271) can be written in the vector/matrix form

$$\boldsymbol{u}(t') = L^3\boldsymbol{v}(t') + g(t')\boldsymbol{e}_3 \tag{11.2.272}$$

where g is any function. We are almost done. Show that inserting (2.263) and (2.264) into (2.272) yields the result

$$R^{-1}\bar{\boldsymbol{\omega}}(t') = L^3R^{-1}\dot{\boldsymbol{s}}(t') + g(t')\boldsymbol{e}_3, \tag{11.2.273}$$

from which it follows, for any generic time $t = t'$, that

$$\begin{aligned} \bar{\boldsymbol{\omega}}(t) &= RL^3R^{-1}\dot{\boldsymbol{s}}(t) + g(t)R\boldsymbol{e}_3 \\ &= [\boldsymbol{s}(t) \cdot \boldsymbol{L}]\dot{\boldsymbol{s}}(t) + g(t)\boldsymbol{s}(t) \\ &= \boldsymbol{s}(t) \times \dot{\boldsymbol{s}}(t) + g(t)\boldsymbol{s}(t). \end{aligned} \tag{11.2.274}$$

If all has been done correctly, (2.274) provides the general solution to (2.248). Verify that this general solution also covers the nongeneric possibilities (2.249) and (2.250) for which the polar angles were not well defined. Verify, by direct computation, that the general solution satisfies (2.248). Hint: Use (3.7.200). In practice we might require that $g(t)$ be continuous, and for convenience we might set $g(t) = 0$.

You have shown that there is a choice of $\bar{\boldsymbol{\omega}}(t)$ that will produce any desired path $\boldsymbol{s}(t) \in S^2$, and that this choice is not unique. What if there are two different paths $\boldsymbol{r}(t) \in S^2$ and $\boldsymbol{s}(t) \in S^2$ that are supposed to be produced by the *same* $\bar{\boldsymbol{\omega}}(t)$. That is, $\boldsymbol{s}(t)$ satisfies (2.1) and $\boldsymbol{r}(t)$ satisfies the analogous relation

$$d\boldsymbol{r}/dt = \bar{\boldsymbol{\omega}}(t) \times \boldsymbol{r}. \tag{11.2.275}$$

Is $\bar{\boldsymbol{\omega}}(t)$ then uniquely determined? You are to show that the answer is *yes*.

Can $\boldsymbol{r}(t) \in S^2$ and $\boldsymbol{s}(t) \in S^2$ be specified arbitrarily and independently? The answer is *no*. There are some mutual restrictions on $\boldsymbol{r}(t) \in S^2$ and $\boldsymbol{s}(t) \in S^2$ since they are supposed to be produced by the same differential equation, namely (2.1) and (2.275). We will call a path on S^2 that satisfies this differential equation an *allowable path*.

First, we must assume that $\boldsymbol{r}^0 \neq \pm\boldsymbol{s}^0$. In the first case the initial conditions would be the same and therefore $\boldsymbol{r}(t)$ and $\boldsymbol{s}(t)$ would be identical. In the second case, since by linearity $-\boldsymbol{s}(t)$ is an allowable path if $\boldsymbol{s}(t)$ is, we have again gained no new information. Therefore we may assume that $\boldsymbol{r}^0$ and $\boldsymbol{s}^0$ are linearly independent. Show that it follows that

$$-1 < \boldsymbol{r}^0 \cdot \boldsymbol{s}^0 < 1 \tag{11.2.276}$$

and

$$|\boldsymbol{r}^0 \times \boldsymbol{s}^0| \neq 0. \tag{11.2.277}$$

Consider the quantity $\boldsymbol{r}(t) \cdot \boldsymbol{s}(t)$. Verify that

$$\begin{aligned}(d/dt)[\boldsymbol{r}(t) \cdot \boldsymbol{s}(t)] &= \dot{\boldsymbol{r}}(t) \cdot \boldsymbol{s}(t) + \boldsymbol{r}(t) \cdot \dot{\boldsymbol{s}}(t) \\ &= [\bar{\boldsymbol{\omega}}(t) \times \boldsymbol{r}(t)] \cdot \boldsymbol{s}(t) + \boldsymbol{r}(t) \cdot [\bar{\boldsymbol{\omega}}(t) \times \boldsymbol{s}(t)] \\ &= [\bar{\boldsymbol{\omega}}(t) \times \boldsymbol{r}(t)] \cdot \boldsymbol{s}(t) + [\boldsymbol{r}(t) \times \bar{\boldsymbol{\omega}}(t)] \cdot \boldsymbol{s}(t) = 0.\end{aligned} \tag{11.2.278}$$

Conclude that

$$\boldsymbol{r}(t) \cdot \boldsymbol{s}(t) = \boldsymbol{r}^0 \cdot \boldsymbol{s}^0. \tag{11.2.279}$$

The dot product of the two time-dependent vectors associated with two allowable paths (and also the dot product of such a vector with itself) remains constant as the paths are traversed.

Next consider the vector $\boldsymbol{r}(t) \times \boldsymbol{s}(t)$. Verify that

$$\begin{aligned}(d/dt)[\boldsymbol{r}(t) \times \boldsymbol{s}(t)] &= \dot{\boldsymbol{r}}(t) \times \boldsymbol{s}(t) + \boldsymbol{r}(t) \times \dot{\boldsymbol{s}}(t) \\ &= [\bar{\boldsymbol{\omega}}(t) \times \boldsymbol{r}(t)] \times \boldsymbol{s}(t) + \boldsymbol{r}(t) \times [\bar{\boldsymbol{\omega}}(t) \times \boldsymbol{s}(t)] \\ &= -\{\boldsymbol{s}(t) \times [\bar{\boldsymbol{\omega}}(t) \times \boldsymbol{r}(t)]\} + \{\boldsymbol{r}(t) \times [\bar{\boldsymbol{\omega}}(t) \times \boldsymbol{s}(t)]\} \\ &= -\{\bar{\boldsymbol{\omega}}(t)[\boldsymbol{r}(t) \cdot \boldsymbol{s}(t)] - \boldsymbol{r}(t)[\bar{\boldsymbol{\omega}}(t) \cdot \boldsymbol{s}(t)]\} \\ &\quad +\{\bar{\boldsymbol{\omega}}(t)[\boldsymbol{r}(t) \cdot \boldsymbol{s}(t)] - \boldsymbol{s}(t)[\bar{\boldsymbol{\omega}}(t) \cdot \boldsymbol{r}(t)]\} \\ &= \boldsymbol{r}(t)[\bar{\boldsymbol{\omega}}(t) \cdot \boldsymbol{s}(t)] - \boldsymbol{s}(t)[\bar{\boldsymbol{\omega}}(t) \cdot \boldsymbol{r}(t)] \\ &= \bar{\boldsymbol{\omega}}(t) \times [\boldsymbol{r}(t) \times \boldsymbol{s}(t)].\end{aligned} \tag{11.2.280}$$

You have shown, apart from normalization, that $\boldsymbol{r}(t) \times \boldsymbol{s}(t)$ is an allowable path if $\boldsymbol{r}(t)$ and $\boldsymbol{s}(t)$ are allowable paths. Argue, from the results of the previous paragraph, that there is also the result

$$|\boldsymbol{r}(t) \times \boldsymbol{s}(t)| = |\boldsymbol{r}^0 \times \boldsymbol{s}^0|. \tag{11.2.281}$$

Define three *fixed* vectors by the rules

$$\boldsymbol{e}_1 = \boldsymbol{r}^0, \tag{11.2.282}$$

$$\boldsymbol{e}_2 = (\boldsymbol{r}^0 \times \boldsymbol{s}^0)/|(\boldsymbol{r}^0 \times \boldsymbol{s}^0)|, \tag{11.2.283}$$

$$\boldsymbol{e}_3 = \boldsymbol{e}_1 \times \boldsymbol{e}_2. \tag{11.2.284}$$

Verify that together the $\boldsymbol{e}_j$ form a right-hand triad of orthonormal vectors. That is,

$$\boldsymbol{e}_j \cdot \boldsymbol{e}_k = \delta_{jk}, \tag{11.2.285}$$

$$\boldsymbol{e}_j \times \boldsymbol{e}_k = \boldsymbol{e}_\ell, \tag{11.2.286}$$

where j, k, ℓ is any cyclic permutation of $1, 2, 3$.

Define three *time-dependent* vectors by the rules

$$\boldsymbol{f}_1(t) = \boldsymbol{r}(t), \tag{11.2.287}$$

$$\boldsymbol{f}_2(t) = [\boldsymbol{r}(t) \times \boldsymbol{s}(t)]/|(\boldsymbol{r}^0 \times \boldsymbol{s}^0)|, \tag{11.2.288}$$

$$\boldsymbol{f}_3(t) = \boldsymbol{f}_1(t) \times \boldsymbol{f}_2(t). \tag{11.2.289}$$

Based on the work above, show that the $\boldsymbol{f}_j(t)$ have the initial conditions

$$\boldsymbol{f}_j(t^0) = \boldsymbol{e}_j \tag{11.2.290}$$

and are all allowable paths,

$$d\boldsymbol{f}_j/dt = \bar{\boldsymbol{\omega}}(t) \times \boldsymbol{f}_j. \tag{11.2.291}$$

Show that they also form a right-hand triad of orthonormal vectors at each instant t,

$$\boldsymbol{f}_j \cdot \boldsymbol{f}_k = \delta_{jk}, \tag{11.2.292}$$

$$\boldsymbol{f}_j \times \boldsymbol{f}_k = \boldsymbol{f}_\ell, \tag{11.2.293}$$

where j, k, ℓ is any cyclic permutation of $1, 2, 3$.

Next observe that since the $\boldsymbol{e}_j$ and $\boldsymbol{f}_j(t)$ both form triads of orthonormal vectors, they must be related by an orthogonal transformation $R(t)$,

$$\boldsymbol{f}_j(t) = R(t)\boldsymbol{e}_j, \tag{11.2.294}$$

with $R(t^0) = I$. Moreover, (2.294) specifies $R(t)$ uniquely. See Section 3.6.3. By continuity $R(t)$ must satisfy $\det R(t) = 1$, and therefore $R(t) \in SO(3, \mathbb{R})$. Thus, from a knowledge of two allowable paths, we are able to define a rigid body motion.

Also, from the work of Exercise 1.1, we know that there is the relation

$$\dot{R}(t)R^{-1}(t) = \boldsymbol{\omega}^{sf}(t) \cdot \boldsymbol{L}. \tag{11.2.295}$$

See (1.114). Are $\bar{\boldsymbol{\omega}}(t)$, $\boldsymbol{\omega}^{sf}(t)$, $\boldsymbol{\omega}^{bf}(t)$, and $\boldsymbol{\omega}(t)$ related? And, if so, how? From (2.294) and (2.295) show that

$$\dot{\boldsymbol{f}}_j = \dot{R}\boldsymbol{e}_j = \dot{R}R^{-1}R\boldsymbol{e}_j = [\boldsymbol{\omega}^{sf}\cdot\boldsymbol{L}]\boldsymbol{f}_j = \boldsymbol{\omega}^{sf}\times\boldsymbol{f}_j. \tag{11.2.296}$$

Upon comparing (2.291) and (2.296) we are led to make the conjecture

$$\bar{\boldsymbol{\omega}}(t) \overset{?}{=} \boldsymbol{\omega}^{sf}(t). \tag{11.2.297}$$

Note that in writing the far right side of (2.296) some explanation must be given as to what is meant by $\boldsymbol{\omega}^{sf}(t)$ when it is employed in a cross product. We will see that it is the vector with the components $\omega_j^{sf}(t)$ when the $\boldsymbol{e}_j$ are used as a basis. We also observe that, according to (1.103), $\boldsymbol{\omega}(t)$ is specified once the $\boldsymbol{f}_j(t)$ are known.

Because there are two basis sets involved, namely the $\boldsymbol{e}_j$ and the $\boldsymbol{f}_j(t)$, let us make this conjecture precise. From the definition (1.4), and the fact that the $\boldsymbol{f}_j(t)$ are all allowable paths, verify that

$$\begin{aligned}\omega_j^{bf}(t) &= -\boldsymbol{f}_k(t)\cdot\dot{\boldsymbol{f}}_\ell(t) = -\boldsymbol{f}_k(t)\cdot[\bar{\boldsymbol{\omega}}(t)\times\boldsymbol{f}_\ell(t)]\\ &= \boldsymbol{f}_k(t)\cdot[\boldsymbol{f}_\ell(t)\times\bar{\boldsymbol{\omega}}(t)] = [\boldsymbol{f}_k(t)\times\boldsymbol{f}_\ell(t)]\cdot\bar{\boldsymbol{\omega}}(t)]\\ &= \boldsymbol{f}_j(t)\cdot\bar{\boldsymbol{\omega}}(t)\end{aligned} \tag{11.2.298}$$

where j,k,ℓ is any cyclic permutation of $1,2,3$. Show, since the $\boldsymbol{f}_j(t)$ form an orthonormal basis, it follows that

$$\bar{\boldsymbol{\omega}}(t) = \sum_j[\boldsymbol{f}_j(t)\cdot\bar{\boldsymbol{\omega}}(t)]\boldsymbol{f}_j(t) = \sum_j\omega_j^{bf}(t)\boldsymbol{f}_j(t) = \sum_j\omega_j^{sf}(t)\boldsymbol{e}_j = \boldsymbol{\omega}(t). \tag{11.2.299}$$

Here we have again used the results and notation of Exercise 1.1. We conclude that a knowledge of two allowable paths completely specifies $\bar{\boldsymbol{\omega}}(t)$.

As an interesting side calculation, verify that there are also the relations

$$\begin{aligned}-\boldsymbol{f}_2(t)\cdot\{\boldsymbol{f}_1(t)\times\dot{\boldsymbol{f}}_2(t)\} &= -\boldsymbol{f}_2(t)\cdot\{\boldsymbol{f}_1(t)\times[\bar{\boldsymbol{\omega}}\times\boldsymbol{f}_2(t)]\}\\ &= -\boldsymbol{f}_2(t)\cdot\{-\boldsymbol{f}_2(t)[\boldsymbol{f}_1(t)\cdot\bar{\boldsymbol{\omega}}(t)]\}\\ &= \boldsymbol{f}_1(t)\cdot\bar{\boldsymbol{\omega}}(t),\end{aligned} \tag{11.2.300}$$

$$\begin{aligned}-\boldsymbol{f}_3(t)\cdot\{\boldsymbol{f}_2(t)\times\dot{\boldsymbol{f}}_3(t)\} &= -\boldsymbol{f}_3(t)\cdot\{\boldsymbol{f}_2(t)\times[\bar{\boldsymbol{\omega}}\times\boldsymbol{f}_3(t)]\}\\ &= -\boldsymbol{f}_3(t)\cdot\{-\boldsymbol{f}_3(t)[\boldsymbol{f}_2(t)\cdot\bar{\boldsymbol{\omega}}(t)]\}\\ &= \boldsymbol{f}_2(t)\cdot\bar{\boldsymbol{\omega}}(t),\end{aligned} \tag{11.2.301}$$

$$\begin{aligned}-\boldsymbol{f}_1(t)\cdot\{\boldsymbol{f}_3(t)\times\dot{\boldsymbol{f}}_1(t)\} &= -\boldsymbol{f}_1(t)\cdot\{\boldsymbol{f}_3(t)\times[\bar{\boldsymbol{\omega}}\times\boldsymbol{f}_1(t)]\}\\ &= -\boldsymbol{f}_1(t)\cdot\{-\boldsymbol{f}_1(t)[\boldsymbol{f}_3(t)\cdot\bar{\boldsymbol{\omega}}(t)]\}\\ &= \boldsymbol{f}_3(t)\cdot\bar{\boldsymbol{\omega}}(t).\end{aligned} \tag{11.2.302}$$

There is one last observation. Suppose $\boldsymbol{q}^0$ is any point in S^2. Since the $\boldsymbol{e}_j$ form a basis in E^3, any such $\boldsymbol{q}^0$ can be written as a linear combination of the $\boldsymbol{e}_j$,

$$\boldsymbol{q}^0 = \sum_{j=1}^{3} \alpha_j \boldsymbol{e}_j \tag{11.2.303}$$

with

$$\alpha_j = \boldsymbol{e}_j \cdot \boldsymbol{q}^0 \tag{11.2.304}$$

and

$$\sum_{j=1}^{3} \alpha_j^2 = 1. \tag{11.2.305}$$

It follows that $\boldsymbol{q}(t)$ given by

$$\boldsymbol{q}(t) = \sum_{j=1}^{3} \alpha_j \boldsymbol{f}_j(t) \tag{11.2.306}$$

will be an allowable path on S^2 with initial condition $\boldsymbol{q}^0$. Alternatively, we may write

$$\boldsymbol{q}(t) = R(t)\boldsymbol{q}^0. \tag{11.2.307}$$

We conclude that at $t = t^0$ every point on S^2 can be viewed as the starting point for a unique allowable path. Conversely, since $R(t)$ is in $SO(3,\mathbb{R})$ and therefore invertible at each time t, every point on S^2 at time t may be viewed as lying on a unique allowable path. Or, put another way, all allowable paths may be viewed as arising from a time-dependent rotation of S^2. Finally, we have learned that $R(t)$, and all allowable paths $\boldsymbol{q}(t)$, can be built from the two allowable paths $\boldsymbol{r}(t)$ and $\boldsymbol{s}(t)$.

11.2.2. Verify that the equations of motion (2.5) through (2.7) follow from assuming the validity of (2.8) through (2.10). That is, if (2.8) through (2.10) are satisfied, then (2.5) through (2.7) are satisfied.

11.2.3. Verify (2.11) through (2.20).

11.2.4. The aim of this exercise is to verify that (2.52) preserves $SU(2)$. Begin by assuming that $u(t)$ belongs to $SU(2)$ at some time $t = t^0$:

$$u^\dagger(t^0)u(t^0) = I \tag{11.2.308}$$

and

$$\det[u(t^0)] = 1. \tag{11.2.309}$$

First show that (2.52) preserves the determinant of u. Verify from (2.52) that

$$\begin{aligned} u(t+dt) &= u(t) + \dot{u}(t)dt + O[(dt)^2] \\ &= u(t) + (\bar{\boldsymbol{\omega}} \cdot \boldsymbol{K})u(t)dt + O[(dt)^2] \\ &= \exp[(dt)\bar{\boldsymbol{\omega}} \cdot \boldsymbol{K}]u(t) + O[(dt)^2]. \end{aligned} \tag{11.2.310}$$

Show that taking the determinant of both sides of (2.310) yields the result

$$\begin{aligned}\det[u(t+dt)] &= \det\{\exp[(dt)\bar{\boldsymbol{\omega}}\cdot\boldsymbol{K}]u(t)\}+O[(dt)^2]\\ &= \det\{\exp[(dt)\bar{\boldsymbol{\omega}}\cdot\boldsymbol{K}]\}\det[u(t)]+O[(dt)^2]\\ &= \exp[(dt)\,\mathrm{tr}(\bar{\boldsymbol{\omega}}\cdot\boldsymbol{K})]\det[u(t)]+O[(dt)^2]\\ &= \det[u(t)]+O[(dt)^2]. \end{aligned}\tag{11.2.311}$$

(Recall that the K^j are traceless.) Show from (2.311) that

$$\{\det[u(t+dt)]-\det[u(t)]\}/dt = O(dt)\tag{11.2.312}$$

and therefore

$$d\{\det[u(t)]\}/dt = 0.\tag{11.2.313}$$

Verify that the solution to the differential equation (2.313) with the initial condition (2.309) is the relation

$$\det[u(t)] = 1.\tag{11.2.314}$$

What remains to be verified is that (2.52) preserves unitarity. Show from (2.52) that

$$(d/dt)u^\dagger(t) = -u^\dagger(t)(\bar{\boldsymbol{\omega}}\cdot\boldsymbol{K}).\tag{11.2.315}$$

Next verify from (2.52) and (2.315) that

$$\begin{aligned}(d/dt)[u^\dagger(t)u(t)] &= [(d/dt)u^\dagger(t)]u(t)]+u^\dagger(t)(d/dt)u(t)\\ &= -u^\dagger(t)(\bar{\boldsymbol{\omega}}\cdot\boldsymbol{K})u(t)+u^\dagger(t)(\bar{\boldsymbol{\omega}}\cdot\boldsymbol{K})u(t)=0.\end{aligned}\tag{11.2.316}$$

Finally, verify that the solution to the differential equation (2.316) with the initial condition (2.308) is the relation

$$u^\dagger(t)u(t) = I.\tag{11.2.317}$$

11.2.5. The purpose of this exercise is to prove that S defined by (2.54) satisfies (2.43) and (2.44) providing u satisfies (2.52) and (2.53). You will need some of the ingredients of Exercise 2.4 above. Begin by verifying that (2.44) is satisfied because

$$(1/2)\mathrm{tr}[u^\dagger(t^0)\sigma^\alpha u(t^0)\sigma^\beta] = (1/2)\,\mathrm{tr}[\sigma^\alpha\sigma^\beta] = \delta_{\alpha\beta} = S_{\alpha\beta}(t^0).\tag{11.2.318}$$

Next work on proving that S satisfies (2.43). Show that

$$\dot{S}_{\alpha\beta}(t) = (1/2)\mathrm{tr}(\dot{u}^\dagger\sigma^\alpha u\sigma^\beta)+(1/2)\mathrm{tr}(u^\dagger\sigma^\alpha\dot{u}\sigma^\beta).\tag{11.2.319}$$

Verify that employing (2.52) and (2.315) in (2.319) yields the result

$$\begin{aligned}\dot{S}_{\alpha\delta}(t) &= -(1/2)\mathrm{tr}[u^\dagger(\bar{\boldsymbol{\omega}}\cdot\boldsymbol{K})\sigma^\alpha u\sigma^\delta]+(1/2)\mathrm{tr}[u^\dagger\sigma^\alpha(\bar{\boldsymbol{\omega}}\cdot\boldsymbol{K})u\sigma^\delta]\\ &= (1/2)\mathrm{tr}[u^\dagger\{\sigma^\alpha,(\bar{\boldsymbol{\omega}}\cdot\boldsymbol{K})\}u\sigma^\delta].\end{aligned}\tag{11.2.320}$$

Verify that

$$\{\sigma^\alpha,(\bar{\boldsymbol{\omega}}\cdot\boldsymbol{K})\} = \sum_\beta \bar{\omega}_\beta\{\sigma^\alpha,\sigma^\beta\} = \sum_{\beta\gamma}\bar{\omega}_\beta\epsilon_{\alpha\beta\gamma}\sigma^\gamma.\tag{11.2.321}$$

Recall (1.143) and (5.7.39). Insert (2.321) into (2.320) and use (3.7.181) to show that

$$\begin{aligned}\dot{S}_{\alpha\delta}(t) &= \sum_{\beta\gamma} \bar{\omega}_\beta \epsilon_{\alpha\beta\gamma}(1/2)\mathrm{tr}[u^\dagger \sigma^\gamma u \sigma^\delta] \\ &= \sum_{\beta\gamma} \bar{\omega}_\beta \epsilon_{\beta\alpha\gamma} S_{\gamma\delta} = \sum_{\beta\gamma} \bar{\omega}_\beta \epsilon_{\alpha\beta\gamma} S_{\gamma\delta} \\ &= \sum_{\beta\gamma} \bar{\omega}_\beta L^\beta_{\alpha\gamma} S_{\gamma\delta} = \sum_\gamma (\bar{\boldsymbol{\omega}} \cdot \boldsymbol{L})_{\alpha\gamma} S_{\gamma\delta}, \end{aligned} \tag{11.2.322}$$

or, in more compact matrix form,

$$\dot{S} = (\bar{\boldsymbol{\omega}} \cdot \boldsymbol{L}) S. \tag{11.2.323}$$

11.2.6. This exercise is in part a continuation of Exercises 1.7 and 1.8, which you should review. Our aim here is to explore the analogy between (2.40), which describes rotations in E^3, and (1.209), which will be seen to be related to rotations in E^4.

Verify that $A(\boldsymbol{\omega}^{bf})$ as given by (1.208) is 4×4 and antisymmetric, and therefore belongs to the Lie algebra $so(4, \mathbb{R})$. Recall that $(\bar{\boldsymbol{\omega}} \cdot \boldsymbol{L})$ is 3×3 and antisymmetric, and therefore belongs to the Lie algebra $so(3, \mathbb{R})$. Thus, (1.209) appears to be a four-dimensional analog of (2.40). Moreover because $A(\boldsymbol{\omega}^{bf}) \in so(4, \mathbb{R})$, (1.209) describes, as asserted, (at least some) rotations in E^4. Therefore it is no wonder that (1.209) preserves $w \cdot w$ (preserves S^3) just as (2.40) preserves S^2.

Verify, however, that $A(\boldsymbol{\omega}^{bf})$ is given by

$$A(\boldsymbol{\omega}^{bf}) = (1/2)(\omega_1^{bf} E^1 + \omega_2^{bf} E^2 + \omega_3^{bf} E^3) = (1/2)\boldsymbol{\omega}^{bf} \cdot \boldsymbol{E}, \tag{11.2.324}$$

and therefore A belongs to one of the $su(2)$ Lie algebras in $so(4, \mathbb{R})$. Thus the matrices A given by (1.208) do not span all of $so(4, \mathbb{R})$. [Recall that $so(4, \mathbb{R})$ is six dimensional.]

We have seen that the vector equation (2.40) has the corresponding matrix equation (2.43). Similarly, the vector equation (1.209) has the 4×4 matrix equation counterpart

$$\dot{T} = A(\boldsymbol{\omega}^{bf})T \tag{11.2.325}$$

with the initial condition

$$T(t^0) = I. \tag{11.2.326}$$

Therefore part of our task is also to explore the analogy between (2.43) and (2.325).

Verify that $T(t) \in SO(4, \mathbb{R})$, but that not all $SO(4, \mathbb{R})$ matrices can be produced in this fashion because the matrices A given by (1.208) do not span all of $so(4, \mathbb{R})$. Therefore the analogy between (2.40) and (1.209), and between (2.43) and (2.325), is not complete.[32]

The observation that A belongs to an $su(2)$ Lie algebra begs further exploration because we know that what counts, when solving differential equations, is not the matrix size of A but rather the Lie algebra to which it belongs. (The same reasoning led to the replacement

[32] Although the analogy between (2.40) and (1.209) is not complete, it can be shown that any path in S^3 can be produced by solution of (1.209) for some choice of $\boldsymbol{\omega}^{bf}(t)$ when employed in $A[\boldsymbol{\omega}^{bf}(t)]$. This is possible for two reasons: First, as manifolds, $SU(2)$ and S^3 are the same. Recall Exercise 5.10.3. Second, $SU(2)$ acts transitively on itself (as does any group) by both left and right multiplication.

of the L_j by the K_j in Exercise 1.5 and in Subsection 2.6.) Thus, we expect that there must be an $SU(2)$ formulation of the equations of motion (2.325). There is. Verify the commutation rules

$$\{(-E^j/2), (-E^k/2)\} = (-E^\ell/2) \tag{11.2.327}$$

where j, k, ℓ are any cyclic permutation of 1,2,3. Evidently these commutation rules are the same as those for the K^j, see (3.7.172, and therefore we may make the correspondence

$$(-E^j/2) \leftrightarrow K^j. \tag{11.2.328}$$

Consequently, in view of (2.324), there is also the correspondence

$$A(\boldsymbol{\omega}^{bf}) \leftrightarrow -\boldsymbol{\omega}^{bf} \cdot \boldsymbol{K} = \bar{\boldsymbol{\omega}} \cdot \boldsymbol{K} \tag{11.2.329}$$

with

$$\bar{\boldsymbol{\omega}} = -\boldsymbol{\omega}^{bf}. \tag{11.2.330}$$

It follows that the $SU(2)$ analog of (2.325) is the differential equation

$$\dot{u}(t) = (\bar{\boldsymbol{\omega}} \cdot \boldsymbol{K})u(t) \tag{11.2.331}$$

with the initial conditions

$$u(t^0) = I \tag{11.2.332}$$

where u is a complex 2×2 matrix.

We know from Exercise 2.4 that $u(t)$, the solution to (2.331) with the initial condition (2.332), will be in $SU(2)$ for all t. Moreover from Exercise 2.5 we know that, because of the homomorphism between $SU(2)$ and $SO(3, \mathbb{R})$, the S associated with u by the rule (2.54) satisfies the equation of motion (2.43) with the initial condition (2.44). Thus, we have come full circle back to (2.43).

There are other interesting paths we can take. For example, Exercise 2.15 below shows that there is a connection between quaternion parameters and solutions to the general Schroedinger equation in a two-dimensional complex Hilbert space.

11.2.7. The aim of this exercise is to explore the relations between matrix differential equations of the form

$$\dot{M}(t) = M(t)A(t) \tag{11.2.333}$$

with the initial condition

$$M(0) = I, \tag{11.2.334}$$

and matrix differential equations of the form

$$\dot{N}(t) = \bar{A}(t)N(t) \tag{11.2.335}$$

with the initial condition

$$N(0) = I. \tag{11.2.336}$$

Begin with $N(t)$, the solution to (2.335) with the initial condition (2.336). Define a matrix $M(t)$ by the rule

$$M = N^{-1}, \tag{11.2.337}$$

from which it follows that

$$M(0) = I \tag{11.2.338}$$

and

$$MN = I. \tag{11.2.339}$$

Verify that differentiating both sides of (2.339) gives the result

$$\dot{M}N + M\dot{N} = 0, \tag{11.2.340}$$

and therefore

$$\dot{M} = -M\dot{N}N^{-1} = -M\bar{A}NN^{-1} = -M\bar{A}. \tag{11.2.341}$$

Here we have also used (2.335). Evidently (2.341) agrees with (2.333) providing we make the identification

$$A = -\bar{A}. \tag{11.2.342}$$

Let us pause for a side check on consistency with previous results. For the case of $SO(3, \mathbb{R})$, verify that what we have just found is consistent with the relations (1.18) and (1.121). For the Cayley parameterization (1.293) in the case of quadratic groups, verify that the substitution

$$M \leftrightarrow M^{-1} \tag{11.2.343}$$

is equivalent to the substitution

$$V \leftrightarrow -V. \tag{11.2.344}$$

Verify that, under the substitution (2.344) and the substitution

$$A \leftrightarrow -\bar{A}, \tag{11.2.345}$$

the relation (1.313) is transformed into the relation (1.320).

Continue on. The only possible difficulty in making the transition between the two cases (2.333) and (2.335) is the inversion (2.337). It can be shown that matrices that satisfy differential equations of the form (2.333) and (2.335) must generally be invertible, and therefore the transition is generally possible. Your next task is to prove this result.

Review Exercise 1.4.6. Using the methods of that exercise show, starting with (2.335), that there is the relation

$$\det N(t) = [\det N(t^0)] \exp[\int_{t^0}^{t} dr' \operatorname{tr} \bar{A}(t')]. \tag{11.2.346}$$

Assume that $\bar{A}(t')$ is finite for all t'. Show it follows that the factor $\exp[\int_{t^0}^{t} dr' \operatorname{tr} \bar{A}(t')]$ is finite and nonzero. Verify it follows that if $N(t^0)$ is invertible at any time t^0, $\det N(t^0) \neq 0$, then $N(t)$ is invertible at all times t. Show, starting with (2.333), that an analogous result holds for $M(t)$.

Although matrix inversion is generally computationally intensive, it can be carried out easily if M (and consequently also N) belong to various groups. Let us recall some groups for which inverse elements are easily computed. The unitary group comes first to mind. If M is unitary, then

$$M^{-1} = M^{\dagger}. \tag{11.2.347}$$

And, if M is orthogonal,

$$M^{-1} = M^T. \tag{11.2.348}$$

Finally, if M belongs to a quadratic group, then

$$M^{-1} = L^{-1}M^T L. \tag{11.2.349}$$

See (3.12.32).

11.2.8. The purpose of this exercise is to prove that the exact solution to (2.99) preserves G. Verify that (2.103) solves, over the interval $[t^n, t^{n+1}]$, the equation (2.99) through terms of order h. It may make local errors of order h^2, but verify that it preserves G. In the terminology of Sections 2.1 and 2.2, let $h \to 0$ and correspondingly $N \to \infty$ to find $Y(t^0+T)$. Verify that this result is the exact solution of (2.99) evaluated at $t = t^0 + T$ and that this result is in G.

11.2.9. We have claimed that the two-stage Lie Runge Kutta routine (2.109) through (2.113) has order $m = 2$. Verify, for example, that this is true in the case of (2.43), when (2.100) and (2.101) hold, and the Butcher tableau (2.3.36) is employed.

11.2.10. Verify that the entries in the Butcher tableau (2.124) satisfy the consistency relation (2.3.16), the order conditions (2.3.42) through (2.3.45), and the additional order 3 condition (2.122).

11.2.11. Verify that (2.156) through (2.159) follow from (2.87) through (2.90) and (2.152) through (2.155).

11.2.12. Verify (2.168) using (2.163), (2.166), and (T.1.29).

11.2.13. Emboldened by the remarkable results in Subsection 2.8, achieved by combining everything into one Lie element using the exponential map, the purpose to the exercise is to explore what happens when everything is combined into one Lie element using the Cayley map. We will call the result *Cayley Lie Runge Kutta*. Again we will concentrate our efforts on $SU(2)$ for ease of computation.

Begin by assuming that $\hat{u}^v(\tau)$ has a *Cayley Taylor* approximation of the form

$$\hat{u}^v(\tau) \simeq \hat{u}^{\text{vcay}}(\tau) = (I + \boldsymbol{\mu}\cdot\boldsymbol{K})/(I - \boldsymbol{\mu}\cdot\boldsymbol{K}) \tag{11.2.350}$$

where

$$\boldsymbol{\mu}(\tau) = \boldsymbol{f}_0\tau + \boldsymbol{f}_1\tau^2 + \cdots + \boldsymbol{f}_M\tau^{M+1}, \tag{11.2.351}$$

$$\boldsymbol{\mu}(H) = \boldsymbol{f}_0 H + \boldsymbol{f}_1 H^2 + \cdots + \boldsymbol{f}_M H^{M+1}, \tag{11.2.352}$$

and the coefficients $\boldsymbol{f}_n$ are to be determined. See (3.12.71).

The coefficients $\boldsymbol{f}_n$ could be determined in terms of the $\boldsymbol{c}_m$ by integrating equations of the form (11.1.71). [.] Alternatively, we may assume that we already know $\hat{u}^v(H)$ in exponential form and therefore can use a relation of the form (3.12.73). Specifically, show that we may write

$$\begin{aligned}\boldsymbol{\mu} &= 2(\boldsymbol{\Omega}/|\boldsymbol{\Omega}|)\tan(|\boldsymbol{\Omega}|/4)\\ &= 2(\boldsymbol{\Omega}/|\boldsymbol{\Omega}|)[(|\boldsymbol{\Omega}|/4) + (1/3)(|\boldsymbol{\Omega}|/4)^3 + (2/15)(|\boldsymbol{\Omega}|/4)^5 + \cdots]\\ &= (1/2)(\boldsymbol{\Omega})[1 + *|\boldsymbol{\Omega}|^2 + *|\boldsymbol{\Omega}|^4 + \cdots]\end{aligned} \tag{11.2.353}$$

with $\boldsymbol{\Omega}$ given, through terms of order H^4, by (2.162). Show , through terms of order H^4, that

$$|\boldsymbol{\Omega}|^2 =, \tag{11.2.354}$$

$$|\boldsymbol{\Omega}|^4 =, \tag{11.2.355}$$

Use these relations and (2.312) to obtain the results

$$\boldsymbol{f}_0 =, \tag{11.2.356}$$

$$\boldsymbol{f}_1 =, \tag{11.2.357}$$

$$\boldsymbol{f}_2 =, \tag{11.2.358}$$

$$\boldsymbol{f}_3 = . \tag{11.2.359}$$

11.2.14. Subsection 2.9 treated the integration of (2.183) in its Lie algebra using both exponential and Cayley representations. Carry out the analogous tasks for the equation of motion

$$\dot{Y}(t) = Y(t)A(Y,t). \tag{11.2.360}$$

Hint: Use (*) in Appendix C and (1.312) in Exercise 1.12.

11.2.15. The Schroedinger equation reads

$$d\psi/dt = (-iH/\hbar)\psi. \tag{11.2.361}$$

Here the state vector ψ is supposed to belong to some Hilbert space (a vector space equipped with an inner product), and $(-iH/\hbar)$ is supposed to be an anti-Hermitian operator with respect to this inner product. Consider the case for which the Hilbert space is two dimensional. Then ψ is a two-component vector, and we may take the inner product $\langle *, * \rangle$ to be the usual complex inner product for finite-dimensional vector spaces over the complex field. Also, $(-iH/\hbar)$ is then a 2×2 anti-Hermitian matrix. Show that the most general such matrix is of the form

$$-iH/\hbar = i\delta(t)I + \breve{\boldsymbol{\omega}}(t) \cdot \boldsymbol{K} \tag{11.2.362}$$

where δ is any real possibly time-dependent number and $\breve{\boldsymbol{\omega}}$ is any real possibly time-dependent three-dimensional vector. Thus, for a two-dimensional Hilbert space, the most general Schroedinger equation reads

$$d\psi/dt = [i\delta(t)I + \breve{\boldsymbol{\omega}}(t) \cdot \boldsymbol{K}]\psi. \tag{11.2.363}$$

Out task is to find $\psi(t)$ given

$$\psi^0 = \psi(t^0). \tag{11.2.364}$$

Since (2.172) is linear, we may write $\psi(t)$ in the form

$$\psi(t) = v(t)\psi^0 \tag{11.2.365}$$

where v is a 2×2 matrix to be determined. Show that the general solution to (2.172) is of the form (2.174) providing v satisfies the equation

$$\dot{v} = [i\delta(t)I + \breve{\boldsymbol{\omega}}(t) \cdot \boldsymbol{K}]v \tag{11.2.366}$$

with the initial condition

$$v(t^0) = I. \tag{11.2.367}$$

Verify that v defined by (2.175) and (2.176) is an element in $U(2)$, and therefore $\langle \psi, \psi \rangle$ is preserved as is necessary for a probability interpretation of the state vector.[33]

Suppose that the δ term in (2.172) and (2.175) is omitted to yield differential equations of the form

$$\dot{\psi}' = \breve{\boldsymbol{\omega}} \cdot \boldsymbol{K} \psi', \tag{11.2.368}$$

with the same initial condition

$$\psi'(t^0) = \psi^0, \tag{11.2.369}$$

and

$$\dot{v}' = \breve{\boldsymbol{\omega}}(t) \cdot \boldsymbol{K} v', \tag{11.2.370}$$

with the same initial condition

$$v'(t^0) = I. \tag{11.2.371}$$

We already know from Exercise 2.3 that v' defined by (2.179) and (2.180) is an element in $SU(2)$. Verify that

$$\psi'(t) = v'(t)\psi^0. \tag{11.2.372}$$

How are ψ and ψ', and v and v', related? Define a quantity $\Delta(t)$ by the rule

$$\Delta(t) = \int_{t^0}^{t} dt' \delta(t'). \tag{11.2.373}$$

Verify the relations

$$\psi(t) = \exp[i\Delta(t)]\psi'(t) \tag{11.2.374}$$

and

$$v(t) = \exp[i\Delta(t)]v'(t). \tag{11.2.375}$$

We see that ψ and ψ', and also v and v', differ only by a phase factor. Since overall phase factors are supposed to be unobservable in quantum mechanics, we conclude there is no loss in generality in omitting the δ term. Thus, without loss of quantum-mechanical generality, we may drop primes and require that v satisfies the differential equation

$$\dot{v} = \breve{\boldsymbol{\omega}}(t) \cdot \boldsymbol{K} v \tag{11.2.376}$$

with the initial condition (2.176). Correspondingly, the Schroedinger equation now reads

$$\dot{\psi} = \breve{\boldsymbol{\omega}} \cdot \boldsymbol{K} \psi, \tag{11.2.377}$$

and has the general solution (2.174) with $v \in SU(2)$.

By construction, the relations (2.185) and (2.186) entail each other. But we now observe that the relations (2.185) and (2.176) have the same form as (2.52) and (2.53). Therefore, relations of the form (2.52) and (2.53) may also be viewed as arising from the most general Schroedinger equation in the case of a two-dimensional Hilbert space.

[33] That is why $(-iH/\hbar)$ is required to be anti-Hermitian.

What can be said about the nature of two-dimensional Hilbert space? Let $\psi^{\uparrow}$ and $\psi^{\downarrow}$ be the orthonormal basis vectors

$$\psi^{\uparrow} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \tag{11.2.378}$$

$$\psi^{\downarrow} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}. \tag{11.2.379}$$

Write the most general ψ in the form

$$\psi = \alpha\psi^{\uparrow} + \beta\psi^{\downarrow}. \tag{11.2.380}$$

Since both α and β are complex, they each have the topology of $\mathbb{C} = E^2$, and together they have the topology of $\mathbb{C} \times \mathbb{C} = E^4$. Show that requiring that ψ be a unit vector, which is necessary for a probability interpretation of quantum mechanics, yields the restriction

$$|\alpha|^2 + |\beta|^2 = (\Re\alpha)^2 + (\Im\alpha)^2 + (\Re\beta)^2 + (\Im\beta)^2 = 1. \tag{11.2.381}$$

Observe that (2.190) is the equation for S^3, the three-dimensional surface of a sphere in E^4. Thus the topology of unit vectors in two-dimensional Hilbert space is that of S^3.

Show that the general solution to the restriction (2.190) is given by

$$\alpha = \exp(i\gamma)\cos(\theta/2), \tag{11.2.382}$$

$$\beta = \exp(i\gamma)\exp(i\phi)\sin(\theta/2), \tag{11.2.383}$$

where γ, θ, and ϕ are real, but otherwise arbitrary. Actually, not all values of γ, θ, and ϕ are required for full generality. Show that all possibilities are covered by making the restrictions $\gamma \in [0, 2\pi]$, $\theta \in [0, \pi]$, $\phi \in [0, 2\pi]$. Moreover, since overall phase factors are unobservable, we may set $\gamma = 0$ if we wish, and without loss of quantum-mechanical generality. Thus, the set (collection of equivalence classes) of all *unit rays* can be written in the form

$$\psi = \cos(\theta/2)\psi^{\uparrow} + \exp(i\phi)\sin(\theta/2)\psi^{\downarrow} \tag{11.2.384}$$

with

$$\theta \in [0, \pi] \text{ and } \phi \in [0, 2\pi]. \tag{11.2.385}$$

(Recall that a unit ray is the equivalence class of a unit vector multiplied by an arbitrary phase factor.) The quantities θ and ϕ with the restrictions (2.194) may be regarded as the polar angles for points on S^2, the unit sphere in E^3. That is, in terms of Cartesian coordinates for E^3, we may write

$$x_1 = \sin(\theta)\cos(\phi), \tag{11.2.386}$$

$$x_2 = \sin(\theta)\sin(\phi), \tag{11.2.387}$$

$$x_3 = \cos(\theta). \tag{11.2.388}$$

Thus, the topology of unit rays in two-dimensional Hilbert space is that of S^2. In the context of quantum mechanics, this S^2 is frequently called the *Bloch sphere*. (It is the Poincaré sphere in the the context of describing polarized light.) Show that the north pole $(0, 0, 1)$ of the

Bloch sphere corresponds to the state $\psi^{\uparrow}$ and the south pole $(0, 0, -1)$ corresponds (up to an irrelevant phase factor) to the state $\psi^{\downarrow}$. Show that points on the equator correspond to the states $(1/\sqrt{2})(\psi^{\uparrow} + \exp(i\phi)\psi^{\downarrow})$. Show that the vectors ψ corresponding to diametrically opposite points on the Bloch sphere are orthogonal.

Let $\psi(\theta, \phi)$ denote the vector given by (2.384). Show that, in terms of the Euler-angle parameterization given by (3.7.194) and (3.7.195), there is the relation

$$\psi(\theta, \phi) = v(\phi, \theta, -\phi)\psi^{\uparrow}. \tag{11.2.389}$$

Let $\boldsymbol{n}$ denote the unit vector defined by the relation

$$\boldsymbol{n} = R(\phi, \theta, -\phi)\boldsymbol{e}_3 = \cos\phi\sin\theta\boldsymbol{e}_1 + \sin\phi\sin\theta\boldsymbol{e}_2 + \cos\theta\boldsymbol{e}_3. \tag{11.2.390}$$

See (3.7.208) and note the resemblance between (2.390) and (2.386) through (2.388). Show that there is the relation

$$(\boldsymbol{n} \cdot \boldsymbol{\sigma})\psi(\theta, \phi) = \psi(\theta, \phi). \tag{11.2.391}$$

That is, $\psi(\theta, \phi)$ is an eigenvector of $\boldsymbol{n} \cdot \boldsymbol{\sigma}$ with eigenvalue $+1$.

Verify the coset relation

$$SU(2)/U(1) = S^2. \tag{11.2.392}$$

See Subsection 5.12..4. Show that the correspondence between unit rays in a two-dimensional Hilbert space and points in S^2 is a consequence of this coset relation.

We are ready for a parenthetical remark about the field of quantum computing and quantum information. Let $|0\rangle$ and $|1\rangle$ be the *qubit* (quantum bit) states corresponding to the states 0 and 1 of a classical bit.[34] In this field it is conventional to define the vectors $|0\rangle$ and $|1\rangle$ by the relations

$$|0\rangle = \psi^{\uparrow}, \tag{11.2.393}$$

$$|1\rangle = \psi^{\downarrow}; \tag{11.2.394}$$

and a general qubit state $|\psi\rangle$ takes the superposition form

$$|\psi\rangle = \cos(\theta/2)|0\rangle + \exp(i\phi)\sin(\theta/2)|1\rangle. \tag{11.2.395}$$

Back to the main thread. There is still more to be said. Define a three-component vector $\boldsymbol{s}$ by the rule

$$\boldsymbol{s} = 2i\langle\psi, \boldsymbol{K}\psi\rangle = \langle\psi, \boldsymbol{\sigma}\psi\rangle. \tag{11.2.396}$$

Show that $\boldsymbol{s}$ is real, and does not depend on the phase of ψ. Show that using (2.193) for ψ and evaluating (2.201) gives the results (2.10) through (2.12). Thus, $\boldsymbol{s}$ is a unit vector with polar angles θ and ϕ. We see that $\boldsymbol{s}$ is a point on the Bloch sphere, and can be any point on the Bloch sphere. Conversely, given any point on the Bloch sphere, we can determine its polar angles θ and ϕ, and from these angles we can determine ψ up to an overall phase factor.

[34] A qubit is a quantum-mechanical system that is well described by a two-dimensional Hilbert space. Examples include spin 1/2 particles and polarized light, plus more complicated systems, including atoms and superconducting devices, that can be effectively regarded as two-state systems consisting of a ground state and first excited state, with higher excited states ignorable because they are well separated in energy from these states.

Therefore, for a two-dimensional Hilbert space, knowledge of a unit ray and knowledge of a unit vector $\boldsymbol{s}$ are equivalent.

Finally, suppose ψ evolves according to (2.186). How does the corresponding $\boldsymbol{s}$ evolve? Show, using (2.186) and (2.201), that in terms of components

$$\begin{aligned} \dot{s}_\alpha &= 2i[\langle\dot{\psi}, K^\alpha\psi\rangle + \langle\psi, K^\alpha\dot{\psi}\rangle] \\ &= 2i[\langle\breve{\boldsymbol{\omega}}\cdot\boldsymbol{K}\psi, K^\alpha\psi\rangle + \langle\psi, K^\alpha\breve{\boldsymbol{\omega}}\cdot\boldsymbol{K}\psi\rangle] \\ &= 2i[\langle\psi, (\breve{\boldsymbol{\omega}}\cdot\boldsymbol{K})^\dagger K^\alpha\psi\rangle + \langle\psi, K^\alpha\breve{\boldsymbol{\omega}}\cdot\boldsymbol{K}\psi\rangle] \\ &= 2i[\langle\psi, (-\breve{\boldsymbol{\omega}}\cdot\boldsymbol{K})K^\alpha\psi\rangle + \langle\psi, K^\alpha\breve{\boldsymbol{\omega}}\cdot\boldsymbol{K}\psi\rangle] \\ &= 2i\langle\psi, \{K^\alpha, \breve{\boldsymbol{\omega}}\cdot\boldsymbol{K}\}\psi\rangle. \end{aligned} \tag{11.2.397}$$

Next verify that

$$\{K^\alpha, \breve{\boldsymbol{\omega}}\cdot\boldsymbol{K}\} = \sum_\beta \{K^\alpha, K^\beta\}\breve{\omega}_\beta = \sum_{\beta\gamma}\epsilon_{\alpha\beta\gamma}\breve{\omega}_\beta K^\gamma. \tag{11.2.398}$$

Now combine (2.202) and (2.203) to show that

$$\dot{s}_\alpha = 2i\sum_{\beta\gamma}\epsilon_{\alpha\beta\gamma}\breve{\omega}_\beta\langle\psi, K^\gamma\psi\rangle = \sum_{\beta\gamma}\epsilon_{\alpha\beta\gamma}\breve{\omega}_\beta s_\gamma = (\breve{\boldsymbol{\omega}}\times\boldsymbol{s})_\alpha. \tag{11.2.399}$$

In vector notation, you have demonstrated that

$$\dot{\boldsymbol{s}} = \breve{\boldsymbol{\omega}}\times\boldsymbol{s}, \tag{11.2.400}$$

a relation of the form (2.1). Moreover, since a knowledge of $\boldsymbol{s}$ determines ψ up to a phase, given the equation (2.205) we may view it as arising from the Schroedinger equation (2.186). That is, given the $\breve{\boldsymbol{\omega}}$ appearing in (2.205), we may insert it into the Schroedinger equation (2.186) to find $\psi(t)$, and this $\psi(t)$ will yield $\boldsymbol{s}(t)$ by way of (2.201). Thus, we may also view (2.186) and (2.205) as entailing each other.

Your last task in this exercise is to verify a relation between components of ψ and quaternion parameters w. Let $\psi^u(t)$ and $\psi^d(t)$ be solutions to the Schroedinger equation (2.186) with the initial conditions

$$\psi^u(t^0) = \psi^\uparrow, \tag{11.2.401}$$

$$\psi^d(t^0) = \psi^\downarrow. \tag{11.2.402}$$

Here the superscript mnemonics u and d stand for *up* and *down*. Suppose v is parameterized in terms of quaternions in analogy to (1.132). Verify, using (1.174), (2.187), (2.188), and (5.10.29), that there are the relations

$$\langle\psi^\uparrow, \psi^u\rangle = v_{11} = w_0 + iw_3, \tag{11.2.403}$$

$$\langle\psi^\uparrow, \psi^d\rangle = v_{12} = iw_1 + w_2, \tag{11.2.404}$$

$$\langle\psi^\downarrow, \psi^u\rangle = v_{21} = iw_1 - w_2, \tag{11.2.405}$$

$$\langle\psi^\downarrow, \psi^d\rangle = v_{22} = w_0 - iw_3. \tag{11.2.406}$$

Solve (2.208) through (2.211) to yield the relations

$$w_0(t) = (1/2)(\langle\psi^\uparrow, \psi^u\rangle + \langle\psi^\downarrow, \psi^d\rangle), \tag{11.2.407}$$

$$w_1(t) = (-i/2)(\langle\psi^\uparrow, \psi^d\rangle + \langle\psi^\downarrow, \psi^u\rangle), \tag{11.2.408}$$

$$w_2(t) = (1/2)(\langle\psi^\uparrow, \psi^d\rangle - \langle\psi^\downarrow, \psi^u\rangle) \tag{11.2.409}$$

$$w_3(t) = (-i/2)(\langle\psi^\uparrow, \psi^u\rangle - \langle\psi^\downarrow, \psi^d\rangle). \tag{11.2.410}$$

11.2.16. Exact solutions to (2.52).

11.2.17. Consider a Stern-Gerlach apparatus in which the beam propagates in the y direction, the main magnetic field is in the z direction, and also has a gradient in the z direction. Such a field, when expanded about the beam axis (taken to be $x = z = 0$) and near the beam axis, consists essentially of a (skew) quadrupole field superimposed on a dipole field. That is, ignoring end effects, the magnetic field has, to the lowest nontrivial order, the expansion

$$\boldsymbol{B}(\boldsymbol{r}) = B^d\boldsymbol{e}_z + Q^q(z\boldsymbol{e}_z - x\boldsymbol{e}_x). \tag{11.2.411}$$

Here B^d is the strength of the main (dipole) field, and Q^q is the strength (field gradient) of the quadrupole field. Verify that this field is divergence and curl free as is desired. Note that there is a desired field gradient in the z direction, intended to produce a Stern-Gerlach force along the z direction, as well as an “undesirable” gradient along the x direction that will produce a Stern-Gerlach force along the x direction.

$$\Psi = f^\uparrow(\boldsymbol{r}, t)\psi^\uparrow + f^\downarrow(\boldsymbol{r}, t)\psi^\downarrow. \tag{11.2.412}$$

The Schroedinger equation reads

$$\partial\Psi/\partial t = (-i/\hbar)H\Psi \tag{11.2.413}$$

where

$$H = \boldsymbol{p}\cdot\boldsymbol{p}/(2m) + \mu\boldsymbol{B}(\boldsymbol{r})\cdot\boldsymbol{\sigma}. \tag{11.2.414}$$

Here m is the particle mass and μ is a measure of its magnetic moment. Indeed, suppose we ignore the kinetic energy term in (2.414). Then we find that

$$-iH/\hbar \approx -i(\mu/\hbar)\boldsymbol{B}(\boldsymbol{r})\cdot\boldsymbol{\sigma} = (2\mu/\hbar)\boldsymbol{B}(\boldsymbol{r})\cdot\boldsymbol{K}. \tag{11.2.415}$$

Upon comparing (2.362) with (2.415) we see that we should make the identification

$$\breve{\boldsymbol{\omega}} = (2\mu/\hbar)\boldsymbol{B}. \tag{11.2.416}$$

$$\partial f^\uparrow(\boldsymbol{r}, t)/\partial t = (-i/\hbar)\{[\hbar^2/(2m)]\nabla^2 f^\uparrow(\boldsymbol{r}, t) + \mu(B^d + Q^q z)f^\uparrow(\boldsymbol{r}, t) + \mu Q^q x f^\downarrow(\boldsymbol{r}, t)\}, \tag{11.2.417}$$

$$\partial f^\downarrow(\boldsymbol{r}, t)/\partial t = (-i/\hbar)\{[\hbar^2/(2m)]\nabla^2 f^\downarrow(\boldsymbol{r}, t) - \mu(B^d + Q^q z)f^\downarrow(\boldsymbol{r}, t) + \mu Q^q x f^\uparrow(\boldsymbol{r}, t)\}. \tag{11.2.418}$$

11.3 Numerical Integration on Manifolds: Charged Particle Motion in a Static Magnetic Field

Overview

Sections 1.1 and 1.2 treated the problem of integrating on manifolds largely either by projection or by integration in the Lie algebra or by parameterizing the manifold in question, finding the associated differential equation for the parameters, and integrating these equations using standard integration algorithms such as those described in Chapter 2. The only exception to this approach was the work of Subsections 2.6 through 2.8. The purpose of the section is to describe how manifold-preserving integration methods may be applied to the problem of charged-particle motion in a static magnetic field.

The reader may have been somewhat puzzled by the assertion (made at the beginning of Section 1.2) that (1.80) was like (1.79). The equation of motion (1.6.112) is equivalent to the pair

$$d\boldsymbol{r}/dt = \boldsymbol{v}, \tag{11.3.1}$$

$$d\boldsymbol{v}/dt = \bar{\boldsymbol{\omega}}(\boldsymbol{r}) \times \boldsymbol{v}, \tag{11.3.2}$$

with

$$\bar{\boldsymbol{\omega}}(\boldsymbol{r}) = -(q/m^*)\boldsymbol{B}(\boldsymbol{r}). \tag{11.3.3}$$

Since $\bar{\boldsymbol{\omega}}$ depends on $\boldsymbol{r}$ and, according to (1.148), $\boldsymbol{r}$ in turn depends on $\boldsymbol{v}$, the $\bar{\boldsymbol{\omega}}$ appearing in (1.149) is *not* a given function of t independent of everything else including $\boldsymbol{v}$. However, it is the case that the pair (1.148) and (1.149) does preserve the quantity $\boldsymbol{v} \cdot \boldsymbol{v}$. That is, the pair preserves the manifold

$$\Gamma = E^3 \times S^{2*} \tag{11.3.4}$$

with $\boldsymbol{r} \in E^3$ and $\boldsymbol{v} \in S^{2*}$. Here S^{2*} denotes a 2-sphere whose radius is given by $v^* = |\boldsymbol{v}^0|$, or equivalently, is determined by $\gamma = m^*/m$ with

$$\gamma = 1/\sqrt{1 - |\boldsymbol{v}^0|^2/c^2}. \tag{11.3.5}$$

See (1.6.113) and (1.6.114).

In Subsection 3.1 we will describe how the methods already developed in Sections 1 and 2 can be exploited to provide numerical integrators that preserve Γ. In Subsection 3.2 we will describe splitting methods that also preserve Γ but are more akin to some of the methods for symplectic integration to be described in Chapter 12.

11.3.1 Exploitation of Previous Results

The purpose of this subsection is to describe how the methods of Sections 1 and 2 can be applied to the computation of charged-particle motion in static magnetic fields. We will begin with the use of local tangent-space coordinates as illustrated in Subsection 2.3.

Use of Local Tangent-Space Coordinates

In analogy with the work of Subsection 2.3, let $\boldsymbol{v}^b$ be the velocity at the *beginning* of an integration step, and write

$$\boldsymbol{v}(t) = \boldsymbol{v}^b + \boldsymbol{v}^v(t) \tag{11.3.6}$$

with

$$\boldsymbol{v}^b = \boldsymbol{v}(t^b) \tag{11.3.7}$$

and

$$\boldsymbol{v}^v(t^b) = 0. \tag{11.3.8}$$

(Here we apologize for our notation: As before, when v appears as a superscript, it stands for *variable.* Elsewhere it denotes vector or scalar *velocity.*) It follows that we may also write

$$\boldsymbol{v}^v(t) = v_1^{vf}(t)\boldsymbol{f}_1 + v_2^{vf}(t)\boldsymbol{f}_2 + v_3^{vf}(t)\boldsymbol{f}_3 \tag{11.3.9}$$

and

$$\boldsymbol{v}(t) = [v^* + v_1^{vf}(t)]\boldsymbol{f}_1 + v_2^{vf}(t)\boldsymbol{f}_2 + v_3^{vf}(t)\boldsymbol{f}_3 \tag{11.3.10}$$

with

$$v_1^{vf}(t) = \{(v^*)^2 - [v_2^{vf}(t)]^2 - [v_3^{vf}(t)]^2\}^{1/2} - v^*. \tag{11.3.11}$$

Here, *mutatis mutandis*, the vectors $\boldsymbol{f}_j$ are constructed as in Subsection 2.3.

We have (locally) parameterized S^{2*} in terms of v_2^{vf} and v_3^{vf}. Put another way, we have changed variables from $\boldsymbol{v}$ to v_2^{vf} and v_3^{vf} in such a way that the S^{2*} manifold condition is built in. Corresponding to this change of variables, the $\boldsymbol{v}$ equations of motion (3.2) becomes the pair

$$\dot{v}_2^{vf}(t) = \bar{\omega}_3^f(\boldsymbol{r})\{(v^*)^2 - [v_2^{vf}(t)]^2 - [v_3^{vf}(t)]^2\}^{1/2} - \bar{\omega}_1^f(\boldsymbol{r})v_3^{vf}(t), \tag{11.3.12}$$

$$\dot{v}_3^{vf}(t) = \bar{\omega}_1^f(\boldsymbol{r})v_2^{vf}(t) - \bar{\omega}_2^f(\boldsymbol{r})\{(v^*)^2 - [v_2^{vf}(t)]^2 - [v_3^{vf}(t)]^2\}^{1/2}. \tag{11.3.13}$$

For the $\boldsymbol{r}$ variables make the decomposition

$$\boldsymbol{r}(t) = \boldsymbol{r}^b + \boldsymbol{r}^v(t) \tag{11.3.14}$$

with

$$\boldsymbol{r}^b = \boldsymbol{r}(t^b) \tag{11.3.15}$$

and

$$\boldsymbol{r}^v(t^b) = 0. \tag{11.3.16}$$

For $\boldsymbol{r}^v$ make the expansion

$$\boldsymbol{r}^v = r_1^{vf}\boldsymbol{f}_1 + r_2^{vf}\boldsymbol{f}_2 + r_3^{vf}\boldsymbol{f}_3. \tag{11.3.17}$$

Then, in view of (3.13) and (3.14), the equations of motion (3.1) for $\boldsymbol{r}$ become the set

$$\dot{r}_1^{vf} = v_1^{vf} = \{(v^*)^2 - [v_2^{vf}(t)]^2 - [v_3^{vf}(t)]^2\}^{1/2} - v^*, \tag{11.3.18}$$

$$\dot{r}_2^{vf} = v_2^{vf}, \tag{11.3.19}$$

$$\dot{r}_3^{vf} = v_3^{vf}. \tag{11.3.20}$$

It is these five equations that are to be numerically integrated from the time t^b to the time t^b+h (or perhaps t^b+kh) starting with the initial conditions $v_2^{vf}(t^b)=v_3^{vf}(t^b)=0$ and $r_1^{vf}(t^b)=r_2^{vf}(t^b)=r_3^{vf}(t^b)=0$. Then, once $\boldsymbol{v}^v(t^b+h)$ and $\boldsymbol{r}^v(t^b+h)$ [or perhaps $\boldsymbol{v}^v(t^b+kh)$ and $\boldsymbol{r}^v(t^b+kh)$] have been obtained, $\boldsymbol{v}(t^b+h)$ and $\boldsymbol{r}(t^b+h)$ [or perhaps $\boldsymbol{v}(t^b+kh)$ and $\boldsymbol{r}(t^b+kh)$] are given by (2.20) and * .[35] At this point, the whole process just described is repeated as often as desired. That is, the vectors $\boldsymbol{f}_j$ are reconstructed based on the most recently obtained $\boldsymbol{v}$, etc. Note that any numerical integration method may be used to carry out the desired integration. By construction, although the numerical integration may make local errors of order h^{m+1} in finding $\boldsymbol{v}(t^b+h)$ and $\boldsymbol{r}(t^b+h)$, these quantities are guaranteed to be in the manifold $\Gamma=E^3\times S^{2*}$ to machine precision.

Use of Connection with Rigid-Body Kinematics

An alternative to the use of local tangent-space coordinates to ensure that $\boldsymbol{v}$ and $\boldsymbol{r}$ lie in Γ is to make an Ansatz for $\boldsymbol{v}$ that involves rotations. We will seek to use the results of Subsections 2.4 and 2.5.

Again let $\boldsymbol{v}^b$ be the velocity at the *beginning* of an integration step,

$$\boldsymbol{v}^b=\boldsymbol{v}(t^b), \tag{11.3.21}$$

and write

$$\boldsymbol{v}(t)=R(t;\boldsymbol{v}^b,\boldsymbol{r}^b)\boldsymbol{v}^b \tag{11.3.22}$$

with and $R(t;\boldsymbol{v}^b,\boldsymbol{r}^b)$ being a rotation to be determined subject to the initial condition

$$R(t^b;\boldsymbol{v}^b,\boldsymbol{r}^b)=I. \tag{11.3.23}$$

At this point, explanations are in order both about the notation $R(t;\boldsymbol{v}^b,\boldsymbol{r}^b)$ and the generality of the Ansatz (3.27). The notation is meant to indicate that the relation (3.27) between $\boldsymbol{v}(t)$ and $\boldsymbol{v}^b$ need not (and generally will not) be linear because $R(t;\boldsymbol{v}^b,\boldsymbol{r}^b)$ can depend on $\boldsymbol{v}^b$ and $\boldsymbol{r}^b$.

11.3.2 Splitting: Exploitation of Future Results

Exercises

However, before doing so, let us consider the cost of implementing (1.156). The evaluation of $\exp[h\bar{\boldsymbol{\omega}}(\boldsymbol{r}^n)\cdot\boldsymbol{L}]$ can be performed using the Rodrigues formula (3.7.202). This evaluation is fairly expensive because it involves, among other the things, the evaluation of trigonometric functions. Alternatively, (1.153) could be rewritten in the form

$$\boldsymbol{v}^{n+1}=[I+h\bar{\boldsymbol{\omega}}(\boldsymbol{r}^n)\cdot\boldsymbol{L}]\boldsymbol{v}^n. \tag{11.3.24}$$

To the same accuracy, one could orthogonalize the matrix $[I+h\bar{\boldsymbol{\omega}}(\boldsymbol{r}^n)\cdot\boldsymbol{L}]$ using one of the methods of Subsection 3.6.4, and then apply this matrix to $\boldsymbol{v}^n$ to obtain $\boldsymbol{v}^{n+1}$. These

[35] If $k>1$ is attempted, one must monitor $[(v_2^{vf})^2+(v_3^{vf})^2]$ to ensure that the square root singularity in (2.30) is not approached too closely.

methods involve the computation of square roots. Finally, as already mentioned, at each step one could simply renormalize the $\boldsymbol{v}^{n+1}$ in (1.153) by simple scaling to project it back onto S^{2*}. So doing requires the evaluation of a square root.

11.3.1. Exercise on the growth of v dot v based on Euler result (1.154).

Chapter 12

Geometric/Structure-Preserving Integration: Symplectic Integration

Overview

Imagine we wish to compute, by numerical integration, a trajectory governed by some Hamiltonian. Suppose z^i is an initial condition and z^f is an associated final condition. A numerical integrator is called a *symplectic integrator* for this Hamiltonian if the relation between z^i and z^f produced by use of this integrator is (to within roundoff errors) a symplectic map. Sometimes we will want an integrator to be a symplectic integrator for general Hamiltonians. Often, as we will see, it suffices to have a symplectic integrator for some class of Hamiltonians.

There are many things that might be said about symplectic integrators. Indeed, books have been and are being written on the subject. However, we must limit our discussion to a single chapter. Are symplectic integrators important, and if so, why? The answers to these questions are not fully known. As we have seen in Chapter 6, the production of symplectic maps is a key feature of Hamiltonian systems, and the preservation of this feature by any approximation scheme, including numerical integration, would appear to be highly desirable. To date, much experience with symplectic integrators, particularly when one is concerned with studying the long-term behavior of trajectories, seems to confirm this belief. A particular aspect of this subject is discussed in Chapter 34. For a broader discussion, see the references listed at the end of the present chapter. However, as might be feared, satisfying the symplectic condition comes at a cost. We will see that in general mth-order but exactly symplectic integrators require much more work (many more function evaluations) than the mth-order methods of Chapter 2, and are therefore considerably slower.[1]

What can be said about the numerical integration methods of Chapter 2 when applied to Hamiltonian systems? In general, they are not symplectic. Typically, at each step, they violate the symplectic condition by an amount of order h^{m+1} if the integration method is

[1] It is sometimes argued that this cost is compensated by the possibility of using larger step sizes in symplectic integration. Although the solution thereby obtained may not be particularly accurate, it is at least qualitatively correct whereas solutions obtained by other integration methods may exhibit spurious damping or spurious growth. Whether this trade-off can be realized or is acceptable depends on the problem being considered.

locally correct through terms of order h^m. Consequently, they are not exactly symplectic for any finite value of h.[2]

Are there modifications of the integration methods of Chapter 2 that make them symplectic? It is known that, for *general* Hamiltonians, there are no *explicit* Runge-Kutta methods that are symplectic. See Exercise 3.1. However, we will learn that there are *implicit* Runge-Kutta methods that are symplectic. Like corrector methods, at each step implicit Runge-Kutta methods require iteration, which may be slow, in order to solve a set of implicit equations.

What about the usual predictor-corrector finite-difference methods? It is known that they cannot be modified to be symplectic. However, as will be discussed, it is possible to use a predictor (that employs, as usual, previously stored trajectory data) along with an implicit symplectic Runge-Kutta method that serves the role of a corrector.

Finally, little seems to be known about possible symplectic modifications of extrapolation methods.

12.1 Splitting, $T + V$ Splitting, and Zassenhaus Formulas

This chapter is devoted to symplectic integration and the use of Zassenhaus formulas. In this section we begin with some background material, and then explore the case where the Hamiltonian is of the special but frequently encountered form $H = T + V$.

We have seen that if $H(z)$ is a time-independent (autonomous) Hamiltonian, the transfer map $\mathcal{M}$ associated with H can be written formally as

$$\mathcal{M} = \exp(t : -H :). \tag{12.1.1}$$

(Here, for convenience, we have taken the initial time to be $t = 0$, which can be done without loss of generality since H by assumption does not depend on t.) Suppose H is time dependent. Then we know that we may introduce a new independent variable τ, extend the phase space to include t and p_t as dynamical variables, and introduce the new Hamiltonian K defined by the relation

$$K(t, q; p_t, p) = p_t + H(q, p, t). \tag{12.1.2}$$

(See Exercise 1.6.5.) Since K does not depend on τ, we may write the transfer map associated with K formally as

$$\mathcal{M} = \exp(\tau : -K :). \tag{12.1.3}$$

At this point a remark is in order: Because (1.1) and (1.3) have identical structures, there seems to be no loss of generality in considering only the autonomous case. This assertion is correct if we have no particular concern about the form of the Hamiltonian. However, as seen in the last chapter, for the case (1.1) we are able to employ certain methods under the assumptions that H can be expanded about the origin $z = 0$ and the term H_1 is absent or

[2] Of course, in the limit $h \to 0$ they are symplectic because they are then exact. They are also symplectic to machine precision, ignoring round-off error, when h is small enough for the integrator to be accurate to machine precision.

small, and these methods make it possible to find expansions for $\mathcal{M}$ that can be evaluated explicitly. By contrast, these methods fail for the Hamiltonian (1.2) because the presence in K of the (linear) term p_t with a coefficient of *one* means that K_1 cannot be regarded as being small. Nevertheless, if a method is capable of handling sufficiently general Hamiltonians, then there is no loss in generality in considering only autonomous Hamiltonians. Such will be the case for the methods in this section and therefore, without loss in generality, we assume that H is time independent.

As in Section 2.1, let us subdivide the t or τ axis, whichever the case may be, into equal steps of duration h. Then, again employing the notation of Chapter 2, we have the exact marching rule

$$z^{n+1} = \exp(h : -H :)z^n. \tag{12.1.4}$$

Here H is to be viewed as a function of the variables z^n.

Equation (1.4) provides a stepping formula that can be used for numerical integration providing we have some method of computing or approximating $\exp(h : -H :)$. Suppose the Hamiltonian H can be *split* into (written as the sum of) two terms A and B,

$$H(q,p) = A(q,p) + B(q,p), \tag{12.1.5}$$

in such a way that both the maps $\exp(-h : A :)$ and $\exp(-h : B :)$ can be evaluated explicitly or have some other desirable property. For example, suppose that H can be written as a sum of kinetic and potential energies,

$$H(q,p) = T(p) + V(q). \tag{12.1.6}$$

(See Exercise 1.1 for a review of when this is possible.) Then we have the exact results

$$\exp(-h : T :)q_i = q_i + h\partial T/\partial p_i, \tag{12.1.7}$$

$$\exp(-h : T :)p_i = p_i, \tag{12.1.8}$$

$$\exp(-h : V :)q_i = q_i, \tag{12.1.9}$$

$$\exp(-h : V :)p_i = p_i - h\partial V/\partial q_i. \tag{12.1.10}$$

Consider making the simple Zassenhaus approximation

$$\exp(h : -H :) = \exp(-h : A : -h : B :) \simeq \exp(-h : A :)\exp(-h : B :). \tag{12.1.11}$$

See Section 8.8. From the BCH formula (3.7.34) we have the result

$$\exp(-h : A :)\exp(-h : B :) = \exp[-h : A : -h : B : +(h^2/2)\{: A :, : B :\} + O(h^3)]. \tag{12.1.12}$$

We see that, as a stepping formula, (1.4) with the approximation (1.11) makes local errors of order h^2. Thus, like the crude Euler method of Section 2.2, it can be used for numerical integration providing the step size is made sufficiently small. However, unlike crude Euler, the combination of (1.4) and (1.11) provides a method that is *exactly symplectic*. That is, the relation between z^f and z^i produced by this method is (apart from numerical roundoff errors) exactly a symplectic map for *any* value of h. See Exercise 1.2.

With this general background in mind, we now turn to the task of improving the approximation (1.11) to obtain integrators that are again exactly symplectic, but have higher order (in h) accuracy. We will seek improved formulas of the Zassenhaus type, but will discover a method that is, in fact, more general. From the BCH formula we find the result

$$\begin{aligned}&\exp[-(h/2) : A :] \exp(-h : B :) \exp[-(h/2) : A :]\\ &= \exp[h : -(A+B) : + h^3(\{: A :, \{: A :, : B :\}\}/24\\ &-\{: B :, \{: B :, : A :\}\}/12) + O(h^4)].\end{aligned} \tag{12.1.13}$$

Consequently, making the approximation

$$\exp(h : -H :) \simeq \exp[-(h/2) : A :] \exp(-h : B :) \exp[-(h/2) : A :], \tag{12.1.14}$$

sometimes called *Strang* splitting, produces a stepping formula that is again exactly symplectic (again assuming the individual factors can be evaluated exactly), but makes local errors of order h^3. This method, in somewhat different guise as the *leap-frog* algorithm, has been known for a long time, and long before the formal advent of symplectic integrators. See Exercise 1.3.

There is a reason why the coefficient of the h^2 term on the right side of (1.13) vanishes. Introduce the notation

$$\mathcal{S}_2(h) = \exp[-(h/2) : A :] \exp(-h : B :) \exp[-(h/2) : A :]. \tag{12.1.15}$$

It is easily verified that the map $\mathcal{S}_2$ satisfies the relation

$$\mathcal{S}_2^{-1}(h) = \mathcal{S}_2(-h). \tag{12.1.16}$$

A map that has the property

$$\mathcal{S}^{-1}(h) = \mathcal{S}(-h) \tag{12.1.17}$$

is called *symmetric*, and we have used the symbol $\mathcal{S}$ for this reason.[3] We have also appended a subscript of 2 in (1.15) because, as we have seen, the use of $\mathcal{S}_2$ furnishes us with an integrator

[3] Any integrator that is exact must satisfy (1.17) because exact integration backwards must send the final conditions back to the initial conditions. However, we are dealing with approximate integration that is only accurate through some power in h, and therefore (1.17) may or may not not be true depending on what integration method is employed. It is not true for the explicit Runge-Kutta methods or Adams predictor-corrector methods or extrapolation methods described in Chapter 2. For any such method (1.17) holds only through terms of order h^m assuming any such method is locally accurate through terms of order h^m. We also remark that the property (1.17) is also sometimes referred to as *reversibility* or *time reversibility*. We avoid this usage, which can lead to confusion, because, properly speaking, reversibility and time reversibility are properties of particular *dynamical systems*, and not others. See Chapter 36. Being symmetric is a property of an integrator, and being reversible or time reversible is a property of a dynamical system, and therefore also of its associated (and exact) transfer map. Of course, if we are integrating a reversible or time reversible system by some approximate integrator, the resulting approximate transfer map may or may not be reversible or time reversible. In this context, it can be shown that there is an interplay between the symmetry of the integrator and the reversibility or time reversibility of the resulting approximate transfer map. Finally, we note that some authors call an integration method symmetric if its global error has an expansion in h that contains only even powers, as is the case for the extrapolation method of Section 2.6. See (2.6.10). This terminology is also potentially confusing because the extrapolation method is not symmetric in the sense (1.17) used here.

that is locally correct through terms of order h^2. We claim that *any* map that satisfies (1.17), when written in exponential form, must have an exponential expansion that involves only *odd* powers of h. That is, if we write

$$\mathcal{S}(h) = \exp[\mathcal{C}(h)], \tag{12.1.18}$$

then $\mathcal{C}(h)$ must be odd in h

$$\mathcal{C}(-h) = -\mathcal{C}(h). \tag{12.1.19}$$

To see the truth of this assertion, make the expansion

$$\mathcal{C}(h) = \sum_{m=1}^{\infty} \mathcal{C}_m h^m. \tag{12.1.20}$$

The series (1.20) has no constant term because, as can be seen from (1.4) and (1.15), we want to impose the condition

$$\mathcal{S}(0) = \mathcal{I}. \tag{12.1.21}$$

Now insert the representation (1.18) into (1.17). Doing so gives the result

$$\exp[-\mathcal{C}(h)] = \exp[\mathcal{C}(-h)]. \tag{12.1.22}$$

We conclude from (1.22) that (1.19) must hold as a result of the uniqueness of the exponent. See Appendix C. [At this point it may be remarked, in passing, that the $O(h^4)$ term indicated in (1.13) must actually vanish so that the next possibly nonvanishing term must be of $O(h^5)$.]

We are now ready to describe a method, sometimes called the *triplet construction*, for parlaying a symmetric integrator of order $2k$ into a symmetric integrator of order $(2k+2)$. It is also sometimes called the *Yoshida trick* or *Yoshida construction* in recognition of one of its discoverers. Suppose an order $2k$ symmetric integrator $\mathcal{S}_{2k}$ is known. Then the map $\mathcal{S}_{2k+2}$ defined by writing

$$\mathcal{S}_{2k+2}(h) = \mathcal{S}_{2k}(\alpha h)\mathcal{S}_{2k}(\beta h)\mathcal{S}_{2k}(\alpha h) \tag{12.1.23}$$

is a symmetric integrator of order $(2k+2)$ providing α and β are the numbers

$$\alpha = 1/[2 - 2^{1/(2k+1)}], \tag{12.1.24}$$

$$\beta = -[2^{1/(2k+1)}]\alpha. \tag{12.1.25}$$

Why is this true? First we verify the relation

$$\begin{aligned} \mathcal{S}_{2k+2}^{-1}(h) &= \mathcal{S}_{2k}^{-1}(\alpha h)\mathcal{S}_{2k}^{-1}(\beta h)\mathcal{S}_{2k}^{-1}(\alpha h) \\ &= \mathcal{S}_{2k}(-\alpha h)\mathcal{S}_{2k}(-\beta h)\mathcal{S}_{2k}(-\alpha h) = \mathcal{S}_{2k+2}(-h), \end{aligned} \tag{12.1.26}$$

which follows from the assumed symmetry of $\mathcal{S}_{2k}$,

$$\mathcal{S}_{2k}^{-1}(h) = \mathcal{S}_{2k}(-h). \tag{12.1.27}$$

We see that $\mathcal{S}_{2k+2}$ is symmetric by construction. Next, because by hypothesis $\mathcal{S}_{2k}$ is an integrator of order $2k$, we have the result

$$\mathcal{S}_{2k}(h) = \exp(h : -H : + \, \mathcal{C}_{2k+1} h^{2k+1} + \cdots). \tag{12.1.28}$$

Consequently we conclude from (1.23), (1.28), the BCH series, and symmetry that $\mathcal{S}_{2k+2}$ must have the form

$$\mathcal{S}_{2k+2} = \exp[(2\alpha + \beta)h : -H : + (2\alpha^{2k+1} + \beta^{2k+1})\mathcal{C}_{2k+1} h^{2k+1} + O(h^{2k+3})]. \tag{12.1.29}$$

Evidently $\mathcal{S}_{2k+2}$ will be an integrator of order $(2k+2)$ if α and β satisfy the relations

$$2\alpha + \beta = 1, \tag{12.1.30}$$

$$2\alpha^{2k+1} + \beta^{2k+1} = 0. \tag{12.1.31}$$

Finally, the relations (1.30) and (1.31) have the solutions (1.24) and (1.25).

Note that nowhere does the demonstration just given depend on any property of $\mathcal{S}_{2k}$ other than symmetry and that it is indeed an integrator of order $2k$. Therefore, if we can produce a symmetric integrator of order $2k$ by any method whatsoever [not necessarily of Zassenhaus type and not necessarily making the splitting assumption (1.5)], then (1.23) through (1.25) produce from it a symmetric integrator of order $(2k+2)$. Finally, suppose $\mathcal{S}_{2k}$ is a symplectic integrator. Then, since any product of symplectic maps is again a symplectic map, (1.23) shows that $\mathcal{S}_{2k+2}$ will also be a symplectic integrator.

As an example of the use of (1.23), let us construct a 4th-order Zassenhaus integrator $\mathcal{S}_4$ from the known 2nd-order integrator $\mathcal{S}_2$ given by (1.15). From (1.23) through (1.25) we get the result

$$\mathcal{S}_4(h) = \mathcal{S}_2(\alpha h)\mathcal{S}_2(\beta h)\mathcal{S}_2(\alpha h) \tag{12.1.32}$$

with

$$\alpha = 1/(2 - 2^{1/3}), \tag{12.1.33}$$

$$\beta = -(2^{1/3})/(2 - 2^{1/3}). \tag{12.1.34}$$

Now carry out the multiplications indicated in (1.32) to obtain the final Zassenhaus relation

$$\begin{aligned} \mathcal{S}_4(h) = \quad & \exp(w_1 h : A :)\exp(w_2 h : B :)\exp(w_3 h : A :)\exp(w_4 h : B :) \times \\ & \exp(w_5 h : A :)\exp(w_6 h : B :)\exp(w_7 h : A :). \end{aligned} \tag{12.1.35}$$

Here the *weights* w_i have the values

$$w_1 = w_7 = -1/[2(2 - 2^{1/3})], \;\; w_3 = w_5 = (1 - 2^{1/3})w_1,$$

$$w_2 = w_6 = 2w_1, \;\; w_4 = -2^{1/3} w_2. \tag{12.1.36}$$

By construction they must have the remarkable property that

$$\mathcal{S}_4(h) = \exp[h : -H : + \, O(h^5)]. \tag{12.1.37}$$

The procedure (1.23) gives a general way of constructing even-order symmetric integrators, but we might also desire odd-order integrators; and we might be willing to give up the prescription (1.23) or even the symmetry condition in favor of having fewer factors in the Zassenhaus product. How does one find general Zassenhaus formulas of the form (1.35)? That is, having decided in advance how many factors we wish to allow in a Zassenhaus product, how do we select weights w_i to achieve a formula of maximum order? For example, there is the 3rd-order formula

$$\begin{aligned}\exp(-h:H:) = \quad & \exp(w_1 h:A:)\exp(w_2 h:B:)\exp(w_3 h:A:)\exp(w_4 h:B:)\times \\ & \exp(w_5 h:A:)\exp(w_6 h:B:)\times[1+O(h^4)] \qquad (12.1.38)\end{aligned}$$

with

$$\begin{aligned} w_1 = -7/24,\ w_3 = -3/4,\ w_5 = 1/24, \\ w_2 = -2/3,\ w_4 = 2/3,\ w_6 = -1. \qquad (12.1.39)\end{aligned}$$

The general answer to this question is difficult, but results are known through modest order, and are discussed in some of the references cited at the end of this chapter.[4]

We also note that if some commutators of the form $C = \{:A:, \{:A:, :B:\}\}$ or $D = \{:B:, \{:B:, :A:\}\}$ are readily computable, and if the maps $\exp(\tau C)$ or $\exp(\tau D)$ can be computed exactly, then one can also construct higher-order symplectic integrators using these quantities. Such methods are sometimes called *force gradient* algorithms. They are known for some examples to have superior accuracy compared to triplet constructed algorithms of the same order. Moreover, there are symmetric force gradient algorithms which can then be employed in a triplet construction to go to still higher order.

Exercises

12.1.1. Hamiltonians of the form $H = T(p) + V(q)$ commonly occur in the case of nonrelativistic motion in a force field derivable from a potential. However, they can also occur in some cases of relativistic motion in an electromagnetic field. Verify from (1.5.30) in Exercise 1.5.3 that H is of the $T+V$ form when there is only an electric field (no magnetic field so that $\boldsymbol{A} = 0$) and the time t is taken to be the independent variable. Verify from (1.6.16) in Exercise 1.6.1 that H is of the $T+V$ if $\psi = 0$, and the magnetic field $\boldsymbol{B}$ is of the form that it can be derived from a vector potential such that only $A_z \neq 0$, and the coordinate z is taken to be the independent variable.

12.1.2. Show that crude Euler is not symplectic. Show that integration using (1.4) and (1.11) is symplectic.

12.1.3. Leapfrog exercise.

12.1.4. Verify that $\mathcal{S}_2$, as given by (1.46), satisfies (1.16).

12.1.5. Verify (1.29).

[4] We remark that the methods we have been describing are sometimes referred to as *composition* methods because $\exp(-h:H:)$ is written as the composition of several factors or as *fractional-step* methods because a step of duration h is accomplished by taking several steps whose durations are sometimes fractions of h.

12.1.6. Verify that (1.30) and (1.31) have the solution (1.24) and (1.25).

12.1.7. Verify (1.35) and (1.36).

12.1.8. Exercise for case where V is time dependent.

12.1.9. For the $\mathcal{S}_2$ given by (1.15), show that

$$\mathcal{S}_2 H = H + h^3 G + O(h^4) \tag{12.1.40}$$

where

$$G = -[A,[A,[A,B]]]/24 - [B,[B,[A,B]]]/12 - [A,[B,[A,B]]]/8. \tag{12.1.41}$$

Evaluate G for the case

$$A = p^2/2 \ , \ \ B = q^2/2. \tag{12.1.42}$$

You have verified a particular case of the general theorem that symplectic integration does not conserve the value of the Hamiltonian.

12.1.10. Verify that the weights of the "A" and "B" terms in (1.36) and (1.39) sum separately to -1. Why should this be?

12.1.11. Review the discussion of backward error analysis that appears near the end of Section 2.7. For a two-dimensional phase space, let H be the Hamiltonian

$$H = (1/2)ap^2 + (1/2)bq^2 = T(p) + V(q), \tag{12.1.43}$$

and let $\mathcal{S}_2(H,h)$ be the symplectic integrator

$$\mathcal{S}_2(H,h) = \exp : -(h/2)T : \exp : -hV : \exp : -(h/2)T : . \tag{12.1.44}$$

Show that there are functions $\alpha(h)$ and $\beta(h)$ such that

$$\mathcal{S}_2(H,h) = \exp : -h\bar{H} : \tag{12.1.45}$$

where

$$\bar{H} = (1/2)\alpha p^2 + (1/2)\beta q^2. \tag{12.1.46}$$

Find $\alpha(h)$ and $\beta(h)$ explicitly. Thus, $\mathcal{S}_2(H,h)$ produces exact trajectories for the modified Hamiltonian $\bar{H}$. Find a Hamiltonian $\hat{H}$ of the form

$$\hat{H} = (1/2)A(h)p^2 + (1/2)B(h)q^2 \tag{12.1.47}$$

such that $\mathcal{S}_2(\hat{H},h)$ produces exact trajectories for the Hamiltonian H.

12.1.12. Exercise on using BCH to combine exponents and backward error analysis to find effective Hamiltonian.

12.2 Symplectic Runge-Kutta Methods for $T+V$ Split Hamiltonians: Partitioned Runge Kutta and Nyström Runge Kutta

The integration methods of the Zassenhaus type, for the *special* Hamiltonians of the form $T+V$, are explicit and symplectic. They can also be viewed as being Runge-Kutta-like in that they involve multiple evaluations of the effects of T and V in the course of making a single integration step. For these special Hamiltonians there are also other methods, called *partitioned* Runge Kutta and Nyström Runge Kutta, that are explicit and symplectic. $\cdots$.

12.3 Symplectic Runge-Kutta Methods for General Hamiltonians

So far, the construction of symplectic integrators has been based on the assumption that the Hamiltonian can be split in the $T+V$ form (1.6). This assumption is not true for a broad class of problems of interest for Accelerator Physics, namely motion in a general electromagnetic field. It is not true for the Hamiltonian (1.5.30), assuming $\boldsymbol{A} \neq 0$, and it is not true for the Hamiltonian (1.6.16) except in the special case $\psi = A_x = A_y = 0$. In this subsection we will describe briefly symplectic Runge-Kutta methods that are applicable to general Hamiltonians.[5]

12.3.1 Background

Let us begin by setting up a notation that is convenient for working with differential equations in Hamiltonian form. Suppose the canonical variables are ordered as in (1.7.9) and Hamilton's equations of motion are written in the form (2.1.1). That is, we make the identification

$$\boldsymbol{y} = (q_1, q_2, \cdots q_\ell; p_1, p_2, \cdots p_\ell), \tag{12.3.1}$$

and therefore, from $\dot{\boldsymbol{y}} = \boldsymbol{f}(\boldsymbol{y}, t)$, it follows that

$$\boldsymbol{f} = J\partial H/\partial \boldsymbol{y}. \tag{12.3.2}$$

Write the Runge-Kutta procedure in terms of canonical variables by introducing the notation

$$\boldsymbol{y}^{n+1} = (Q_1, Q_2, \cdots Q_\ell; P_1, P_2, \cdots P_\ell) \tag{12.3.3}$$

and the slightly modified notation

$$\boldsymbol{y}^{n} = (q_1, q_2, \cdots q_\ell; p_1, p_2, \cdots p_\ell). \tag{12.3.4}$$

[5] We remark that the Hamiltonian for the restricted 3-body problem, when formulated in a rotating coordinate system in order to exploit the existence of the Jacobi integral that appears in this formulation, also cannot be split in the form $T+V$.

As in Sections 4.8 and 6.5.1, it is also convenient to employ the notation

$$z = (\boldsymbol{q}; \boldsymbol{p}), \tag{12.3.5}$$

$$Z = (\boldsymbol{Q}; \boldsymbol{P}). \tag{12.3.6}$$

In this terminology, performing a Runge-Kutta step from $t = t^n$ to $t = t^{n+1}$ sends the old pair $\boldsymbol{q}, \boldsymbol{p}$ to the new pair $\boldsymbol{Q}, \boldsymbol{P}$. Or, equivalently, it sends z to Z. In map notation, this transformation can be expressed in the form

$$Z = \mathcal{M}_{\text{RK}} z. \tag{12.3.7}$$

We would like the map $\mathcal{M}_{\text{RK}}$ to be exactly symplectic.

As further notation, decompose the vector $\boldsymbol{f}$ into q-like and p-like components,

$$\boldsymbol{f} = (\boldsymbol{f}^q; \boldsymbol{f}^p). \tag{12.3.8}$$

Also, introduce the ℓ-component vectors $\boldsymbol{H_q}$ and $\boldsymbol{H_p}$ by the rules

$$\boldsymbol{H_q}(\boldsymbol{q}, \boldsymbol{p}, t) = \partial H(\boldsymbol{q}, \boldsymbol{p}, t)/\partial \boldsymbol{q}, \tag{12.3.9}$$

$$\boldsymbol{H_p}(\boldsymbol{q}, \boldsymbol{p}, t) = \partial H(\boldsymbol{q}, \boldsymbol{p}, t)/\partial \boldsymbol{p}. \tag{12.3.10}$$

With these definitions, in view of (3.2), we have the relations

$$\boldsymbol{f}^q = \boldsymbol{H_p}, \tag{12.3.11}$$

$$\boldsymbol{f}^p = -\boldsymbol{H_q}. \tag{12.3.12}$$

Recall that a Runge-Kutta method is specified by a Butcher tableau. Review Section 2.3.4. From (2.3.6) we see that application of the Runge-Kutta stepping formula gives the relations

$$\boldsymbol{Q} = \boldsymbol{q} + h \sum_{i=1}^{s} b_i \boldsymbol{k}_i^q, \tag{12.3.13}$$

$$\boldsymbol{P} = \boldsymbol{p} + h \sum_{i=1}^{s} b_i \boldsymbol{k}_i^p. \tag{12.3.14}$$

Here we have introduced the notation

$$\boldsymbol{k}_i = (\boldsymbol{k}_i^q; \boldsymbol{k}_i^p) \tag{12.3.15}$$

to indicate that the $\boldsymbol{k}_i$ also have q-like and p-like components. In terms of this notation, (2.3.7), (3.11), and (3.12) yield the definitions

$$\boldsymbol{k}_i^q = \boldsymbol{f}^q(\boldsymbol{q}_i, \boldsymbol{p}_i, t_i) = \boldsymbol{H_p}(\boldsymbol{q}_i, \boldsymbol{p}_i, t_i), \tag{12.3.16}$$

$$\boldsymbol{k}_i^p = \boldsymbol{f}^p(\boldsymbol{q}_i, \boldsymbol{p}_i, t_i) = -\boldsymbol{H_q}(\boldsymbol{q}_i, \boldsymbol{p}_i, t_i). \tag{12.3.17}$$

For each value of i the right sides of (3.16) and (3.17) are to be evaluated at the points $(\boldsymbol{q}_i, \boldsymbol{p}_i, t_i)$ specified by the relations

$$\boldsymbol{q}_i = \boldsymbol{q} + h \sum_{j=1}^{s} a_{ij} \boldsymbol{k}_j^q, \tag{12.3.18}$$

$$\boldsymbol{p}_i = \boldsymbol{p} + h \sum_{j=1}^{s} a_{ij} \boldsymbol{k}_j^p, \tag{12.3.19}$$

$$t_i = t^n + c_i h. \tag{12.3.20}$$

We will see, in view of (3.16) and (3.17) and results to follow, that the relations (3.18) and (3.19) are implicit if the integrator is to be symplectic. They therefore must be solved by simple iteration or the more involved Newton's method.

12.3.2 Condition for Symplecticity

We will subsequently see that a necessary and sufficient condition for a Runge-Kutta method to be symplectic is that the entries in the matrix a and the vector b satisfy the relations

$$b_i a_{ij} + b_j a_{ji} - b_i b_j = 0 \text{ for } i, j = 1, \cdots, s. \tag{12.3.21}$$

As usual, the entries c are given by (2.3.11). From the condition (3.21) it is easy to prove that there are no explicit symplectic Runge-Kutta methods. See Exercise 3.1.

Note that the condition (3.21) makes no mention of the number of equations being integrated. Of course, in the Hamiltonian case, one is always integrating an even number equations, say ℓ for the q's and ℓ for the p's. When the number of equations is odd, it makes no sense to talk about a symplectic condition. However, it can be shown that in general a Runge-Kutta integrator satisfying (3.21) has additional desirable stability properties compared to other Runge-Kutta integrators, and therefore the condition (3.21) is also of interest when any set of differential equations, including non-Hamiltonian or odd numbers of equations, is being integrated.

12.3.3 The Single-Stage Case

Before verifying the necessity and sufficiency of the condition (3.21), let us consider the simplest case, the one-stage case $s = 1$. In this case the Butcher tableau has the general form

$$\begin{array}{c|c} c_1 & a_{11} \\ \hline & b_1 \end{array}\,, \tag{12.3.22}$$

and use of (3.21) yields the relation

$$2a_{11}b_1 = (b_1)^2. \tag{12.3.23}$$

But, in order for the method to at least be of order 1, we must have b_1=1. See (2.3.31). It follows from (3.23) that $a_{11} = 1/2$. Thus, if (3.21) holds, the Butcher tableau for a one-stage symplectic Runge-Kutta method is

$$\begin{array}{c|c} 1/2 & 1/2 \\ \hline & 1 \end{array}\,. \tag{12.3.24}$$

Here we have also used (2.3.11).

We have seen this Butcher tableau before. Look at (2.3.12) and (2.3.13) to see that this method is the implicit midpoint rule. And, as we learned from Exercise 2.3.7, this method is of order two. We will soon observe that this method is related to Gaussian quadrature, and for this reason we will refer to it as *Gauss2*. And, given equations of motion, we will call $\mathcal{M}_{\mathrm{G2}}$ the transfer map that arises from integrating these equations of motion using Gauss2.

Let us now verify, in the Hamiltonian context, that $\mathcal{M}_{\mathrm{G2}}$ is a symplectic map. For the coefficients (3.24), and in the Hamiltonian case, the Runge-Kutta relations become

$$\boldsymbol{Q} = \boldsymbol{q} + h\boldsymbol{k}_1^q, \tag{12.3.25}$$

$$\boldsymbol{P} = \boldsymbol{p} + h\boldsymbol{k}_1^p, \tag{12.3.26}$$

where

$$\boldsymbol{k}_1^q = \boldsymbol{H}_{\boldsymbol{p}}(\boldsymbol{q}_1, \boldsymbol{p}_1, t_1), \tag{12.3.27}$$

$$\boldsymbol{k}_i^p = -\boldsymbol{H}_{\boldsymbol{q}}(\boldsymbol{q}_1, \boldsymbol{p}_1, t_1), \tag{12.3.28}$$

with

$$\boldsymbol{q}_1 = \boldsymbol{q} + (h/2)\boldsymbol{k}_1^q, \tag{12.3.29}$$

$$\boldsymbol{p}_1 = \boldsymbol{p} + (h/2)\boldsymbol{k}_1^p, \tag{12.3.30}$$

$$t_1 = t^n + h/2. \tag{12.3.31}$$

Suppose small changes $d\boldsymbol{q}$ and $d\boldsymbol{p}$ are made in $\boldsymbol{q}$ and $\boldsymbol{p}$. Then, there will be related small changes $d\boldsymbol{Q}$ and $d\boldsymbol{P}$ in $\boldsymbol{Q}$ and $\boldsymbol{P}$. What we wish to verify is that the matrix M_{G2} in the relation

$$dZ = M_{\mathrm{G2}}dz \tag{12.3.32}$$

is symplectic, and therefore the map $\mathcal{M}_{\mathrm{G2}}$ is symplectic.

According to (3.25) and (3.26), there will be the relations

$$d\boldsymbol{Q} = d\boldsymbol{q} + hd\boldsymbol{k}_1^q, \tag{12.3.33}$$

$$d\boldsymbol{P} = d\boldsymbol{p} + hd\boldsymbol{k}_1^p. \tag{12.3.34}$$

From (3.27) and (3.28) we find the relations

$$d\boldsymbol{k}_1^q = \mathcal{H}_{\boldsymbol{pq}}(\boldsymbol{q}_1, \boldsymbol{p}_1, t_1)d\boldsymbol{q}_1 + \mathcal{H}_{\boldsymbol{pp}}(\boldsymbol{q}_1, \boldsymbol{p}_1, t_1)d\boldsymbol{p}_1, \tag{12.3.35}$$

$$d\boldsymbol{k}_1^p = -\mathcal{H}_{\boldsymbol{qq}}(\boldsymbol{q}_1, \boldsymbol{p}_1, t_1)d\boldsymbol{q}_1 - \mathcal{H}_{\boldsymbol{qp}}(\boldsymbol{q}_1, \boldsymbol{p}_1, t_1)d\boldsymbol{p}_1. \tag{12.3.36}$$

Here $\mathcal{H}_{\boldsymbol{qq}}$, $\mathcal{H}_{\boldsymbol{pq}}$, etc. are the $\ell \times \ell$ Hessian block matrices,

$$\begin{aligned}
&\mathcal{H}_{\boldsymbol{qq}}(\boldsymbol{q}, \boldsymbol{p}, t) = \partial^2 H(\boldsymbol{q}, \boldsymbol{p}, t)/\partial\boldsymbol{q}\partial\boldsymbol{q}, \\
&\mathcal{H}_{\boldsymbol{pq}}(\boldsymbol{q}, \boldsymbol{p}, t) = \mathcal{H}_{\boldsymbol{qp}}(\boldsymbol{q}, \boldsymbol{p}, t) = \partial^2 H(\boldsymbol{q}, \boldsymbol{p}, t)/\partial\boldsymbol{p}\partial\boldsymbol{q}, \\
&\mathcal{H}_{\boldsymbol{pp}}(\boldsymbol{q}, \boldsymbol{p}, t) = \partial^2 H(\boldsymbol{q}, \boldsymbol{p}, t)/\partial\boldsymbol{p}\partial\boldsymbol{p}.
\end{aligned} \tag{12.3.37}$$

And, from (3.29) and (3.30), we find the relations

$$d\boldsymbol{q}_1 = d\boldsymbol{q} + (h/2)d\boldsymbol{k}_1^q, \tag{12.3.38}$$

$$d\boldsymbol{p}_1 = d\boldsymbol{p} + (h/2)d\boldsymbol{k}_1^p. \tag{12.3.39}$$

Now substitute (3.38) and (3.39) into (3.35) and (3.36) to yield the results

$$d\boldsymbol{k}_1^q = \mathcal{H}_{\boldsymbol{pq}}[d\boldsymbol{q} + (h/2)d\boldsymbol{k}_1^q] + \mathcal{H}_{\boldsymbol{pp}}[d\boldsymbol{p} + (h/2)d\boldsymbol{k}_1^p], \tag{12.3.40}$$

$$d\boldsymbol{k}_1^p = -\mathcal{H}_{\boldsymbol{qq}}[d\boldsymbol{q} + (h/2)d\boldsymbol{k}_1^q] - \mathcal{H}_{\boldsymbol{qp}}[d\boldsymbol{p} + (h/2)d\boldsymbol{k}_1^p], \tag{12.3.41}$$

which can be rewritten in the form

$$[1 - (h/2)\mathcal{H}_{\boldsymbol{pq}}]d\boldsymbol{k}_1^q - (h/2)\mathcal{H}_{\boldsymbol{pp}}d\boldsymbol{k}_1^p = \mathcal{H}_{\boldsymbol{pq}}d\boldsymbol{q} + \mathcal{H}_{\boldsymbol{pp}}d\boldsymbol{p}, \tag{12.3.42}$$

$$(h/2)\mathcal{H}_{\boldsymbol{qq}}d\boldsymbol{k}_1^q + [1 + (h/2)\mathcal{H}_{\boldsymbol{qp}}]d\boldsymbol{k}_1^p = -\mathcal{H}_{\boldsymbol{qq}}d\boldsymbol{q} - \mathcal{H}_{\boldsymbol{qp}}d\boldsymbol{p}. \tag{12.3.43}$$

Our goal is to solve the relations (3.42) and (3.43) for $d\boldsymbol{k}_1^q$ and $d\boldsymbol{k}_1^p$, and then substitute the results into (3.33) and (3.34). To do so it is convenient to rewrite (3.42) and (3.43) in matrix/vector form. Let A be the matrix

$$A = \begin{pmatrix} \mathcal{H}_{\boldsymbol{pq}} & \mathcal{H}_{\boldsymbol{pp}} \\ -\mathcal{H}_{\boldsymbol{qq}} & -\mathcal{H}_{\boldsymbol{qp}} \end{pmatrix}. \tag{12.3.44}$$

Then (3.42) and (3.43) can be written in the form

$$[I - (h/2)A]d\boldsymbol{k}_1 = Adz, \tag{12.3.45}$$

and therefore

$$d\boldsymbol{k}_1 = [I - (h/2)A]^{-1}Adz. \tag{12.3.46}$$

Correspondingly, (3.33) and (3.34) become

$$dZ = M_{\mathrm{G2}}dz \tag{12.3.47}$$

with

$$M_{\mathrm{G2}} = I + h[I - (h/2)A]^{-1}A = [I - (h/2)A]^{-1}[I + (h/2)A]. \tag{12.3.48}$$

We claim that M_{G2} is a symplectic matrix. Correspondingly, in this Hamiltonian case, $\mathcal{M}_{\mathrm{G2}}$ is a symplectic map. To verify this claim, observe that A can be written in the form

$$A = JS \tag{12.3.49}$$

where

$$S = \begin{pmatrix} \mathcal{H}_{\boldsymbol{qq}} & \mathcal{H}_{\boldsymbol{qp}} \\ \mathcal{H}_{\boldsymbol{pq}} & \mathcal{H}_{\boldsymbol{pp}} \end{pmatrix}. \tag{12.3.50}$$

As the notation is intended to indicate, and because of the equality of mixed partial derivatives, S is a symmetric matrix. Consequently M_{G2} can also written in the form

$$M_{\mathrm{G2}} = [I - (h/2)JS]^{-1}[I + (h/2)JS]. \tag{12.3.51}$$

Reference to Section 3.12 shows that (3.51) is a Cayley representation when we make the identification

$$W = (h/2)S, \tag{12.3.52}$$

and therefore M_{G2} is indeed a symplectic matrix.

12.3.4 Two-, Three-, and More-Stage Methods

In Subsection 3.3 we studied the single-stage symplectic Runge-Kutta method, found its Butcher tableau (3.24), and observed that this method is of order two. Remarkably, it is also known that, for s stages, there are Runge-Kutta methods of order $m = 2s$, and these methods are symplectic when applied to Hamiltonian systems. Butcher tableaux for these methods, for the cases of two and three stages, are given below.

$$\begin{array}{c|cc} 1/2-\sqrt{3}/6 & 1/4 & 1/4-\sqrt{3}/6 \\ 1/2+\sqrt{3}/6 & 1/4+\sqrt{3}/6 & 1/4 \\ \hline & 1/2 & 1/2 \end{array}\ , \tag{12.3.53}$$

$$\begin{array}{c|ccc} 1/2-\sqrt{15}/10 & 5/36 & 2/9-\sqrt{15}/15 & 5/36-\sqrt{15}/30 \\ 1/2 & 5/36+\sqrt{15}/24 & 2/9 & 5/36-\sqrt{15}/24 \\ 1/2+\sqrt{15}/10 & 5/36+\sqrt{15}/30 & 2/9+\sqrt{15}/15 & 5/36 \\ \hline & 5/18 & 8/18 & 5/18 \end{array}\ . \tag{12.3.54}$$

They have orders 4 and 6, respectively. Observe that, in tableaux (3.24), (3.53), and (3.54), the b_i are weights and the c_i are evaluation points for Gaussian quadrature. This circumstance arises from the fact that the Runge-Kutta methods based on these tableaux are related to Gaussian quadrature. See Appendix T. For this reason these methods are sometimes referred to as Gauss2, Gauss4, and Gauss6. Butcher tableaux for Gauss8 and Gauss10 are also known. See the book of Sanz-Serna and Calvo listed in the Bibliography for this chapter.

We also remark that these methods are symmetric,

$$\mathcal{M}_{\rm G2s}(-h) = [\mathcal{M}_{\rm G2s}(h)]^{-1}. \tag{12.3.55}$$

See the book of Hairer, Nørsett, and Wanner listed in the Bibliography for this chapter.

Exercises

12.3.1. The purpose of this exercise is to verify that a Runge-Kutta, in order to be symplectic, must be implicit. Set $j = i$ in (3.21) to obtain the condition

$$b_i a_{ii} + b_i a_{ii} - b_i b_i = 0 \text{ for } i = 1, \cdots, s, \tag{12.3.56}$$

from which it follows that

$$2 b_i a_{ii} = (b_i)^2 \text{ for } i = 1, \cdots, s. \tag{12.3.57}$$

Verify that, for a Runge-Kutta method to be explicit, the matrix a must be lower triangular. In particular, it must satisfy the condition

$$a_{ii} = 0 \text{ for } i = 1, \cdots, s. \tag{12.3.58}$$

Combine (3.56) and (3.57) to conclude that

$$b_i = 0 \text{ for } i = 1, \cdots, s, \tag{12.3.59}$$

in which case, according to (2.3.6), the associated Runge-Kutta method fails to advance the solution $\boldsymbol{y}$ at all.

12.3.2. Repeat the calculations of Subsection 3.3 for the case of general a_{11} and general b_1. Show that (3.21) must be satisfied for M_{G2} to be a symplectic matrix.

12.4 Study of Single-Stage Method

We have already confessed that the integration formulas associated with each of the Butcher tableaux (3.24), (3.53), and (3.54) are implicit, and therefore must be made explicit (repeatedly solved) at each integration step in order to actually produce a trajectory. Let us see what is involved by first examining the simplest case, that of Gauss2 specified by the single-stage Butcher tableau (3.24). Application of (2.3.6) and (2.3.7) shows that Gauss2 employs the stepping formula

$$\boldsymbol{y}^{n+1} = \boldsymbol{y}^n + h\boldsymbol{k}_1 \tag{12.4.1}$$

where, at each step,

$$\boldsymbol{k}_1 = \boldsymbol{f}[\boldsymbol{y}^n + h(1/2)\boldsymbol{k}_1,\ t^n + (1/2)h]. \tag{12.4.2}$$

Let us now examine how to deal with/solve the implicit relation (4.2). Suppose we have some initial guess, which we will call $\boldsymbol{k}_1^0$, for $\boldsymbol{k}_1$. It might be $\boldsymbol{f}(\boldsymbol{y}^n, t^n)$, but we could hope for something better. Let us convert (4.2) into a recursion relation by making the rule

$$\boldsymbol{k}_1^{j+1} = \boldsymbol{f}[\boldsymbol{y}^n + h(1/2)\boldsymbol{k}_1^j,\ t^n + (1/2)h]. \tag{12.4.3}$$

It can be verified that (4.3) is a contraction map for small enough h. Therefore, providing the initial guess $\boldsymbol{k}_1^0$ is in the basin of attraction, we have the result

$$\boldsymbol{k}_1 = \lim_{j\to\infty} \boldsymbol{k}_1^j. \tag{12.4.4}$$

Finally, having found $\boldsymbol{k}_1$, $\boldsymbol{y}^{n+1}$ is given by (4.1).

To learn a bit more about the nature of the iteration process (4.3) and (4.4) for the solution of (4.2), it is instructive to study a simple example, that of the harmonic oscillator with Hamiltonian

$$H = (p^2 + q^2)/2. \tag{12.4.5}$$

For this case, with $\boldsymbol{y} = (q, p)$, we find the results

$$f_1 = \dot{y}_1 = \dot{q} = \partial H/\partial p = p = y_2, \tag{12.4.6}$$

$$f_2 = \dot{y}_2 = \dot{p} = -\partial H/\partial q = -q = -y_1, \tag{12.4.7}$$

which can be written more compactly in the matrix form

$$\dot{\boldsymbol{y}} = \boldsymbol{f} = J\boldsymbol{y}. \tag{12.4.8}$$

Here J is the matrix J_2 given by (3.2.11). Correspondingly, application of (4.2) yields the relations

$$\{\boldsymbol{k}_1\}_1 = \{\boldsymbol{f}[\boldsymbol{y}^n + h(1/2)\boldsymbol{k}_1,\ t^n + (1/2)h]\}_1 = \{\boldsymbol{y}^n\}_2 + h(1/2)\{\boldsymbol{k}_1\}_2, \tag{12.4.9}$$

$$\{\boldsymbol{k}_1\}_2 = \{\boldsymbol{f}[\boldsymbol{y}^n + h(1/2)\boldsymbol{k}_1,\ t^n + (1/2)h]\}_2 = -\{\boldsymbol{y}^n\}_1 - h(1/2)\{\boldsymbol{k}_1\}_1, \tag{12.4.10}$$

which can be conveniently written together in the matrix form

$$\boldsymbol{k}_1 = J[\boldsymbol{y}^n + h(1/2)\boldsymbol{k}_1], \tag{12.4.11}$$

and solved for $\boldsymbol{k}_1$ to yield the result

$$\boldsymbol{k}_1 = (I - hJ/2)^{-1}J\boldsymbol{y}^n. \tag{12.4.12}$$

Note that in general we are only able to explicitly solve for $\boldsymbol{k}_1$ in the case that the right side of (4.2) is linear in $\boldsymbol{k}_1$, as is true for this special example.

At this point we cannot resist the urge to employ (4.12) in (4.1) to obtain the explicit stepping relation

$$\boldsymbol{y}^{n+1} = I\boldsymbol{y}^n + h(I - hJ/2)^{-1}J\boldsymbol{y}^n = (I + hJ/2)(I - hJ/2)^{-1}\boldsymbol{y}^n = M_{\mathrm{G2}}\boldsymbol{y}^n \tag{12.4.13}$$

with

$$M_{\mathrm{G2}} = (I + hJ/2)(I - hJ/2)^{-1}. \tag{12.4.14}$$

Observe that M_{G2} is in the Cayley form (3.12.5) with

$$W = (h/2)I. \tag{12.4.15}$$

Since W is symmetric, it follows that M_{G2} is symplectic, as expected. See (3.12.6).

We also know from Section 3.12 that M_{G2} can be written in the form

$$M_{\mathrm{G2}} = \exp(JS) \tag{12.4.16}$$

with S given by

$$S = -2J\tanh^{-1}(JW). \tag{12.4.17}$$

See (3.12.4). Use of (4.15) in (4.17) yields the result

$$\begin{aligned} S &= -2J\tanh^{-1}[(h/2)J] = (-2J)[(hJ/2) + (hJ/2)^3/3 + (hJ/2)^5/5 + \cdots] \\ &= 2[(h/2) - (h/2)^3/3 + (h/2)^5/5 + \cdots]I \\ &= 2\tan^{-1}(h/2)I = h(2/h)\tan^{-1}(h/2)I = h(1 - h^2/12 + h^4/80 - \cdots)I. \end{aligned} \tag{12.4.18}$$

It follows that, for H given by (4.5), M_{G2} can be written in the form

$$M_{\mathrm{G2}} = \exp(JS) = \exp[(2/h)\tan^{-1}(h/2)hJ]. \tag{12.4.19}$$

Consider the Hamiltonian H' defined by

$$H' = \omega(p^2 + q^2)/2. \tag{12.4.20}$$

It can be verified that the exact solution to the equation of motion generated by H' is given by the relation

$$\boldsymbol{y}_{\mathrm{true}}(t) = \exp[\omega(t - t^0)J]\boldsymbol{y}^0_{\mathrm{true}}, \tag{12.4.21}$$

and therefore

$$\boldsymbol{y}_{\rm true}^{n+1} = \exp(\omega hJ)\boldsymbol{y}_{\rm true}^{n}. \tag{12.4.22}$$

Upon comparing (4.13) and (4.19) with (4.22), we conclude that use of Gauss2 to integrate the equations of motion generated by the Hamiltonian H gives the exact solution to the equations of motion generated by H' with

$$\omega = (2/h)\tan^{-1}(h/2) = 1 - h^2/12 + h^4/80 - \cdots . \tag{12.4.23}$$

We observe that H' is conserved and therefore, since H and H' are proportional, H is also conserved by Gauss2. Finally, according to (4.23), the trajectory given by Gauss2, since it is the exact trajectory for H', differs from the exact trajectory for H only by a reparameterization of the time.

Also, here we have an instance of backward error analysis. *Approximately* but symplectically integrating the equations of motion generated by H yields the *exact* trajectory for the equations of motion generated by H' with H' being a small (when h is small) modification of H. See the discussion of backward error analysis in Section 2.7. Conversely, given H, it should be possible to find a related Hamiltonian H'' such that symplectically integrating the equations of motion generated by H'' yields the *exact* trajectory for the equations of motion generated by H. See Exercise 4.1.

With this diversion behind us, let us return to an analysis of the iteration process (4.3). By reasoning analogous to that which produced (4.11), the iteration process (4.3) for the case of H given by (4.5) yields the matrix relation

$$\boldsymbol{k}_1^{j+1} = J[\boldsymbol{y}^n + h(1/2)\boldsymbol{k}_1^j]. \tag{12.4.24}$$

We may view it as a mapping with fixed point $\boldsymbol{k}_1$. How do points near this fixed point behave under the influence of this map? Introduce deviation variables $\boldsymbol{\delta}^j$ by writing

$$\boldsymbol{k}_1^j = \boldsymbol{k}_1 + \boldsymbol{\delta}^j. \tag{12.4.25}$$

In terms of these variables, (4.24) takes the form

$$\boldsymbol{\delta}^{j+1} = (hJ/2)\boldsymbol{\delta}^j. \tag{12.4.26}$$

This recursion relation has the solution

$$\boldsymbol{\delta}^j = (hJ/2)^j\boldsymbol{\delta}^0. \tag{12.4.27}$$

The eigenvalues of J are $\pm i$, and therefore the eigenvalues of $hJ/2$ are $\pm ih/2$. These eigenvalues lie within the unit circle as long as the step size satisfies $|h/2| < 1$, and therefore the fixed point $\boldsymbol{k}_1$ is attracting under this condition. That is, if $|h/2| < 1$, then

$$\lim_{j\to\infty} \boldsymbol{\delta}^j = 0. \tag{12.4.28}$$

Moreover, examination of (4.27) shows that, for the H of this example, the basin of attraction is the entire $\boldsymbol{\delta}^0$ plane, and therefore also the entire $\boldsymbol{k}_1^0$ plane.

There remains the problem of constructing a good initial guess $\boldsymbol{k}_1^0$. Suppose we begin with the initial guess

$$\boldsymbol{k}_1^0 = J\boldsymbol{y}^n. \tag{12.4.29}$$

Doing so is equivalent to ignoring the order h terms in the argument of the right side of (4.2) thereby setting $\boldsymbol{k}_1^0 = \boldsymbol{f}(\boldsymbol{y}^n, t^n)$. We then find the results

$$\boldsymbol{k}_1^1 \;=\; J\boldsymbol{y}^n + (h/2)J\boldsymbol{k}_1^0 = J\boldsymbol{y}^n + Jh(1/2)J\boldsymbol{y}^n = (I + hJ/2)J\boldsymbol{y}^n, \tag{12.4.30}$$

$$\begin{aligned} \boldsymbol{k}_1^2 &= J\boldsymbol{y}^n + (h/2)J\boldsymbol{k}_1^1 = J\boldsymbol{y}^n + (hJ/2)(I + hJ/2)J\boldsymbol{y}^n \\ &= [I + (hJ/2) + (hJ/2)^2]J\boldsymbol{y}^n, \text{ etc.} \end{aligned} \tag{12.4.31}$$

Observe that (4.12) has the expansion

$$\boldsymbol{k}_1 = (I - hJ/2)^{-1}J\boldsymbol{y}^n = [I + (hJ/2) + (hJ/2)^2 + \cdots]J\boldsymbol{y}^n. \tag{12.4.32}$$

Evidently, the iterative process, with the initial guess (4.29), reproduces this expansion in such a way that each iteration produces one more term in the expansion.

Suppose instead we begin with the guess

$$\boldsymbol{k}_1^0 = (I + hJ/2)J\boldsymbol{y}^n. \tag{12.4.33}$$

Then we find

$$\boldsymbol{k}_1^1 = J\boldsymbol{y}^n + (h/2)J\boldsymbol{k}_1^0 = J\boldsymbol{y}^n + (hJ/2)(I + hJ/2)J\boldsymbol{y}^n = [I + (hJ/2) + (hJ/2)^2]J\boldsymbol{y}^n. \tag{12.4.34}$$

Evidently, this is a better guess because it moves us one further step down the chain of iterations.

How could we have anticipated that this would be a better guess? We have remarked that the Butcher tableaux (3.24), (3.53), and (3.54) are related to Gaussian quadrature. Integrate both sides of (2.1.1) over the interval $[t^n, t^{n+1}]$. So doing yields the result

$$\boldsymbol{y}^{n+1} - \boldsymbol{y}^n = \int_{t^n}^{t^{n+1}} d\tau \dot{\boldsymbol{y}}(\tau) = \int_{t^n}^{t^{n+1}} d\tau \boldsymbol{f}[\boldsymbol{y}(\tau),\ \tau]. \tag{12.4.35}$$

Estimate the integral on the right side of (4.35) using lowest-order Gaussian quadrature, which amounts to the midpoint rule, to find the approximation

$$\boldsymbol{y}^{n+1} - \boldsymbol{y}^n = \int_{t^n}^{t^{n+1}} d\tau \boldsymbol{f}[\boldsymbol{y}(\tau),\ \tau] \simeq h\boldsymbol{f}[\boldsymbol{y}(t^n + h/2),\ t^n + h/2] = h\boldsymbol{f}[\boldsymbol{y}(t^n + c_1 h),\ t^n + c_1 h]. \tag{12.4.36}$$

Comparison of (4.36) with (4.1) suggests that a good first guess in the one-stage case would be

$$\boldsymbol{k}_1^0 = \boldsymbol{f}[\boldsymbol{y}(t^n + h/2),\ t^n + h/2]. \tag{12.4.37}$$

Here $\boldsymbol{y}$ is the exact solution to (2.1.1). But, of course, we do not know the exact solution. However, we can imagine having computed and stored $\boldsymbol{f}^n$ as given by (2.1.4). Then, in predictor-corrector terminology with $N = 0$ (see Section 2.4), we can construct a predictor formula using jet formulation (see Section 2.5.3) that will produce $\boldsymbol{y}_{\rm pred}(t^n + h/2)$ with a local error of order h^2 [see (2.4.38)].[6] With a knowledge of $\boldsymbol{y}_{\rm pred}(t^n + h/2)$ we can define $\boldsymbol{k}_1^0$ by the rule

$$\boldsymbol{k}_1^0 = \boldsymbol{f}[\boldsymbol{y}_{\rm pred}(t^n + h/2),\ t^n + h/2]. \qquad (12.4.38)$$

Use of the $N = 0$ predictor in jet formulation gives the result

$$\boldsymbol{y}_{\rm pred}(t^n + h/2) = \boldsymbol{y}^n + (h/2)\boldsymbol{f}^n. \qquad (12.4.39)$$

For the current example,

$$\boldsymbol{y}^n + (h/2)\boldsymbol{f}^n = (I + hJ/2)\boldsymbol{y}^n. \qquad (12.4.40)$$

Combining (4.38) through (4.40) yields the result

$$\begin{aligned} \boldsymbol{k}_1^0 &= \boldsymbol{f}[\boldsymbol{y}_{\rm pred}(t^n + h/2),\ t^n + h/2] \\ &= \boldsymbol{f}[\boldsymbol{y}^n + (h/2)\boldsymbol{f}^n,\ t^n + h/2] \\ &= \boldsymbol{f}[(I + hJ/2)\boldsymbol{y}^n] \\ &= (I + hJ/2)J\boldsymbol{y}^n, \end{aligned} \qquad (12.4.41)$$

in agreement with (4.33). With this $\boldsymbol{k}_1^0$ in hand, we can proceed to carry out the iterations (4.3) to yield, depending on the number of iterations made, some approximation to $\boldsymbol{k}_1$, and then finally determine $\boldsymbol{y}^{n+1}$ using (4.1). Note that, if we wish, we may view (4.3) as a kind of corrector formula.

Let us make two last comments about the solution of (4.2). First, as we have seen from the harmonic oscillator example, its solution by iteration, as in (4.3) and (4.4), requires an infinite number of iterations. Therefore if we, as we must, make only make a finite number iterations, the result of the integration method will not be exactly symplectic. It will only be symplectic to some high power of h depending on how many iterations are made at each step. Each iteration makes the method exactly symplectic through terms of yet one order higher in h. Of course, no matter how many iterations are made, the result is only locally accurate through terms of order h^2. That is, although the result may be highly symplectic, depending on the number of iterations, an error of order h^3 is still made at each step. Second, in order to speed convergence, we might attempt to solve (5.2) by Newton's method. This is possible at the cost of extra programming.[7] For an introduction to Newton's method, see Section 29.4.3.

[6] One might wonder about storing more previous $\boldsymbol{f}$ values so that $\boldsymbol{y}_{\rm pred}(t^n + h/2)$ would be given with yet higher order accuracy. The use of an additional $\boldsymbol{f}$ value would yield an h^2 contribution to $\boldsymbol{k}_1^0$ and an h^3 contribution to $\boldsymbol{k}_1^1$. However, there would seem to be no point in doing so. We know that the predictor is attempting to integrate the trajectories associated with H and the symplectic Runge-Kutta procedure integrates the trajectories associated with H', and these Hamiltonians differ by terms of order h^2. Therefore, the higher-order terms produced by a higher-order predictor would not be expected to improve the guess of $\boldsymbol{k}_1^0$.

[7] Of course, whatever method is used to solve (4.2), it can, if desired, be solved to machine precision in a finite number of steps.

Exercises

12.4.1. This is a study in backward error analysis for the harmonic oscillator when its equations of motion are integrated using Gauss2. We have learned, when integrating the equations of motion associated with the Hamiltonian H given by (4.5), that use of Gauss2 yields exact trajectories for the nearby Hamiltonian H' given by (4.20) and (4.23). Find a Hamiltonian H'' whose equations of motion, when integrated using Gauss2, produces the exact trajectories for the Hamiltonian H.

12.4.2. This is a study in backward error analysis for the general static quadratic Hamiltonian when its associated equations of motion are integrated using Gauss2. Review Subsection 3.3. There we were able to find $M_{\rm G2}$, the matrix for the linear part of $\mathcal{M}_{\rm G2}$, for a general trajectory generated by a general Hamiltonian. Verify that if the equations of motion are linear, as will be the case if the Hamiltonian is quadratic, then the various implicit equations that have to be solved using Gauss2 are all linear. Moreover, again because the Hamiltonian is assumed to be quadratic, the matrix S given by (3.50) will have constant entries. Correspondingly, the map $\mathcal{M}_{\rm G2}$ will be linear, and will be completely represented by its linear part $M_{\rm G2}$ with $M_{\rm G2}$ given by (3.51).

Verify, at least when H is quadratic and static, that $\mathcal{M}_{\rm G2}$ is symmetric,

$$\mathcal{M}_{\rm G2}(-h) = [\mathcal{M}_{\rm G2}(h)]^{-1}. \tag{12.4.42}$$

As stated earlier, an analogous result is known to hold in general when any Gauss2s is used to integrate any set of differential equations.

How does $\mathcal{M}_{\rm G2}$ compare with the exact map $\mathcal{M}$? In the case that H is static, we know that

$$\mathcal{M} = \exp(-h : H :). \tag{12.4.43}$$

Recall (1.4). Show that if H is quadratic, then $\mathcal{M}$ will be linear and will be described by the matrix M given by

$$M = \exp(hJS). \tag{12.4.44}$$

We can now compare $\mathcal{M}_{\rm G2}$ and $\mathcal{M}$. From (3.12.1) through (3.12.5) show that

$$M_{\rm G2} = \exp(hJS') \tag{12.4.45}$$

with

$$JS' = (2/h)\tanh^{-1}[(h/2)JS], \tag{12.4.46}$$

and therefore

$$S' = -J(2/h)\tanh^{-1}[(h/2)JS]. \tag{12.4.47}$$

Consequently, show that use of Gauss2 to integrate the equations of motion associated with the quadratic Hamiltonian H given by

$$H(z) = (1/2)(z, Sz) \tag{12.4.48}$$

produces the exact trajectory for the equations of motion associated with the Hamiltonian H' given by

$$H'(z) = (1/2)(z, S'z). \tag{12.4.49}$$

(Here, as before, we assume that S is time independent.)

Use the results of Exercise 3.12.1, the machinery of (5.5.1) through (5.5.13), and (4.45) to show that

$$[H, H'] = 0, \tag{12.4.50}$$

and therefore $\mathcal{M}_{\mathrm{G2}}$ conserves H.

Given a quadratic time independent H, find a Hamiltonian H'' such that integrating its associated equations of motion using Gauss2 produces the exact trajectories for the Hamiltonian H.

12.5 Study of Two-Stage Method

Now that we have explored the behavior of the single-stage method Gauss2, let us make a similar exploration of the two-stage method Gauss4. Doing so will give us a general understanding of what to expect in the multi-stage case. For the two-stage case use of (2.3.6) and (2.3.7) and the Butcher tableau (3.53) provides the stepping formula

$$\boldsymbol{y}^{n+1} = \boldsymbol{y}^n + h(1/2)\boldsymbol{k}_1 + h(1/2)\boldsymbol{k}_2 \tag{12.5.1}$$

where, at each step,

$$\boldsymbol{k}_1 = \boldsymbol{f}[\boldsymbol{y}^n + h(1/4)\boldsymbol{k}_1 + h(1/4 - \sqrt{3}/6)\boldsymbol{k}_2,\ t^n + h(1/2 - \sqrt{3}/6)], \tag{12.5.2}$$

$$\boldsymbol{k}_2 = \boldsymbol{f}[\boldsymbol{y}^n + h(1/4 + \sqrt{3}/6)\boldsymbol{k}_1 + h(1/4)\boldsymbol{k}_2,\ t^n + h(1/2 + \sqrt{3}/6)]. \tag{12.5.3}$$

Like (4.2) in the single-stage case, the relations (5.2) and (5.3) are implicit. To solve them numerically, we may make initial guesses $\boldsymbol{k}_1^0$ and $\boldsymbol{k}_2^0$ for $\boldsymbol{k}_1$ and $\boldsymbol{k}_2$, respectively, and set up the recursion relations

$$\boldsymbol{k}_1^{j+1} = \boldsymbol{f}[\boldsymbol{y}^n + h(1/4)\boldsymbol{k}_1^j + h(1/4 - \sqrt{3}/6)\boldsymbol{k}_2^j,\ t^n + h(1/2 - \sqrt{3}/6)], \tag{12.5.4}$$

$$\boldsymbol{k}_2^{j+1} = \boldsymbol{f}[\boldsymbol{y}^n + h(1/4 + \sqrt{3}/6)\boldsymbol{k}_1^j + h(1/4)\boldsymbol{k}_2^j,\ t^n + h(1/2 + \sqrt{3}/6)]. \tag{12.5.5}$$

It can be shown that the relations (5.4) and (5.5) constitute a contraction map for sufficiently small h. Consequently, assuming that the $\boldsymbol{k}_i^0$ are in the basin of attraction, there will be the result

$$\boldsymbol{k}_i = \lim_{j\to\infty} \boldsymbol{k}_i^j. \tag{12.5.6}$$

Alternatively, to achieve more rapid convergence at the expense of a more involved procedure, we may solve (5.2) and (5.3) by Newton's method, which will also be convergent for sufficiently small h and a sufficiently good guess for the $\boldsymbol{k}_i^0$. Finally, having found the $\boldsymbol{k}_i$ by whatever method, $\boldsymbol{y}^{n+1}$ is given by (5.1).

It is again instructive to apply this method to the harmonic oscillator example with the Hamiltonian (4.5) and the equations of motion (4.8). In this case the relations (5.2) and (5.3) take the specific form

$$\boldsymbol{k}_1 = J[\boldsymbol{y}^n + h(1/4)\boldsymbol{k}_1 + h(1/4 - \sqrt{3}/6)\boldsymbol{k}_2], \tag{12.5.7}$$

$$\boldsymbol{k}_2 = J[\boldsymbol{y}^n + h(1/4 + \sqrt{3}/6)\boldsymbol{k}_1 + h(1/4)\boldsymbol{k}_2]. \tag{12.5.8}$$

As they stand these relations, because of their vector/matrix form, comprise four linear equations in four unknowns, namely the components of the two two-dimensional vectors $\boldsymbol{k}_1$ and $\boldsymbol{k}_2$. With sufficient effort, linear equations can always be solved. In this case there is a trick that simplifies the problem. First rewrite (5.8) to bring all terms involving $\boldsymbol{k}_2$ to the left and all other terms to the right. So doing yields the relation

$$(I - hJ/4)\boldsymbol{k}_2 = J[\boldsymbol{y}^n + h(1/4 + \sqrt{3}/6)\boldsymbol{k}_1]. \tag{12.5.9}$$

Next solve (5.9) for $\boldsymbol{k}_2$ in terms of everything else to find the result

$$\boldsymbol{k}_2 = (I - hJ/4)^{-1}J[\boldsymbol{y}^n + h(1/4 + \sqrt{3}/6)\boldsymbol{k}_1]. \tag{12.5.10}$$

Now substitute (5.10) into (5.7) to obtain a relation involving only $\boldsymbol{k}_1$,

$$\boldsymbol{k}_1 = J\{\boldsymbol{y}^n + h(1/4)\boldsymbol{k}_1 + h(1/4 - \sqrt{3}/6)(I - hJ/4)^{-1}J[\boldsymbol{y}^n + h(1/4 + \sqrt{3}/6)\boldsymbol{k}_1]\}. \tag{12.5.11}$$

Manipulate this relation to find, as intermediate steps, the results

$$\begin{aligned}&\boldsymbol{k}_1 - Jh(1/4)\boldsymbol{k}_1 + h(1/4 - \sqrt{3}/6)(I - hJ/4)^{-1}h(1/4 + \sqrt{3}/6)\boldsymbol{k}_1\\ &= J[\boldsymbol{y}^n + h(1/4 - \sqrt{3}/6)(I - hJ/4)^{-1}J\boldsymbol{y}^n],\end{aligned} \tag{12.5.12}$$

or,

$$\begin{aligned}&[I - Jh(1/4) - h^2(1/48)(I - hJ/4)^{-1}]\boldsymbol{k}_1\\ &= [J - h(1/4 - \sqrt{3}/6)(I - hJ/4)^{-1}]\boldsymbol{y}^n,\end{aligned} \tag{12.5.13}$$

and, as a last step, the explicit solution

$$\boldsymbol{k}_1 = [I - hJ/4 - (h^2/48)(I - hJ/4)^{-1}]^{-1}[J - h(1/4 - \sqrt{3}/6)(I - hJ/4)^{-1}]\boldsymbol{y}^n. \tag{12.5.14}$$

(Here we have used the relation $J^2 = -I$.) Finally, insert (5.14) into (5.10) to yield an explicit result for $\boldsymbol{k}_2$,

$$\boldsymbol{k}_2 = . \tag{12.5.15}$$

Exercises

12.5.1.

12.5.2.

12.6 Numerical Examples for One- and Two-Stage Methods

12.7 Proof of Condition for Symplecticity

There are at least three ways to verify that (3.21) is a necessary and sufficient condition for $\mathcal{M}_{\rm RK}$ to be symplectic. The first requires making a brute force calculation of the Jacobian matrix M_{RK} associated with $\mathcal{M}_{\rm RK}$ followed by a verification that M_{RK} is a symplectic matrix. That is what we have just done for the simplest case $s = 1$. See also Exercise 3.2. The second, far more elegant and compact, makes use of differential forms. The third, which we will employ here, uses the contents of the Butcher tableau to define a generating function F_2. It then demonstrates that the generating produced by F_2 reproduces the Runge-Kutta step for the Butcher tableau provided the contents of the Butcher tableau satisfy (3.21).

Consider the generating function $F_2(\boldsymbol{q},\boldsymbol{P},t^n;h)$ defined by writing

$$F_2(\boldsymbol{q},\boldsymbol{P},t^n;h) = \boldsymbol{q}\cdot\boldsymbol{P} + G_2(\boldsymbol{q},\boldsymbol{P},t^n;h), \tag{12.7.1}$$

where

$$G_2 = G_2^1 + G_2^2 \tag{12.7.2}$$

with

$$G_2^1 = h\sum_{i=1}^{s} b_i H(\boldsymbol{q}_i,\boldsymbol{p}_i,t_i), \tag{12.7.3}$$

$$G_2^2 = -h^2\sum_{i,j=1}^{s} b_i a_{ij}[\boldsymbol{H_q}(\boldsymbol{q}_i,\boldsymbol{p}_i,t_i)\cdot\boldsymbol{H_p}(\boldsymbol{q}_j,\boldsymbol{p}_j,t_j)]. \tag{12.7.4}$$

The thoughtful reader may find the definition given by (7.1) through (7.4) puzzling because the terms on the right sides of (7.3) and (7.4) are functions of the old phase-space variables variables $\boldsymbol{q},\boldsymbol{p}$ while the phase-space arguments of G_2 are specified as being the mixed pair $\boldsymbol{q},\boldsymbol{P}$. Here is what is meant: The relation (3.14) specifies $\boldsymbol{P}$ as a function of $\boldsymbol{q},\boldsymbol{p},t^n$; and h,

$$\boldsymbol{P} = \boldsymbol{P}(\boldsymbol{q},\boldsymbol{p},t^n;h). \tag{12.7.5}$$

This relation is to be partially inverted to yield $\boldsymbol{p}$ as a function of $\boldsymbol{q},\boldsymbol{P},t^n$ and h,

$$\boldsymbol{p} = \boldsymbol{p}(\boldsymbol{q},\boldsymbol{P},t^n;h). \tag{12.7.6}$$

From the form of (3.14) we see, by the inverse function theorem, that such an inversion is possible for small enough h because then $\boldsymbol{p}\simeq\boldsymbol{P}$. Finally, the right side of (7.6) is to be substituted for $\boldsymbol{p}$ in the right sides of (7.3) and (7.4) to yield $G_2(\boldsymbol{q},\boldsymbol{P},t^n;h)$.

Suppose we use $F_2(\boldsymbol{q},\boldsymbol{P},t^n;h)$ to produce a transformation that sends $\boldsymbol{q},\boldsymbol{p}$ to $\boldsymbol{Q},\boldsymbol{P}$ by the standard rules (6.5.5),

$$p_k = \partial F_2/\partial q_k\ ,\ Q_k = \partial F_2/\partial P_k. \tag{12.7.7}$$

From the work of Section 6.5.1 we know that so doing will produce a symplectic map, which we will call $\mathcal{M}$. With a view to implementing (7.7), let us compute (save for holding t^n fixed) the total differential of $G_2(\boldsymbol{q},\boldsymbol{P},t^n;h)$.

12.8 Symplectic Integration of General Hamiltonians Using Generating Functions

Section 6.7.3 on the Hamilton-Jacobi equation studied the relation between Hamiltonians and generating functions. There it was shown, once a Darboux matrix α has been selected, that there is a unique relation between the Hamiltonian $H(Z,t)$ and the source function $g(u,t)$. Given H, some time t^n, some phase-space point z^n, and a time step h, we wish to find z^{n+1} at time $t^{n+1} = t^n + h$ in such a way that the relation between z^{n+1} and z^n is symplectic and z^{n+1} is very nearly (with error of order h^{m+1}) equal to the result found by exactly integrating the equations generated by H starting with initial conditions z^n at $t = t^n$ and integrating to $t = t^n + h$. We assume that the trajectory generated by H is analytic in t, which will be the case if $H(z,t)$ is analytic in the phase-space variables z and the time t. (See Poincaré's theorem in Section 1.3.) Then $z(t^n + h)$ will have a Taylor expansion in h.

12.9 Special Symplectic Integrator for Motion in General Electromagnetic Fields

We have seen that there are *implicit* symplectic Runge-Kutta integrators for general Hamiltonians, and hence also for motion in general electromagnetic fields. Remarkably, there are *explicit* symplectic integrators for the Hamiltonian (1.6.192) and, by extension, for the Hamiltonian (1.6.77).

We begin with the simpler case, the Hamiltonian (1.6.192), which can be written in the form

$$H = H_x + H_y + H_z \tag{12.9.1}$$

where

$$H_x = (p_x - qA_x)^2/(2m^*), \tag{12.9.2}$$

$$H_y = (p_y - qA_y)^2/(2m^*), \tag{12.9.3}$$

$$H_z = (p_z - qA_z)^2/(2m^*). \tag{12.9.4}$$

Since H is time independent, the relation (1.1) still holds. Moreover, we may again subdivide the time axis into equal steps of duration h to obtain the exact marching rule (1.4). However, since in the present context the symbol z is being used to denote a coordinate, we rewrite (1.4) in the form

$$w^{n+1} = \exp(h : -H :)w^n \tag{12.9.5}$$

where w denotes the collection of phase-space variables

$$w = (x, y, z, ; p_x, p_y, p_z). \tag{12.9.6}$$

We next make the approximation

$$\exp(h : -H :) \cong \mathcal{S}_2(h) \tag{12.9.7}$$

where $\mathcal{S}_2(k)$ is now defined by the rule

$$\begin{aligned} \mathcal{S}_2(h) \;=\; & \exp[-(h/2) : H_x :] \exp[-(h/2) : H_y :] \times \\ & \exp[-h : H_z :] \exp[-(h/2) : H_y :] \exp[-(h/2) : H_x :]. \end{aligned} \tag{12.9.8}$$

Upon combining the exponents on the right side of (9.8) to first order in h, we see that the exponent on the left side of (9.7) is regained. Also, by construction, $\mathcal{S}_2$ satisfies (1.16). Therefore, as the notation is intended to indicate, $\mathcal{S}_2$ is a symmetric integrator that is locally correct through terms of order h^2. Note other permutations of H_x, H_y, and H_z could have been used in the definition of $\mathcal{S}_2$. There are thus 3! possible formulas of the kind (9.8).

We are still faced with the problem of evaluating the action of the individual factors on the right side of (9.8). Define functions $U_x(x, y, z)$, $U_y(x, y, z)$, and $U_z(x, y, z)$ by the requirements

$$A_x = \partial U_x/\partial x \;,\; A_y = \partial U_y/\partial y \;,\; A_z = \partial U_z/\partial z. \tag{12.9.9}$$

There are many such functions, and we may choose among them at will at each integration step. For example, we may write

$$U_x = \int^x A_x(x', y, z)dx' \tag{12.9.10}$$

and add to it any function of y and z. Use the U's to make symplectic maps $\mathcal{A}_x$, $\mathcal{A}_y$, and $\mathcal{A}_z$ defined by the relations

$$\mathcal{A}_x = \exp(-q : U_x :) \;,\; \mathcal{A}_y = \exp(-q : U_y :) \;,\; \mathcal{A}_z = \exp(-q : U_z :). \tag{12.9.11}$$

These maps produce gauge transformations. See Exercise 6.2.8. It is easily verified, for example, that $\mathcal{A}_x$ and $\mathcal{A}_x^{-1}$ have the phase-space actions

$$\mathcal{A}_x x = x \;,\; \mathcal{A}_x y = y \;,\; \mathcal{A}_x z = z, \tag{12.9.12}$$

$$\mathcal{A}_x^{-1} x = x \;,\; \mathcal{A}_x^{-1} y = y \;,\; \mathcal{A}_x^{-1} z = z, \tag{12.9.13}$$

$$\mathcal{A}_x p_x = p_x - q : U_x : p_x = p_x - q[U_x, p_x] = p_x - q(\partial U_x/\partial x) = p_x - qA_x, \tag{12.9.14}$$

$$\mathcal{A}_x^{-1} p_x = p_x + q : U_x : p_x = p_x + qA_x, \tag{12.9.15}$$

$$\mathcal{A}_x p_y = p_y - q : U_x : p_y = p_y - q[U_x, p_y] = p_y - q(\partial U_x/\partial y), \tag{12.9.16}$$

$$\mathcal{A}_x^{-1} p_y = p_y + q : U_x : p_y = p_y + q(\partial U_x/\partial y), \tag{12.9.17}$$

$$\mathcal{A}_x p_z = p_z - q : U_x : p_z = p_z - q[U_x, p_z] = p_z - q(\partial U_x/\partial z), \tag{12.9.18}$$

$$\mathcal{A}_x^{-1} p_z = p_z + q : U_x : p_z = p_z + q(\partial U_x/\partial z). \tag{12.9.19}$$

In particular, it follows from (9.14) and (9.15) that $\mathcal{A}_x$ has the property

$$\begin{aligned} & \mathcal{A}_x \exp[-(h/2) : p_x^2/(2m^*) :]\mathcal{A}_x^{-1} = \exp[-(h/2) : (p_x - qA_x)^2/(2m^*)] \\ & = \exp[-(h/2) : H_x :]. \end{aligned} \tag{12.9.20}$$

We note at this point that it does not matter what special choice is made for U_x, see (9.10), because from (9.20) it is evident that all allowed choices yield the same net result.

As a consequence of (9.20) and similar relations, $\mathcal{S}_2$ can be rewritten in the factored product form

$$\begin{aligned}\mathcal{S}_2 = \quad & \mathcal{A}_x \exp[-(h/2) : \bar{H}_x :]\mathcal{A}_x^{-1} \times \\ & \mathcal{A}_y \exp[-(h/2) : \bar{H}_y :]\mathcal{A}_y^{-1} \times \\ & \mathcal{A}_z \exp[-h : \bar{H}_z :]\mathcal{A}_z^{-1} \times \\ & \mathcal{A}_y \exp[-(h/2) : \bar{H}_y :]\mathcal{A}_y^{-1} \times \\ & \mathcal{A}_x \exp[-(h/2) : \bar{H}_x :]\mathcal{A}_x^{-1}, \end{aligned} \tag{12.9.21}$$

where we have used the notation

$$\bar{H}_x = p_x^2/(2m^*), \tag{12.9.22}$$

$$\bar{H}_y = p_y^2/(2m^*), \tag{12.9.23}$$

$$\bar{H}_z = p_z^2/(2m^*). \tag{12.9.24}$$

We have already seen that the phase-space actions of the $\mathcal{A}$'s and $\mathcal{A}^{-1}$'s can be evaluated exactly using relations of the form (9.12) through (9.19). Evidently the actions of the maps $\exp[-(h/2) : \bar{H}_x :]$, $\exp[-(h/2) : \bar{H}_y :]$, and $\exp[-h : \bar{H}_z :]$ can also be evaluated exactly. See Exercises 5.4.1 and 5.4.2. Therefore, use of the approximation (9.7) with $\mathcal{S}_2$ given by (9.21) produces a symmetric integrator that is locally correct through terms of order h^2 and is exactly symplectic.

At this point, two remarks are in order. The first is that, with $\mathcal{S}_2(k)$ in hand, the triplet construction can be used to produce higher-order symmetric and symplectic integrators. For example, $\mathcal{S}_4$ is given by (1,32) through (1.34).

The second remark is less triumphant. For a symmetric integrator there is the general relation

$$\mathcal{S}_{2k}(h) = \exp[h : -H : +O(h^{2k+1})]. \tag{12.9.25}$$

Moreover, the error term does not commute with $: H :$ so that for each integration step there is the result

$$\mathcal{S}_{2k}(h)H = H + O(h^{2k+1}) \tag{12.9.26}$$

where the error term is *nonzero*. In fact *Ge* and *Marsden* have essentially shown that it is impossible to construct an integrator that is exactly symplectic and also exactly conserves H.[8] In some applications this may not much matter. Indeed, it is sometimes argued that a symplectic integrator can be used with a larger time step h than a nonsymplectic integrator of the same order because the symplectic integrator at least respects the underlying structure of any Hamiltonian system. And the fact (hope) that a larger time step can be used compensates for the relatively large amount of work associated with each time step.

[8] Ge and Marsden have shown that if a symplectic integrator conserves H, it must be exact or, at worst, produce exact trajectories up to a reparameterization of the time. (See Section 4 for an example where this happens.) Now in general a symplectic integrator cannot produce exact trajectories because in general it makes errors of some order in h. Moreover, it is unlikely that these errors only amount to a reparameterization of the time. Therefore, generally H is not conserved. Of course, one can easily check during the course of an integration to see if the value H is changing, and in general, as expected, one finds that it is.

[Moreover, the variation in H during symplectic integration is often observed to be essentially periodic when the trajectory being integrated is essentially periodic, and this good behavior can be understood using the BCH series. By contrast, the value of H typically grows (or damps) linearly or quadratically, or eventually even exponentially, in time when nonsymplectic integration is employed.] However, for the Hamiltonian (1.6.192) we know that the only physically meaningful trajectories are those for which H has the value (1.6.193. Therefore in this case it is necessary to use a time step h that is sufficiently small to ensure that over the course of integration H obeys (1.6.193) to high accuracy. In particular, one should monitor the value of H during the course of integration to verify that (1.6.193) is met with sufficient accuracy.

While in the mode of exploring difficulties associated with this approach, we should also consider how much effort is required to carry out the integrations of the form (9.10) required to compute the functions $U_x(x, y, z)$ through $U_z(x, y, z)$. If the vector potential $\boldsymbol{A}(\boldsymbol{r})$ is known in analytic form and has a sufficiently simple structure, then these integrals can be evaluated analytically in terms of elementary functions prior to any use of the symplectic integrator. However for most if not all realistic applications, these integrations yield higher transcendental functions that are expensive to evaluate, or these integrations must be carried out numerically. And these evaluations/numerical integrations must be performed with high accuracy if the symplecticity of the overall integration process is to be assured. These evaluations/integrations further add to the already high computational overhead associated with symplectic integration. (See Exercise 9.3.) The considerations of this and the previous paragraph make one wonder if the computational burden for symplectic integration of the kind just described for trajectories in realistic electromagnetic fields is so high as to make nonsymplectic, but high-order, integration superior to symplectic integration. The answer to this question is presumably problem dependent. Its answer for any realistic problem would require the comparison of symplectic integration and high accuracy (probably not Runge-Kutta) nonsymplectic integration. When such explorations are made, one should also consider symplectic (but implicit) Runge-Kutta methods and symplectic generating function methods of the kind described in the previous subsections.

We close this section with an analogous discussion of the Hamiltonian (1.6.77), which can be written in the form

$$H_R = H_x + H_y + H_z + H_t \tag{12.9.27}$$

where

$$H_x = (p_x - qA_x)^2/(2mc), \tag{12.9.28}$$

$$H_y = (p_y - qA_y)^2/(2mc), \tag{12.9.29}$$

$$H_z = (p_z - qA_z)^2/(2mc), \tag{12.9.30}$$

$$H_t = -(p_4 + qA^4)^2/(2mc), \tag{12.9.31}$$

and w becomes the collection of phase-space variables

$$w = (x, y, z, x^4; p_x, p_y, p_z, p_4). \tag{12.9.32}$$

Since H_R is τ independent, the transfer map associated with H_R is given by the relation

$$\mathcal{M} = \exp(\tau : -H_R :). \tag{12.9.33}$$

As expected, we subdivide the τ axis into steps of equal amount h to obtain the exact marching rule (9.5).

In analogy with (9.7) and (9.8), we next make the approximation

$$\exp(h : -H_R :) \cong \mathcal{S}_2(h) \tag{12.9.34}$$

where $\mathcal{S}_2(h)$ is now defined by the rule

$$\begin{aligned}\mathcal{S}_2(h) \quad = \quad & \exp[-(h/2) : H_x :] \exp[-(h/2) : H_y :] \times \\ & \exp[-(h/2) : H_z :] \exp[-h : H_t :] \exp[-(h/2) : H_z :] \times \\ & \exp[-(h/2) : H_y :] \exp[-(h/2) : H_x :].\end{aligned} \tag{12.9.35}$$

By construction this $\mathcal{S}_2$ is a symmetric integrator that is locally correct through terms of order h^2. Other permutations of H_x through H_t could have been used in the definition of $\mathcal{S}_2$, and there are therefore 4! possible integrators of this kind.

We again define functions U_x through U_z by the requirements (9.10), and we add to their collection the function U^4 defined by the requirement

$$A^4 = -\partial U^4/\partial x^4. \tag{12.9.36}$$

The symplectic maps $\mathcal{A}_x$ through $\mathcal{A}_z$ are also again defined by (9.11), and to their collection we add the symplectic map $\mathcal{A}_4$ defined by

$$\mathcal{A}_4 = \exp : -qU^4 : . \tag{12.9.37}$$

This map has the property

$$\mathcal{A}_4 p_4 = p_4 - q : U^4 : p_4 = p_4 - q[U^4, p_4] = p_4 - q\partial U^4/\partial x^4 = p_4 + qA^4, \tag{12.9.38}$$

from which it follows that

$$\exp(-h : H_t :) = \mathcal{A}_4 \exp[h : p_4^2/(2mc) :]\mathcal{A}_4^{-1}. \tag{12.9.39}$$

We are now able to proceed as before to express $\mathcal{S}_2$ as a product of maps, all of which can be evaluated explicitly,

$$\begin{aligned}\mathcal{S}_2 \quad = \quad & \mathcal{A}_x \exp[-(h/2) : \bar{H}_x :]\mathcal{A}_x^{-1} \times \\ & \mathcal{A}_y \exp[-(h/2) : \bar{H}_y :]\mathcal{A}_y^{-1} \times \\ & \mathcal{A}_z \exp[-(h/2) : \bar{H}_z :]\mathcal{A}_z^{-1} \times \\ & \mathcal{A}_4 \exp[-h : \bar{H}_t :]\mathcal{A}_4^{-1} \times \\ & \mathcal{A}_z \exp[-(h/2) : \bar{H}_z :]\mathcal{A}_z^{-1} \times \\ & \mathcal{A}_y \exp[-(h/2) : \bar{H}_y :]\mathcal{A}_y^{-1} \times \\ & \mathcal{A}_x \exp[-(h/2) : \bar{H}_x :]\mathcal{A}_x^{-1}.\end{aligned} \tag{12.9.40}$$

Here we have used the notation

$$\bar{H}_x = p_x^2/(2mc),$$

$$\bar{H}_y = p_y^2/(2mc),$$

$$\bar{H}_z = p_z^2/(2mc),$$

$$\bar{H}_t = -p_4^2/(2mc). \tag{12.9.41}$$

We must again be aware that trajectories generated by H_R are only physically meaningful when H_R has a special value, namely that given by the (mass shell) condition (1.6.92), and that this value cannot be maintained exactly by any symplectic integrator. Therefore it is again necessary to choose h sufficiently small to ensure that over the course of integration H_R obeys (1.6.92) to high accuracy. Moreover there is again added overhead. Now we must compute the functions U_x through U^4. See Exercise 9.3.

Exercises

12.9.1. Exercise on what happens when, in H_R, $A^4 = 0$ and $\boldsymbol{A}$ is static.

12.9.2. Show that in the nonrelativistic approximation the Lagrangian (1.5.1) may be replaced by the Langrangian

$$L_{NR} = (1/2)mv^2 - q\psi(\boldsymbol{r}, t) + q\boldsymbol{v} \cdot \boldsymbol{A}(\boldsymbol{r}, t). \tag{12.9.42}$$

Find the associated Hamiltonian H_{NR}. Show that H_{NR} is conserved if the electromagnetic fields are static. Construct a symplectic integrator for H_{NR}. Show that this integrator does not conserve H_{NR}. Perhaps this nonconservation is not so important in the nonrelativistic case because it might be argued that H_{NR} has no *fundamental* significance. Moreover, H_{NR} is not conserved anyway for the exact motion if the electromagnetic fields are time dependent.

12.9.3. Exercise on what exactly is involved in computing the integrals U_x through U_z or U_x through U^4.

12.10 Zassenhaus Formulas and Map Computation

The discussion so far has dealt mostly with the use of Zassenhaus formulas of the kinds (1.14), (1.35), (1.38), (9.21), and (9.40) as *symplectic integrators*. However, Zassenhaus formulas can also be used to *compute maps* both in Taylor and factored product form.

12.10.1 Case of $T + V$ or General Electromagnetic Field Hamiltonians

As a simple example, suppose that H has the $T + V$ decomposition (1.6). Then, the Taylor maps for $\exp(\sigma : T :)$ and $\exp(\sigma : V :)$, where σ is some parameter, can be computed exactly by formulas analogous to (1.7) through (1.10); and therefore we can find the net Taylor map for any factored map of the kinds (1.14), (1.35), or (1.38). Also, we can expand T and V in homogeneous polynomials. For example, we can write

$$T = \sum_{m=0}^{\infty} T_m \tag{12.10.1}$$

with a similar expansion for V. Then we have the factored product representation

$$\exp(\sigma : T :) = \exp(\sigma : T_1 :) \exp(\sigma : T_2 :) \exp(\sigma : T_3 :) \cdots , \tag{12.10.2}$$

with a similar representation for $\exp(\sigma : V :)$. It follows that each of the factors appearing in any approximation of the kinds (1.14), (1.35), or (1.38) for the map $\exp(h : -H :)$ can be written in factored product form. The resulting factors can then be concatenated together to yield for the map $\exp(h : -H :)$ a final approximation that is also in factored product form.

After some reflection, we see that the same procedure can be applied to the symplectic integrators (9.21) and (9.40). Each of the factors can be be expanded in Taylor form or written in factored product form, and these maps can then be concatenated to yield a net map either in Taylor or factored product form.

There is one last remark to be made: As explained in Section 1.6, it is often convenient to have maps for which some coordinate is the independent variable, and in this subsection we have been using the time t or some world-line parameter τ as the independent variable. If we wish to compute maps rather than trajectories (apart from the reference trajectory) this problem can be overcome with the use of *matching* maps. When the map for some element has been computed using t or τ as an independent variable, the necessary conversion can be made by preceding the map with a matching map that transforms from phase-space variables for which some coordinate is the independent variable to phase-space variables for which t or τ is the independent variable, and following the map by a second matching map that transforms back to the phase-space variables for which some coordinate is the independent variable. See Section *.*.

12.10.2 Case of Hamiltonians Expanded in Homogeneous Polynomials

Zassenhaus formulas can also be used to provide factored product approximations for $\mathcal{M} = \exp(h : -H :)$ when H is decomposed into homogeneous polynomials as in (10.9.1). Here we will consider the autonomous case. The nonautonomous case is best treated using the methods of Sections 10.5.2 and 10.6.2.

Derivation

Define A and B by writing the equations

$$A = H_1 + H_2, \tag{12.10.3}$$

$$B = H_r = H_3 + H_4 + \cdots . \tag{12.10.4}$$

Evidently, any map of the kind $\exp(-h : A :)$ with A given by (10.3) can be written in factored product form using the methods of Section 9.2. See (9.2.4), (9.2.7), and (9.2.9). What about maps of the kind $\exp(-h : B :)$ with B given by (10.4)? How do we find generators f_m such that

$$\exp(-h : B :) = \exp(-h : H_3 + H_4 + \cdots :) = \exp(: f_3 :) \exp(: f_4 :) \cdots ? \tag{12.10.5}$$

We note that, since there is no H_2 term in (10.4), we may use the methods of Section 10.6.2 with the understanding that

$$\mathcal{M}_2 = \mathcal{I} \tag{12.10.6}$$

and therefore

$$H_m^{\text{int}} = H_m. \tag{12.10.7}$$

It follows from (10.6.14) through (10.6.20) that

$$f_3 = -hH_3, \tag{12.10.8}$$

$$f_4 = -hH_4, \tag{12.10.9}$$

$$f_5 = -hH_5 - (h^2/2)[H_3, H_4], \tag{12.10.10}$$

$$f_6 = -hH_6 - (h^2/2)[H_3, H_5] - (h^3/6)[H_3, [H_3, H_4]], \tag{12.10.11}$$

$$\begin{aligned} f_7 &= -hH_7 - (h^2/2)([H_3, H_6] + [H_4, H_5]) - h^3(H_3, [H_3, H_5]]/6 + [H_4, [H_3, H_4]/3) \\ &- (h^4/24)[H_3, [H_3, [H_3, H_4], \end{aligned} \tag{12.10.12}$$

$$\begin{aligned} f_8 &= -hH_8 - (h^2/2)([H_3, H_7] + [H_4, H_6]) \\ &- h^3([H_3, [H_3, H_6]]/6 + [H_4, [H_3, H_5]]/3 + [H_5, [H_3, H_4]]/12) \\ &- h^4([H_3, [H_3, [H_3, H_5]]]/24 + [H_4, [H_3, [H_3, H_4]]]/8) \\ &- (h^5/120)[H_3, [H_3, [H_3, [H_3, H_4]]]], \end{aligned} \tag{12.10.13}$$

$$f_m = \text{ expression involving } H_m \text{ and the } H_\ell \text{ with } \ell < m. \tag{12.10.14}$$

See Exercise 10.1.

We conclude that all the factors in a Zassenhaus representation can themselves be written in factored product form. These maps can now be concatenated together to yield a final approximation for $\exp(h : -H :)$ that is also in factored product form and is accurate through some order in h. (Note that if H_1 terms are present in H, then we must at this point assume they are small in order to use the concatenation formulas of Section 9.3.) The net result of our discussion is that the use of Zassenhaus symplectic integrator formulas makes it possible to find "linear" maps $\mathcal{R}(h)$ and generators $f_m(h)$ such that $\exp(-h : H :)$ has the factorization

$$\exp(-h : H :) = \exp[: f_1(h) :]\mathcal{R}(h) \exp[: f_3(h) :] \exp[: f_4(h) :] \cdots \times [1 + O(h^{N+1})] \tag{12.10.15}$$

where $(N + 1)$ is the order of the error in the Zassenhaus formula.

Application to Scaling, Splitting, and Squaring

For the autonomous case that we have just been considering, we are now able to use scaling, splitting, and squaring (as in Section 10.7) with (10.17) now playing the role of a splitting formula. As before, we define τ by writing

$$\tau = t/2^n, \tag{12.10.16}$$

and find the approximation

$$\begin{aligned}\mathcal{M} &= \exp(t : -H :) = [\exp(\tau : -H :)]^{2^n}\\ &= \{\cdots\{\{\exp[: f_1(\tau) :]\mathcal{R}(\tau)\exp[: f_3(\tau) :]\exp[: f_4(\tau) :]\cdots\}^2\}^2\cdots\}^2\\ &(n \text{ squarings}).\end{aligned} \tag{12.10.17}$$

[Note: The quantity τ as given by (10.16) should not be confused with that used in (1.3) or (9.33.]

What will be the relative error for this approximation? We expect that it will scale as $(1/2^n)^N$. For a more precise result we need an estimate for the error term in the underlying Zassenhaus formula. Suppose, for example, we use the Zassenhaus formula $\mathcal{S}_4$ as given by (1.35). Although we have discussed Zassenhaus formulas in the context of symplectic integrators, they are really *operator identities* that hold for any set of linear operators. (Consequently, they may be used in other contexts including the construction of integrators designed to preserve group properties for any Lie group. For example, they may be used in the context of rigid-body motion to preserve the orthogonality condition and in the context of quantum dynamics to preserve the unitarity condition.) To emphasize this fact, let us introduce the notation

$$\begin{aligned}\mathcal{S}_4(h\mathcal{A}, h\mathcal{B}) \;\;=\;\; & \exp(w_1 h\mathcal{A})\exp(w_2 h\mathcal{B})\exp(w_3 h\mathcal{A})\exp(w_4 h\mathcal{B})\,\times\\ & \exp(w_5 h\mathcal{A})\exp(w_6 h\mathcal{B})\exp(w_7 h\mathcal{A}),\end{aligned} \tag{12.10.18}$$

where $\mathcal{A}$ and $\mathcal{B}$ are any pair of linear operators. Then we have a result of the form

$$\mathcal{S}_4(h\mathcal{A}, h\mathcal{B}) = \exp[-h(\mathcal{A}+\mathcal{B}) + \mathcal{C}_5 h^5 + O(h^7)]. \tag{12.10.19}$$

What we need for error analysis is an estimate for the term $\mathcal{C}_5$. In analogy to the error term in (9.13) and based on the general properties of the BCH series, we expect that $\mathcal{C}_5$ will be made of multiple commutators of $\mathcal{A}$ and $\mathcal{B}$. First there will be a term with four $\mathcal{A}$'s and one $\mathcal{B}$. Next there will be terms with three $\mathcal{A}$'s and two $\mathcal{B}$'s, etc. Finally, there will be a term with one $\mathcal{A}$ and four $\mathcal{B}$'s. Consequently, $\mathcal{C}_5$ can be written in the form

$$\mathcal{C}_5(\mathcal{A}, \mathcal{B}) = d_1 \#\mathcal{A}\#^4\mathcal{B} + \cdots + d_{\text{last}}\#\mathcal{B}\#^4\mathcal{A}. \tag{12.10.20}$$

Here, in accord with the notation of Chapter 8, $\#\mathcal{A}\#$ denotes the adjoint of $\mathcal{A}$ as defined in terms of the commutator,

$$\#\mathcal{A}\#\mathcal{B} = \{\mathcal{A}, \mathcal{B}\}. \tag{12.10.21}$$

Thus, to specify $\mathcal{C}_5$, we need to determine the coefficients $d_1 \cdots d_{\text{last}}$.

The determination of all the coefficients $d_1 \cdots d_{\text{last}}$ is a sizable algebraic task. However, we can find d_1 and d_{last} fairly easily. Since (10.16) is an operator identity, as we have just discussed, it must hold for any linear operators $\mathcal{A}$ and $\mathcal{B}$. In particular, it must hold for 2×2 matrices. Left F and G be the matrices

$$F = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \tag{12.10.22}$$

$$G = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}. \tag{12.10.23}$$

They satisfy the commutation rules

$$\#F\#G = \{F, G\} = 2G, \tag{12.10.24}$$

$$\#G\#F = \{G, F\} = -\{F, G\} = -2G. \tag{12.10.25}$$

It follows from these rules that

$$\mathcal{C}_5(F, G) = d_1\#F\#^4G + \cdots + d_{\text{last}}\#G\#^4F = 2^4 d_1 G, \tag{12.10.26}$$

$$\mathcal{C}_5(G, F) = d_1\#G\#^4F + \cdots + d_{\text{last}}\#F\#^4G = 2^4 d_{\text{last}} G. \tag{12.10.27}$$

That is, only the first term in the expansion (10.17) contributes to $\mathcal{C}_5(F, G)$, and only the last term contributes to $\mathcal{C}_5(G, F)$. Consequently, we have the matrix identity

$$\begin{aligned} \mathcal{S}_4(hF, hG) &= \exp[-h(F + G) + 16d_1Gh^5 + O(h^7)] \\ &= \exp[-h(F + G)] \exp[16d_1Gh^5 + O(h^6)] \\ &= \exp[-h(F + G)][1 + 16d_1Gh^5 + O(h^6)]. \end{aligned} \tag{12.10.28}$$

From (10.25) it follows that

$$16d_1Gh^5 = \mathcal{S}_4(hF, hG) - \exp[-h(F + G)] + O(h^6). \tag{12.10.29}$$

Similarly, we have the result

$$16d_{\text{last}}Gh^5 = \mathcal{S}_4(hG, hF) - \exp[-h(F + G)] + O(h^6). \tag{12.10.30}$$

At this point we observe that the right sides of (10.26) and (10.27) can be evaluated exactly. First, it is easily verified that the matrix $(F + G)$ has the property

$$(F + G)^2 = I. \tag{12.10.31}$$

Consequently, we have the relation

$$\begin{aligned} \exp[-h(F + G)] &= \cosh[h(F + G)] - \sinh[h(F + G)] = I\cosh(h) - (F + G)\sinh(h) \\ &= \begin{pmatrix} \exp(-h) & -\sinh(h) \\ 0 & \exp(h) \end{pmatrix}. \end{aligned} \tag{12.10.32}$$

Now take 1,2 matrix elements of both sides of (10.26) and (10.27) to get the results

$$16d_1h^5 = [\mathcal{S}_4(hF, hG)]_{12} + \sinh(h), \tag{12.10.33}$$

$$16d_{\text{last}}h^5 = [\mathcal{S}_4(hG, hF)]_{12} + \sinh(h). \tag{12.10.34}$$

Next, we have the relations

$$\exp(\sigma F) = \begin{pmatrix} \exp(\sigma) & 0 \\ 0 & \exp(-\sigma) \end{pmatrix}, \tag{12.10.35}$$

$$\exp(\sigma G) = \begin{pmatrix} 1 & \sigma \\ 0 & 1 \end{pmatrix}. \tag{12.10.36}$$

Consequently, all the factors in $\mathcal{S}_4(hF, hG)$ and $\mathcal{S}_4(hG, hF)$ are known, and the multiplications indicated in (10.15) can be carried out exactly. Finally, we can expand the right sides of (10.30) and (10.31) as power series in h and extract the terms of degree 5. Doing so gives the results

$$d_1 = (1/16)[18(2)^{2/3} - 40(2^{1/3}) + 22]/[9360(2)^{2/3} - 7200(2)^{1/3} - 5760] \simeq 4.14 \times 10^{-4}, \tag{12.10.37}$$

$$d_{\text{last}} = (1/16)(1/12)\{(1/10) + [14(2^{1/3}) - 11(2^{2/3})]/[2 - (2^{1/3})]^5 \simeq 4.68 \times 10^{-3}. \tag{12.10.38}$$

We are now prepared to make an error analysis similar to that of Section 10.7. For A and B given by (10.3) and (10.4), and assuming $H_1 = 0$ for simplicity, we find for $\mathcal{C}_5$ the result

$$\mathcal{C}_5 = d_1\#H_2\#^4 : H_r : + \cdots + d_{\text{last}}\#H_r\#^4 : H_2 : . \tag{12.10.39}$$

We know, in this context, that $\mathcal{C}_5$ must be a Lie operator. Let C be the function associated with $\mathcal{C}_5$,

$$\mathcal{C}_5 =: C : . \tag{12.10.40}$$

With this notation, (10.39) is equivalent to the relation

$$C = d_1 : H_2 :^4 H_r + \cdots + d_{\text{last}} : H_r :^4 H_2. \tag{12.10.41}$$

We will also focus our attention on the first term in (10.41), which is equivalent to the assumption that H_2 has a larger effect than H_r. Then, in view of (9.36) and in line with our assumption, we want to make the comparison

$$hH_r \overset{?}{\leftrightarrow} h^5 d_1 : H_2 :^4 H_r \tag{12.10.42}$$

where, according to (10.13) and (10.14),

$$h = \tau = t/2^n. \tag{12.10.43}$$

By making use of (7.52) and (7.55), and looking at (10.39), we see that the relative error can be written in the form

$$\text{relative error } \sim d_1(m\lambda/2^n)^4. \tag{12.10.44}$$

Suppose, as in Section 10.7, we limit our attention to the case $m \leq 8$ and select n so that (7.57) is satisfied. Then we find the result

$$\text{relative error } \sim d_1(1/20)^4 \simeq 3 \times 10^{-9}. \tag{12.10.45}$$

This error is somewhat larger than that given by (7.59). However, the relations (10.6) through (10.11) are simpler than the relations (7.28) through (7.32). Consequently, the use of Zassenhaus formulas for splitting is easier to program. Of course both errors can be decreased substantially, if desired, by a modest increase in the number of squarings n.

Exercises

12.10.1. The aim of this exercise is to show that the results (10.8) through (10.14) can be obtained from (10.6.14) through (10.6.20). What you are to do is to integrate the equations (10.6.14) through (10.6.20) with respect to t over the interval $t = 0$ to $t = h$. Let us begin. Verify that integrating (10.6.14), remembering (10.7) and that H_3 is assumed to be time independent, gives the result

$$f_3 = \int_0^h dt\ \dot{f}_3 = -\int_0^h dt\ H_3 = -hH_3. \tag{12.10.46}$$

Therefore (10.8) follows from (10.6.14). Next consider f_4. From (10.46) we know that

$$f_3(t) = -tH_3. \tag{12.10.47}$$

With regard to the ingredients of (10.5.15), show, in view of (10.7) and (10.47), that in our case

$$(: f_3 : /2)(-H_3^{\text{int}}) = 0. \tag{12.10.48}$$

Verify, therefore, that integration of (10.6.15) in our case yields the result

$$f_4 = \int_0^h dt\ \dot{f}_4 = -\int_0^h dt\ H_4 = -hH_4, \tag{12.10.49}$$

in agreement with (10.9). Move on to the case of f_5. Verify that in our case some of the ingredients in (10.6.16) also vanish so that there is the result

$$f_5 = \int_0^h dt\ \dot{f}_5 = -\int_0^h dt\ H_5 + \int_0^h dt\ t[H_4, H_3] = -hH_5 - (h^2/2)[H_3, H_4], \tag{12.10.50}$$

in agreement with (10.10). What about f_6? Verify that in our case several of the ingredients in (10.6.17) vanish so that there is the result

$$\begin{aligned} f_6 &= \int_0^h dt\ \dot{f}_6 = -\int_0^h dt\ H_6 + \int_0^h dt\ \ : f_5 : (-H_3) \\ &= -hH_6 - \int_0^h dt\ \ : tH_5 + (t^2/2)[H_3, H_4] : (-H_3) \\ &= -hH_6 - (h^2/2)[H_3, H_5] - (h^3/6)[H_3, [H_3, H_4]], \end{aligned} \tag{12.10.51}$$

in agreement with (10.11). Show that (10.12) and (10.13) can be obtained analogously.

12.10.2.

12.11 Other Zassenhaus Formulas and Their Use

There is a somewhat different class of Zassenhaus formulas that also merits discussion. Suppose we rewrite (9.13) in the more general form

$$\exp[(s/2)\mathcal{A}]\exp(t\mathcal{B})\exp[(s/2)\mathcal{A}] = \exp[(s\mathcal{A}+t\mathcal{B})+\mathcal{C}(s\mathcal{A},t\mathcal{B})] \tag{12.11.1}$$

where

$$\mathcal{C} = (s^2t/24)\{\mathcal{A},\{\mathcal{A},\mathcal{B}\}\} - (st^2/12)\{\mathcal{B},\{\mathcal{B},\mathcal{A}\}\} + \cdots . \tag{12.11.2}$$

Here, as before, $\mathcal{A}$ and $\mathcal{B}$ are any pair of linear operators, and s and t are expansion parameters. We see that the left side of (11.1) produces the desired result $\exp(s\mathcal{A}+t\mathcal{B})$ save for an error $\mathcal{C}$ that contains, among other things, terms linear in s (but higher order in t) and terms linear in t (but higher order is s). Examination of (10.15) through (10.17) shows that the higher order Zassenhaus integrator formulas have similar properties. For example, reference to (10.16) and (10.17) shows that the $\mathcal{S}_4$ given by (10.15) has errors linear in t that are proportional to s^4, errors quadratic in t that are proportional to s^3, etc.

Suppose we set for ourselves what will turn out to be an easier goal: find Zassenhaus approximations that are only correct through terms linear in t, but the term that is independent of t and the term that is linear in t should be correct to *high* order in s. Our starting point is the relation (8.8.13). See Section 8.8. This relation has the generalization

$$\exp(s\mathcal{A}+t\mathcal{B}) = \exp[O(t^2)]\exp[\text{iex}(s\#\mathcal{A}\#)(t\mathcal{B})]\exp(s\mathcal{A}) \tag{12.11.3}$$

where

$$\text{iex}(s\#\mathcal{A}\#)(t\mathcal{B}) = \int_0^1 d\tau\exp(\tau s\#\mathcal{A}\#)(t\mathcal{B}). \tag{12.11.4}$$

By construction we know that the term in (11.3) that is independent of t and the term that is linear in t are both *exact* in s.

The next step is to convert the integral (11.4) into a finite sum with the aid of a *quadrature formula*. Suppose we wish to integrate some function (operator) $\mathcal{G}(\tau)$. A quadrature formula is a set of k successive *sampling points* τ_i in the interval $[0,1]$ and *weights* w_i such that

$$\int_0^1 d\tau\mathcal{G}(\tau) \simeq \sum_{i=1}^k w_i\mathcal{G}(\tau_i). \tag{12.11.5}$$

In our case

$$\mathcal{G}(\tau) = \exp(\tau s\#\mathcal{A}\#)(t\mathcal{B}). \tag{12.11.6}$$

Shortly we will consider how the τ_i and w_i might be chosen. First, let us see how a quadrature formula can be used. With the aid of (11.5) and (11.6) we find the result

$$\begin{aligned}\exp[\text{iex}(s\#\mathcal{A}\#)(t\mathcal{B}) &= \exp[\int_0^1 d\tau\mathcal{G}(\tau)] \simeq \exp\left[\sum_{i=1}^k w_i\mathcal{G}(\tau_i)\right]\\ = \quad &\exp[O(t^2)]\exp[w_1\mathcal{G}(\tau_1)]\exp[w_2\mathcal{G}(\tau_2)]\cdots\exp[w_k\mathcal{G}(\tau_k)]. \end{aligned}\tag{12.11.7}$$

Note that the operators $\mathcal{G}(\tau_i)$ generally do not commute. Therefore the conversion of the exponential of a sum into a product of exponentials, which occurs as the last step in (11.7), produces correction terms that involve commutators. However, since the $\mathcal{G}(\tau_i)$ are linear in t, these commutators are $O(t^2)$ as indicated in (11.7).

For each factor in (11.7) we have the result

$$\begin{aligned}\exp[w_i\mathcal{G}(\tau_i)] &= \exp[\exp(\tau_i s\#\mathcal{A}\#)(w_i t\mathcal{B})]\\ &= \exp[\exp(\tau_i s\mathcal{A})(w_i t\mathcal{B})\exp(-\tau_i s\mathcal{A})]\\ &= \exp(\tau_i s\mathcal{A})\exp(w_i t\mathcal{B})\exp(-\tau_i s\mathcal{A}). \end{aligned} \tag{12.11.8}$$

Putting all these results together gives the relation

$$\begin{aligned}&\exp(s\mathcal{A}+t\mathcal{B}) \simeq \exp[O(t^2)]\exp(\tau_1 s\mathcal{A})\exp(w_1 t\mathcal{B})\exp(-\tau_1 s\mathcal{A}) \times\\ &\exp(\tau_2 s\mathcal{A})\exp(w_2 t\mathcal{B})\exp(-\tau_2 s\mathcal{A})\cdots \times\\ &\exp(\tau_k s\mathcal{A})\exp(w_k t\mathcal{B})\exp(-\tau_k s\mathcal{A})\exp(s\mathcal{A}).\end{aligned} \tag{12.11.9}$$

Finally, carrying out the indicated multiplications gives the result

$$\begin{aligned}&\exp(s\mathcal{A}+t\mathcal{B}) \simeq \exp[O(t^2)]\exp(\tau_1 s\mathcal{A})\exp(w_1 t\mathcal{B})\\ &\exp[(\tau_2-\tau_1)s\mathcal{A}]\exp(w_2 t\mathcal{B})\exp[(\tau_3-\tau_2)s\mathcal{A}]\cdots\\ &\exp(w_k t\mathcal{B})\exp[(1-\tau_k)s\mathcal{A}].\end{aligned} \tag{12.11.10}$$

This is the desired Zassenhaus approximation.

We must still consider how to select the τ_i and w_i. One possibility is to space the τ_i evenly with $\tau_1 = 0$ and $\tau_k = 1$,

$$\tau_i = (i-1)/(k-1). \tag{12.11.11}$$

In this case we should use *Newton-Cotes* weights. See Appendix T. For example, for the case $k = 3$ we have the celebrated *Simpson's rule* 1-4-1 formula

$$\int_0^1 d\tau\mathcal{G}(\tau) \simeq (1/6)\mathcal{G}(0) + (4/6)\mathcal{G}(1/2) + (1/6)\mathcal{G}(1). \tag{12.11.12}$$

Another appealing possibility is not to space the τ_i evenly, but rather to select them (as well as the weights w_i) in such a way that (for a fixed k) the order is maximized. This choice produces the family of *Legendre-Gauss* quadrature formulas. Again see Appendix T. For example, for $k = 3$ there is the formula

$$\int_0^1 d\tau\mathcal{G}(\tau) \simeq (5/18)\mathcal{G}(1/2-\sqrt{15}/10) + (8/18)\mathcal{G}(1/2) + (5/18)\mathcal{G}(1/2+\sqrt{15}/10). \tag{12.11.13}$$

As another example, consider the case $k = 2$. Then there is the formula

$$\int_0^1 d\tau\mathcal{G}(\tau) \simeq (1/2)\mathcal{G}(1/2-\sqrt{3}/6) + (1/2)\mathcal{G}(1/2+\sqrt{3}/6). \tag{12.11.14}$$

Because (11.5) replaces an integral by a sum, the term in the Zassenhaus approximation (11.10) that is linear in t is no longer exact in s. (However, the term independent of t still is exact.) We can estimate the error made in s from formulas of the kind (11.14), (11.16), and (11.18). Taylor series expansion of $G(\tau)$ as given by (11.6) provides the result

$$\sum_{i=1}^{k} w_i G(\tau_i) = \sum_{n=0}^{\infty} (s^n/n!)\#\mathcal{A}\#^n t\mathcal{B} \sum_{i=1}^{k} w_i \tau_i^n. \tag{12.11.15}$$

Let c_k be the error term in the relation

$$\sum_{i=1}^{k} w_i (\tau_i)^{\ell_{\max}+1} = 1/(\ell_{\max}+2) + c_k. \tag{12.11.16}$$

Again see Appendix T, and the example relations (T.1.6), (T.1.12), and (T.1.15). From (12.15) and (12.16) we find the error estimate

$$\sum_{i=1}^{k} w_i G(\tau_i) = \mathrm{iex}(s\#\mathcal{A}\#)(t\mathcal{B}) + [c_k/(\ell_{\max}+1)!] s^{(\ell_{\max}+1)} (\#\mathcal{A}\#)^{(\ell_{\max}+1)}(t\mathcal{B}) + O[t(s)^{(\ell_{\max}+2)}]. \tag{12.11.17}$$

Consequently, to examine relative error, we must make the comparison

$$t\mathcal{B} \overset{?}{\leftrightarrow} [c_k/(\ell_{\max+1}+1)!] s^{(\ell_{\max}+1)} (\#\mathcal{A}\#)^{\ell_{\max}+1}(t\mathcal{B}). \tag{12.11.18}$$

For example, suppose that $\mathcal{A}$ is the Lie operator $: H_2 :$ for a quadratic Hamiltonian, and $(t\mathcal{B})$ is the Lie operator $: H_r :$ for the remaining piece as in (10.4). Let JS be the matrix associated with H_2. In analogy to (7.56), define λ by the relation

$$\lambda = \|sJS\|. \tag{12.11.19}$$

Also, suppose that H_r does not contain terms beyond degree m. Then, in analogy to (6.5.2), we have the estimate

$$s^{\ell_{\max}+1} (\#\mathcal{A}\#)^{\ell_{\max}+1}(t\mathcal{B}) \sim (m\lambda)^{\ell_{\max}+1}(t\mathcal{B}). \tag{12.11.20}$$

Consequently, we conclude that the relative error in the Zassenhaus approximation (11.10) has the estimate

$$\text{relative error } \sim [c_k/(\ell_{\max}+1)!](m\lambda)^{(\ell_{\max}+1)}. \tag{12.11.21}$$

What uses can be made of Zasshaus approximations of the form (11.10)? In the context of Accelerator Physics, we will see in Chapters 12 and 12 that H_r becomes small in the limit of high energies. Therefore, at least three possible uses come to mind.

First, in the autonomous case, these Zassenhaus approximations can be used as splitting formulas for map computation by scaling, splitting, and squaring. Second, they can be used as symplectic integrators. The autonomous case can be treated using the form (11.10), and the nonautonomous case can be treated using related formulas. See Exercise 11.*. In the context of symplectic integrators, employing the Gaussian sampling points and weights seems particularly attractive because doing so minimizes (for a given k) the number of operators $\exp(w_i t\mathcal{B})$, whose evaluation is relatively expensive.

Finally, these Zassenhaus approximations can be used as the basis of an accelerator lattice *correction* scheme. Suppose we find H_r, or some terms in H_r, to be offensive. Then we can counter the effect of these terms on the performance of an accelerator lattice by placing, at the sampling points, local correctors having these same offensive properties. These correctors should be powered with strengths proportional to $(-w_i)$ in such a way that the *net* effect of the correctors and the offensive terms in H_r *cancel* to first order in t and high order in s. See Exercise *.*. In this case perhaps, although not necessarily, use of the Newton-Cotes sampling points might be more convenient from an engineering perspective.

Chapter 13

Transfer Maps for Idealized Straight Beam-Line Elements

13.1 Background

In this chapter we will describe the computation of transfer maps for idealized straight beam-line elements. Here we make two assumptions: First, the element geometry is such that Cartesian coordinates can conveniently be employed. Second, the design orbit is a straight line, which we take to be the z axis. For simplicity we will treat only magnetic elements, but the case of straight electric elements or straight electromagnetic elements can be handled similarly. Since the design orbit is assumed to be a straight line, the case of magnetic dipole fields is excluded.

We further assume that the design orbit is traversed in time with *constant* velocity v_z^0. In particular, to ensure that the velocity v_z^0 is indeed constant we also assume that the electric scalar potential vanishes, $\psi = 0$. For the same reason, the vector potential $\boldsymbol{A}$ is taken to be *time independent*. See (1.5.2). More complicated situations where v_z^0 is not constant, such as occurs in RF accelerating cavities, can be treated in an analogous way.

Since the design orbit is taken to lie along the z axis, it is convenient to take z as the independent variable. In this case, according to (1.6.16), the Hamiltonian K is given by the relation

$$K = -[(p_t^{\text{can}})^2/c^2 - m^2c^2 - (p_x^{\text{can}} - qA_x)^2 - (p_y^{\text{can}} - qA_y)^2]^{1/2} - qA_z. \tag{13.1.1}$$

Here we have taken care to indicate that the momenta employed are *canonical*. The idealizations we will make in this chapter are that the vector potential $\boldsymbol{A}$ is z *independent* and fringe-field effects can be neglected. These restrictions will be removed in the subsequent Chapters 15 through 21.

13.1.1 Specification of Design Orbit

Under the assumptions made about the *design* orbit, we may write the relations

$$x^d = y^d = 0. \tag{13.1.2}$$

Also, the transverse velocities and therefore the transverse mechanical momenta will vanish on the design orbit. We further assume that the fields and selected gauge for the vector potential are such that the transverse components of the vector potential vanish on the design orbit. It follows that in this case the transverse canonical momenta will also vanish on the design orbit,

$$p_x^{\text{can d}} = p_x^{\text{can d}} = 0. \tag{13.1.3}$$

With regard to the the momentum p_t^{can}, since we have assumed that $\psi = 0$ and v_z^0 is constant, we may write

$$p_t^{\text{can d}} = p_t^0 \tag{13.1.4}$$

where p_t^0 is the value of p_t^{can} on the design orbit.

To complete our description of the design orbit, we need to find the time t as a function of z on this orbit. We may write

$$(dt/dz)|_{\text{design orbit}} = 1/[(dz/dt)|_{\text{design orbit}}] = 1/v_z^0. \tag{13.1.5}$$

Here, as described earlier, v_z^0 is the design velocity on the design orbit, from which it follows that there is the relation

$$v_z^0 = (c^2\gamma m v_z^0)/(\gamma m c^2) = -c^2 p^0/p_t^0 \tag{13.1.6}$$

where γ denotes the usual relativistic factor and p^0 is the value of p_z^{mech} on the design orbit. [This same result can be obtained from (1.1) by observing that p_x^{can}, p_y^{can}, A_x, and A_y all vanish on the design orbit. See Exercise *.] Note also that there are the relations

$$p_t^0 = -[m^2c^4 + (p^0)^2c^2]^{1/2}, \tag{13.1.7}$$

$$p^0 = [(p_t^0/c)^2 - m^2c^2]^{1/2}. \tag{13.1.8}$$

Since v_z^0 is constant, integration of (1.5) yields the relation

$$t^d(z) = z/v_z^0 \tag{13.1.9}$$

where we have taken the origin in time to be such that the design orbit passes through $z = 0$ at the time $t = 0$.

13.1.2 Deviation Variables

Under the assumptions just made about the design orbit, we may introduce transverse coordinate deviation variables ξ, η by the definitions

$$\xi = x - x^d = x, \tag{13.1.10}$$

$$\eta = y - y^d = y. \tag{13.1.11}$$

We also introduce transverse momentum deviation variables p_ξ, p_η by the definitions

$$p_\xi = p_x^{\text{can}} - p_x^{\text{can d}} = p_x^{\text{can}}, \tag{13.1.12}$$

$$p_\eta = p_y^{\mathrm{can}} - p_y^{\mathrm{can\ d}} = p_y^{\mathrm{can}}. \tag{13.1.13}$$

With the results and definitions (1.2) through (1.4) and (1.9) through (1.13) in hand, we are now able to introduce a full set of of deviation variables $(\xi, \eta, T; p_\xi, p_\eta, p_T)$ by adding to the definitions (1.10) through (1.13) the definitions

$$T = t - t^d = t - z/v_z^0, \tag{13.1.14}$$

$$p_T = p_t^{\mathrm{can}} - p_t^{\mathrm{can\ d}} = p_t^{\mathrm{can}} - p_t^0. \tag{13.1.15}$$

Note that by construction the deviation variables all vanish on the design orbit as desired. Since the relations (1.9) through (1.14) simply amount to a phase-space translation, it follows that the relation between the original variables and the deviation variables is a canonical transformation.

13.1.3 Deviation Variable Hamiltonian

Since the transformation given by (1.9) through (1.14) is canonical, the equations of motion for the deviation variables must also arise from a Hamiltonian, which we will call $K^{\mathrm{new}}(\xi, \eta, T, p_\xi, p_\eta, p_T; z)$. Our task is to find K^{new} in terms of K. To do so, we will use the machinery of Subsection 10.4.1.

Following (10.4.2), define a function $\bar{K}(\xi, \eta, T, p_\xi, p_\eta, p_T; z)$ by the rule

$$\bar{K}(\xi, \eta, T, p_\xi, p_\eta, p_T; z) = K(\xi, \eta, z/v_z^0 + T, p_\xi, p_\eta, p_t^0 + p_T; z). \tag{13.1.16}$$

Then, according to (10.4.20), the new Hamiltonian is given by the rule

$$\begin{aligned} &K^{\mathrm{new}}(\xi, \eta, T, p_\xi, p_\eta, p_T; z) = \\ &\quad \bar{K}(\xi, \eta, T, p_\xi, p_\eta, p_T; z) - \bar{K}_1(\xi, \eta, T, p_\xi, p_\eta, p_T; z). \end{aligned} \tag{13.1.17}$$

Let us work out the implications of this rule for the case where K is given by (1.1). For $\bar{K}$ we find the result

$$\begin{aligned} &\bar{K}(\xi, \eta, T, p_\xi, p_\eta, p_T; z) = \\ &\quad -[(p_t^0 + p_T)^2/c^2 - m^2c^2 - (p_\xi - qA_x)^2 - (p_\eta - qA_y)^2]^{1/2} - qA_z. \end{aligned} \tag{13.1.18}$$

We next assume that $\boldsymbol{A}$ is time independent, the expansions of A_x and A_y begin with linear terms, and the expansion of A_z begins with quadratic terms. In that case $\boldsymbol{A}$ does not contribute to $\bar{K}_1(\xi, \eta, T, p_\xi, p_\eta, p_T; z)$, and we find from (1.17) the result

$$\begin{aligned} \bar{K}_1(\xi, \eta, T, p_\xi, p_\eta, p_T; z) &= -(p_t^0/c^2)[(p_t^0/c)^2 - m^2c^2]^{-1/2} p_T \\ &= -(p_t^0/c^2)(1/p^0) p_T \\ &= p_T/v_z^0. \end{aligned} \tag{13.1.19}$$

Here we have used (1.6) and (1.8). Finally, combining (1.17) through (1.19) gives the result

$$\begin{aligned} &K^{\mathrm{new}}(\xi, \eta, T, p_\xi, p_\eta, p_T; z) = \\ &\quad -[(p_t^0 + p_T)^2/c^2 - m^2c^2 - (p_\xi - qA_x)^2 - (p_\eta - qA_y)^2]^{1/2} - qA_z - p_T/v_z^0. \end{aligned} \tag{13.1.20}$$

13.1.4 Dimensionless Scaled Deviation Variables

For many purpose it is useful to describe trajectories and maps in terms of dimensionless variables. Let ℓ be some convenient scale length.[1] Introduce dimensionless variables $(X, Y, \tau; P_x, P_y, P_\tau)$, defined in terms of the deviation variables and the scale length, by the rules

$$X = \xi/\ell, \tag{13.1.21}$$

$$Y = \eta/\ell, \tag{13.1.22}$$

$$\tau = cT/\ell; \tag{13.1.23}$$

$$P_x = p_\xi/p^0, \tag{13.1.24}$$

$$P_y = p_\eta/p^0, \tag{13.1.25}$$

$$P_\tau = p_T/(p^0 c). \tag{13.1.26}$$

At this point it is useful to relate P_τ, which may be viewed as a scaled energy deviation (with a minus sign), to the momentum deviation parameter δ of Exercise 1.7.6. They are connected by the relations

$$\begin{aligned} P_\tau &= -(1/\beta_0)\{[1 + (2\delta + \delta^2)\beta_0^2]^{1/2} - 1\} \\ &= -\beta_0\delta + (\delta^2/2)(\beta_0^3 - \beta_0) - (\delta^3/2)(\beta_0^5 - \beta_0^3) + \cdots , \end{aligned} \tag{13.1.27}$$

$$\begin{aligned} \delta &= (1 - 2P_\tau/\beta_0 + P_\tau^2)^{1/2} - 1 \\ &= -P_\tau/\beta_0 + (P_\tau^2/2)(1 - \beta_0^{-2}) + \cdots . \end{aligned} \tag{13.1.28}$$

Here β_0 is the usual relativistic factor evaluated on the design orbit,

$$\beta_0 = v_z^0/c = -cp^0/p_t^0. \tag{13.1.29}$$

Note that in the ultra relativistic limit $\beta_0 \to 1$ there are the relations

$$P_\tau = -\delta, \tag{13.1.30}$$

$$\delta = -P_\tau. \tag{13.1.31}$$

See Exercise *.

13.1.5 Scaled Deviation-Variable Hamiltonian

We will now seek equations of motion for the scaled deviation variables. We will learn that they also can be derived from what we will call *scaled* deviation-variable Hamiltonian and will denote by the symbol H^s. To do so requires some care.

Although the Poisson brackets of the new coordinates with each other and the Poisson brackets of the new momenta with each other all vanish, the transformation given by (2.54)

[1] Here the coordinate scale factor ℓ is not to be confused with the "path length" ℓ of Exercise 1.7.6. Note also that in this subsection we use the notation p^0 to denote the quantity $p_0^{\rm mech}$ of Exercise 1.7.6.

through (2.59) is not canonical because the Poisson brackets of the new coordinates with their corresponding new momenta do not have the value 1. Instead they have the common value

$$[X, P_x] = [Y, P_y] = [\tau, P_\tau] = (p^0\ell)^{-1}. \tag{13.1.32}$$

Nevertheless, it is still possible to obtain the equations of motion for the deviation variables from a Hamiltonian providing the Hamiltonian, which we now denote by H, is taken to be the function

$$H^s = K^{\rm new}/(p^0\ell), \tag{13.1.33}$$

and we treat the deviation variables as being canonically conjugate. That is, the Poisson brackets of the new coordinates with each other and the Poisson brackets of the new momenta with each other all vanish, and the Poisson brackets of the new coordinates with their corresponding new momenta are taken to have the value 1,

$$[X, P_x] = [Y, P_y] = [\tau, P_\tau] = 1. \tag{13.1.34}$$

See Exercise *.

Let us apply the Ansatz (2.66) to the Hamiltonian $\bar{H}$ given by (2.53) and (1.1). So doing gives the preliminary result

$$\begin{aligned} H(X, Y, \tau, P_x, P_y, P_\tau; z) &= [1/(p^0\ell)][K - (p_T + p_t^0)/v_z^0] \\ &= [1/(p^0\ell)]K - [1/(p^0\ell)](p_T + p_t^0)/v_z^0. \end{aligned} \tag{13.1.35}$$

We will work separately on each of the two terms appearing on the far right side of (2.68).

Save for the $1/\ell$ factor the first term takes the form

$$(1/p^0)K = -\{[(p_t^{\rm can}/p^0c)^2 - (mc/p^0)^2 - (p_x^{\rm can}/p^0 - A_x^s)^2 - (p_y^{\rm can}/p^0 - A_y^s)^2]^{1/2} + A_z^s\} \tag{13.1.36}$$

where $\boldsymbol{A}^s$ is a *scaled* vector potential given by

$$\boldsymbol{A}^s(X, Y, z) = (q/p^0)\boldsymbol{A}(\ell X, \ell Y, z). \tag{13.1.37}$$

Further manipulation employing (2.45) and (2.59) produces the relation

$$\begin{aligned} [p_t^{\rm can}/(p^0c)]^2 - (mc/p^0)^2 &= [(p_T + p_t^0)/(p^0c)]^2 - (mc/p^0)^2 \\ &= [(p^0cP_\tau + p_t^0)/(p^0c)]^2 - (mc/p^0)^2 \\ &= [P_\tau + p_t^0/(p^0c)]^2 - (mc/p^0)^2. \end{aligned} \tag{13.1.38}$$

From (2.62) there is the relation

$$p_t^0/(p^0c) = -1/\beta_0. \tag{13.1.39}$$

There is also the relation

$$mc/p^0 = mc/(m\gamma_0\beta_0c) = 1/(\gamma_0\beta_0) \tag{13.1.40}$$

where γ_0 is the usual relativistic factor evaluated on the design orbit. It follows that there is the relation

$$\begin{aligned}[p_t^{\rm can}/(p^0c)]^2-(mc/p^0)^2 &= (P_\tau-1/\beta_0)^2-1/(\gamma_0\beta_0)^2\\ &= P_\tau^2-(2P_\tau/\beta_0)+1/\beta_0^2-1/(\gamma_0\beta_0)^2. \end{aligned} \tag{13.1.41}$$

But, there is the identity

$$1/\beta_0^2-1/(\gamma_0\beta_0)^2=(1/\beta_0)^2[1-1/\gamma_0^2]=(1/\beta_0)^2[1-(1-\beta_0^2)]=1. \tag{13.1.42}$$

Consequently there is the net result

$$[p_t^{\rm can}/(p^0c)]^2-(mc/p^0)^2=P_\tau^2-(2P_\tau/\beta_0)+1. \tag{13.1.43}$$

We conclude that

$$[1/(p_0\ell)]K=-(1/\ell)\{[1-(2P_\tau/\beta_0)+P_\tau^2-(P_x-A_x^s)^2-(P_y-A_y^s)^2]^{1/2}+A_z^s\} \tag{13.1.44}$$

where we have also used (2.38), (2.39), (2.57), and (2.58).

What remains is to work on he second term on the right side of (2.68). Save for a $(-1/\ell)$ factor it takes the form

$$\begin{aligned}(1/p^0)(p_T+p_t^0)/v_z^0 &= (1/p^0)(p_0cP_\tau+p_t^0)[-p_t^0/(p_0c^2)]\\ &= -[p_t^0/(p^0c)]P_\tau-(p_t^0)^2/(p^0c)^2\\ &= (P_\tau/\beta_0)-(1/\beta_0^2). \end{aligned} \tag{13.1.45}$$

Here we have used (2.59) and (2.72). We conclude that

$$-[1/(p^0\ell)](p_T+p_t^0)/v_z^0=(1/\ell)[(P_\tau/\beta_0)-(1/\beta_0^2)]. \tag{13.1.46}$$

We are, at last, ready to compute H. Upon combining (2.68), (2.77), and (2.79) we find the final result

$$H=-(1/\ell)\{[1-(2P_\tau/\beta_0)+P_\tau^2-(P_x-A_x^s)^2-(P_y-A_y^s)^2]^{1/2}+A_z^s+(P_\tau/\beta_0)\}. \tag{13.1.47}$$

In the case of no magnetic field (1.45) takes the form

$$H=-(1/\ell)\{[1-(2P_\tau/\beta_0)+P_\tau^2-P_x^2-P_y^2]^{1/2}+(P_\tau/\beta_0)\}. \tag{13.1.48}$$

Let us use this Hamiltonian to compute x'. From Hamilton's equations of motion we find the result

$$\begin{aligned} x' &= dx/dz=\ell dX/dz=\ell\partial H/\partial P_x\\ &= P_x[1-(2P_\tau/\beta_0)+P_\tau^2-P_x^2-P_y^2]^{-1/2}\\ &= P_x+P_xP_\tau/\beta_0+(1/2)P_x[P_\tau^2(3\beta_0^{-2}-1)+P_x^2+P_y^2]+\cdots. \end{aligned} \tag{13.1.49}$$

We see that x' agrees with P_x in lowest order; but there are second-order chromatic differences, and third- and higher-order geometric and chromatic differences. Also, X and x' are *not* canonically conjugate, $[X,x']\neq 1$.

Exercises

13.2 Axial Rotation

13.3 Drift

In this subsection we will compute the transfer map for a drift. To do so we begin with the Hamiltonian (1.1) and employ the vector potential given by (2.7) through (2.10). We then introduce deviation variables followed by scaled deviation variables. Next we find the scaled deviation-variable Hamiltonian. Finally, we expand the scaled deviation-variable Hamiltonian in a Taylor series, and employ this Taylor series to compute the transfer map.

Taylor and Spherical and Cylindrical Harmonic Expansions

15.1 Introduction

Chapters 13 and 14 treated idealized beam-line elements for which variations in the field with position along the beam-line element, and fringe-field effects, were neglected. There are situations for which these neglected effects can be important when accurate modeling is desired. By developing various mathematical tools, this chapter prepares the way for Chapters 16 through 21 that describe the calculation of realistic transfer maps for straight beam-line elements, and Chapter 22 that describes the calculation of realistic transfer maps for general curved beam-line elements.

Restrictions Discovered by Hamilton (Symplecticity)

In previous chapters we learned that the motion of charged particles through any beam-line element can be described by the transfer map $\mathcal{M}$ for that element. We also learned that the equations of motion for charged particle motion can be derived from a Hamiltonian, and therefore $\mathcal{M}$ cannot be an arbitrary map, but must be a symplectic map. Consequently, through aberrations of order $(n-1)$, such a map has the Lie representation

$$\mathcal{M} = \mathcal{R}_2 \exp(:f_3:) \exp(:f_4:) \cdots \exp(:f_n:) \tag{15.1.1}$$

where $\mathcal{R}_2$ describes the linear part of the map. The linear map $\mathcal{R}_2$ and the Lie generators f_ℓ are determined by solving the equation of motion

$$\dot{\mathcal{M}} = \mathcal{M} : -H : \tag{15.1.2}$$

where

$$H = H_2 + H_3 + H_4 + \cdots \tag{15.1.3}$$

is the Hamiltonian expressed in terms of deviation variables and expanded in a homogeneous polynomial series. See Sections 10.1 and 10.4. The deviation variable Hamiltonian

H is determined in turn by the Hamiltonian K for which some coordinate is the independent variable. For example, in Cartesian coordinates and with z taken as the independent variable, K is given by the relation

$$K = -[(p_t + q\psi)^2/c^2 - m^2c^2 - (p_x - qA_x)^2 - (p_y - qA_y)^2]^{1/2} - qA_z. \tag{15.1.4}$$

Here ψ and $\boldsymbol{A}$ are the electric scalar and magnetic vector potentials, respectively. See (1.6.16). We conclude that (in the case of no electric fields, $\psi = 0$) what we need are Taylor expansions for the vector potential components A_x, A_y, A_z in the deviation variables x and y.

Restrictions Associated with Maxwell's Equations

For common beam-line elements the charged particles move in an evacuated beam pipe, and therefore the electric and magnetic fields controlling particle motion are source free in the vicinity of the beam. Correspondingly, the source-free Maxwell equations impose restrictions on what fields can be employed. This chapter begins with a discussion of harmonic functions and the use of spherical coordinates to obtain *spherical harmonic* expansions thereby leading to suitable Taylor expansions for source-free magnetic fields and their scalar and vector potentials. For our purposes this material is of particular use in terminating end fields. See Sections 16.7 and 22.8. It has other general uses as well including the treatment of ambient fields.

Next we will find, for the case of straight beam-line elements, expressions for the required Taylor expansions in terms of *on-axis gradients* with the aid of *cylindrical harmonic* expansions.[1] The on-axis gradients themselves are generally unspecified functions of z. In some simple cases they can be found analytically, as illustrated in Chapter 16. However, in general they must be determined numerically. Chapters 17 through 21 describe how this can be done in terms of magnetic field or magnetic potential values determined numerically at points on some regular 3-dimensional grid with the aid of some electromagnetic code.

In this part of the present chapter we will first learn how to characterize the magnetic scalar potential in terms of cylindrical harmonics described by on-axis gradients. Next we will find field expansions in terms of cylindrical harmonics. Then we will relate vector potentials to on-axis gradients. The work of this part of the chapter concludes with the treatment of an analytically soluble model problem, that of the magnetic monopole doublet, which will be used in Chapter 19 to benchmark the methods to be developed in Chapters 17 through 21.

The chapter ends with some closing remarks meant to provide added perspective.

[1] In this chapter we will use the word *cylindrical* to mean *circular* cylindrical. In subsequent chapters we will distinguish between circular, elliptic, and rectangular cylinders.

15.2 Spherical Expansion

15.2.1 Harmonic Functions and Absolute and Expansion Coordinates

In a current-free region the magnetic field $\boldsymbol{B}$ is curl free, and can therefore be described most simply in terms of a *magnetic scalar potential* Ψ with

$$\boldsymbol{B} = +\nabla\Psi. \tag{15.2.1}$$

Because $\boldsymbol{B}$ is also divergence free, Ψ must obey the Laplace equation,

$$\nabla^2\Psi = \nabla \cdot \boldsymbol{B} = 0. \tag{15.2.2}$$

Functions Ψ that obey the Laplace equation are said to be *harmonic.*

At this point it is convenient to introduce an "absolute" coordinate $\boldsymbol{R}$ and an "expansion" coordinate $\boldsymbol{r}$ about some "reference/expansion" point $\boldsymbol{R}_0$ by writing

$$\boldsymbol{R} = \boldsymbol{R}_0 + \boldsymbol{r}. \tag{15.2.3}$$

In terms of these variables we may define a related scalar potential ψ by writing

$$\psi(x, y, z; \boldsymbol{R}_0) = \Psi(\boldsymbol{R}_0 + \boldsymbol{r}) \tag{15.2.4}$$

where

$$\boldsymbol{r} = x\boldsymbol{e}_x + y\boldsymbol{e}_y + z\boldsymbol{e}_z. \tag{15.2.5}$$

Like Ψ, the related scalar potential ψ satisfies the relations

$$\boldsymbol{B} = +\nabla\psi, \tag{15.2.6}$$

and

$$\nabla^2\psi = 0. \tag{15.2.7}$$

Here, ψ is not to be confused with the ψ that was used in other sections to describe an electric field. Note also the + sign in (2.1 and (2.6) compared to the − sign in (1.4.2). These sign choices are a matter of convention. Also, strictly speaking, the derivatives in (2.1) and (2.2) are to be taken with respect to the components of $\boldsymbol{R}$, and the derivatives in (2.6) and (2.7) are to be taken with respect to the components of $\boldsymbol{r}$. Moreover, in subsequent work, we will sometimes suppress the dependence of ψ on $\boldsymbol{R}_0$ and simply write $\psi(x, y, z)$.

Finally we note that, since we will assume that $\boldsymbol{R}_0$ is in a current free region, $\boldsymbol{B}$ will be analytic is this region. Consequently, Ψ will be analytic in this region. Correspondingly, $\boldsymbol{B}(\boldsymbol{r})$ and $\psi(\boldsymbol{r})$ will be analytic about $\boldsymbol{r} = 0$. See Chapter 35 and Appendix F.

15.2.2 Spherical and Cylindrical Coordinates

Introduce spherical coordinates r,θ,ϕ by the usual rules

$$r^2 = x^2 + y^2 + z^2, \tag{15.2.8}$$

$$x = r\sin(\theta)\cos(\phi), \tag{15.2.9}$$

$$y = r\sin(\theta)\sin(\phi), \tag{15.2.10}$$

$$z = r\cos\theta. \tag{15.2.11}$$

Also, for future use, introduce cylindrical coordinates ρ, ϕ, and z by the usual rules

$$\rho^2 = x^2 + y^2, \tag{15.2.12}$$

$$x = \rho\cos\phi, \tag{15.2.13}$$

$$y = \rho\sin\phi. \tag{15.2.14}$$

Note these two coordinate systems have the coordinate ϕ in common. In both cases there is the ϕ-defining pair of relations

$$\sin\phi = y/\sqrt{x^2 + y^2}, \tag{15.2.15}$$

$$\cos\phi = x/\sqrt{x^2 + y^2}. \tag{15.2.16}$$

The other coordinates are related by (2.11) and the equations

$$r^2 = \rho^2 + z^2, \tag{15.2.17}$$

$$\rho = r\sin\theta. \tag{15.2.18}$$

We also record results for the orthonormal triads $\boldsymbol{e}_r$, $\boldsymbol{e}_\theta$, $\boldsymbol{e}_\phi$ and $\boldsymbol{e}_\rho$, $\boldsymbol{e}_\phi$, $\boldsymbol{e}_z$, and their relation to $\boldsymbol{r}$. For the spherical orthonormal triad there are the results

$$\begin{aligned} \boldsymbol{e}_r &= \sin(\theta)\cos(\phi)\boldsymbol{e}_x + \sin(\theta)\sin(\phi)\boldsymbol{e}_y + \cos(\theta)\boldsymbol{e}_z \\ &= (1/r)(x\boldsymbol{e}_x + y\boldsymbol{e}_y + z\boldsymbol{e}_z) = \boldsymbol{r}/r, \\ \boldsymbol{e}_\theta &= \cos(\theta)\cos(\phi)\boldsymbol{e}_x + \cos(\theta)\sin(\phi)\boldsymbol{e}_y - \sin(\theta)\boldsymbol{e}_z, \\ \boldsymbol{e}_\phi &= -\sin(\phi)\boldsymbol{e}_x + \cos(\phi)\boldsymbol{e}_y, \\ \boldsymbol{r} &= r\boldsymbol{e}_r. \end{aligned} \tag{15.2.19}$$

For the cylindrical orthonormal triad there are the results

$$\begin{aligned} &\boldsymbol{e}_\rho = \cos\phi\ \boldsymbol{e}_x + \sin\phi\ \boldsymbol{e}_y = (1/\rho)(x\boldsymbol{e}_x + y\boldsymbol{e}_y), \\ &\boldsymbol{e}_\phi = -\sin\phi\ \boldsymbol{e}_x + \cos\phi\ \boldsymbol{e}_y = (1/\rho)(-y\boldsymbol{e}_x + x\boldsymbol{e}_y), \\ &\boldsymbol{r} = \rho\boldsymbol{e}_\rho + z\boldsymbol{e}_z. \end{aligned} \tag{15.2.20}$$

See Exercises 2.1 and 2.2.

Finally, with regard to the relation between Cartesian and cylindrical coordinates, if one defines Cartesian and cylindrical components for any vector $\boldsymbol{A}$ by writing

$$\boldsymbol{A} = A_x\boldsymbol{e}_x + A_y\boldsymbol{e}_y + A_z\boldsymbol{e}_z = A_\rho\boldsymbol{e}_\rho + A_\phi\boldsymbol{e}_\phi + A_z\boldsymbol{e}_z, \tag{15.2.21}$$

then there are the component relations

$$A_\rho = \boldsymbol{e}_\rho \cdot \boldsymbol{A} = \cos\phi\ A_x + \sin\phi\ A_y, \tag{15.2.22}$$

$$A_\phi = \boldsymbol{e}_\phi \cdot \boldsymbol{A} = -\sin\phi\ A_x + \cos\phi\ A_y, \tag{15.2.23}$$

and their inverses

$$A_x = \boldsymbol{e}_x \cdot \boldsymbol{A} = \cos\phi\ A_\rho - \sin\phi\ A_\phi, \tag{15.2.24}$$

$$A_y = \boldsymbol{e}_y \cdot \boldsymbol{A} = \sin\phi\ A_\rho + \cos\phi\ A_\phi. \tag{15.2.25}$$

15.2.3 Harmonic Polynomials, Harmonic Polynomial Expansions, and General Spherical Polynomials

Polynomials in x, y, and z that are harmonic are called *harmonic polynomials* or *solid harmonics*. In *complex* form these polynomials, call them H_ℓ^m, can be defined in terms of the spherical harmonics $Y_\ell^m(\theta,\phi)$ and the associated Legendre functions P_ℓ^m by the rule

$$\begin{aligned} H_\ell^m(\boldsymbol{r}) &= r^\ell Y_\ell^m(\theta,\phi) \\ &= r^\ell\{[(2\ell+1)(\ell-m)!]/[4\pi(\ell+m)!]\}^{1/2}P_\ell^m(\cos\theta)\exp(im\phi) \\ &\quad \text{with } -\ell \le m \le \ell. \end{aligned} \tag{15.2.26}$$

The H_ℓ^m are homogeneous polynomials of degree ℓ in the variables x, y, and z.[2] For example, there are the definitions

$$H_0^0(\boldsymbol{r}) = 1/\sqrt{4\pi}; \tag{15.2.27}$$

$$\begin{aligned} &H_1^1(\boldsymbol{r}) = \sqrt{3/(4\pi)}(-1/\sqrt{2})(x+iy) = -\sqrt{3/(8\pi)}(x+iy), \\ &H_1^0(\boldsymbol{r}) = \sqrt{3/(4\pi)}z, \\ &H_1^{-1}(\boldsymbol{r}) = \sqrt{3/(4\pi)}(1/\sqrt{2})(x-iy) = \sqrt{3/(8\pi)}(x-iy); \end{aligned} \tag{15.2.28}$$

$$\begin{aligned} &H_2^2(\boldsymbol{r}) = \sqrt{15/(32\pi)}(x+iy)^2, \\ &H_2^1(\boldsymbol{r}) = -\sqrt{15/(8\pi)}(x+iy)z, \\ &H_2^0(\boldsymbol{r}) = \sqrt{5/(16\pi)}(2z^2-x^2-y^2), \\ &H_2^{-1}(\boldsymbol{r}) = \sqrt{15/(8\pi)}(x-iy)z, \\ &H_2^{-2}(\boldsymbol{r}) = \sqrt{15/(32\pi)}(x-iy)^2. \end{aligned} \tag{15.2.29}$$

See Appendix U. Because thy are defined in terms of the Y_ℓ^m and powers of r, the harmonic polynomials H_ℓ^m have well-defined properties under the action of the rotation group $SO(3)$.[3]

From potential theory we know that any harmonic function analytic at the origin $\boldsymbol{r}=0$ can be expanded in harmonic polynomials. Thus, under the assumption that a harmonic function ψ is analytic at the origin, it has the expansion

$$\psi(x,y,z) = \sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell} g_{\ell m}H_\ell^m(\boldsymbol{r}) \tag{15.2.30}$$

where the coefficients $g_{\ell m}$ are arbitrary.

We can also define *real* versions of harmonic polynomials, call them $H_\ell^{m,\alpha}$ where $m \ge 0$ and $\alpha = c$ or s, by writing

$$\begin{aligned} &H_\ell^{m,c}(x,y,z) = \{[(2\ell+1)(\ell-m)!]/[4\pi(l+m)!]\}^{1/2}r^\ell P_\ell^m(\cos\theta)\cos(m\phi) \\ &\text{with } \ell = 0,1,\cdots,\infty \text{ and } m = 0,1,\cdots,\ell \end{aligned} \tag{15.2.31}$$

[2] Note that although we initially work with spherical coordinates, the final result is in the form of power series in *Cartesian* coordinates.

[3] We note that the spherical harmonics Y_ℓ^m could better be called *surface* harmonics. Then we could use the name *spherical harmonics* to refer to the functions H_ℓ^m.

and

$$H_\ell^{m,s}(x,y,z) = \{[(2\ell+1)(\ell-m)!]/[4\pi(l+m)!]\}^{1/2} r^\ell P_\ell^m(\cos\theta)\sin(m\phi)$$
$$\text{with } \ell = 1,2,\cdots,\infty \text{ and } m = 1,2,\cdots,\ell. \tag{15.2.32}$$

These definitions yield, for example, the results

$$H_0^{0,c} = 1/\sqrt{4\pi}; \tag{15.2.33}$$

$$\begin{aligned} H_1^{1,c} &= -[3/(8\pi)]^{1/2}x, \\ H_1^{0,c} &= [3/(4\pi)]^{1/2}z, \\ H_1^{1,s} &= -[3/(8\pi)]^{1/2}y; \end{aligned} \tag{15.2.34}$$

$$\begin{aligned} H_2^{2,c} &= (1/4)[15/(2\pi)]^{1/2}(x^2-y^2), \\ H_2^{1,c} &= -[15/(8\pi)]^{1/2}xz, \\ H_2^{0,c} &= (1/2)[5/(4\pi)]^{1/2}(2z^2-x^2-y^2), \\ H_2^{2,s} &= (1/2)[15/(2\pi)]^{1/2}xy, \\ H_2^{1,s} &= -[15/(8\pi)]^{1/2}yz; \end{aligned} \tag{15.2.35}$$

$$\begin{aligned} H_3^{3,c} &= -(1/4)[35/(4\pi)]^{1/2}(x^3-3xy^2), \\ H_3^{2,c} &= (1/4)[105/(2\pi)]^{1/2}[z(x^2-y^2)], \\ H_3^{1,c} &= -(1/4)[21/(2\pi)]^{1/2}[x(4z^2-x^2-y^2)], \\ H_3^{0,c} &= (1/2)[7/(4\pi)]^{1/2}[2z^3-3z(x^2+y^2)], \\ H_3^{3,s} &= (1/4)[35/(4\pi)]^{1/2}(y^3-3x^2y), \\ H_3^{2,s} &= (1/2)[105/(2\pi)]^{1/2}(xyz), \\ H_3^{1,s} &= -(1/4)[21/(4\pi)]^{1/2}[y(4z^2-x^2-y^2)]. \end{aligned} \tag{15.2.36}$$

In terms of these polynomials any harmonic function ψ analytic at the origin has an expansion of the form

$$\psi(x,y,z) = \sum_{\ell=0}^{\infty}\sum_{m=0}^{\ell} g_{\ell,m,c}H_\ell^{m,c}(\boldsymbol{r}) + \sum_{\ell=1}^{\infty}\sum_{m=1}^{\ell} g_{\ell,m,s}H_\ell^{m,s}(\boldsymbol{r}), \tag{15.2.37}$$

where the coefficients $g_{\ell,m,\alpha}$ are arbitrary.

It is also convenient to define general *spherical polynomials* $S_{n\ell}^m(\boldsymbol{r})$ in terms of the spherical harmonics and powers of r by making the definition

$$S_{n\ell}^m(\boldsymbol{r}) = r^n Y_\ell^m(\theta,\phi). \tag{15.2.38}$$

See Subsection U.2.4. The $S_{n\ell}^m(\boldsymbol{r})$ are evidently of degree n. They form a basis for the space of all functions that are anaytic at the origin, and harmonic polynomials comprise special cases for which $\ell = n$,

$$H_n^m(\boldsymbol{r}) = S_{nn}^m(\boldsymbol{r}). \tag{15.2.39}$$

Therefore, we may also write (2.30) in the form

$$\psi(x,y,z) = \sum_{n=0}^{\infty} \sum_{m=-n}^{n} g_{nm} S_{nn}^{m}(\boldsymbol{r}). \tag{15.2.40}$$

Finally, because they are constructed from the Y_ℓ^m and powers of r, the $S_{n\ell}^m(\boldsymbol{r})$ also have well-defined properties under the action of $SO(3)$.

15.2.4 Spherical Polynomial Vector Fields

We have been working with *scalar* fields such as $\psi(\boldsymbol{r})$. Just as it is possible to construct scalar polynomial fields $S_{n\ell}^m(\boldsymbol{r})$ having well-defined properties under the action of $SO(3)$, it is also possible to construct polynomial *vector* fields that have well-defined properties under the action of $SO(3)$. We call such polynomial vector fields *spherical polynomial* vector fields and denote them by the symbols $\boldsymbol{S}_{n\ell J}^{M}(\boldsymbol{r})$. These are vector fields whose components are homogenous polynomials of degree n in the components of $\boldsymbol{r}$. See Subsections U.3.2 and U.3.3 for their definition and some examples.

Any vector field analytic at the origin can be expanded in terms of spherical polynomial vector fields. In particular, both the magnetic field $\boldsymbol{B}(\boldsymbol{r})$ and any associated vector potential $\boldsymbol{A}(\boldsymbol{r})$ can be expanded in terms of spherical polynomial vector fields.

Because of their properties under the action of $SO(3)$, there are well-organized relations between spherical polynomials and spherical polynomial vector fields. For example, there is the relation

$$\nabla H_n^m(\boldsymbol{r}) = \nabla S_{nn}^m(\boldsymbol{r}) = \sqrt{n(2n+1)}\boldsymbol{S}_{n-1,n-1,n}^{m}(\boldsymbol{r}). \tag{15.2.41}$$

See (U.5.6). Upon combining (2.40) and (2.41) we see that a general source-free field $\boldsymbol{B}$ has a spherical polynomial vector field expansion of the form

$$\boldsymbol{B}(\boldsymbol{r}) = \nabla\psi = \sum_{n=0}^{\infty} \sum_{m=-n}^{n} g_{nm}\sqrt{n(2n+1)}\boldsymbol{S}_{n-1,n-1,n}^{m}(\boldsymbol{r}). \tag{15.2.42}$$

Note that the $n = 0$ term does not actually contribute, as expected.

15.2.5 Determination of Minimum Vector Potential: the Poincaré-Coulomb Gauge

Suppose we are given a magnetic field, specified either by a scalar potential presented in the forms (2.30) or (2.40), or equivalently by a spherical polynomial vector field expansion of the form (2.42). And suppose, in order to treat charged-particle motion in this field using a Hamiltonian formulation, we wish to find an associated vector potential. We know that in principle there are many such vector potentials, all of which are related by gauge transformations. Given $\boldsymbol{B}(\boldsymbol{r})$ in some region, the goal of this subsection is to find an associated vector potential $\boldsymbol{A}^{\min}(\boldsymbol{r})$ that is, at least *locally*, as *minimal*/small as possible in the sense that $\boldsymbol{A}^{\min}(\boldsymbol{r})$ is small if $\boldsymbol{B}(\boldsymbol{r})$ is small. The reason for this goal is that, according to (1.5.30), mechanical and canonical momenta differ by the vector potential; and there are situations where we would like this difference to be as small as possible. See Sections 16.7 and 22.8.

Conceptually, our plan is as follows: Make Taylor expansions, with initially unknown coefficients, for the Cartesian components of $\boldsymbol{A}^{\min}(\boldsymbol{r})$, organize these expansions into homogeneous polynomials, and then further organize them as spherical polynomial vector fields. Then use this representation to compute and organize $\nabla \times \boldsymbol{A}^{\min}$ in terms of spherical polynomial vector fields. At the same time parameterize $\boldsymbol{B}(\boldsymbol{r})$ in terms of a scalar potential ψ expanded in harmonic polynomials. Finally, compare the two expansions for $\boldsymbol{B}(\boldsymbol{r})$ given by $\boldsymbol{B} = \nabla\psi$ and $\boldsymbol{B} = \nabla \times \boldsymbol{A}^{\min}$, equate coefficients of like terms, and thereby determine the coefficients in the Taylor expansion for the components of $\boldsymbol{A}^{\min}$ in terms of the coefficients in the expansion for ψ. Do all this while keeping the minimal/small goal in mind. For the notation and machinery required for the execution of this plan, again see Appendix U. What lies ahead may seem complicated, but the final result will prove to be remarkably simple.

Construction of Minimum Vector Potential

We begin with the harmonic polynomial expansion (2.40) for the scalar potential ψ, which we rewrite in the form

$$\psi(\boldsymbol{r}) = \sum_{n=1}^{n_{\max}} \sum_{m} g_{nm} S_{nn}^{m}(\boldsymbol{r}). \tag{15.2.43}$$

Here we assume an expansion through terms of degree $n_{\max}$, and omit $n = 0$ terms since constant terms make no contribution to $\boldsymbol{B}$ as given by (2.42).

For the associated vector potential $\boldsymbol{A}^{\min}$ we make the spherical polynomial vector field expansion

$$\boldsymbol{A}^{\min}(\boldsymbol{r}) = \sum_{n=1}^{n_{\max}} \sum_{\ell} \sum_{J} \sum_{M} f_{n\ell JM} \boldsymbol{S}_{n\ell J}^{M}(\boldsymbol{r}). \tag{15.2.44}$$

Again see Appendix U. Given the coefficients g_{nm}, our task is to use the equality

$$\nabla \times \boldsymbol{A}^{\min}(\boldsymbol{r}) = \nabla \times \sum_{n=1}^{n_{\max}} \sum_{\ell} \sum_{J} \sum_{M} f_{n\ell JM} \boldsymbol{S}_{n\ell J}^{M}(\boldsymbol{r}) = \nabla \sum_{n=1}^{n_{\max}} \sum_{m} g_{nm} S_{nn}^{m}(\boldsymbol{r}) = \nabla\psi(\boldsymbol{r}) \tag{15.2.45}$$

to find the coefficients $f_{n\ell JM}$ in terms of the g_{nm}.

We already know the result of evaluating the right side of (2.45). Use of (2.42) gives the result

$$\boldsymbol{B}(\boldsymbol{r}) = \nabla\psi(\boldsymbol{r}) = \nabla \sum_{n=1}^{n_{\max}} \sum_{m} g_{nm} S_{nn}^{m}(\boldsymbol{r}) = \sum_{n=1}^{n_{\max}} \sum_{m} g_{nm} \sqrt{n(2n+1)} \boldsymbol{S}_{n-1,n-1,n}^{m}(\boldsymbol{r}). \tag{15.2.46}$$

Next work on evaluating the left side of (2.45). This is a more complicated task. In accord with the range rules (U.3.7) and (U.3.8), we decompose the expansion into the sum of four pieces with each containing a particular kind of term:

a) All terms for which $\ell = 0$ and hence $J = 1$. Also, therefore, $n = 2k$ with $k > 0$. The associated spherical polynomial vectors are of the form $\boldsymbol{S}_{2k,0,1}^{M}(\boldsymbol{r})$.

b) All terms for which $\ell > 0$ and $J = \ell + 1$. The associated spherical polynomial vectors are of the form $\boldsymbol{S}^M_{n,\ell,\ell+1}(\boldsymbol{r})$.

c) All terms for which $\ell > 0$ and $J = \ell$. The associated spherical polynomial vectors are of the form $\boldsymbol{S}^M_{n,\ell,\ell}(\boldsymbol{r})$.

d) All terms for which $\ell > 0$ and $J = \ell - 1$. The associated spherical polynomial vectors are of the form $\boldsymbol{S}^M_{n,\ell,\ell-1}(\boldsymbol{r})$.

Thus, we write

$$\boldsymbol{A}^{\min} = \boldsymbol{A}^{\min a} + \boldsymbol{A}^{\min b} + \boldsymbol{A}^{\min c} + \boldsymbol{A}^{\min d} \tag{15.2.47}$$

where

$$\boldsymbol{A}^{\min a}(\boldsymbol{r}) = \sum_{k=1}^{k_{\max}} \sum_{M} f_{2k,0,1,M} \boldsymbol{S}^M_{2k,0,1}(\boldsymbol{r}), \tag{15.2.48}$$

$$\boldsymbol{A}^{\min b}(\boldsymbol{r}) = \sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} f_{n,\ell,\ell+1,M} \boldsymbol{S}^M_{n,\ell,\ell+1}(\boldsymbol{r}), \tag{15.2.49}$$

$$\boldsymbol{A}^{\min c}(\boldsymbol{r}) = \sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} f_{n,\ell,\ell,M} \boldsymbol{S}^M_{n,\ell,\ell}(\boldsymbol{r}), \tag{15.2.50}$$

$$\boldsymbol{A}^{\min d}(\boldsymbol{r}) = \sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} f_{n,\ell,\ell-1,M} \boldsymbol{S}^M_{n,\ell,\ell-1}(\boldsymbol{r}). \tag{15.2.51}$$

We are ready to proceed. For the $\boldsymbol{A}^{\min a}$ term we find, using (U.5.20), the result

$$\nabla \times \boldsymbol{A}^{\min a}(\boldsymbol{r}) = \nabla \times \sum_{k=1}^{k_{\max}} \sum_{M} f_{2k,0,1,M} \boldsymbol{S}^M_{2k,0,1}(\boldsymbol{r}) = \sum_{k=1}^{k_{\max}} \sum_{M} f_{2k,0,1,M} [i(\sqrt{2/3})(2k)] \boldsymbol{S}^M_{2k-1,1,1}(\boldsymbol{r}). \tag{15.2.52}$$

For the $\boldsymbol{A}^{\min b}$ term we find, using (U.5.17), the result

$$\nabla \times \boldsymbol{A}^{\min b}(\boldsymbol{r}) = \nabla \times \sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} f_{n,\ell,\ell+1,M} \boldsymbol{S}^M_{n,\ell,\ell+1}(\boldsymbol{r}) =$$
$$\sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} f_{n,\ell,\ell+1,M} [i\sqrt{(\ell+2)/(2\ell+3)}(n-\ell)] \boldsymbol{S}^M_{n-1,\ell+1,\ell+1}(\boldsymbol{r}). \tag{15.2.53}$$

For the $\boldsymbol{A}^{\min c}$ term we find, using (U.5.18), the result

$$\nabla \times \boldsymbol{A}^{\min c}(\boldsymbol{r}) = \nabla \times \sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} f_{n,\ell,\ell,M} \boldsymbol{S}^M_{n,\ell,\ell}(\boldsymbol{r}) =$$
$$\sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} f_{n,\ell,\ell,M} [i\sqrt{(\ell+1)/(2\ell+1)}(n+\ell+1)] \boldsymbol{S}^M_{n-1,\ell-1,\ell}(\boldsymbol{r})$$
$$+ \sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} f_{n,\ell,\ell,M} [i\sqrt{\ell/(2\ell+1)}(n-\ell)] \boldsymbol{S}^M_{n-1,\ell+1,\ell}(\boldsymbol{r}). \tag{15.2.54}$$

Finally, for the $\boldsymbol{A}^{\min d}$ term we find, using (U.5.19), the result

$$\nabla \times \boldsymbol{A}^{\min d}(\boldsymbol{r}) = \nabla \times \sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} f_{n,\ell,\ell-1,M} \boldsymbol{S}^{M}_{n,\ell,\ell-1}(\boldsymbol{r}) =$$
$$\sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} f_{n,\ell,\ell-1,M} [i\sqrt{(\ell-1/(2\ell-1)}(n+\ell+1)] \boldsymbol{S}^{M}_{n-1,\ell-1,\ell-1}(\boldsymbol{r}). \quad (15.2.55)$$

We can now equate coefficients of like terms. Let us begin with the first few corresponding to small values of n. The first of these, corresponding to $n=0$, is $\boldsymbol{S}^{M}_{0,0,1}$. For the right side of (2.45) we see from (2.46) that

$$\text{coefficient of } \boldsymbol{S}^{M}_{0,0,1} \text{ in } \nabla\psi = \sqrt{3}\, g_{1M}. \quad (15.2.56)$$

Next, for the left side, examine the terms in $\nabla \times \boldsymbol{A}^{\min}$: From (2.52) we see that there are no terms of the desired kind, namely terms involving $\boldsymbol{S}^{M}_{0,0,1}$, in $\nabla \times \boldsymbol{A}^{\min a}$. From (2.53) we see that there are no terms of the desired kind in $\nabla \times \boldsymbol{A}^{\min b}$. From (2.54) we see that there are terms of the desired kind in $\nabla \times \boldsymbol{A}^{\min c}$, and find the result

$$\text{coefficient of } \boldsymbol{S}^{M}_{0,0,1} \text{ in } \nabla \times \boldsymbol{A}^{\min c} = i\sqrt{6}\, f_{1,1,1,M}. \quad (15.2.57)$$

Finally, from (2.55) we see that there are no terms of the desired kind in $\nabla \times \boldsymbol{A}^{\min d}$.

Upon comparing (2.56) and (2.57) we conclude that there must be the relation

$$i\sqrt{6}\, f_{1,1,1,M} = \sqrt{3}\, g_{1M}, \quad (15.2.58)$$

and therefore

$$f_{1,1,1,M} = -i\sqrt{1/2}\, g_{1M}. \quad (15.2.59)$$

Note that this relation is consistent with (U.6.39). Moreover, we conclude that the six remaining $n=1$ coefficients in $\boldsymbol{A}^{\min}$, namely $f_{1,1,0,0}$ and the $f_{1,1,2,M}$, can be anything since there are the relations (U.6.38) and (U.6.40). In pursuit of our minimal/small goal, we set these coefficients to zero. Then, so far, we have the result

$$\boldsymbol{A}^{\min}(\boldsymbol{r}) = \sum_{M} (-i)\sqrt{1/2}\, g_{1M}\ \boldsymbol{S}^{M}_{111}(\boldsymbol{r}) + \text{ terms of degree } > 1. \quad (15.2.60)$$

In terms of Cartesian components, (2.60) yields the relation

$$\boldsymbol{A}^{\min}(\boldsymbol{r}) = -(1/2)\boldsymbol{r} \times \boldsymbol{B}(0) + \text{ terms of degree } > 1. \quad (15.2.61)$$

Here we have used (2.42), (2.43), and (U.6.25) evaluated for $n=1$.

Let us push on to the case $n=1$; in which case there are the spherical polynomial vector fields $\boldsymbol{S}^{0}_{110}$, $\boldsymbol{S}^{M}_{111}$ with $-1 \le M \le 1$, and $\boldsymbol{S}^{M}_{112}$ with $-2 \le M \le 2$. First see where/how they occur in $\nabla\psi$. Examination of (2.46) shows that the only such term in $\nabla\psi$ is $\boldsymbol{S}^{M}_{112}$, and we have the relation

$$\text{coefficient of } \boldsymbol{S}^{M}_{1,1,2} \text{ in } \nabla\psi = \sqrt{10}\, g_{2M}. \quad (15.2.62)$$

We next examine the terms in $\nabla \times \boldsymbol{A}^{\min}$: From (2.52) we see that there are no terms of the desired kind, namely terms involving $\boldsymbol{S}^M_{1,1,2}$, in $\nabla \times \boldsymbol{A}^{\min a}$. From (2.53) we see that there are no terms of the desired kind in $\nabla \times \boldsymbol{A}^{\min b}$. From (2.54) we see that there are terms of the desired kind in $\nabla \times \boldsymbol{A}^{\min c}$, and find the relation

$$\text{coefficient of } \boldsymbol{S}^M_{1,1,2} \text{ in } \nabla \times \boldsymbol{A}^{\min c} = i\sqrt{15}\, f_{2,2,2,M}. \tag{15.2.63}$$

Finally, from (2.55) we see that there are no terms of the desired kind in $\nabla \times \boldsymbol{A}^{\min d}$.

Upon comparing (2.62) and (2.63) we conclude that there must be the relation

$$i\sqrt{15}\, f_{2,2,2,M} = \sqrt{10}\, g_{2M}, \tag{15.2.64}$$

and therefore

$$f_{2,2,2,M} = -i\sqrt{2/3}\, g_{2M}. \tag{15.2.65}$$

What can be said about the thirteen remaining $n = 2$ coefficients in $\boldsymbol{A}^{\min}$, namely the coefficients f_{201M}, $f_{2,2,3,M}$, and $f_{2,2,1,M}$? It can be shown that $\nabla \times \boldsymbol{S}^M_{223}(\boldsymbol{r}) = 0$, and therefore the terms with coefficients $f_{2,2,3,M}$ make no contribution to $\boldsymbol{B}(\boldsymbol{r})$. See Exercise (U.6.21). In further pursuit of our minimal/small goal, we set these coefficients to zero. It can be shown that terms with the coefficients f_{201M} and $f_{2,2,1,M}$ produce terms in $\boldsymbol{B}(\boldsymbol{r})$ having nonzero curl. Again see Exercise (U.6.21). We also set these coefficients to zero to ensure that $\boldsymbol{B}(\boldsymbol{r})$ is curl free. Putting everything together we have learned so far yields the result

$$\boldsymbol{A}^{\min}(\boldsymbol{r}) = \sum_M (-i)\sqrt{1/2}\, g_{1M}\, \boldsymbol{S}^M_{111}(\boldsymbol{r}) + \sum_M (-i)\sqrt{2/3}\, g_{2M}\, \boldsymbol{S}^M_{222}(\boldsymbol{r}) + \text{ terms of degree } > 2. \tag{15.2.66}$$

The pattern should now be clear. There are the general relations

$$\nabla S^M_{nn}(\boldsymbol{r}) = \sqrt{n(2n+1)}\boldsymbol{S}^M_{n-1,n-1,n}(\boldsymbol{r}) \tag{15.2.67}$$

and

$$\nabla \times \boldsymbol{S}^M_{n,n,n}(\boldsymbol{r}) = i\sqrt{(n+1)(2n+1)}\boldsymbol{S}^M_{n-1,n-1,n}(\boldsymbol{r}). \tag{15.2.68}$$

Therefore there is the general relation

$$\boldsymbol{A}^{\min}(\boldsymbol{r}) = \sum_{n=1}^{n_{\max}} \sum_{M=-n}^{n} (-i)\sqrt{n/(n+1)}\, g_{nM}\boldsymbol{S}^M_{nnn}(\boldsymbol{r}). \tag{15.2.69}$$

We have found a formula for the vector potential $\boldsymbol{A}^{\min}(\boldsymbol{r})$ in terms of the harmonic expansion coefficients for the scalar potential $\psi(\boldsymbol{r})$.

Properties of Minimum Vector Potential

It can be verified that this particular choice of $\boldsymbol{A}^{\min}(\boldsymbol{r})$ has the property

$$\nabla \cdot \boldsymbol{A}^{\min}(\boldsymbol{r}) = 0. \tag{15.2.70}$$

See (U.5.11). Therefore $\boldsymbol{A}^{\min}(\boldsymbol{r})$ is in a *Coulomb/solenoidal* gauge.[4] It also has the property

$$\boldsymbol{r} \cdot \boldsymbol{A}^{\min}(\boldsymbol{r}) = 0. \tag{15.2.71}$$

See (U.6.9). This is the condition that $\boldsymbol{A}^{\min}(\boldsymbol{r})$ be in what is called a *Poincaré* gauge.[5] Taken together, we will say that a vector potential that satisfies both (2.70) and (2.71) is in the *Poincaré-Coulomb* gauge.[6]

At this point we observe that any vector potential $\boldsymbol{A}(\boldsymbol{r})$ that obeys the Poincaré gauge condition

$$\boldsymbol{r} \cdot \boldsymbol{A}(\boldsymbol{r}) = 0 \tag{15.2.72}$$

must vanish at the origin,

$$\boldsymbol{A}(0) = 0. \tag{15.2.73}$$

That is, it has no constant part. Note that, according to (2.3), $\boldsymbol{r} = 0$ corresponds to the expansion point $\boldsymbol{R} = \boldsymbol{R}_0$, and we again assume analyticity so that $\boldsymbol{A}$ is analytic at the origin.

To see that $\boldsymbol{A}(\boldsymbol{r})$ has no constant part, expand it in homogeneous polynomials of degree n by writing

$$\boldsymbol{A}(\boldsymbol{r}) = \sum_{n=0}^{\infty} \boldsymbol{A}^n(\boldsymbol{r}). \tag{15.2.74}$$

Combining (2.72) and (2.74) gives the relation

$$\boldsymbol{r} \cdot \boldsymbol{A}(\boldsymbol{r}) = \sum_{n=0}^{\infty} \boldsymbol{r} \cdot \boldsymbol{A}^n(\boldsymbol{r}) = 0, \tag{15.2.75}$$

from which it follows, upon equating terms of like degree, that

$$\boldsymbol{r} \cdot \boldsymbol{A}^n(\boldsymbol{r}) = 0 \tag{15.2.76}$$

for all n. In particular, there is the result

$$\boldsymbol{r} \cdot \boldsymbol{A}^0(\boldsymbol{r}) = \boldsymbol{r} \cdot \boldsymbol{A}(0) = 0 \tag{15.2.77}$$

for all $\boldsymbol{r}$, from which (2.73) follows.

Evaluation of Work

Have we achieved our goal of finding a *minimal* vector potential? We have, in the following sense: Inspection of (2.46) shows that it provides an expansion of $\boldsymbol{B}(\boldsymbol{r})$ in terms of spherical polynomial vector fields $\boldsymbol{S}^m_{n-1,n-1,n}(\boldsymbol{r})$ with expansion coefficients proportional to the g_{nm}. Inspection of (2.69) shows that it provides an expansion of $\boldsymbol{A}^{\min}(\boldsymbol{r})$ in terms of spherical

[4] Fields that are divergence free are also called *solenoidal*.

[5] A Poincaré gauge is also sometimes called a *multipolar* gauge.

[6] It is interesting to observe that these two conditions have related "Fourier analogs". In Fourier space the condition (2.70) becomes $\boldsymbol{k} \cdot \tilde{\boldsymbol{A}}^{\min}(\boldsymbol{k}) = 0$ and the condition (2.71) becomes $\nabla_{\boldsymbol{k}} \cdot \tilde{\boldsymbol{A}}^{\min}(\boldsymbol{k}) = 0$. Here a tilde denotes a Fourier transform. See Exercise 22.2.23.

polynomial vector fields $\boldsymbol{S}_{nnn}^{M}(\boldsymbol{r})$ with expansion coefficients again proportional to the g_{nM}. As shown above, the vector potential $\boldsymbol{A}^{\min}(\boldsymbol{r})$ has no constant part. We also see that its non-constant parts are directly proportional to the coefficients g_{nm} that describe the constant and non-constant parts of $\boldsymbol{B}(\boldsymbol{r})$. Moreover, there is an order-by-order relation. Terms of order n in $\boldsymbol{A}^{\min}(\boldsymbol{r})$ are proportional to terms of order $n-1$ in $\boldsymbol{B}(\boldsymbol{r})$. Thus, $\boldsymbol{A}^{\min}(\boldsymbol{r})$ is small if $\boldsymbol{B}(\boldsymbol{r})$ is small. In particular, if high-order terms in $\boldsymbol{B}(\boldsymbol{r})$ are negligible, they will also be negligible in $\boldsymbol{A}^{\min}(\boldsymbol{r})$.

There is yet another sense in which the vector potential we have found is minimal. Suppose, for example, that we confine our attention to the case of a vector potential that is homogeneous of degree 1, which is the case we need to produce a constant magnetic field. When $n = 1$ we see from Table U.3.1 that $\ell = 1$ and $J = 0, 1, 2$. Therefore, such a vector potential, call it $\boldsymbol{A}^1$, can be written in the form

$$\boldsymbol{A}^1(\boldsymbol{r}) = \sum_J \sum_M f_{11JM} \boldsymbol{S}_{11J}^{M}(\boldsymbol{r}). \tag{15.2.78}$$

Recall (2.44). Let us compute the *norm* of $\boldsymbol{A}^1$ as defined by the rule

$$||\boldsymbol{A}^1(\boldsymbol{r})||^2 = \int d\Omega\ [\boldsymbol{A}^1(\boldsymbol{r})]^* \cdot \boldsymbol{A}^1(\boldsymbol{r}). \tag{15.2.79}$$

Since the $\boldsymbol{S}_{11J}^{M}(\boldsymbol{r})$ are mutually orthogonal under angular integration, we find from (2.78), (U.3.18), and (U.4.3) the result

$$||\boldsymbol{A}^1(\boldsymbol{r})||^2 = r^2 \sum_J \sum_M |f_{11JM}|^2. \tag{15.2.80}$$

We know the value of f_{111M} is fixed by (2.59), and we have chosen to set the remaining f_{11JM} to zero. We now see, since (2.80) is a sum of squares, that doing so *minimizes* $||\boldsymbol{A}^1(\boldsymbol{r})||$. Similar computations may be made for other values of n. The result is that the choice we have made for $\boldsymbol{A}^{\min}$ minimizes $||\boldsymbol{A}^n(\boldsymbol{r})||$ for each value of n.

A Further Simplification

We close this subsection by observing that the relation (2.69) can be further manipulated using (U.6.25). Doing so gives the pleasing result

$$\begin{aligned} \boldsymbol{A}^{\min}(\boldsymbol{r}) &= -\sum_{n=1}^{n_{\max}} \sum_{M=-n}^{n} [1/(n+1)] g_{nM} [\boldsymbol{r} \times \nabla S_{nn}^{M}(\boldsymbol{r})] \\ &= -\sum_{n=1}^{n_{\max}} \sum_{M=-n}^{n} [1/(n+1)] g_{nM} [\boldsymbol{r} \times \nabla H_{n}^{M}(\boldsymbol{r})]. \end{aligned} \tag{15.2.81}$$

Note that this result has the virtue that none of the extensive machinery of Appendix U is required for its evaluation.

15.2.6 Uniqueness of Poincaré-Coulomb Gauge

Is a vector potential in the Poincaré-Coulomb gauge unique? It is. Suppose $\boldsymbol{A}$ and $\boldsymbol{A}'$ are two vector potentials associated with the same field $\boldsymbol{B}$. Then we know they are related by a gauge transformation of the form

$$\boldsymbol{A}'(\boldsymbol{r}) = \boldsymbol{A}(\boldsymbol{r}) + \nabla\chi(\boldsymbol{r}). \tag{15.2.82}$$

If we require that both $\boldsymbol{A}$ and $\boldsymbol{A}'$ be in the Coulomb gauge, then χ must be harmonic: taking the divergence of both sides of (2.82) yields the result

$$\nabla^2\chi = 0. \tag{15.2.83}$$

See Section 15.6. If we further require that both $\boldsymbol{A}$ and $\boldsymbol{A}'$ be in the Poincaré-Coulomb gauge, then there must be the additional relations

$$\boldsymbol{r}\cdot\boldsymbol{A}(\boldsymbol{r}) = 0 \text{ and } \boldsymbol{r}\cdot\boldsymbol{A}'(\boldsymbol{r}) = 0. \tag{15.2.84}$$

Requiring (2.84) of (2.82 yields the result that χ must also obey the condition

$$\boldsymbol{r}\cdot\nabla\chi = 0. \tag{15.2.85}$$

Suppose χ is decomposed into homogeneous polynomials of degree n by writing

$$\chi = \sum_{n=0}^{\infty}\chi^n. \tag{15.2.86}$$

Then, by Euler's relation for homogeneous functions, it follows that

$$\boldsymbol{r}\cdot\nabla\chi = \sum_{n=0}^{\infty}n\chi^n. \tag{15.2.87}$$

Comparison of (2.85) and (2.87) and equating terms of like degree yields the result

$$n\chi^n = 0, \tag{15.2.88}$$

from which it follows that $\chi^n = 0$ for $n \neq 0$. We see that all that is left in the sum (2.86) and in the relation (2.82) is the *constant* term χ^0, and this term does not contribute to (2.82). We therefore conclude that $\boldsymbol{A}'(\boldsymbol{r}) = \boldsymbol{A}(\boldsymbol{r})$.

15.2.7 Direct Construction of Poincaré-Coulomb Gauge Vector Potential

Subsection 2.5 obtained the final result (2.81) using the machinery of Appendix U. The purpose of this subsection is to proceed in reverse. After some stage setting, we will make an Ansatz that is essentially equivalent to (2.81), and then verify that the vector potential produced by this Ansatz yields $\boldsymbol{B}(\boldsymbol{r})$ as desired, and has other desired/interesting properties.

With reference to (2.37), define scalar fields $\psi_{\ell,m,\alpha}$ by the rule

$$\psi_{\ell,m,\alpha} = H_\ell^{m,\alpha} \tag{15.2.89}$$

so that we may write

$$\psi(x,y,z) = \sum_{\ell=0}^{\infty}\sum_{m=0}^{\ell} g_{\ell,m,c}\psi_{\ell,m,c} + \sum_{\ell=1}^{\infty}\sum_{m=1}^{\ell} g_{\ell,m,s}\psi_{\ell,m,s}. \tag{15.2.90}$$

Next define related vector fields $\boldsymbol{B}^{\ell,m,\alpha}$ by the rule

$$\boldsymbol{B}^{\ell,m,\alpha} = \nabla\psi_{\ell,m,\alpha}. \tag{15.2.91}$$

Then, with the aid of (2.90) and (2.91), we may write

$$\boldsymbol{B} = \nabla\psi = \sum_{\ell=1}^{\infty}\sum_{m=0}^{\ell} g_{\ell,m,c}\boldsymbol{B}^{\ell,m,c} + \sum_{\ell=1}^{\infty}\sum_{m=1}^{\ell} g_{\ell,m,s}\boldsymbol{B}^{\ell,m,s}. \tag{15.2.92}$$

We now seek individual vector potentials $\boldsymbol{A}^{\ell,m,\alpha}$ such that

$$\nabla\times\boldsymbol{A}^{\ell,m,\alpha} = \boldsymbol{B}^{\ell,m,\alpha}. \tag{15.2.93}$$

Simple calculation shows that If we can find them, then we may write

$$\boldsymbol{B} = \nabla\times\boldsymbol{A} \tag{15.2.94}$$

with

$$\boldsymbol{A} = \sum_{\ell=1}^{\infty}\sum_{m=0}^{\ell} g_{\ell,m,c}\boldsymbol{A}^{\ell,m,c} + \sum_{\ell=1}^{\infty}\sum_{m=1}^{\ell} g_{\ell,m,s}\boldsymbol{A}^{\ell,m,s}. \tag{15.2.95}$$

We claim that a solution to (2.93) is given by the Ansatz

$$\boldsymbol{A}^{\ell,m,\alpha} = [-1/(\ell+1)][\boldsymbol{r}\times\boldsymbol{B}^{\ell,m,\alpha}] = [-1/(\ell+1)][\boldsymbol{r}\times\nabla\psi_{\ell,m,\alpha}]. \tag{15.2.96}$$

Let us check this claim. Recall the vector identity

$$\nabla\times(\boldsymbol{a}\times\boldsymbol{b}) = \boldsymbol{a}(\nabla\cdot\boldsymbol{b}) - \boldsymbol{b}(\nabla\cdot\boldsymbol{a}) + (\boldsymbol{b}\cdot\nabla)\boldsymbol{a} - (\boldsymbol{a}\cdot\nabla)\boldsymbol{b}. \tag{15.2.97}$$

Then, with

$$\boldsymbol{a} = \boldsymbol{r} \tag{15.2.98}$$

and

$$\boldsymbol{b} = \nabla\psi_{\ell,m,\alpha} = \boldsymbol{B}^{\ell,m,\alpha}, \tag{15.2.99}$$

the identity (2.97) yields the result

$$\nabla\times(\boldsymbol{r}\times\nabla\psi_{\ell,m,\alpha}) = \boldsymbol{r}(\nabla^2\psi_{\ell,m,\alpha}) - \boldsymbol{B}^{\ell,m,\alpha}(\nabla\cdot\boldsymbol{r}) + (\boldsymbol{B}^{\ell,m,\alpha}\cdot\nabla)\boldsymbol{r} - (\boldsymbol{r}\cdot\nabla)\boldsymbol{B}^{\ell,m,\alpha}. \tag{15.2.100}$$

Moreover, there are the relations

$$\nabla^2 \psi_{\ell,m,\alpha} = 0, \tag{15.2.101}$$

$$\nabla \cdot \boldsymbol{r} = 3, \tag{15.2.102}$$

$$(\boldsymbol{B}^{\ell,m,\alpha} \cdot \nabla)\boldsymbol{r} = \boldsymbol{B}^{\ell,m,\alpha}, \tag{15.2.103}$$

and

$$(\boldsymbol{r} \cdot \nabla)\boldsymbol{B}^{\ell,m,\alpha} = (\ell - 1)\boldsymbol{B}^{\ell,m,\alpha}. \tag{15.2.104}$$

This last relation follows from the fact that the Cartesian components of $\boldsymbol{B}^{\ell,m,\alpha}$ are homogenous polynomials of degree $(\ell - 1)$. We conclude that

$$\nabla \times (\boldsymbol{r} \times \nabla \psi_{\ell,m,\alpha}) = [-3 + 1 - (\ell - 1)]\boldsymbol{B}^{\ell,m,\alpha} = [-(\ell + 1)]\boldsymbol{B}^{\ell,m,\alpha}. \tag{15.2.105}$$

Therefore, the $\boldsymbol{A}^{\ell,m,\alpha}$ defined by (2.96) satisfy (2.93). We also note that the Cartesian components of the $\boldsymbol{A}^{\ell,m,\alpha}$ are homogeneous polynomials of degree ℓ.

In addition there is the vector identity

$$\nabla \cdot (\boldsymbol{a} \times \boldsymbol{b}) = \boldsymbol{b} \cdot (\nabla \times \boldsymbol{a}) - \boldsymbol{a} \cdot (\nabla \times \boldsymbol{b}). \tag{15.2.106}$$

From this identity and from (2.96), (2.98), and (2.99) it follows that

$$\nabla \cdot \boldsymbol{A}^{\ell,m,\alpha} = 0. \tag{15.2.107}$$

Thus, the $\boldsymbol{A}^{\ell,m,\alpha}$ are in the Coulomb gauge. Moreover, from (2.96), there is the relation

$$\boldsymbol{r} \cdot \boldsymbol{A}^{\ell,m,\alpha}(\boldsymbol{r}) = 0. \tag{15.2.108}$$

Therefore the $\boldsymbol{A}^{\ell,m,\alpha}$ are also in the Poincaré gauge, and thus in the Poincaré-Coulomb gauge.

Three final points: First, suppose the magnetic field $\boldsymbol{B}(\boldsymbol{r})$ is decomposed into homogeneous polynomials by writing

$$\boldsymbol{B}(\boldsymbol{r}) = \sum_{n=0}^{\infty} \boldsymbol{B}^n(\boldsymbol{r}). \tag{15.2.109}$$

The vector potential can also be decomposed into homogeneous polynomials by writing

$$\boldsymbol{A}(\boldsymbol{r}) = \sum_{n=1}^{\infty} \boldsymbol{A}^n(\boldsymbol{r}). \tag{15.2.110}$$

From (2.96) we see that there is the relation

$$\boldsymbol{A}^n(\boldsymbol{r}) = -[1/(n+1)][\boldsymbol{r} \times \boldsymbol{B}^{n-1}(\boldsymbol{r})] \text{ for } n = 1, 2, \cdots . \tag{15.2.111}$$

Second, suppose that (2.109) and (2.110) are *truncated* by writing

$$\boldsymbol{B}^{\text{trunc}}(\boldsymbol{r}) = \sum_{n=0}^{N} \boldsymbol{B}^n(\boldsymbol{r}), \tag{15.2.112}$$

$$\boldsymbol{A}^{\rm trunc}(\boldsymbol{r})=\sum_{n=1}^{N+1}\boldsymbol{A}^n(\boldsymbol{r}), \tag{15.2.113}$$

with (2.111) continuing to hold for $n=1,2,\cdots N+1$. It is easy to verify that $\boldsymbol{B}^{\rm trunc}(\boldsymbol{r})$ is curl and divergence free if $\boldsymbol{B}(\boldsymbol{r})$ is. It is also true that

$$\boldsymbol{B}^{\rm trunc}(\boldsymbol{r})=\nabla\times\boldsymbol{A}^{\rm trunc}(\boldsymbol{r}). \tag{15.2.114}$$

Thus, truncation by degree does not violate the Maxwell equations.

Finally, we note that the relation (2.111) specifies the vector potential order-by-order in terms of the order-by-order magnetic field. There is an equivalent integral relation that specifies the full vector potential in terms of the full magnetic field. It is given by the relation

$$\boldsymbol{A}(\boldsymbol{r})=-\boldsymbol{r}\times\int_0^1 d\lambda\;\lambda\boldsymbol{B}(\lambda\boldsymbol{r}). \tag{15.2.115}$$

See Exercise 2.4.

Exercises

15.2.1. The purpose of this exercise is to verify (2.19). In terms of the spherical coordinates r,θ,ϕ defined in Subsection 15.2.2 there is the result

$$\boldsymbol{r}=x\boldsymbol{e}_x+y\boldsymbol{e}_y+z\boldsymbol{e}_z=r\sin(\theta)\cos(\phi)\boldsymbol{e}_x+r\sin(\theta)\sin(\phi)\boldsymbol{e}_y+r\cos(\theta)\boldsymbol{e}_z. \tag{15.2.116}$$

Verify that there is an associated orthonormal triad $\boldsymbol{e}_r$, $\boldsymbol{e}_\theta$, $\boldsymbol{e}_\phi$ obeying the relations

$$\begin{aligned}\boldsymbol{e}_r &= [\partial\boldsymbol{r}/\partial r]/||[\partial\boldsymbol{r}/\partial r]||=\sin(\theta)\cos(\phi)\boldsymbol{e}_x+\sin(\theta)\sin(\phi)\boldsymbol{e}_y+\cos(\theta)\boldsymbol{e}_z\\ &= (1/r)(x\boldsymbol{e}_x+y\boldsymbol{e}_y+z\boldsymbol{e}_z)=\boldsymbol{r}/r,\end{aligned} \tag{15.2.117}$$

$$\boldsymbol{e}_\theta = [\partial\boldsymbol{r}/\partial\theta]/||[\partial\boldsymbol{r}/\partial\theta]||=\cos(\theta)\cos(\phi)\boldsymbol{e}_x+\cos(\theta)\sin(\phi)\boldsymbol{e}_y-\sin(\theta)\boldsymbol{e}_z, \tag{15.2.118}$$

$$\boldsymbol{e}_\phi=[\partial\boldsymbol{r}/\partial\phi]/||[\partial\boldsymbol{r}/\partial\phi]||=-\sin(\phi)\boldsymbol{e}_x+\cos(\phi)\boldsymbol{e}_y, \tag{15.2.119}$$

$$\boldsymbol{r}=r\boldsymbol{e}_r. \tag{15.2.120}$$

15.2.2. The purpose of this exercise is to verify (2.20) and (2.22) through (2.25). In terms of the cylindrical coordinates ρ,ϕ,z defined in Section 15.2 there is the result

$$\boldsymbol{r}=x\boldsymbol{e}_x+y\boldsymbol{e}_y+z\boldsymbol{e}_z=\rho\cos\phi\;\boldsymbol{e}_x+\rho\sin\phi\;\boldsymbol{e}_y+z\boldsymbol{e}_z. \tag{15.2.121}$$

Verify that there is an associated orthonormal triad $\boldsymbol{e}_\rho$, $\boldsymbol{e}_\phi$, $\boldsymbol{e}_z$ obeying the relations

$$\boldsymbol{e}_\rho=[\partial\boldsymbol{r}/\partial\rho]/||[\partial\boldsymbol{r}/\partial\rho]||=\cos\phi\;\boldsymbol{e}_x+\sin\phi\;\boldsymbol{e}_y=(1/\rho)(x\boldsymbol{e}_x+y\boldsymbol{e}_y), \tag{15.2.122}$$

$$\boldsymbol{e}_\phi=[\partial\boldsymbol{r}/\partial\phi]/||[\partial\boldsymbol{r}/\partial\phi]||=-\sin\phi\;\boldsymbol{e}_x+\cos\phi\;\boldsymbol{e}_y=(1/\rho)(-y\boldsymbol{e}_x+x\boldsymbol{e}_y), \tag{15.2.123}$$

$$\boldsymbol{e}_z=[\partial\boldsymbol{r}/\partial z]/||[\partial\boldsymbol{r}/\partial z]||, \tag{15.2.124}$$

$$x\boldsymbol{e}_x+y\boldsymbol{e}_y=\rho\boldsymbol{e}_\rho, \tag{15.2.125}$$

$$\boldsymbol{r}=\rho\boldsymbol{e}_\rho+z\boldsymbol{e}_z. \tag{15.2.126}$$

Verify (2.22) through (2.25).

15.2.3. Define an operator $\boldsymbol{L}$ by the rule

$$\boldsymbol{L} = \boldsymbol{r} \times \nabla. \tag{15.2.127}$$

Show that it has the components

$$L_x = y\partial_z - z\partial_y, \tag{15.2.128}$$

$$L_y = z\partial_x - x\partial_z, \tag{15.2.129}$$

$$L_z = x\partial_y - y\partial_x. \tag{15.2.130}$$

Verify that the components of $\boldsymbol{L}$ satisfy the commutation rules

$$\{L_x, L_y\} = -L_z, \text{ etc.}, \tag{15.2.131}$$

which are a variant of the commutation rules for $so(3, \mathbb{R})$.

Show that (2.96) can be rewritten in the form

$$\boldsymbol{A}^{\ell,m,\alpha} = [-1/(\ell+1)][\boldsymbol{L}\psi_{\ell,m,\alpha}]. \tag{15.2.132}$$

Verify that $\boldsymbol{L}$ and ∇^2 commute, and use this fact to show (as expected, see Section 5) that all the Cartesian components of $\boldsymbol{A}^{\ell,m,\alpha}$ are harmonic functions,

$$\nabla^2 \boldsymbol{A}^{\ell,m,\alpha} = 0. \tag{15.2.133}$$

Verify that $\boldsymbol{L}$ and r commute,

$$\{\boldsymbol{L}, r\} = 0. \tag{15.2.134}$$

Of course, this result is to be expected since r is invariant under rotations. Next, in view of (2.31) and (2.32), we may define functions $h_\ell^{m,\alpha}(\theta, \phi)$ by writing

$$\psi_{\ell,m,\alpha} = H_\ell^{m.\alpha} = r^\ell h_\ell^{m,\alpha}(\theta, \phi). \tag{15.2.135}$$

Show it follows from (2.134) and (2.135) that

$$\boldsymbol{L}\psi_{\ell,m,\alpha} = r^\ell \boldsymbol{L} h_\ell^{m,\alpha}(\theta, \phi). \tag{15.2.136}$$

Therefore, if we wish, we can evaluate (2.132) using a raising and lowering operator formalism.

15.2.4. The purpose of this exercise is to verify (2.115) thus showing that the relations (2.109) through (2.111) can be written in a more compact form. By the definition of homogeneity, there is the relation

$$\boldsymbol{B}^n(\lambda \boldsymbol{r}) = \lambda^n \boldsymbol{B}^n(\boldsymbol{r}) \tag{15.2.137}$$

where λ is a scalar. Show from (2.109) that

$$\boldsymbol{B}(\lambda \boldsymbol{r}) = \sum_{n=0}^{\infty} \lambda^n \boldsymbol{B}^n(\boldsymbol{r}). \tag{15.2.138}$$

Next integrate both sides of (2.138) to demonstrate that

$$\int_0^1 d\lambda\, \lambda \boldsymbol{B}(\lambda \boldsymbol{r}) = \sum_{n=0}^{\infty}[1/(n+2)]\boldsymbol{B}^n(\boldsymbol{r}) = \sum_{n=1}^{\infty}[1/(n+1)]\boldsymbol{B}^{n-1}(\boldsymbol{r}). \tag{15.2.139}$$

Finally, using (2.110), (2.111), and (2.139), verify that there is the integral relation

$$\boldsymbol{A}(\boldsymbol{r}) = -\boldsymbol{r} \times \int_0^1 d\lambda\, \lambda \boldsymbol{B}(\lambda \boldsymbol{r}). \tag{15.2.140}$$

15.2.5. Subsection 2.6 showed that the Poincaré-Coulomb gauge is unique. Accordingly, starting from the requirement $\boldsymbol{B} = \nabla \times \boldsymbol{A}^{\rm min}$ and the requirements (2.70) and (2.71) and the assumption that $\boldsymbol{B}(\boldsymbol{r})$ is analytic in a neighborhood of $\boldsymbol{r} = 0$, it should be possible to derive the relations (2.111) and (2.115). Do so! Acknowledgement: This exercise was motivated by a suggestion of Sateesh Mane.

15.2.6. The relations (2.111) and(2.115) specify the minimum vector potential $\boldsymbol{A}^{\rm min}$in terms of the magnetic field $\boldsymbol{B}$. The purpose of this exercise is to derive relations that specify the scalar potential ψ in terms of $\boldsymbol{B}$.

Since B is assumed to be analytic and curl free, show that ψ may be defined by the rule

$$\psi(\boldsymbol{r}) = \int_0^r \boldsymbol{B}(\boldsymbol{r}') \cdot d\boldsymbol{r}' \tag{15.2.141}$$

where the integral (because $\boldsymbol{B}$ is curl free) may be carried out over any path joining 0 and $\boldsymbol{r}$. Note that with this definition

$$\psi(0) = 0. \tag{15.2.142}$$

Choose the path to be the straight line joining 0 and $\boldsymbol{r}$ by making the Ansatz

$$\boldsymbol{r}' = \lambda \boldsymbol{r} \text{ with } \lambda \in [0, 1]. \tag{15.2.143}$$

Show that so doing yields the result

$$\psi(\boldsymbol{r}) = \boldsymbol{r} \cdot \int_0^1 d\lambda\, \boldsymbol{B}(\lambda \boldsymbol{r}). \tag{15.2.144}$$

Assume that $\boldsymbol{B}(\boldsymbol{r})$ is decomposed into homogeneous polynomials as in (2.109). Show, using (2.138) and (2.144), that

$$\psi(\boldsymbol{r}) = \boldsymbol{r} \cdot \sum_{n=0}^{\infty}[1/(n+1)]\boldsymbol{B}^n(\boldsymbol{r}). \tag{15.2.145}$$

Suppose that $\psi(\boldsymbol{r})$ is also decomposed into homogeneous polynomials by writing

$$\psi(\boldsymbol{r}) = \sum_{n=1}^{\infty} \psi^n(\boldsymbol{r}). \tag{15.2.146}$$

Show that

$$\psi^n(\boldsymbol{r}) = (1/n)\boldsymbol{r} \cdot \boldsymbol{B}^{n-1}(\boldsymbol{r}) \text{ for } n = 1, 2, \cdots . \tag{15.2.147}$$

Verify directly that

$$\nabla\psi^n(\boldsymbol{r}) = \boldsymbol{B}^{n-1}(\boldsymbol{r}). \tag{15.2.148}$$

Hint: Use the vector identity

$$\nabla(\boldsymbol{a} \cdot \boldsymbol{b}) = (\boldsymbol{a} \cdot \nabla)\boldsymbol{b} + (\boldsymbol{b} \cdot \nabla)\boldsymbol{a} + \boldsymbol{a} \times (\nabla \times \boldsymbol{b}) + \boldsymbol{b} \times (\nabla \times \boldsymbol{a}) \tag{15.2.149}$$

with

$$\boldsymbol{a} = \boldsymbol{r} \tag{15.2.150}$$

and

$$\boldsymbol{b} = \boldsymbol{B}^{n-1}(\boldsymbol{r}). \tag{15.2.151}$$

15.2.7. Review Exercise 1.5.7. There it is found that a uniform vertical magnetic field $\boldsymbol{B} = B\boldsymbol{e}_y$ can be derived from the vector potential

$$\boldsymbol{A} = -Bx\boldsymbol{e}_z. \tag{15.2.152}$$

Recall the definition (2.79), the relations (2.9) through (2.11), and the definition

$$\int d\Omega = \int_0^{\pi} \int_0^{2\pi} \sin\theta \; d\theta d\phi. \tag{15.2.153}$$

Show that

$$\int x^2 d\Omega = \int y^2 d\Omega = \int z^2 d\Omega = (4/3)\pi r^2, \tag{15.2.154}$$

and therefore

$$||\boldsymbol{A}(\boldsymbol{r})||^2 = (4/3)\pi B^2 r^2. \tag{15.2.155}$$

Let $\boldsymbol{A}^{PC}$ be the associated vector potential in the Poincaré-Coulomb gauge. Verify that

$$\boldsymbol{A}^{PC} = -(B/2)(x\boldsymbol{e}_z - z\boldsymbol{e}_x). \tag{15.2.156}$$

Show that

$$||\boldsymbol{A}^{PC}(\boldsymbol{r})||^2 = (2/3)\pi B^2 r^2. \tag{15.2.157}$$

Comparison of (2.155) and (2.157) shows that the Poincaré-Coulomb gauge vector potential has a smaller norm, as expected. Show that

$$\boldsymbol{A}^{PC} = \boldsymbol{A} + \nabla\chi \tag{15.2.158}$$

with

$$\chi = (B/2)xz. \tag{15.2.159}$$

Verify that χ is harmonic, as expected.

15.2.8. Review Exercise 1.5.9. There it is found that a quadrupole magnetic field with midplane symmetry,

$$\boldsymbol{B} = Qy\boldsymbol{e}_x + Qx\boldsymbol{e}_y, \tag{15.2.160}$$

can be derived from the vector potential

$$\boldsymbol{A} = -(Q/2)(x^2 - y^2)\boldsymbol{e}_z. \tag{15.2.161}$$

Recall the definition (2.79), the relations (2.9) through (2.11), and the definition (2.153). Show that

$$\int (x^2 - y^2)^2 d\Omega = (16/15)\pi r^4, \tag{15.2.162}$$

and therefore

$$||\boldsymbol{A}(\boldsymbol{r})||^2 = (4/15)\pi Q^2 r^4. \tag{15.2.163}$$

Let $\boldsymbol{A}^{PC}$ be the associated vector potential in the Poincaré-Coulomb gauge. Verify that

$$\boldsymbol{r} \times \boldsymbol{B} = Q[(x^2 - y^2)\boldsymbol{e}_z + zy\boldsymbol{e}_y - zx\boldsymbol{e}_x], \tag{15.2.164}$$

and therefore

$$\boldsymbol{A}^{PC} = -(Q/3)[-zx\boldsymbol{e}_x + zy\boldsymbol{e}_y + (x^2 - y^2)\boldsymbol{e}_z]. \tag{15.2.165}$$

Show that

$$\int z^2x^2 d\Omega = \int z^2y^2 d\Omega = \int x^2y^2 d\Omega = (4/15)\pi r^4, \tag{15.2.166}$$

$$\int x^4 d\Omega = \int y^4 d\Omega = \int z^4 d\Omega = (4/5)\pi r^4, \tag{15.2.167}$$

and therefore

$$||\boldsymbol{A}^{PC}(\boldsymbol{r})||^2 = (2/3)(4/15)\pi Q^2 r^4. \tag{15.2.168}$$

Comparison of (2.163) and (2.168) shows that the Poincaré-Coulomb gauge vector potential has a smaller norm, as expected. Show that

$$\boldsymbol{A}^{PC} = \boldsymbol{A} + \nabla\chi \tag{15.2.169}$$

with

$$\chi = (Q/6)z(x^2 - y^2). \tag{15.2.170}$$

Verify that χ is harmonic, as expected.

15.2.9. Demonstration that harmonic functions take their extrema on boundaries.

15.3 Cylindrical Harmonic Expansion

In the previous section we employed spherical coordinates to find *local* expansions (expansions about a point $\boldsymbol{R}_0$) for the scalar potential ψ and the associated magnetic field $\boldsymbol{B}$. We also found a suitable vector potential $\boldsymbol{A}^{\min}$. The goal of this section is to show that it is possible to obtain *semi-global* expansions for ψ and $\boldsymbol{B}$ in the case of a *straight* geometry, the case of straight beam-line elements. By semi-global we mean that an expansion holds all along the vicinity of the beam-line axis (which we take to be the z axis). That is, while the variables x and y are treated as being small, the variable z need not be small.

For this purpose is convenient to work in cylindrical coordinates ρ, ϕ, and z as given by (2.12) through (2.14). We also note, for future use, that (2.13) and (2.14) can be written in the form

$$x + iy = \rho \exp(i\phi). \tag{15.3.1}$$

From this form it follows that

$$\rho^{2\ell} = (x^2 + y^2)^\ell \tag{15.3.2}$$

and, for $m \geq 0$,

$$\rho^m \cos m\phi = \Re[(x + iy)^m], \tag{15.3.3}$$

$$\rho^m \sin m\phi = \Im[(x + iy)^m]. \tag{15.3.4}$$

We see that *even* powers of ρ and the combinations $\rho^m \cos m\phi$ and $\rho^m \sin m\phi$ are *analytic* (in fact, *polynomial*) functions of x and y.

15.3.1 Complex Cylindrical Harmonic Expansion

To find the general ψ in cylindrical coordinates that satisfies Laplace's equation, recall that the functions $\exp(im\phi)$ form a complete set for the Hilbert space of functions over the interval $\phi \in [0, 2\pi]$, and the functions $\exp(ikz)$ form a complete set for the Hilbert space of functions over the interval $z \in [-\infty, \infty]$. Therefore any function ψ in the product Hilbert space can be written as a superposition of functions of the form $\Omega_m(k, \rho) \exp(ikz) \exp(im\phi)$ where the functions $\Omega_m(k, \rho)$ are yet to be determined. In cylindrical coordinates the Laplacian has the form

$$\nabla^2 = (1/\rho)(\partial/\partial\rho)(\rho\partial/\partial\rho) + (1/\rho^2)(\partial^2/\partial\phi^2) + \partial^2/\partial z^2. \tag{15.3.5}$$

Thus if the product $\Omega_m(k, \rho) \exp(ikz) \exp(im\phi)$ is to satisfy Laplace's equation, the functions $\Omega_m(k, \rho)$ must satisfy the modified Bessel equation,

$$(1/\rho)(\partial/\partial\rho)(\rho\partial\Omega_m/\partial\rho) - (m^2/\rho^2)\Omega_m - k^2\Omega_m = 0. \tag{15.3.6}$$

The solutions to this equation (that are regular for small ρ) are the modified Bessel functions $I_m(k\rho)$. Consequently, in cylindrical coordinates, a general ψ satisfying Laplace's equation and analytic in x,y near the z axis has the expansion

$$\psi(x, y, z) = \sum_{m=-\infty}^{\infty} \int_{-\infty}^{\infty} dk\; G_m(k) \exp(ikz) \exp(im\phi) I_m(k\rho) \tag{15.3.7}$$

where the functions $G_m(k)$ are arbitrary. We remark, for future use, that the modified Bessel functions $I_m(w)$ have the property

$$I_{-m}(w) = I_m(w). \tag{15.3.8}$$

The representation (3.7) is a *cylindrical harmonic* or *cylindrical multipole* expansion, where m is related to the order of the multipole. For example, $m = 0$ for a 'monopole' source (including a solenoid), $m = 1$ for a dipole, $m = 2$ for a quadrupole, etc. We also remark that these are what we will call *pure* multipoles. For example, a real/physical quadrupole (even one with perfect four-fold symmetry) will have primarily $m = 2$ components plus smaller higher-order pure multipole components that are not forbidden by symmetry. Both pole/coil shape and rotational symmetry matter. See Subsection 3.5. Finally we should remark that (3.7) could more accurately be called a *circular* cylinder harmonic expansion. In Section 17.4 we will extend this work to include the case of cylinders with *elliptic* cross sections, and in Section 17.5 we will treat the case of cylinders with *rectangular* cross sections.

As stated at the beginning of this chapter, our ultimate goal is a Taylor expansion of the vector potential $\boldsymbol{A}$ in the variables x, y. To do this, we first seek an expansion of ψ as a Taylor series in the variables x, y with coefficients that depend on z. This can be achieved, by using the Taylor expansions for $I_m(w)$, as follows: Using (3.7) we may write

$$\begin{aligned}
\psi(x,y,z) &= \sum_{m=-\infty}^{\infty} \int_{-\infty}^{\infty} dk\ G_m(k)\exp(ikz)\exp(im\phi)I_m(k\rho) \\
&= \sum_{m=-\infty}^{\infty} \exp(im\phi) \int_{-\infty}^{\infty} dk\ G_m(k)\exp(ikz)I_m(k\rho) \\
&= \sum_{m=-\infty}^{\infty} \exp(im\phi)\Psi_m(\rho,z) \qquad (15.3.9)
\end{aligned}$$

where

$$\Psi_m(\rho,z) = \int_{-\infty}^{\infty} dk\ G_m(k)\exp(ikz)I_m(k\rho). \qquad (15.3.10)$$

The modified Bessel functions have the expansions

$$I_m(w) = (1/2)^{|m|}w^{|m|}\sum_{\ell=0}^{\infty} w^{2\ell}/[2^{2\ell}\ell!(\ell+|m|)!]. \qquad (15.3.11)$$

Therefore we may also write

$$\begin{aligned}
&\Psi_m(\rho,z) = \int_{-\infty}^{\infty} dk\ G_m(k)\exp(ikz)I_m(k\rho) = \\
&\int_{-\infty}^{\infty} dk\ G_m(k)\exp(ikz)(1/2)^{|m|}(k\rho)^{|m|}\sum_{\ell=0}^{\infty}(k\rho)^{2\ell}/[2^{2\ell}\ell!(\ell+|m|)!] = \\
&\sum_{\ell=0}^{\infty}\{1/[2^{2\ell}\ell!(\ell+|m|)!]\}\rho^{2\ell+|m|}(1/2)^{|m|}\int_{-\infty}^{\infty} dk\ k^{2\ell+|m|}G_m(k)\exp(ikz).
\end{aligned} \qquad (15.3.12)$$

Define functions $C_m^{[0]}(z)$ by writing

$$C_m^{[0]}(z) \overset{\text{def}}{=} (1/2)^{|m|}(1/|m|!)\int_{-\infty}^{\infty} dk\ k^{|m|}G_m(k)\exp(ikz). \qquad (15.3.13)$$

Also, define functions $C_m^{[n]}(z)$ by writing

$$C_m^{[n]}(z) = (\partial_z)^n C_m^{[0]}(z). \qquad (15.3.14)$$

Then, by differentiating under the integral sign, we have the result

$$C_m^{[n]}(z) = (\partial_z)^n C_m^{[0]}(z) = i^n (1/2)^{|m|}(1/|m|!)\int_{-\infty}^{\infty} dk\ k^{n+|m|} G_m(k)\exp(ikz) \tag{15.3.15}$$

and, in particular,

$$C_m^{[2\ell]}(z) = (-1)^\ell (1/2)^{|m|}(1/|m|!)\int_{-\infty}^{\infty} dk\ k^{2\ell+|m|} G_m(k)\exp(ikz). \tag{15.3.16}$$

Thus, we may also write the relation

$$(1/2)^{|m|}\int_{-\infty}^{\infty} dk\ k^{2\ell+|m|} G_m(k)\exp(ikz) = (-1)^\ell |m|! C_m^{[2\ell]}(z). \tag{15.3.17}$$

Putting everything together gives the result

$$\Psi_m(\rho,z) = \sum_{\ell=0}^{\infty} (-1)^\ell \frac{|m|!}{2^{2\ell}\ell!(\ell+|m|)!} C_m^{[2\ell]}(z)\rho^{2\ell+|m|}. \tag{15.3.18}$$

Consequently, $\psi(x,y,z)$ has the representation

$$\psi(x,y,z) = \sum_{m=-\infty}^{\infty} \exp(im\phi) \sum_{\ell=0}^{\infty} (-1)^\ell \frac{|m|!}{2^{2\ell}\ell!(\ell+|m|)!} C_m^{[2\ell]}(z)\rho^{2\ell+|m|}. \tag{15.3.19}$$

Note that, in view of (3.2) through (3.4), the terms appearing on the right side of (3.19) are polynomial in the variables x and y.

From (3.18) we see that

$$C_m^{[0]}(z) = \lim_{\rho\to 0}(1/\rho^{|m|})\Psi_m(\rho,z). \tag{15.3.20}$$

For this reason, the functions $C_m^{[0]}(z)$ are called the *generalized on-axis gradients*.[7] Note that the generalized gradients depend on the longitudinal variable z. However we will soon see that, for fields produced by long well-made magnets, the z dependence will be significant only at the ends.

15.3.2 Real Cylindrical Harmonic Expansion

So far, for mathematical convenience, we have worked with a possibly complex representation for ψ. We will now convert our results into equivalent real forms suitable for physical applications. We begin with the relation (3.19). Suppose we require that $\psi(x,y,z)$ be real. Forming the complex conjugate of (3.19) gives the result

$$\bar{\psi}(x,y,z) = \sum_{m=-\infty}^{\infty} \exp(-im\phi) \sum_{\ell=0}^{\infty} (-1)^\ell \frac{|m|!}{2^{2\ell}\ell!(\ell+|m|)!} \bar{C}_m^{[2\ell]}(z)\rho^{2\ell+|m|}. \tag{15.3.21}$$

[7] Although (3.20) is mathematically correct, it is not a good way to actually compute the on-axis gradients due to the delicate nature of the limiting process. Indeed, one of the aims of Chapters 17 through 21 is to provide reliable ways of computing the on-axis gradients.

The right side of (3.21) can be rewritten to give the relation

$$\begin{aligned}\sum_{m=-\infty}^{\infty} \exp(-im\phi) \sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{|m|!}{2^{2\ell}\ell!(\ell+|m|)!}\bar{C}_m^{[2\ell]}(z)\rho^{2\ell+|m|} &= \\ \sum_{m=-\infty}^{\infty} \exp(im\phi) \sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{|m|!}{2^{2\ell}\ell!(\ell+|m|)!}\bar{C}_{-m}^{[2\ell]}(z)\rho^{2\ell+|m|}. \qquad (15.3.22)\end{aligned}$$

Therefore requiring

$$\bar{\psi}(x,y,z) = \psi(x,y,z) \qquad (15.3.23)$$

is equivalent to the requirement

$$\bar{C}_{-m}^{[2\ell]}(z) = C_m^{[2\ell]}(z), \qquad (15.3.24)$$

or

$$C_{-m}^{[2\ell]}(z) = \bar{C}_m^{[2\ell]}(z). \qquad (15.3.25)$$

Let us now use this information to rewrite ψ. From (3.19) we have, in the general case,

$$\begin{aligned}\psi(x,y,z) &= \sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!\ell!}C_0^{[2\ell]}(z)\rho^{2\ell} \\ &+ \sum_{m\neq 0}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{|m|!}{2^{2\ell}\ell!(\ell+|m|)!}C_m^{[2\ell]}(z)\rho^{2\ell+|m|} \\ &+ i\sum_{m\neq 0}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{|m|!}{2^{2\ell}\ell!(\ell+|m|)!}C_m^{[2\ell]}(z)\rho^{2\ell+|m|}.\end{aligned} \qquad (15.3.26)$$

The second sum over m in (3.26) can be rewritten as

$$\begin{aligned}\sum_{m\neq 0}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{|m|!}{2^{2\ell}\ell!(\ell+|m|)!}C_m^{[2\ell]}(z)\rho^{2\ell+|m|} &= \\ \sum_{m=1}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}[C_m^{[2\ell]}(z)+C_{-m}^{[2\ell]}(z)]\rho^{2\ell+m}. \qquad (15.3.27)\end{aligned}$$

Now define functions $C_{m,c}^{[2\ell]}(z)$ by the rule

$$C_{m,c}^{[2\ell]}(z) = C_m^{[2\ell]}(z) + C_{-m}^{[2\ell]}(z) \text{ for } m \geq 1, \qquad (15.3.28)$$

so we may also write

$$\begin{aligned}\sum_{m\neq 0}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{|m|!}{2^{2\ell}\ell!(\ell+|m|)!}C_m^{[2\ell]}(z)\rho^{2\ell+|m|} &= \\ \sum_{m=1}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,c}^{[2\ell]}(z)\rho^{2\ell+m}. \qquad (15.3.29)\end{aligned}$$

According to (3.25), the functions $C_{m,c}^{[2\ell]}(z)$ will be real if ψ is real. The third sum over m in (3.26) can be rewritten as

$$i\sum_{m\neq 0}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{|m|!}{2^{2\ell}\ell!(\ell+|m|)!}C_m^{[2\ell]}(z)\rho^{2\ell+|m|} =$$
$$i\sum_{m=1}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}[C_m^{[2\ell]}(z)-C_{-m}^{[2\ell]}(z)]\rho^{2\ell+m}. \tag{15.3.30}$$

Now define functions $C_{m,s}^{[2\ell]}(z)$ by the rule

$$C_{m,s}^{[2\ell]}(z) = i[C_m^{[2\ell]}(z)-C_{-m}^{[2\ell]}(z)] \text{ for } m\geq 1, \tag{15.3.31}$$

so we may also write

$$i\sum_{m\neq 0}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{|m|!}{2^{2\ell}\ell!(\ell+|m|)!}C_m^{[2\ell]}(z)\rho^{2\ell+|m|} =$$
$$\sum_{m=1}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,s}^{[2\ell]}(z)\rho^{2\ell+m}. \tag{15.3.32}$$

According to (3.25), the functions $C_{m,s}^{[2\ell]}(z)$ with $m\geq 1$ will be real if ψ is real. Combining the various results so far gives the representation

$$\begin{aligned}\psi(x,y,z) &= \sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!\ell!}C_0^{[2\ell]}(z)\rho^{2\ell}\\ &+ \sum_{m=1}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,c}^{[2\ell]}(z)\rho^{2\ell+m}\\ &+ \sum_{m=1}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,s}^{[2\ell]}(z)\rho^{2\ell+m}.\end{aligned} \tag{15.3.33}$$

Observe that, according to (3.25), the $C_0^{[2\ell]}(z)$ will be real if ψ is real,

$$C_0^{[0]}(z) = \bar{C}_0^{[0]}(z). \tag{15.3.34}$$

Thus, all the quantities appearing in (3.33) are real if ψ is real. For future use it will be convenient to extend the definitions (3.28) and (3.31) to the $m=0$ case by writing

$$C_{0,c}^{[0]}(z) = C_0^{[0]}(z), \tag{15.3.35}$$

$$C_{0,s}^{[0]}(z) = 0. \tag{15.3.36}$$

We note that all the functions $C_0^{[0]}(z)$, $C_{m,c}^{[0]}(z)$, and $C_{m,s}^{[0]}(z)$ may be chosen independently, and any such choice produces a harmonic function when employed in (3.33). Finally, we observe that all the terms in (3.33) are sums of quantities of the form $\rho^m\cos(m\phi)$ or $\rho^m\sin(m\phi)$

multiplied by powers of ρ^2 with z-dependent coefficients $C_0^{[2\ell]}(z)$, $C_{m,c}^{[2\ell]}(z)$, and $C_{m,s}^{[2\ell]}(z)$. Thus, in view of (3.2) through (3.4), we have achieved our goal of finding a Taylor expansion for $\psi(x,y,z)$ in powers of x,y with coefficients that depend on z.

We close this subsection by introducing some further notation that will be of future use. Define quantities $\Psi_0(\rho,z)$, $\Psi_{m,c}(\rho,z)$, and $\Psi_{m,s}(\rho,z)$ by the equations

$$\Psi_0(\rho,z)=\Psi_{0,c}(\rho,z)=\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!\ell!}C_0^{[2\ell]}(z)\rho^{2\ell}, \tag{15.3.37}$$

$$\Psi_{m,c}(\rho,z)=\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,c}^{[2\ell]}(z)\rho^{2\ell+m}, \tag{15.3.38}$$

$$\Psi_{m,s}(\rho,z)=\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,s}^{[2\ell]}(z)\rho^{2\ell+m}, \tag{15.3.39}$$

so that, in view of (3.33), we may write

$$\begin{aligned}\psi(x,y,z) &= \Psi_0(\rho,z)+\sum_{m=1}^{\infty}\Psi_{m,c}(\rho,z)\cos m\phi+\sum_{m=1}^{\infty}\Psi_{m,s}(\rho,z)\sin m\phi\\ &= \psi_0(x,y,z)+\sum_{m=1}^{\infty}\psi_{m,c}(x,y,z)+\sum_{m=1}^{\infty}\psi_{m,s}(x,y,z) \qquad (15.3.40)\end{aligned}$$

where

$$\psi_0(x,y,z)=\psi_{0,c}(x,y,z)=\Psi_0(\rho,z), \tag{15.3.41}$$

$$\psi_{m,c}(x,y,z)=\psi_{m,c}(\rho,\phi,z)=\cos(m\phi)\Psi_{m,c}(\rho,z), \tag{15.3.42}$$

$$\psi_{m,s}(x,y,z)=\psi_{m,s}(\rho,\phi,z)=\sin(m\phi)\Psi_{m,s}(\rho,z). \tag{15.3.43}$$

Finally, there is a variant coefficient relation that will be of subsequent use. Begin by rewriting (3.07) in the form

$$\begin{aligned}\psi(x,y,z) &= \sum_{m=-\infty}^{\infty}\int_{-\infty}^{\infty}dk\ G_m(k)\exp(ikz)\cos(m\phi)I_m(k\rho)\\ &+ i\sum_{m=-\infty}^{\infty}\int_{-\infty}^{\infty}dk\ G_m(k)\exp(ikz)\sin(m\phi)I_m(k\rho), \qquad (15.3.44)\end{aligned}$$

from which it follows that

$$\begin{aligned}\psi(x,y,z) &= \int_{-\infty}^{\infty}dk\ G_0(k)\exp(ikz)I_0(k\rho)\\ &+ \sum_{m=1}^{\infty}\int_{-\infty}^{\infty}dk\ [G_m(k)+G_{-m}(k)]\exp(ikz)\cos(m\phi)I_m(k\rho)\\ &+ \sum_{m=1}^{\infty}\int_{-\infty}^{\infty}dk\ [iG_m(k)-iG_{-m}](k)\exp(ikz)\sin(m\phi)I_m(k\rho). \qquad (15.3.45)\end{aligned}$$

Next, with $m \geq 1$, introduce the notation

$$G_{m,c}(k) = G_m(k) + G_{-m}(k), \tag{15.3.46}$$

$$G_{m,s}(k) = iG_m(k) - iG_{-m}(k), \tag{15.3.47}$$

with the conventions

$$G_{0,c}(k) = G_0(k), \tag{15.3.48}$$

$$G_{0,s}(k) = 0. \tag{15.3.49}$$

In terms of this notation, ψ has the representation

$$\begin{aligned} \psi(x,y,z) &= \sum_{m=0}^{\infty} \int_{-\infty}^{\infty} dk\ G_{m,c}(k)\exp(ikz)\cos(m\phi)I_m(k\rho) \\ &+ \sum_{m=1}^{\infty} \int_{-\infty}^{\infty} dk\ G_{m,s}(k)\exp(ikz)\sin(m\phi)I_m(k\rho). \end{aligned} \tag{15.3.50}$$

We observe that (3.28) and (3.31) can now also be written in the forms

$$C_{m,c}^{[n]}(z) = (\partial_z)^n C_{m,c}^{[0]}(z) = i^n(1/2)^m(1/m!)\int_{-\infty}^{\infty} dk\ k^{n+m}G_{m,c}(k)\exp(ikz), \tag{15.3.51}$$

$$C_{m,s}^{[n]}(z) = (\partial_z)^n C_{m,s}^{[0]}(z) = i^n(1/2)^m(1/m!)\int_{-\infty}^{\infty} dk\ k^{n+m}G_{m,s}(k)\exp(ikz). \tag{15.3.52}$$

15.3.3 Some Simple Examples: $m = 0, 1, 2$

Let us seek a physical interpretation for the functions $C_0^{[0]}(z)$, $C_{m,c}^{[0]}(z)$, and $C_{m,s}^{[0]}(z)$ by computing the associated magnetic fields using (2.6).

The Case $m = 0$

If only the $C_0^{[0]}(z)$ related terms (the $m = 0$ terms) are present in (3.33), ψ has the expansion

$$\psi_0(x,y,z) = C_0^{[0]}(z) - (1/4)(x^2+y^2)C_0^{[2]}(z) + \cdots, \tag{15.3.53}$$

and therefore

$$B_x = \partial_x\psi_0 = -(1/2)xC_0^{[2]}(z) + \cdots, \tag{15.3.54}$$

$$B_y = \partial_y\psi_0 = -(1/2)yC_0^{[2]}(z) + \cdots, \tag{15.3.55}$$

$$B_z = \partial_z\psi_0 = C_0^{[1]}(z) - (1/4)(x^2+y^2)C_0^{[3]}(z) + \cdots. \tag{15.3.56}$$

We see that $\boldsymbol{B}$ is primarily in the z direction and that $B_z(0,0,z)$, the on-axis z component of $\boldsymbol{B}$, has a profile given by $C_0^{[1]}(z)$. As long as $C_0^{[1]}(z)$ is nearly constant, $C_0^{[2]}(z)$ will be small, and therefore the transverse field components B_x and B_y will be small. Such would be the case for the field of a solenoid where the field is primarily longitudinal and only has transverse components in the fringe-field regions at each end where $C_0^{[1]}(z)$ is changing. (See

Sections 16.1 and 21.1.) We know that for any solenoid-like element (an element having a nonvanishing $m=0$ component in the cylindrical harmonic expansion of its scalar potential and a nonvanishing longitudinal field somewhere on axis) $C_0^{[1]}(z)$ must depend on z because this on-axis gradient must be nonzero somewhere for such an element and must vanish far outside any such element because $\boldsymbol{B}$ vanishes there. Therefore the functions $C_0^{[2]}(z)$, $C_0^{[3]}(z)$, etc., must be nonzero, at least near the end and fringe-field regions of any such element. We conclude that, as a consequence of Maxwell's equations, the scalar potential ψ_0 (and as we will see, the associated vector potential) for any such element must contain terms beyond degree two in the variables x, y. Correspondingly, the transfer map for any real solenoid must contain nonlinear terms.

The same set up could also describe some portion of the field due to an off-center dipole (or any other off-center higher-order multipole) since such magnets would also have an on-axis B_z component somewhere in the fringe-field regions. In all cases we know that $C_0^{[1]}(z)$ must depend on z because this on-axis gradient must be nonzero somewhere in or near the element and must vanish far outside the element, again because $\boldsymbol{B}$ vanishes there.

The Case $m = 1$

Next, suppose that only the $C_{1,s}^{[0]}(z)$ related terms are present in (3.33). In this $m=1$ case, ψ has an expansion of the form

$$\begin{aligned}\psi_{1,s}(x,y,z) &= \rho\sin(\phi)[C_{1,s}^{[0]}(z)-(1/8)(x^2+y^2)C_{1,s}^{[2]}(z)+\cdots]\\ &= y[C_{1,s}^{[0]}(z)-(1/8)(x^2+y^2)C_{1,s}^{[2]}(z)+\cdots]\end{aligned}\tag{15.3.57}$$

and therefore

$$B_x=\partial_x\psi_{1,s}=-(1/4)xyC_{1,s}^{[2]}(z)+\cdots\ ,\tag{15.3.58}$$

$$B_y=\partial_y\psi_{1,s}=C_{1,s}^{[0]}(z)-(1/8)(x^2+3y^2)C_{1,s}^{[2]}(z)+\cdots\ ,\tag{15.3.59}$$

$$B_z=\partial_z\psi_{1,s}=y[C_{1,s}^{[1]}(z)-(1/8)(x^2+y^2)C_{1,s}^{[3]}(z)+\cdots].\tag{15.3.60}$$

We see that $\boldsymbol{B}$ is primarily in the y direction with a profile given by $C_{1,s}^{[0]}(z)$. As long as $C_{1,s}^{[0]}(z)$ is nearly constant, $C_{1,s}^{[1]}(z)$ and higher derivatives of $C_{1,s}^{[0]}(z)$ will be small, and therefore the other field components B_x and B_z will be small. Such would be the case for the field of a (normal) dipole where the field is primarily vertical and only has x and z components in the fringe-field regions at each end where $C_{1,s}^{[0]}(z)$ is changing. (See Exercise 1.5.7.) However, there will always be nonlinear terms at the ends where $C_{1,s}^{[0]}(z)$ and higher derivatives cannot be constant. Correspondingly, the transfer map for any real dipole must contain nonlinear terms. We end the discussion of the $m=1$ case by remarking that the $C_{1,c}^{[0]}(z)$ related terms describe the field of a *skew* dipole. See Exercise 4.1.

The Case $m = 2$

As a last example, suppose that only the $C^{[0]}_{2,s}(z)$ related terms are present in (3.33). In this $m = 2$ case, ψ has an expansion of the form

$$\begin{aligned}\psi_{2,s}(x,y,z) &= \rho^2 \sin(2\phi)[C^{[0]}_{2,s}(z) - (1/24)(x^2+y^2)C^{[2]}_{2,s}(z) + \cdots] \\ &= 2xy[C^{[0]}_{2,s}(z) - (1/24)(x^2+y^2)C^{[2]}_{2,s}(z) + \cdots] \qquad (15.3.61)\end{aligned}$$

and therefore

$$B_x = \partial_x \psi_{2,s} = 2yC^{[0]}_{2,s}(z) - (1/12)(3x^2y + y^3)C^{[2]}_{2,s}(z) + \cdots , \qquad (15.3.62)$$

$$B_y = \partial_y \psi_{2,s} = 2xC^{[0]}_{2,s}(z) - (1/12)(x^3 + 3xy^2)C^{[2]}_{2,s}(z) + \cdots , \qquad (15.3.63)$$

$$B_z = \partial_z \psi_{2,s} = 2xy[C^{[1]}_{2,s}(z) - (1/24)(x^2+y^2)C^{[3]}_{2,s}(z) + \cdots]. \qquad (15.3.64)$$

We see that $\boldsymbol{B}$ is primarily the field of a (normal) quadrupole with a profile given by $Q = 2C^{[0]}_{2,s}(z)$. See Exercise 1.5.9. As long as $C^{[0]}_{2,s}(z)$ is nearly constant, $C^{[1]}_{2,s}(z)$ and higher derivatives of $C^{[0]}_{2,s}(z)$ will be small, and therefore the other field components will be small. Such would be the case for the field of a (normal) quadrupole where the field is primarily of the form given by (1.5.62) through (1.5.64) and only has z components in the fringe-field regions at each end where $C^{[0]}_{2,s}(z)$ is changing. Again, the transfer map for a real quadrupole must contain nonlinear terms because $C^{[0]}_{2,s}(z)$ must have nonzero derivatives in the fringe-field regions. We close the discussion of the $m = 2$ case by remarking that the $C^{[0]}_{2,c}(z)$ related terms describe the field of a skew quadrupole. See Exercise 4.2.

15.3.4 Magnetic Field Expansions for the General Case

General Results

Since ψ is a harmonic function and the operators $\partial_x, \partial_y, \partial_z$ commute with ∇^2, it follows from (2.6) that the (Cartesian) components of $\boldsymbol{B}$ must also be harmonic functions. Consequently each component of $\boldsymbol{B}$ must have a cylindrical multipole expansion of the form (3.33). Indeed, if ψ has the expansion (3.33), then it can be shown that the components of $\boldsymbol{B}$ have the expansions

$$
\begin{aligned}
B_x = \partial_x \psi(x,y,z) = &\sum_{\ell=0}^{\infty}(-1)^\ell \frac{1}{2^{2\ell}\ell!\ell!} C_{1,c}^{[2\ell]}(z)\rho^{2\ell} \\
&+ \cos(\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{2}{2^{2\ell}\ell!(\ell+1)!}[C_{2,c}^{[2\ell]}(z) - (1/4)C_0^{[2\ell+2]}(z)]\rho^{2\ell+1} \\
&+ \sum_{m=2}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m)!}\{(m+1)C_{m+1,c}^{[2\ell]}(z) - [1/(4m)]C_{m-1,c}^{[2\ell+2]}(z)\}\rho^{2\ell+m} \\
&+ \sin(\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{2}{2^{2\ell}\ell!(\ell+1)!} C_{2,s}^{[2\ell]}(z)\rho^{2\ell+1} \\
&+ \sum_{m=2}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m)!}\{(m+1)C_{m+1,s}^{[2\ell]}(z) - [1/(4m)]C_{m-1,s}^{[2\ell+2]}(z)\}\rho^{2\ell+m},
\end{aligned}
\tag{15.3.65}
$$

$$
\begin{aligned}
B_y = \partial_y \psi(x,y,z) = &\sum_{\ell=0}^{\infty}(-1)^\ell \frac{1}{2^{2\ell}\ell!\ell!} C_{1,s}^{[2\ell]}(z)\rho^{2\ell} \\
&+ \cos(\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{2}{2^{2\ell}\ell!(\ell+1)!} C_{2,s}^{[2\ell]}(z)\rho^{2\ell+1} \\
&+ \sum_{m=2}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m)!}\{(m+1)C_{m+1,s}^{[2\ell]}(z) + [1/(4m)]C_{m-1,s}^{[2\ell+2]}(z)\}\rho^{2\ell+m} \\
&- \sin(\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{2}{2^{2\ell}\ell!(\ell+1)!}[C_{2,c}^{[2\ell]}(z) + (1/4)C_0^{[2\ell+2]}(z)]\rho^{2\ell+1} \\
&- \sum_{m=2}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m)!}\{(m+1)C_{m+1,c}^{[2\ell]}(z) + [1/(4m)]C_{m-1,c}^{[2\ell+2]}(z)\}\rho^{2\ell+m},
\end{aligned}
\tag{15.3.66}
$$

$$
\begin{aligned}
B_z = \partial_z \psi(x,y,z) = &\sum_{\ell=0}^{\infty}(-1)^\ell \frac{1}{2^{2\ell}\ell!\ell!} C_0^{[2\ell+1]}(z)\rho^{2\ell} \\
+ &\sum_{m=1}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m)!} C_{m,c}^{[2\ell+1]}(z)\rho^{2\ell+m} \\
+ &\sum_{m=1}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m)!} C_{m,s}^{[2\ell+1]}(z)\rho^{2\ell+m}.
\end{aligned}
\tag{15.3.67}
$$

See Appendix H.[8]

[8] That the components of $\boldsymbol{B}$ should depend on the coordinates ρ, ϕ, z and the coefficients $C_{m,c}^{[n]}, C_{m,s}^{[n]}$ in some fashion is a consequence of (2.6). That they should do so in the particular combinations (3.65) through

Leading Behavior in Body

Let us compute the leading behavior of the various components of $\boldsymbol{B}$. For the monopole (solenoid) case, for which $m = 0$, we assume $C_0^{[1]}(z)$ is *constant* and all other coefficients are zero. Then we find from (3.65) through (3.67) the results

$$B_x^0 = 0, \tag{15.3.68}$$

$$B_y^0 = 0, \tag{15.3.69}$$

$$B_z^0 = C_0^{[1]}. \tag{15.3.70}$$

For the dipole ($m = 1$) cases, assuming $C_{1,c}^{[0]}(z)$ or $C_{1,s}^{[0]}(z)$ is constant and all other coefficients are zero, we find the results

$$B_x^{1,c} = C_{1,c}^{[0]}, \tag{15.3.71}$$

$$B_y^{1,c} = 0, \tag{15.3.72}$$

$$B_z^{1,c} = 0; \tag{15.3.73}$$

$$B_x^{1,s} = 0, \tag{15.3.74}$$

$$B_y^{1,s} = C_{1,s}^{[0]}, \tag{15.3.75}$$

$$B_z^{1,s} = 0. \tag{15.3.76}$$

For the $m \geq 2$ cases, assuming $C_{m,c}^{[0]}(z)$ or $C_{m,s}^{[0]}(z)$ is constant and therefore all other coefficients $C_{m,c}^{[n]}(z)$ and $C_{m,s}^{[n]}(z)$ vanish for $n > 0$, we find the results

$$B_x^{m,c} = m\cos[(m-1)\phi]\rho^{m-1}C_{m,c}^{[0]} = mC_{m,c}^{[0]}\,\Re[(x+iy)^{m-1}], \tag{15.3.77}$$

$$B_y^{m,c} = -m\sin[(m-1)\phi]\rho^{m-1}C_{m,c}^{[0]} = -mC_{m,c}^{[0]}\,\Im[(x+iy)^{m-1}], \tag{15.3.78}$$

$$B_z^{m,c} = 0; \tag{15.3.79}$$

$$B_x^{m,s} = m\sin[(m-1)\phi]\rho^{m-1}C_{m,s}^{[0]} = mC_{m,s}^{[0]}\,\Im[(x+iy)^{m-1}], \tag{15.3.80}$$

$$B_y^{m,s} = m\cos[(m-1)\phi]\rho^{m-1}C_{m,s}^{[0]} = mC_{m,s}^{[0]}\,\Re[(x+iy)^{m-1}], \tag{15.3.81}$$

$$B_z^{m,s} = 0. \tag{15.3.82}$$

Here we have used (3.3) and (3.4). Note that, if the relations (3.77) through (3.82) are evaluated for $m = 1$, they reproduce the results (3.71) through (3.76). They therefore actually hold for all $m > 0$.

When both $C_{m,c}^{[0]}(z)$ and $C_{m,s}^{[0]}(z)$ are present and constant, and all other coeffciients are zero, we may write

$$\boldsymbol{B}^m = \boldsymbol{B}^{m,c} + \boldsymbol{B}^{m,s}. \tag{15.3.83}$$

(3.67) is in part a consequence of the components of $\boldsymbol{B}$ being harmonic. See Exercise 3.4.

With this notation, the relations (3.71), (3.72), (3.74), (3.75), (3.77), (3.78), (3.80), and (3.81) can be rewritten in the compact (but complex) form

$$B_y^m + iB_x^m = m(C_{m,s}^{[0]} + iC_{m,c}^{[0]})(x+iy)^{m-1}. \tag{15.3.84}$$

It must be emphasized, however, that (3.84) holds only in the *body* of a pure multipole magnet, and not in the fringe-field regions at the ends. Moreover, fringe fields and their nonlinear contributions to transfer maps are inescapable consequences of Maxwell's equations.

15.3.5 Symmetry and Allowed and Forbidden Multipoles

There are restrictions on multipole content dictated by symmetry conditions. As a first example, consider a rectangular bending magnet such as that shown in Figures 1.6.1 and 1.6.2. Suppose the magnet is rotated by 180° about the z axis, and simultaneously the strength of the magnet is reversed in sign (so that ψ is replaced by $-\psi$). Assuming perfect symmetry, doing so should produce the same magnetic field as before. Correspondingly, the scalar potential ψ should remain unchanged. Suppose ψ as given by (3.33) is regarded as a function of ρ, ϕ, and z. Then we demand that

$$-\psi(\rho, \phi - \pi, z) = \psi(\rho, \phi, z). \tag{15.3.85}$$

Inspection of (3.33) shows that the requirement (3.85) forces all the coefficients $C_{m,c}^{[2\ell]}$ and $C_{m,s}^{[2\ell]}$ to be zero save those for which $m = 1, 3, 5, \cdots$.

Next consider a quadrupole magnet. Again assuming perfect symmetry, its magnet field should be unchanged if it is rotated by 90° about the z axis, and simultaneously the strength of the magnet is reversed in sign. In this case we demand that

$$-\psi(\rho, \phi - \pi/2, z) = \psi(\rho, \phi, z). \tag{15.3.86}$$

Now inspection of (3.33) shows that the requirement (3.86) forces all the coefficients $C_{m,c}^{[2\ell]}$ and $C_{m,s}^{[2\ell]}$ to be zero save those for which $m = 2, 6, 10, \cdots$.

Finally, consider a perfectly symmetric $2n$-pole magnet for $n = 1, 2, 3, \cdots$. In this case a rotation by $(360/2n)°$ and reversing the strength should leave the field unchanged. Now we conclude all multipole coefficients must vanish save possibly those for which

$$m = n(2j+1) \text{ with } j = 0, 1, 2, 3, \cdots . \tag{15.3.87}$$

In addition to rotational symmetry, there is the consideration of *midplane* symmetry in which one observes what happens when $y \to -y$, or equivalently, in view of (2.13) and (2.14), $\phi \to -\phi$. From (3.2) and (3.37) through (3.39) we see that the functions Ψ_0, $\Psi_{m,c}$, and $\Psi_{m,s}$ are invariant under this operation. It follows from (3.41) through (3.43) that there are the relations

$$\psi_0(x, -y, z) = \psi_0(x, y, z), \tag{15.3.88}$$

$$\psi_{m,c}(x, -y, z) = \psi_{m,c}(x, y, z), \tag{15.3.89}$$

$$\psi_{m,s}(x, -y, z) = -\psi_{m,s}(x, y, z). \tag{15.3.90}$$

We will say that a magnetic field $\boldsymbol{B}$ has *midplane* symmetry if it arises from a scalar potential that only has terms of the form $\psi_{m,s}$,

$$\boldsymbol{B} = \nabla \sum_{m=1}^{\infty} \psi_{m,s}. \tag{15.3.91}$$

Such a field is also said to be *normal* or produced by normal multipoles. Correspondingly, fields of the form

$$\boldsymbol{B} = \nabla \sum_{m=1}^{\infty} \psi_{m,c} \tag{15.3.92}$$

are said to be *skew* or produced by skew multipoles. From (2.6) we see that normal fields have the symmetry property

$$\boldsymbol{B}_x^{\rm normal}(x,-y,z) = -\boldsymbol{B}_x^{\rm normal}(x,y,z), \tag{15.3.93}$$

$$\boldsymbol{B}_y^{\rm normal}(x,-y,z) = \boldsymbol{B}_y^{\rm normal}(x,y,z), \tag{15.3.94}$$

$$\boldsymbol{B}_z^{\rm normal}(x,-y,z) = -\boldsymbol{B}_z^{\rm normal}(x,y,z); \tag{15.3.95}$$

and skew fields have the property

$$\boldsymbol{B}_x^{\rm skew}(x,-y,z) = \boldsymbol{B}_x^{\rm skew}(x,y,z), \tag{15.3.96}$$

$$\boldsymbol{B}_y^{\rm skew}(x,-y,z) = -\boldsymbol{B}_y^{\rm skew}(x,y,z), \tag{15.3.97}$$

$$\boldsymbol{B}_z^{\rm skew}(x,-y,z) = \boldsymbol{B}_z^{\rm skew}(x,y,z). \tag{15.3.98}$$

The same conclusions can be drawn from (3.65) through (3.67). Observe that, by these definitions, the field arising from ψ_0, for example the field of a solenoid, is also skew.

We note that, multipole by multipole, skew elements are related to normal elements and vice versa by rotations about the z axis. From (3.42) and (3.43) we find the relations

$$\psi_{m,c}[\rho,\phi-\pi/(2m),z] = \sin(m\phi)\Psi_{m,c}(\rho,z), \tag{15.3.99}$$

$$\psi_{m,s}[\rho,\phi-\pi/(2m),z] = -\cos(m\phi)\Psi_{m,s}(\rho,z). \tag{15.3.100}$$

We see that a skew element is converted into a normal element, but with on-axis gradients $C_{m,c}^{[2\ell]}(z)$; and a normal element is converted into a skew element, but with on-axis gradients $-C_{m,s}^{[2\ell]}(z)$.

Finally, we observe that a similar discussion could be given to the possible symmetry operation $x \to -x$, for which the properties of $\psi_{m,c}$ and $\psi_{m,s}$ are interchanged.

15.3.6 Relation between Harmonic Polynomials in Spherical and Cylindrical Coordinates

Equation (2.26) defined Harmonic polynomials in terns of a radius r and the spherical harmonics $Y_\ell^m(\theta,\phi)$, thereby providing a description in terms of spherical coordinates; and the relations (2.27) through (2.29) illustrate that the results of this definition are indeed polynomials in the Cartesian coordinates x, y, z. Suppose these polynomials are re-expressed in terms of cylindrical coordinates. This could be done using the z axis as the axis of the cylinder as in the relations (2.13) and (2.14), or with some other axis taken to be the axis of the cylinder as in Exercise 1.5.4.. What would be the appearance of such expansions? And how are such expansions related to the cylindrical harmonic expansions found in (3.19) and (3.33)? The answers to these questions are the subject of this section.

Suppose the substitutions (2.13) and (2.14) are made in the relations (2.27) through (2.29). So doing and employing (3.1) yields the results

$$H_0^0(\boldsymbol{r}) = 1/\sqrt{4\pi}; \tag{15.3.101}$$

$$\begin{aligned} H_1^1(\boldsymbol{r}) &= -\sqrt{3/(8\pi)}\rho\exp(i\phi), \\ H_1^0(\boldsymbol{r}) &= \sqrt{3/(4\pi)}z, \\ H_1^{-1}(\boldsymbol{r}) &= \sqrt{3/(8\pi)}\rho\exp(-i\phi); \end{aligned} \tag{15.3.102}$$

$$\begin{aligned} H_2^2(\boldsymbol{r}) &= \sqrt{15/(32\pi)}\rho^2\exp(2i\phi), \\ H_2^1(\boldsymbol{r}) &= -\sqrt{15/(8\pi)}z\rho\exp(i\phi), \\ H_2^0(\boldsymbol{r}) &= \sqrt{5/(16\pi)}(2z^2-\rho^2), \\ H_2^{-1}(\boldsymbol{r}) &= \sqrt{15/(8\pi)}z\rho\exp(-i\phi), \\ H_2^{-2}(\boldsymbol{r}) &= \sqrt{15/(32\pi)}\rho^2\exp(-2i\phi). \end{aligned} \tag{15.3.103}$$

How are these results related to cylindrical harmonic expansions? For the expansion (3.19) consider the special case in which $C_m^0(z) \neq 0$ for only one value of m, and suppose for this value of m that $C_m^{[0]}(z)$ has the special form

$$C_m^{[0]}(z) = a_n^m f_n(z) \tag{15.3.104}$$

with

$$f_n(z) = z^n. \tag{15.3.105}$$

Call the result $\psi_n^m(x, y, z)$. That is, make the Ansatz

$$\psi_n^m(x,y,z) = a_n^m\rho^{|m|}\exp(im\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{|m|!}{2^{2\ell}\ell!(\ell+|m|)!}f_n^{[2\ell]}(z)\rho^{2\ell}. \tag{15.3.106}$$

What are the properties of this Ansatz?

We begin by observing that the combination $f_n^{[2\ell]}(z)\rho^{2\ell+|m|}$ is a monomial in the variables z and ρ for each value of ℓ, with $2\ell \leq n$, and all these monomials are of degree $n + |m|$. For example, there are the relations

$$f_0^{[0]} = 1, \tag{15.3.107}$$

$$f_0^{[2]} = 0; \tag{15.3.108}$$

$$f_1^{[0]} = z, \tag{15.3.109}$$

$$f_1^{[2]} = 0; \tag{15.3.110}$$
$$f_2^{[0]} = z^2, \tag{15.3.111}$$
$$f_2^{[2]} = 2, \tag{15.3.112}$$
$$f_2^{[4]} = 0; \tag{15.3.113}$$
$$f_3^{[0]} = z^3, \tag{15.3.114}$$
$$f_3^{[2]} = 6z, \tag{15.3.115}$$
$$f_3^{[4]} = 0, \text{ etc.} \tag{15.3.116}$$

It follows that there are the results

$$f_0^{[2\ell]}(z)\rho^{2\ell} = 1 \text{ when } \ell = 0; \tag{15.3.117}$$

$$f_1^{[2\ell]}(z)\rho^{2\ell} = z \text{ when } \ell = 0; \tag{15.3.118}$$

$$f_2^{[2\ell]}(z)\rho^{2\ell} = z^2 \text{ when } \ell = 0, \tag{15.3.119}$$
$$f_2^{[2\ell]}(z)\rho^{2\ell} = 2\rho^2 \text{ when } \ell = 1; \tag{15.3.120}$$

$$f_3^{[2\ell]}(z)\rho^{2\ell} = z^3 \text{ when } \ell = 0, \tag{15.3.121}$$
$$f_3^{[2\ell]}(z)\rho^{2\ell} = 6z\rho^2 \text{ when } \ell = 1, \text{ etc.} \tag{15.3.122}$$

Now let us use these results to work out the first few $\psi_n^m(x, y, z)$. So doing gives the relations

$$\psi_0^0(x, y, z) = a_0^0 \propto H_0^0(\boldsymbol{r}); \tag{15.3.123}$$

$$\psi_0^1(x, y, z) = a_0^1 \rho \exp(i\phi) \propto H_1^1(\boldsymbol{r}), \tag{15.3.124}$$
$$\psi_1^0(x, y, z) = a_1^0 z \propto H_1^0(\boldsymbol{r}), \tag{15.3.125}$$
$$\psi_0^{-1}(x, y, z) = a_0^{-1} \rho \exp(-i\phi) \propto H_1^{-1}(\boldsymbol{r}); \tag{15.3.126}$$

$$\psi_0^2(x, y, z) = a_0^2 \rho^2 \exp(2i\phi) \propto H_2^2(\boldsymbol{r}), \tag{15.3.127}$$
$$\psi_1^1(x, y, z) = a_1^1 z\rho \exp(i\phi) \propto H_2^1(\boldsymbol{r}), \tag{15.3.128}$$
$$\psi_2^0(x, y, z) = a_2^0 (z^2 - \rho^2/2) \propto H_2^0(\boldsymbol{r}), \tag{15.3.129}$$
$$\psi_1^{-1}(x, y, z) = a_1^{-1} z\rho \exp(-i\phi) \propto H_2^{-1}(\boldsymbol{r}), \tag{15.3.130}$$
$$\psi_0^{-2}(x, y, z) = a_0^{-2} \rho^2 \exp(-2i\phi) \propto H_2^{-2}(\boldsymbol{r}). \tag{15.3.131}$$

These examples illustrate that the Ansatz specified by (3.105) and (3.106) produces the harmonic polynomials expressed in cylindrical coordinates. There is the general relation

$$\psi_n^m(x, y, z) \propto H_{n+|m|}^m(\boldsymbol{r}) \tag{15.3.132}$$

where both sides of (3.132) are to be expressed in terms of cylindrical coordinates. Moreover, we note that the functions (3.105) provide a basis for the set of functions $C_m^{[0]}(z)$. Therefore, as we already know from other arguments, harmonic polynomials form a basis for the set of harmonic functions.

Exercises

15.3.1. Given (3.65) through (3.67), verify (3.68) through (3.84).

15.3.2. Suppose that some beam line element is described by the magnetic scalar potential $\psi(x, y, z) = \psi(\rho, \phi, z)$ and suppose this element is rotated by angle θ about the z axis. With regard to sign convention, look down the z axis in the direction of increasing z and suppose the rotation is made in the clockwise direction by an angle θ when θ is positive. Let $\hat{\psi}$ be the magnetic scalar potential for this rotated element. Show that there is the relation

$$\hat{\psi}(\rho, \phi, z) = \psi(\rho, \phi - \theta, z). \tag{15.3.133}$$

Suppose that ψ has the expansion given by the first line of (3.40) and that $\hat{\psi}$ has an expansion of the form

$$\hat{\psi}(x, y, z) = \hat{\Psi}_0(\rho, z) + \sum_{m=1}^{\infty} \hat{\Psi}_{m,c}(\rho, z) \cos m\phi + \sum_{m=1}^{\infty} \hat{\Psi}_{m,s}(\rho, z) \sin m\phi. \tag{15.3.134}$$

Show that

$$\hat{\Psi}_0(\rho, z) = \Psi_0(\rho, z), \tag{15.3.135}$$

$$\hat{\Psi}_{m,c}(\rho, z) = \cos(m\theta)\ \Psi_{m,c}(\rho, z) - \sin(m\theta)\ \Psi_{m,s}(\rho, z), \tag{15.3.136}$$

$$\hat{\Psi}_{m,s}(\rho, z) = \sin(m\theta)\ \Psi_{m,c}(\rho, z) + \cos(m\theta)\ \Psi_{m,s}(\rho, z). \tag{15.3.137}$$

With regard to on-axis gradients, suppose the original on-axis gradients are the functions $C^{[n]}_{m,\alpha}(z)$. See (3.33). Suppose that the on-axis gradients for the rotated element are the functions $\hat{C}^{[n]}_{m,\alpha}(z)$. Show that there the relations

$$\hat{C}^{[n]}_0(z) = C^{[n]}_0(z), \tag{15.3.138}$$

$$\hat{C}^{[n]}_{m,c}(z) = \cos(m\theta)\ C^{[n]}_{m,c}(z) - \sin(m\theta)\ C^{[n]}_{m,s}(z), \tag{15.3.139}$$

$$\hat{C}^{[n]}_{m,s}(z) = \sin(m\theta)\ C^{[n]}_{m,c}(z) + \cos(m\theta)\ C^{[n]}_{m,s}(z). \tag{15.3.140}$$

15.3.3. Show that the definitions (3.28) and (3.31) can be inverted to give the relations

$$C^{[0]}_m(z) = (1/2)[C^{[0]}_{m,c}(z) - iC^{[0]}_{m,s}(z)] \text{ for } m \geq 1, \tag{15.3.141}$$

$$C^{[0]}_{-m}(z) = (1/2)[C^{[0]}_{m,c}(z) + iC^{[0]}_{m,s}(z)] \text{ for } m \geq 1. \tag{15.3.142}$$

15.3.4. The relation (3.5) displays the Laplacian in cylindrical coordinates. Verify that one may write

$$\nabla^2 = \nabla^2_\perp + \partial^2/\partial z^2 \tag{15.3.143}$$

where

$$\begin{aligned} \nabla^2_\perp &= \partial^2/\partial x^2 + \partial^2/\partial y^2 = (1/\rho)(\partial/\partial\rho)(\rho\partial/\partial\rho) + (1/\rho^2)(\partial^2/\partial\phi^2) \\ &= \partial^2/\partial\rho^2 + (1/\rho)\partial/\partial\rho + (1/\rho^2)(\partial^2/\partial\phi^2). \end{aligned} \tag{15.3.144}$$

Define functions χ_c and χ_s by the rules

$$\chi_c = \rho^{2\ell+m} \cos m\phi, \tag{15.3.145}$$

$$\chi_s = \rho^{2\ell+m} \sin m\phi. \tag{15.3.146}$$

Show that they have the property

$$\nabla_\perp^2 \chi_\alpha = 4\ell(\ell+m)\chi_\alpha/\rho^2 \tag{15.3.147}$$

where $\alpha = c, s$. Use this property to show that ψ as given by (3.33) satisfies the Laplace equation (2.7).

15.3.5. Review Exercise 3.4. Next, note the resemblance between the functional forms of ψ as given by (3.33) and the Cartesian components of the gradient of ψ as given by (3.65) through (3.67). Looking forward, observe that the Cartesian components of the associated vector potential in a Coulomb gauge, see (5.89) through (5.94), also have analogous functional forms. Why should this be?

15.3.6. Suppose the Fourier coefficient $G_m(k)$ appearing in (3.7) has the form

$$G_m(k) = \lambda \delta_{m,m'} \delta(k)/k^{|m|}. \tag{15.3.148}$$

Show, using (3.11), that in this case

$$\psi(x, y, z) = [\lambda/(2^{|m'|}|m'|!)]\rho^{|m'|} \exp(im'\phi). \tag{15.3.149}$$

Verify, by direct calculation, that ψ as given by (3.149) is harmonic.

15.4 Determination of the Vector Potential: Azimuthal-Free Gauge

Although the description of magnetic fields $\boldsymbol{B}$ in terms of the scalar potential ψ is convenient, it is not what we ultimately need. What we need, if we wish to exploit the symplectic structure of Hamiltonian dynamics, is a description of $\boldsymbol{B}$ in terms of a vector potential $\boldsymbol{A}$ such that

$$\boldsymbol{B} = \nabla \times \boldsymbol{A}. \tag{15.4.1}$$

We recall that in cylindrical coordinates the radial and azimuthal components of a vector, in this case the vector potential $\boldsymbol{A}$, are related to the transverse Cartesian components by equations (2.22) through (2.25). Since there is gauge freedom in the choice of a vector potential, it is sometimes convenient, if possible, to work in a gauge for which the azimuthal component vanishes,

$$A_\phi = 0. \tag{15.4.2}$$

According to (2.24) and (2.25), in this gauge we have the relations

$$A_x = A_\rho \cos\phi, \tag{15.4.3}$$

$$A_y = A_\rho \sin\phi. \tag{15.4.4}$$

We call this gauge the *azimuthal-free* gauge. We will see that it is possible to find a vector potential in the azimuthal-free gauge for the magnetic field of any multipole save for $m = 0$. (In subsequent sections, we will find a vector potential for the $m = 0$ case in a Coulomb gauge.)

15.4.1 Derivation

We will employ the notation (3.38) and (3.39). With this notation in mind, define vector potentials $\boldsymbol{A}^{m,c}$ and $\boldsymbol{A}^{m,s}$ by the rules

$$A_\rho^{m,c} = -\frac{\sin(m\phi)}{m}\rho\frac{\partial}{\partial z}\Psi_{m,c}, \tag{15.4.5}$$

$$A_\phi^{m,c} = 0, \tag{15.4.6}$$

$$A_z^{m,c} = \frac{\sin(m\phi)}{m}\rho\frac{\partial}{\partial \rho}\Psi_{m,c}; \tag{15.4.7}$$

$$A_\rho^{m,s} = \frac{\cos(m\phi)}{m}\rho\frac{\partial}{\partial z}\Psi_{m,s}, \tag{15.4.8}$$

$$A_\phi^{m,s} = 0, \tag{15.4.9}$$

$$A_z^{m,s} = -\frac{\cos(m\phi)}{m}\rho\frac{\partial}{\partial \rho}\Psi_{m,s}. \tag{15.4.10}$$

(Note that these definitions fail for the $m = 0$ case. See Exercise 4.5.) Then, it is easily verified that

$$\nabla \times \boldsymbol{A}^{m,c} = \nabla\psi_{m,c}, \tag{15.4.11}$$

$$\nabla \times \boldsymbol{A}^{m,s} = \nabla\psi_{m,s}. \tag{15.4.12}$$

See Exercise 4.6. Correspondingly, if we define $\boldsymbol{A}$ by the sum

$$\boldsymbol{A} = \sum_{m=1}^{\infty} \boldsymbol{A}^{m,c} + \sum_{m=1}^{\infty} \boldsymbol{A}^{m,s}, \tag{15.4.13}$$

we have, by linearity and again omitting the $m = 0$ term, the result,

$$\nabla \times \boldsymbol{A} = \nabla\psi = \boldsymbol{B}. \tag{15.4.14}$$

At this point we make an important observation. We know that $\boldsymbol{B}$ falls to zero for large $|z|$ because for large $|z|$ the observation point must be well outside the beam-line element in question. From (3.65) through (3.67) and the definitions of $\Psi_{m,c}$ and $\Psi_{m,c}$, we see that these Ψ must also fall to zero for large $|z|$. Correspondingly, from (4.5) through (4.7), we see that $\boldsymbol{A}^{m,c}$ and $\boldsymbol{A}^{m,s}$ must fall to zero for large $|z|$. This behavior is important because it guarantees that, for the azimuthal-free gauge, the canonical and mechanical momenta will be *equal* far outside any beam-line element. See (1.5.30).

We close this subsection by presenting explicit formulas for the cylindrical and Cartesian components of $\boldsymbol{A}^{m,c}$ and $\boldsymbol{A}^{m,s}$ for general $m \geq 1$. From (4.5) through (4.10) and the expansions (3.38) and (3.39) we find the results

$$A_\rho^{m,c} = -\frac{\sin(m\phi)}{m}\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,c}^{[2\ell+1]}(z)\rho^{2\ell+m+1}, \tag{15.4.15}$$

$$A_\phi^{m,c} = 0, \tag{15.4.16}$$

$$A_z^{m,c} = \frac{\sin(m\phi)}{m} \sum_{\ell=0}^{\infty} (-1)^\ell \frac{(2\ell+m)(m!)}{2^{2\ell}\ell!(\ell+m)!} C_{m,c}^{[2\ell]}(z)\rho^{2\ell+m}; \tag{15.4.17}$$

$$A_\rho^{m,s} = \frac{\cos(m\phi)}{m} \sum_{\ell=0}^{\infty} (-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m)!} C_{m,s}^{[2\ell+1]}(z)\rho^{2\ell+m+1}, \tag{15.4.18}$$

$$A_\phi^{m,s} = 0, \tag{15.4.19}$$

$$A_z^{m,s} = -\frac{\cos(m\phi)}{m} \sum_{\ell=0}^{\infty} (-1)^\ell \frac{(2\ell+m)(m!)}{2^{2\ell}\ell!(\ell+m)!} C_{m,s}^{[2\ell]}(z)\rho^{2\ell+m}. \tag{15.4.20}$$

From (4.3), (4.4), and (4.15) through (4.17) we find the results

$$A_x^{m,c} = -(1/m)x\Im[(x+iy)^m] \sum_{\ell=0}^{\infty} (-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m)!} C_{m,c}^{[2\ell+1]}(z)(x^2+y^2)^\ell, \tag{15.4.21}$$

$$A_y^{m,c} = -(1/m)y\Im[(x+iy)^m] \sum_{\ell=0}^{\infty} (-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m)!} C_{m,c}^{[2\ell+1]}(z)(x^2+y^2)^\ell, \tag{15.4.22}$$

$$A_z^{m,c} = -(1/m)\Im[(x+iy)^m] \sum_{\ell=0}^{\infty} (-1)^\ell \frac{(2\ell+m)(m!)}{2^{2\ell}\ell!(\ell+m)!} C_{m,c}^{[2\ell]}(z)(x^2+y^2)^\ell. \tag{15.4.23}$$

From (4.3), (4.4), and (4.18) through (4.20) we find the results

$$A_x^{m,s} = -(1/m)x\Re[(x+iy)^m] \sum_{\ell=0}^{\infty} (-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m)!} C_{m,s}^{[2\ell+1]}(z)(x^2+y^2)^\ell, \tag{15.4.24}$$

$$A_y^{m,s} = -(1/m)y\Re[(x+iy)^m] \sum_{\ell=0}^{\infty} (-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m)!} C_{m,s}^{[2\ell+1]}(z)(x^2+y^2)^\ell, \tag{15.4.25}$$

$$A_z^{m,s} = -(1/m)\Re[(x+iy)^m] \sum_{\ell=0}^{\infty} (-1)^\ell \frac{(2\ell+m)(m!)}{2^{2\ell}\ell!(\ell+m)!} C_{m,s}^{[2\ell]}(z)(x^2+y^2)^\ell. \tag{15.4.26}$$

Note that (4.21) through (4.26) provide expansions of the vector potential in terms of homogeneous polynomials in the variables x, y with z-dependent coefficients $C_{m,\alpha}^{[n]}(z)$, and that the *minimum* degree of these polynomials is m. Therefore, if the design orbit is on the z axis, as it will be for all beam-line elements not having $m = 1$ (dipole) content, only a finite number of m and ℓ values are required to to compute the transfer map through some finite order in the Lie generators.

15.4.2 Some Simple Examples: $m = 1, 2$

As a first example of a vector potential in the azimuthal-free gauge, suppose all terms in (3.33) vanish save for the 'pure' dipole terms $C_{1,s}^{[n]}(z)$. Then, using (4.24) through (4.26), we find through terms of degree five that $\boldsymbol{A}^{1,s}$ has the expansion

$$A_x^{1,s} = x^2 C_{1,s}^{[1]}(z) - (1/8)(x^4 + x^2y^2)C_{1,s}^{[3]}(z) + \cdots , \tag{15.4.27}$$

$$A_y^{1,s} = xyC_{1,s}^{[1]}(z) - (1/8)(x^3y + xy^3)C_{1,s}^{[3]}(z) + \cdots , \tag{15.4.28}$$

$$\begin{aligned} A_z^{1,s} &= -xC_{1,s}^{[0]}(z) + (3/8)(x^3 + xy^2)C_{1,s}^{[2]}(z) \\ &- (5/192)(x^5 + 2x^3y^2 + xy^4)C_{1,s}^{[4]}(z) + \cdots . \end{aligned} \tag{15.4.29}$$

Note that the results (4.27) through (4.29) agree with (1.5.77) if we make the identification $B = C_{1,s}^{[0]}$. However, we know that $C_{1,s}^{[0]}(z)$ must depend on z because the on-axis gradients must vanish far outside any magnet. Therefore the functions $C_{1,s}^{[1]}(z)$, $C_{1,s}^{[2]}(z)$, $C_{1,s}^{[3]}(z)$, etc. must be nonzero, at least near the end and fringe-field regions of any (rectangular) dipole magnet. We conclude that, as a consequence of Maxwell's equations, the vector potential must contain terms beyond degree two in the variables x, y. Correspondingly, as already stated earlier, the transfer map for any real dipole must contain nonlinear terms.

As a second example of a vector potential in the azimuthal-free gauge, suppose all terms in (3.33) vanish save for the 'pure' (normal) quadrupole terms $C_{2,s}^{[n]}(z)$. Then, again using (4.24) through (4.26), we find through terms of degree four that $\boldsymbol{A}^{2,s}$ has the expansion

$$A_x^{2,s} = (1/2)(x^3 - xy^2)C_{2,s}^{[1]}(z) + \cdots , \tag{15.4.30}$$

$$A_y^{2,s} = -(1/2)(y^3 - yx^2)C_{2,s}^{[1]}(z) + \cdots , \tag{15.4.31}$$

$$A_z^{2,s} = -(x^2 - y^2)C_{2,s}^{[0]}(z) + (1/6)(x^4 - y^4)C_{2,s}^{[2]}(z) + \cdots . \tag{15.4.32}$$

Note that the results (4.30) through (4.32) agree with (1.5.83) if we make the identification $Q/2 = C_{2,s}^{[0]}$. However, we know that $C_{2,s}^{[0]}(z)$ must depend on z because the on-axis gradients must vanish far outside any magnet. Therefore the functions $C_{2,s}^{[1]}(z)$, $C_{2,s}^{[2]}(z)$, etc. must be nonzero, at least near the end and fringe-field regions of any quadrupole magnet. We conclude again that, as a consequence of Maxwell's equations, the vector potential must contain terms beyond degree two in the variables x, y. Correspondingly, the transfer map for any real quadrupole must contain nonlinear terms. Analogous results hold for the skew case corresponding to nonvanishing $C_{2,c}^{[n]}(z)$.

Exercises

15.4.1. Show that the scalar potential $\psi_{1,c}$ produces a skew dipole magnetic field that is primarily in the x direction. Assuming the magnet has iron pole faces, sketch the pole faces and windings required to produce such a field, and label the pole faces N and S. Also sketch the magnetic field lines and the directions the current must flow in the windings. Compare your results with those of Exercise 1.5.7.

15.4.2. Show that the scalar potential $\psi_{2,c}$ produces a skew quadrupole magnetic field. Assuming the magnet has iron pole faces, sketch the pole faces and windings required to produce such a field, and label the pole faces N and S. Also sketch the magnetic field lines and the directions the current must flow in the windings. Compare your results with those of Exercise 1.5.9.

15.4.3. Verify (3.84).

15.4.4. Consider, as a model, the field of an iron-dominated dipole with very wide (in the x direction) pole faces. See Figures 1.6.1 and 1.6.2. Based on symmetry one might imagine that the field of such a magnet would have no B_x component and, correspondingly, ψ for such a magnet would have no x dependence. Let us make the Ansatz

$$\begin{aligned}\psi(y,z) &= \sum_{n=0}^{\infty}(-1)^n[1/(2n+1)!]y^{2n+1}O^{[2n]}(z)\\ &= yO^{[0]}(z)-(1/6)y^3O^{[2]}(z)+(1/120)y^5O^{[4]}(z)+\cdots \qquad (15.4.33)\end{aligned}$$

where $O^{[0]}(z)$ is, in principle, an arbitrary function, but required in our case to go to zero as $|z|\to\infty$. Show that this ψ is harmonic. Hint: See Appendix H.

Next, show that this ψ will produce a magnetic field $\boldsymbol{B}^{\text{iwd}}$, the field of an *infinite-width dipole*, with components

$$B_x^{\text{iwd}}=0, \qquad (15.4.34)$$

$$\begin{aligned}B_y^{\text{iwd}} &= \sum_{n=0}^{\infty}(-1)^n[1/(2n)!]y^{2n}O^{[2n]}(z)\\ &= O^{[0]}(z)-(1/2)y^2O^{[2]}(z)+(1/24)y^4O^{[4]}(z)+\cdots, \qquad (15.4.35)\end{aligned}$$

$$\begin{aligned}B_z^{\text{iwd}} &= \sum_{n=0}^{\infty}(-1)^n[1/(2n+1)!]y^{2n+1}O^{[2n+1]}(z)\\ &= yO^{[1]}(z)-(1/6)y^3O^{[3]}(z)+(1/120)y^5O^{[5]}(z)+\cdots. \qquad (15.4.36)\end{aligned}$$

Thus, $\boldsymbol{B}^{\text{iwd}}$ is primarily in the y direction, has no x component, but does have a z component in the fringe-field regions where $O^{[n]}(z)\neq 0$ for $n>0$.

How is the expansion (4.33) related to a cylindrical multipole expansion? Note the identities

$$y=\rho\sin\phi, \qquad (15.4.37)$$

$$y^3=\rho^3\sin^3\phi=\rho^3[(3/4)\sin\phi-(1/4)\sin 3\phi], \qquad (15.4.38)$$

$$y^5=\rho^5\sin^5\phi=\rho^5[(10/16)\sin\phi-(5/16)\sin 3\phi+(1/16)\sin 5\phi],\ \text{etc.} \qquad (15.4.39)$$

Show from (3.43) that there the relations

$$\Psi_{1,s}(\rho,z)=O^{[0]}(z)\rho-(1/8)O^{[2]}(z)\rho^3+(1/192)O^{[4]}(z)\rho^5+\cdots, \qquad (15.4.40)$$

$$\Psi_{3,s}(\rho,z)=(1/24)O^{[2]}(z)\rho^3-(1/384)O^{[4]}(z)\rho^5+\cdots, \qquad (15.4.41)$$

$$\Psi_{5,s}(\rho,z) = (1/1920)O^{[4]}(z)\rho^5 + \cdots\ , \text{ etc}, \tag{15.4.42}$$

Using (3.39), show that there are the expansions

$$\Psi_{1,s}(\rho,z) = C^{[0]}_{1,s}(z)\rho - (1/8)C^{[2]}_{1,s}(z)\rho^3 + (1/192)C^{[4]}_{1,s}\rho^5 + \cdots\ , \tag{15.4.43}$$

$$\Psi_{3,s}(\rho,z) = C^{[0]}_{3,s}(z)\rho^3 - (1/16)C^{[2]}_{3,s}(z)\rho^5 + \cdots\ , \tag{15.4.44}$$

$$\Psi_{5,s}(\rho,z) = C^{[0]}_{5,s}(z)\rho^5 + \cdots\ . \tag{15.4.45}$$

Now derive the relations

$$C^{[n]}_{1,s}(z) = O^{[n]}(z), \tag{15.4.46}$$

$$C^{[n]}_{3,s}(z) = (1/24)O^{[n+2]}(z), \tag{15.4.47}$$

$$C^{[n]}_{5,s}(z) = (1/1920)O^{[n+4]}(z), \text{ etc.} \tag{15.4.48}$$

Thus the infinite-width dipole has a major contribution from $\psi_{1,s}(x,y,z)$, and further contributions, in the fringe-field regions, from all the $\psi_{m,s}(x,y,z)$ with $m = 3, 5, \cdots$; and all the relevant $C^{[n]}_{m,s}(z)$ are determined by the $O^{[n+m-1]}(z)$.

What is the azimuthal-free vector potential for this model field? The vector potential for $\psi_{1,s}$ has already been found. It is given by (4.27) through (4.29). Show that an analogous calculation for $\psi_{3,s}$ gives the result

$$A^{3,s}_x = (1/3)x(x^3 - 3xy^2)C^{[1]}_{3,s}(z) + \cdots\ , \tag{15.4.49}$$

$$A^{3,s}_y = (1/3)y(x^3 - 3xy^2)C^{[1]}_{3,s}(z) + \cdots\ , \tag{15.4.50}$$

$$A^{3,s}_z = -(x^3 - 3xy^2)C^{[0]}_{3,s}(z) + (5/48)(x^5 - 2x^3y^2 - 3xy^4)C^{[2]}_{3,s}(z) + \cdots\ ; \tag{15.4.51}$$

and an analogous calculation for $\psi_{5,s}$ gives the result

$$A^{5,s}_x = (1/5)x(x^5 - 10x^3y^2 + 5xy^4)C^{[1]}_{5,s}(z) + \cdots\ , \tag{15.4.52}$$

$$A^{5,s}_y = (1/5)y(x^5 - 10x^3y^2 + 5xy^4)C^{[1]}_{5,s}(z) + \cdots\ , \tag{15.4.53}$$

$$A^{5,s}_z = -(x^5 - 10x^3y^2 + 5xy^4)C^{[0]}_{5,s}(z) + \cdots\ . \tag{15.4.54}$$

Add all these vector potentials together and use (4.46) through (4.48) to show that the azimuthal-free vector potential for the model field is given by the relations

$$A_x = x^2O^{[1]}(z) - (1/18)(2x^4 + 3x^2y^2)O^{[3]}(z) + \cdots\ , \tag{15.4.55}$$

$$A_y = xyO^{[1]}(z) - (1/18)(2x^3y + 3xy^3)O^{[3]}(z) + \cdots\ , \tag{15.4.56}$$

$$\begin{aligned} A_z = &-xO^{[0]}(z) + (1/6)(2x^3 + 3xy^2)O^{[2]}(z) \\ &- (1/360)(8x^5 + 20x^3y^2 + 15xy^4)O^{[4]}(z) + \cdots\ . \end{aligned} \tag{15.4.57}$$

We have learned, as inspection of (4.55) through (4.57) illustrates, that in the azimuthal-free gauge the vector potential associated with even a fairly simple magnetic field, such as that of our infinite-width dipole model, is quite complicated. Perhaps other gauges would give simpler results? Indeed, consider the infinite-width-dipole vector potential $\boldsymbol{A}^{\rm iwd}$ defined by the equations

$$A_x^{\rm iwd} = \sum_{n=1}^{\infty}(-1)^n[1/(2n)!]y^{2n}O^{[2n-1]}(z) = -(1/2)y^2O^{[1]}(z)+(1/24)y^4O^{[3]}(z)+\cdots, \quad (15.4.58)$$

$$A_y^{\rm iwd} = 0, \quad (15.4.59)$$

$$A_z^{\rm iwd} = -xO^{[0]}(z). \quad (15.4.60)$$

Show that use of this much simpler vector potential also yields the field $\boldsymbol{B}^{\rm iwd}$ given by (4.34) through (4.36). The question of other gauges will be explored in Sections 15.5 and 15.6. Also, see Exercise 6.2.

Finally note that, for the vector potentials given either by (4.55) through (4.57) or by (4.58) through (4.60), the primary component is in the z direction with additional components in some transverse direction significant only in the fringe-field regions. This feature is advantageous when using z as the independent variable, see Exercise 1.6.1, because then the z component of the vector potential appears only outside the square root that is ubiquitous in all canonical and relativistic formulations.

15.4.5. Let $\mathcal{C}$ be a circle in some plane of constant z and centered on $x = y = 0$. Show that for any vector potential $\boldsymbol{A}$ in the azimuthal-free gauge there is the result

$$\int_{\mathcal{C}} \boldsymbol{A}\cdot d\boldsymbol{r} = 0. \quad (15.4.61)$$

But, by Stokes' theorem, there is also the result

$$\int_{\mathcal{C}} \boldsymbol{A}\cdot d\boldsymbol{r} = \int_{\mathcal{D}} (\nabla\times\boldsymbol{A})\cdot d\boldsymbol{S} = \int_{\mathcal{D}} \boldsymbol{B}\cdot d\boldsymbol{S} = \int_{\mathcal{D}} B_z dS \quad (15.4.62)$$

where $\mathcal{D}$ is the disc in the constant z plane surrounded by $\mathcal{C}$. For the monopole case ($m = 0$) we know that the magnetic field is predominantly in the z direction when x, y are near zero. Therefore the integral (4.62) cannot vanish. Correspondingly, an $m = 0$ magnetic field cannot be derived from an azimuthal-free vector potential.

15.4.6. The goal of this exercise is to verify (4.11) and (4.12). Begin with the fact that, by construction, $\psi_{m,c}$ and $\psi_{m,s}$ are harmonic. Show, using (3.5), that

$$[(1/\rho)(\partial/\partial\rho)(\rho\partial/\partial\rho) + \partial^2/\partial z^2]\Psi_{m,c} = (m/\rho)^2\Psi_{m,c}, \quad (15.4.63)$$

with an analogous result for $\Psi_{m,s}$. Using these results, verify (4.11) and (4.12) by employing the formulas for $\nabla\times$ and ∇ in cylindrical coordinates.

15.4.7. Assume that (3.77) through (3.83) hold in the *body* of a pure multipole. Let

$$\boldsymbol{B}^m = \nabla\times\boldsymbol{A}^m \quad (15.4.64)$$

with

$$\boldsymbol{A}^m = \boldsymbol{A}^{m,c} + \boldsymbol{A}^{m,s}. \tag{15.4.65}$$

Show from (4.21) through (4.26) that in this case (the azimuthal-free gauge case)

$$A_x^m = A_y^m = 0, \tag{15.4.66}$$

and

$$\begin{aligned} A_z^m &= C_{m,c}^{[0]}\Im[(x+iy)^m] - C_{m,s}^{[0]}\Re[(x+iy)^m] \\ &= -\Re[(C_{m,s}^{[0]} + iC_{m,c}^{[0]})(x+iy)^m] = \Im[(C_{m,c}^{[0]} - iC_{m,s}^{[0]})(x+iy)^m]. \end{aligned} \tag{15.4.67}$$

Here the quantities $C_{m,\alpha}^{[0]}$ are assumed to be *constant* (z independent).

15.5 Determination of the Vector Potential: Symmetric Coulomb Gauge

Sometimes it is convenient to work in a Coulomb gauge rather than the azimuthal-free gauge. In this section we will find such a vector potential which, for reasons that will become apparent, we will call the *symmetric* Coulomb gauge vector potential. Before doing so, there is an important fact to be noted about Coulomb-gauge vector potentials for source-free magnetic fields. Suppose that $\hat{\boldsymbol{A}}$ is a vector potential for $\boldsymbol{B}$ that satisfies the Coulomb gauge condition

$$\nabla \cdot \hat{\boldsymbol{A}} = 0. \tag{15.5.1}$$

We know by construction that

$$\nabla \times (\nabla \times \hat{\boldsymbol{A}}) = \nabla \times \boldsymbol{B} = 0. \tag{15.5.2}$$

(Here we have assumed that $\boldsymbol{B}$ is source free.) But there is also the vector identity

$$\nabla \times (\nabla \times \hat{\boldsymbol{A}}) = \nabla(\nabla \cdot \hat{\boldsymbol{A}}) - \nabla^2 \hat{\boldsymbol{A}}. \tag{15.5.3}$$

It follows from (5.1) through (5.3) that there is the relation

$$\nabla^2 \hat{\boldsymbol{A}} = 0. \tag{15.5.4}$$

That is, each *Cartesian* component of a Coulomb-gauge vector potential is a harmonic function. (It need not be true of other components such as spherical and cylindrical components.) This fact will be useful in the next section.

15.5.1 The $m = 0$ Case

We now turn to the task of computing vector potentials in a Coulomb gauge. We begin with the $m = 0$ case, for which there is no azimuthal-free gauge vector potential. In the $m = 0$ case ψ takes the form

$$\psi_0(x, y, z) = \sum_{\ell=0}^{\infty} (-1)^\ell \frac{1}{2^{2\ell}\ell!\ell!} C_0^{[2\ell]}(z)\rho^{2\ell}. \tag{15.5.5}$$

See (3.33). Define a function $U(\rho, z)$ by the rule

$$U(\rho, z) = (1/2)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!(\ell+1)!}C_0^{[2\ell+1]}(z)\rho^{2\ell}. \tag{15.5.6}$$

Now define a vector potential $\hat{\boldsymbol{A}}^0$ by the Ansatz

$$\hat{A}_x^0 = -yU, \tag{15.5.7}$$

$$\hat{A}_y^0 = xU, \tag{15.5.8}$$

$$\hat{A}_z^0 = 0. \tag{15.5.9}$$

We will soon see that this vector potential produces $\boldsymbol{B}$ and is in a Coulomb gauge. Because the two transverse components of this vector potential involve the same master function U in analogous ways, we will refer to this vector potential as the *symmetric* $m = 0$ Coulomb gauge vector potential.

Let us verify that this vector potential produces $\boldsymbol{B}$. First we have to answer the question

$$(\nabla \times \hat{\boldsymbol{A}}^0)_z = \partial_x \hat{A}_y^0 - \partial_y \hat{A}_x^0 = \partial_z \psi_0? \tag{15.5.10}$$

From (5.8) we find the result

$$\partial_x \hat{A}_y^0 = U + x\partial_x U. \tag{15.5.11}$$

But, by the chain rule we have the result

$$\partial_x U = (\partial U/\partial\rho)(\partial\rho/\partial x) = (x/\rho)(\partial U/\partial\rho). \tag{15.5.12}$$

Here we have used the relation

$$\partial\rho/\partial x = x/\rho. \tag{15.5.13}$$

See Appendix H. From (5.11) and (5.12) we conclude that

$$\partial_x \hat{A}_y^0 = U + (x^2/\rho)(\partial U/\partial\rho). \tag{15.5.14}$$

Similarly, we find that

$$-\partial_y \hat{A}_x^0 = U + (y^2/\rho)(\partial U/\partial\rho), \tag{15.5.15}$$

and therefore

$$\partial_x \hat{A}_y^0 - \partial_y \hat{A}_x^0 = 2U + \rho(\partial U/\partial\rho). \tag{15.5.16}$$

But, from the definition (5.6), we see that

$$\rho(\partial U/\partial\rho) = (1/2)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{2\ell}{2^{2\ell}\ell!(\ell+1)!}C_0^{[2\ell+1]}(z)\rho^{2\ell} \tag{15.5.17}$$

and consequently,

$$\begin{aligned}\partial_x \hat{A}_y^0 - \partial_y \hat{A}_x^0 = 2U + \rho(\partial U/\partial\rho) &= (1/2)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{2\ell+2}{2^{2\ell}\ell!(\ell+1)!}C_0^{[2\ell+1]}(z)\rho^{2\ell} \\ = \sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!\ell!}C_0^{[2\ell+1]}(z)\rho^{2\ell} &= \partial_z\psi_0 = B_z.\end{aligned} \tag{15.5.18}$$

Next examine the question

$$(\nabla \times \hat{\boldsymbol{A}}^0)_x = \partial_y \hat{A}_z^0 - \partial_z \hat{A}_y^0 = -\partial_z \hat{A}_y^0 = \partial_x \psi_0? \tag{15.5.19}$$

From (5.8) we see that

$$-\partial_z \hat{A}_y^0 = -x(\partial U/\partial z) = -(x/2)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{1}{2^{2\ell}\ell!(\ell+1)!}C_0^{[2\ell+2]}(z)\rho^{2\ell}. \tag{15.5.20}$$

But we also see from the form (5.5) for ψ_0 that

$$\partial_x \psi_0 = (\partial\psi_0/\partial\rho)(\partial\rho/\partial x) = (x/\rho)(\partial\psi_0/\partial\rho). \tag{15.5.21}$$

Similarly, and for future use, there is the relation

$$\partial_y \psi_0 = (\partial\psi_0/\partial\rho)(\partial\rho/\partial y) = (y/\rho)(\partial\psi_0/\partial\rho). \tag{15.5.22}$$

But from the representation (5.5) we see that

$$\begin{aligned}(1/\rho)(\partial\psi_0/\partial\rho) &= \sum_{\ell=0}^{\infty}(-1)^\ell \frac{2\ell}{2^{2\ell}\ell!\ell!}C_0^{[2\ell]}(z)\rho^{2\ell-2} \\ &= \sum_{\ell=1}^{\infty}(-1)^\ell \frac{2\ell}{2^{2\ell}\ell!\ell!}C_0^{[2\ell]}(z)\rho^{2\ell-2} = \sum_{n=0}^{\infty}(-1)^{n+1}\frac{(2n+2)}{2^{(2n+2)}(n+1)!(n+1)!}C_0^{[2n+2]}(z)\rho^{2n} \\ &= (-1/2)\sum_{n=0}^{\infty}(-1)^n \frac{1}{2^{2n}n!(n+1)!}C_0^{[2n+2]}(z)\rho^{2n},\end{aligned} \tag{15.5.23}$$

and consequently

$$\partial_x \psi_0 = (x/\rho)(\partial\psi_0/\partial\rho) = (-x/2)\sum_{n=0}^{\infty}(-1)^n \frac{1}{2^{2n}n!(n+1)!}C_0^{[2n+2]}(z)\rho^{2n}. \tag{15.5.24}$$

Comparison of (5.20) and (5.24) shows that (5.19) is satisfied.

The last question to examine is

$$(\nabla \times \hat{\boldsymbol{A}}^0)_y = \partial_z \hat{A}_x^0 - \partial_x \hat{A}_z^0 = \partial_z \hat{A}_x^0 = \partial_y \psi_0? \tag{15.5.25}$$

From (5.7) we see that

$$\partial_z \hat{A}_x^0 = -y(\partial U/\partial z) = -(y/2)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{1}{2^{2\ell}\ell!(\ell+1)!}C_0^{[2\ell+2]}(z)\rho^{2\ell}. \tag{15.5.26}$$

But from (5.22) and (5.23) we have

$$\partial_y \psi_0 = (y/\rho)(\partial\psi_0/\partial\rho) = (-y/2)\sum_{n=0}^{\infty}(-1)^n \frac{1}{2^{2n}n!(n+1)!}C_0^{[2n+2]}(z)\rho^{2n}. \tag{15.5.27}$$

Comparison of (5.26) and (5.27) shows that (5.25) is satisfied.

We can also check that $\hat{\boldsymbol{A}}^0$ is divergence free. From (5.7) through (5.9) we see that

$$\nabla \cdot \hat{\boldsymbol{A}}^0 = \partial_x \hat{A}^0_x + \partial_y \hat{A}^0_y + \partial_z \hat{A}^0_z = -y\partial_x U + x\partial_y U. \tag{15.5.28}$$

Now use (5.12) and its y analog to find the result

$$-y\partial_x U + x\partial_y U = [(-yx/\rho) + (xy/\rho)](\partial U/\partial\rho) = 0. \tag{15.5.29}$$

From (5.6) through (5.8), we see that $\hat{A}^0_x$ and $\hat{A}^0_y$ can be written as

$$\hat{A}^0_x = -\sin(\phi)(1/2)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!(\ell+1)!}C_0^{[2\ell+1]}(z)\rho^{2\ell+1} \tag{15.5.30}$$

and

$$\hat{A}^0_y = \cos(\phi)(1/2)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!(\ell+1)!}C_0^{[2\ell+1]}(z)\rho^{2\ell+1}. \tag{15.5.31}$$

Comparison of these expressions with (3.33) shows that both $\hat{A}^0_x$ and $\hat{A}^0_y$ are harmonic functions, as expected.

Inserting (2.13) and (2.14) into (5.30) and (5.31) gives the even more explicit results

$$\begin{aligned}\hat{A}^0_x &= -(y/2)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!(\ell+1)!}C_0^{[2\ell+1]}(z)(x^2+y^2)^{\ell}\\ &= -(y/2)[C_0^{[1]} - (1/8)C_0^{[3]}(x^2+y^2) + \cdots],\end{aligned} \tag{15.5.32}$$

$$\begin{aligned}\hat{A}^0_y &= (x/2)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!(\ell+1)!}C_0^{[2\ell+1]}(z)(x^2+y^2)^{\ell}\\ &= (x/2)[C_0^{[1]} - (1/8)C_0^{[3]}(x^2+y^2) + \cdots],\end{aligned} \tag{15.5.33}$$

$$\hat{A}^0_z = 0. \tag{15.5.34}$$

From the relation

$$B_z = \partial_z\psi_0 = \sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!\ell!}C_0^{[2\ell+1]}(z)\rho^{2\ell}, \tag{15.5.35}$$

we see that

$$C_0^{[1]}(z) = B_z(0,0,z). \tag{15.5.36}$$

Since we assume that $B_z(0,0,z)$ falls of for large $|z|$, the same will be true for $C_0^{[1]}(z)$ and for the $C_0^{[2\ell+1]}(z)$, and hence, according to (5.32) through (5.34), also for $\hat{\boldsymbol{A}}^0$.

For future work it is also useful to have expressions for $\hat{\boldsymbol{A}}^0$ in cylindrical components. Using (2.22), (2.23), and (5.7) through (5.9) gives the results

$$\hat{A}^0_\rho = 0, \tag{15.5.37}$$

$$\hat{A}^0_\phi = \rho U(\rho, z) = (1/2)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{1}{2^{2\ell}\ell!(\ell+1)!}C_0^{[2\ell+1]}(z)\rho^{2\ell+1}, \tag{15.5.38}$$

$$\hat{A}^0_z = 0. \tag{15.5.39}$$

Note that, in contrast to the azimuthal-free gauge of Section 15.4, this vector potential has *only* an azimuthal component.

15.5.2 The $m \geq 1$ Cases

Derivation

Let us begin with some notation: Since we will often be dealing with both the skew and normal cases simultaneously, we will use the symbol α to denote either c or s. For example, we will use $\psi_{m,\alpha}$ to denote either $\psi_{m,c}$ or $\psi_{m,s}$. With this convention in mind, the purpose of the present subsection is to find vector potentials $\hat{\boldsymbol{A}}^{m,\alpha}$ that are in a Coulomb gauge,

$$\nabla \cdot \hat{\boldsymbol{A}}^{m,\alpha} = 0, \tag{15.5.40}$$

and also produce the $\boldsymbol{B}$ fields associated with the $\psi_{m,\alpha}$,

$$\nabla \times \hat{\boldsymbol{A}}^{m,\alpha} = \nabla\psi_{m,\alpha}. \tag{15.5.41}$$

The requirements (5.41), when combined with the relations (4.11) and (4.12), yield the conditions

$$\nabla \times (\hat{\boldsymbol{A}}^{m,\alpha} - \boldsymbol{A}^{m,\alpha}) = 0, \tag{15.5.42}$$

from which it follows that there are functions $\chi_{m,\alpha}$ such that

$$\hat{\boldsymbol{A}}^{m,\alpha} = \boldsymbol{A}^{m,\alpha} + \nabla\chi_{m,\alpha}. \tag{15.5.43}$$

Of course, the relations (5.43) are simply gauge transformations. Our strategy will be to find the functions $\chi_{m,\alpha}$ and then use (5.43) to yield the desired vector potentials.

Upon taking the divergence of both sides of (5.43), and using the Coulomb conditions (5.40), we find that the $\chi_{m,\alpha}$ must satisfy the equations

$$\nabla^2\chi_{m,\alpha} = -\nabla \cdot \boldsymbol{A}^{m,\alpha}. \tag{15.5.44}$$

For an azimuthal-free $\boldsymbol{A}$, see (4.2), we have the relation

$$\nabla \cdot \boldsymbol{A} = (1/\rho)(\partial/\partial\rho)(\rho A_\rho) + (\partial/\partial z)A_z. \tag{15.5.45}$$

Using the representations (4.5) through (4.10) for the right sides of (5.44) gives the results

$$\nabla \cdot \boldsymbol{A}^{m,\alpha} = (2/\rho)A^{m,\alpha}_\rho. \tag{15.5.46}$$

Consequently, the $\chi_{m,\alpha}$ must satisfy the relations

$$\nabla^2\chi_{m,\alpha} = -(2/\rho)A^{m,\alpha}_\rho. \tag{15.5.47}$$

To find the $\chi_{m,\alpha}$, let us make the Ansätze

$$\chi_{m,c} = -(\sin m\phi) d_{m,c}(\rho, z), \tag{15.5.48}$$

$$\chi_{m,s} = (\cos m\phi) d_{m,s}(\rho, z), \tag{15.5.49}$$

where the functions $d_{m,\alpha}(\rho, z)$ are yet to be determined. From the representations (5.48) and (5.49) we find the relations

$$\nabla^2 \chi_{m,c} = -(\sin m\phi)[(1/\rho)(\partial/\partial\rho)(\rho\partial/\partial\rho) - m^2/\rho^2 + (\partial/\partial z)^2] d_{m,s}(\rho, z), \tag{15.5.50}$$

$$\nabla^2 \chi_{m,s} = (\cos m\phi)[(1/\rho)(\partial/\partial\rho)(\rho\partial/\partial\rho) - m^2/\rho^2 + (\partial/\partial z)^2] d_{m,s}(\rho, z). \tag{15.5.51}$$

See (3.5). Upon using (5.47) and comparing (5.50) and (5.51) with (4.5) and (4.8), we find the relations

$$[(1/\rho)(\partial/\partial\rho)(\rho\partial/\partial\rho) - m^2/\rho^2 + (\partial/\partial z)^2] d_{m,\alpha}(\rho, z) = (-2/m)(\partial/\partial z)\Psi_{m,\alpha}(\rho, z). \tag{15.5.52}$$

Next assume that each $d_{m,\alpha}(\rho, z)$ has an expansion of the form

$$d_{m,\alpha}(\rho, z) = \sum_{\ell=0}^{\infty} D_{m,\alpha}^{2\ell}(z)\rho^{2\ell+m+2} \tag{15.5.53}$$

where the functions $D_{m,\alpha}^{2\ell}(z)$ are yet to be determined. It easily verified that there is the relation

$$[(1/\rho)(\partial/\partial\rho)(\rho\partial/\partial\rho) - m^2/\rho^2]\rho^n = (n^2 - m^2)\rho^{n-2}. \tag{15.5.54}$$

It follows, by using the expansion (5.53), that there is the relation

$$\begin{aligned} &[(1/\rho)(\partial/\partial\rho)(\rho\partial/\partial\rho) - m^2/\rho^2 + (\partial/\partial z)^2] d_{m,\alpha}(\rho, z) \\ = \ &\sum_{\ell=0}^{\infty}[(2\ell + m + 2)^2 - m^2] D_{m,\alpha}^{2\ell}(z)\rho^{2\ell+m} + \sum_{\ell=0}^{\infty}[(\partial/\partial z)^2 D_{m,\alpha}^{2\ell}(z)]\rho^{2\ell+m+2}. \end{aligned} \tag{15.5.55}$$

The sum consisting of the second set of terms on the right side of (5.55) can be rewritten in the form

$$\sum_{\ell=0}^{\infty}[(\partial/\partial z)^2 D_{m,\alpha}^{2\ell}(z)]\rho^{2\ell+m+2} = \sum_{n=1}^{\infty}[(\partial/\partial z)^2 D_{m,\alpha}^{2n-2}(z)]\rho^{2n+m} \tag{15.5.56}$$

or, equivalently, in the form

$$\sum_{\ell=0}^{\infty}[(\partial/\partial z)^2 D_{m,\alpha}^{2\ell}(z)]\rho^{2\ell+m+2} = \sum_{\ell=0}^{\infty}[(\partial/\partial z)^2 D_{m,\alpha}^{2\ell-2}(z)]\rho^{2\ell+m} \tag{15.5.57}$$

with the understanding that

$$D_{m,\alpha}^{-2} = 0. \tag{15.5.58}$$

Consequently, we also have the relation

$$\begin{aligned}&[(1/\rho)(\partial/\partial\rho)(\rho\partial/\partial\rho) - m^2/\rho^2 + (\partial/\partial z)^2]d_{m,\alpha}(\rho,z)\\ = &\sum_{\ell=0}^{\infty}\{[(2\ell+m+2)^2 - m^2]D^{2\ell}_{m,\alpha}(z) + [(\partial/\partial z)^2 D^{2\ell-2}_{m,\alpha}(z)]\}\rho^{2\ell+m}.\end{aligned} \tag{15.5.59}$$

We have found an expansion in powers of ρ for the left side of (5.52). From (3.38) and (3.39) we already have such an expansion for the right side of (5.52), which we write in the form

$$(-2/m)(\partial/\partial z)\Psi_{m,\alpha}(\rho,z) = \sum_{\ell=0}^{\infty} r(\ell,m)C^{[2\ell+1]}_{m,\alpha}(z)\rho^{2\ell+m} \tag{15.5.60}$$

where

$$r(\ell,m) = -2(-1)^{\ell}(m!)/[m2^{2\ell}\ell!(l+m)!]. \tag{15.5.61}$$

Equating like powers of ρ on both sides of (5.52) gives the relation

$$[(2\ell+m+2)^2 - m^2]D^{2\ell}_{m,\alpha}(z) + (\partial/\partial z)^2 D^{2\ell-2}_{m,\alpha}(z) = r(\ell,m)C^{[2\ell+1]}_{m,\alpha}(z), \tag{15.5.62}$$

which can be rewritten as the recursion relation

$$D^{2\ell}_{m,\alpha}(z) = s(\ell,m)C^{[2\ell+1]}_{m,\alpha}(z) + t(\ell,m)(\partial/\partial z)^2 D^{2\ell-2}_{m,\alpha}(z) \tag{15.5.63}$$

where $s(\ell,m)$ and $t(\ell,m)$ are the coefficients

$$s(\ell,m) = r(\ell,m)/[(2\ell+m+2)^2 - m^2], \tag{15.5.64}$$

$$t(\ell,m) = -1/[(2\ell+m+2)^2 - m^2]. \tag{15.5.65}$$

We find, for the first few terms, the results

$$D^0_{m,\alpha}(z) = s(0,m)C^{[1]}_{m,\alpha}(z) = -\{1/[2m(m+1)]\}C^{[1]}_{m,\alpha}(z), \tag{15.5.66}$$

$$\begin{aligned}D^2_{m,\alpha}(z) &= s(1,m)C^{[3]}_{m,\alpha}(z) + t(1,m)(\partial/\partial z)^2 D^0_{m,\alpha}(z)\\ &= s(1,m)C^{[3]}_{m,\alpha}(z) + t(1,m)s(0,m)C^{[3]}_{m,\alpha}(z)\\ &= [s(1,m) + t(1,m)s(0,m)]C^{[3]}_{m,\alpha}(z)\\ &= \{1/[8m(m+1)(m+2)]\}C^{[3]}_{m,\alpha}(z),\end{aligned} \tag{15.5.67}$$

$$\begin{aligned}D^4_{m,\alpha}(z) &= s(2,m)C^{[5]}_{m,\alpha}(z) + t(2,m)(\partial/\partial z)^2 D^2_{m,\alpha}(z)\\ &= \{s(2,m) + t(2,m)[s(1,m) + t(1,m)s(0,m)]\}C^{[5]}_{m,\alpha}(z),\\ &= -\{1/[64m(m+1)(m+2)(m+3)]\}C^{[5]}_{m,\alpha}(z), \text{ etc.}\end{aligned} \tag{15.5.68}$$

We conclude that the $D^{2\ell}_{m,\alpha}(z)$ are completely specified in terms of the $C^{[2\ell+1]}_{m,\alpha}(z)$. Indeed, we have by induction the relation

$$D^{2\ell}_{m,\alpha}(z) = u(\ell, m)C^{[2\ell+1]}_{m,\alpha}(z) \tag{15.5.69}$$

where the coefficients $u(\ell, m)$ are given by the recursion relation

$$u(\ell, m) = s(\ell, m) + t(\ell, m)u(l - 1, m) \tag{15.5.70}$$

with

$$u(-1, m) = 0. \tag{15.5.71}$$

This recursion relation has the solution

$$u(\ell, m) = -(-1)^\ell c_\ell\{[(m - 1)!]/[(m + \ell + 1)!]\} \tag{15.5.72}$$

where

$$c_\ell = 1/[(2)(2^{2\ell})(\ell!)]. \tag{15.5.73}$$

We are now able to write explicit series expansions for the $d_{m,\alpha}(\rho, z)$ and the $\chi_{m,\alpha}$ in terms of the $C^{[n]}_{m,\alpha}(z)$. Upon combining (5.53), (5.69), (5.72), and (5.73), we find the result

$$d_{m,\alpha}(\rho, z) = -(1/2)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{(m-1)!}{2^{2\ell}\ell!(\ell+m+1)!}C^{[2\ell+1]}_{m,\alpha}(z)\rho^{2\ell+m+2}. \tag{15.5.74}$$

And, with the use of (5.48) and (5.49), we find for the $\chi_{m,\alpha}$ the expansions

$$\chi_{m,c} = (1/2)(\sin m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{(m-1)!}{2^{2\ell}\ell!(\ell+m+1)!}C^{[2\ell+1]}_{m,c}(z)\rho^{2\ell+m+2}, \tag{15.5.75}$$

$$\chi_{m,s} = -(1/2)(\cos m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{(m-1)!}{2^{2\ell}\ell!(\ell+m+1)!}C^{[2\ell+1]}_{m,s}(z)\rho^{2\ell+m+2}. \tag{15.5.76}$$

Next, we can compute series expansions for the $\nabla\chi_{m,\alpha}$. It is convenient to work out the gradients in cylindrical coordinates. We find from (5.75) and (5.76) the results

$$\begin{aligned}(\nabla\chi_{m,c})_\rho &= \partial_\rho\chi_{m,c}\\ &= (1/2)(\sin m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{(m-1)!(2\ell+m+2)}{2^{2\ell}\ell!(\ell+m+1)!}C^{[2\ell+1]}_{m,c}(z)\rho^{2\ell+m+1},\end{aligned} \tag{15.5.77}$$

$$\begin{aligned}(\nabla\chi_{m,c})_\phi &= (1/\rho)\partial_\phi\chi_{m,c}\\ &= (1/2)(\cos m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{(m)(m-1)!}{2^{2\ell}\ell!(\ell+m+1)!}C^{[2\ell+1]}_{m,c}(z)\rho^{2\ell+m+1}\\ &= (1/2)(\cos m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C^{[2\ell+1]}_{m,c}(z)\rho^{2\ell+m+1},\end{aligned} \tag{15.5.78}$$

$$\begin{aligned}(\nabla\chi_{m,c})_z &= \partial_z\chi_{m,c}\\ &= (1/2)(\sin m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{(m-1)!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,c}^{[2\ell+2]}(z)\rho^{2\ell+m+2};\end{aligned} \tag{15.5.79}$$

$$\begin{aligned}(\nabla\chi_{m,s})_\rho &= \partial_\rho\chi_{m,s}\\ &= -(1/2)(\cos m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{(m-1)!(2\ell+m+2)}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,s}^{[2\ell+1]}(z)\rho^{2\ell+m+1},\end{aligned} \tag{15.5.80}$$

$$\begin{aligned}(\nabla\chi_{m,s})_\phi &= (1/\rho)\partial_\phi\chi_{m,s}\\ &= (1/2)(\sin m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{(m)(m-1)!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,s}^{[2\ell+1]}(z)\rho^{2\ell+m+1}\\ &= (1/2)(\sin m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,s}^{[2\ell+1]}(z)\rho^{2\ell+m+1},\end{aligned} \tag{15.5.81}$$

$$\begin{aligned}(\nabla\chi_{m,s})_z &= \partial_z\chi_{m,s}\\ &= -(1/2)(\cos m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{(m-1)!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,s}^{[2\ell+2]}(z)\rho^{2\ell+m+2}.\end{aligned} \tag{15.5.82}$$

We have all the ingredients at hand to compute the $\hat{\boldsymbol{A}}^{m,\alpha}$. We find, in cylindrical coordinates and using (4.15) through (4.20), (5.43), and (5.77) through (5.82), the results

$$\hat{A}_\rho^{m,c} = -(1/2)(\sin m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,c}^{[2\ell+1]}(z)\rho^{2\ell+m+1}, \tag{15.5.83}$$

$$\hat{A}_\phi^{m,c} = (1/2)(\cos m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,c}^{[2\ell+1]}(z)\rho^{2\ell+m+1}, \tag{15.5.84}$$

$$\hat{A}_z^{m,c} = (\sin m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,c}^{[2\ell]}(z)\rho^{2\ell+m}; \tag{15.5.85}$$

$$\hat{A}_\rho^{m,s} = (1/2)(\cos m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,s}^{[2\ell+1]}(z)\rho^{2\ell+m+1}, \tag{15.5.86}$$

$$\hat{A}_\phi^{m,s} = (1/2)(\sin m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,s}^{[2\ell+1]}(z)\rho^{2\ell+m+1}, \tag{15.5.87}$$

$$\hat{A}_z^{m,s} = -(\cos m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,s}^{[2\ell]}(z)\rho^{2\ell+m}. \tag{15.5.88}$$

Correspondingly, using (2.24) and (2.25), we find for the Cartesian components of the $\hat{\boldsymbol{A}}^{m,\alpha}$ the results

$$\begin{aligned}\hat{A}_x^{m,c} &= -(1/2)[(\cos\phi)(\sin m\phi)+(\sin\phi)(\cos m\phi)]\times \\ &\quad \sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,c}^{[2\ell+1]}(z)\rho^{2\ell+m+1} \\ &= -(1/2)[\sin(m+1)\phi]\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,c}^{[2\ell+1]}(z)\rho^{2\ell+m+1}, \\ &= -(1/2)\Im[(x+iy)^{m+1}]\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,c}^{[2\ell+1]}(z)(x^2+y^2)^\ell,\end{aligned} \tag{15.5.89}$$

$$\begin{aligned}\hat{A}_y^{m,c} &= (1/2)[-(\sin\phi)(\sin m\phi)+(\cos\phi)(\cos m\phi)]\times \\ &\quad \sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,c}^{[2\ell+1]}(z)\rho^{2\ell+m+1} \\ &= (1/2)[\cos(m+1)\phi]\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,c}^{[2\ell+1]}(z)\rho^{2\ell+m+1}, \\ &= (1/2)\Re[(x+iy)^{m+1}]\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,c}^{[2\ell+1]}(z)(x^2+y^2)^\ell,\end{aligned} \tag{15.5.90}$$

$$\begin{aligned}\hat{A}_z^{m,c} &= (\sin m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,c}^{[2\ell]}(z)\rho^{2\ell+m} \\ &= \Im[(x+iy)^m]\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,c}^{[2\ell]}(z)(x^2+y^2)^\ell;\end{aligned} \tag{15.5.91}$$

$$\begin{aligned}
\hat{A}_x^{m,s} &= (1/2)[(\cos\phi)(\cos m\phi) - (\sin\phi)(\sin m\phi)] \times \\
&\quad \sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,s}^{[2\ell+1]}(z)\rho^{2\ell+m+1} \\
&= (1/2)[\cos(m+1)\phi]\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,s}^{[2\ell+1]}(z)\rho^{2\ell+m+1} \\
&= (1/2)\Re[(x+iy)^{m+1}]\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,s}^{[2\ell+1]}(z)(x^2+y^2)^{\ell},
\end{aligned} \tag{15.5.92}$$

$$\begin{aligned}
\hat{A}_y^{m,s} &= (1/2)[(\sin\phi)(\cos m\phi) + (\cos\phi)(\sin m\phi)] \times \\
&\quad \sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,s}^{[2\ell+1]}(z)\rho^{2\ell+m+1} \\
&= (1/2)[\sin(m+1)\phi]\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,s}^{[2\ell+1]}(z)\rho^{2\ell+m+1} \\
&= (1/2)\Im[(x+iy)^{m+1}]\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,s}^{[2\ell+1]}(z)(x^2+y^2)^{\ell},
\end{aligned} \tag{15.5.93}$$

$$\begin{aligned}
\hat{A}_z^{m,s} &= -(\cos m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,s}^{[2\ell]}(z)\rho^{2\ell+m} \\
&= -\Re[(x+iy)^{m}]\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,s}^{[2\ell]}(z)(x^2+y^2)^{\ell}.
\end{aligned} \tag{15.5.94}$$

Note four important facts: First, we see that the relations (5.83) through (5.88) for $\hat{\boldsymbol{A}}^{m,\alpha}$ are also defined for $m = 0$. When so evaluated they produce, in the case $\alpha = c$, a result that agrees with the $\hat{\boldsymbol{A}}^{0}$ given by (5.37) through (5.39); and [recalling (3.36)] they produce, in the case $\alpha = s$, the zero vector. That is, we may make the definitions

$$\hat{\boldsymbol{A}}^{0,c} = \hat{\boldsymbol{A}}^{0}, \tag{15.5.95}$$

$$\hat{\boldsymbol{A}}^{0,s} = 0. \tag{15.5.96}$$

Second, from their form in (5.89) through (5.94), it is evident that the Cartesian components of $\hat{\boldsymbol{A}}^{m,\alpha}$ are all harmonic functions, as expected. Third, we observe that $\hat{A}_x^{m,c}$ and $\hat{A}_y^{m,c}$ as given by (5.89) and (5.90) involve complementary trigonometric functions multiplying the same master function. The same is true of $\hat{A}_x^{m,s}$ and $\hat{A}_y^{m,s}$ as given by (5.92) and (5.93). See Exercise 5.6. For this reason we refer to the Coulomb gauge vector potential we have found as being the *symmetric* Coulomb gauge vector potential. Finally, note again that (5.89) through

(5.94) provide expansions of the vector potential in terms of homogeneous polynomials in the variables x, y with z-dependent coefficients $C^{[n]}_{m,\alpha}(z)$, and that the *minimum* degree of these polynomials is m. In summary, we have found formulas for the $\chi_{m,\alpha}$ and the $\hat{\boldsymbol{A}}^{m,\alpha}$ in terms of the $C^{[n]}_{m,\alpha}(z)$.

Symmetric Coulomb Gauge Examples for $m = 1, 2$

As an example of the use of these relations, let us compute $\hat{\boldsymbol{A}}^{1,s}$ for the dipole case $m = 1$. As before, suppose all terms in (3.33) vanish save for the dipole terms $C^{[n]}_{1,s}(z)$. Using (5.92) through (5.94) we then find, through terms of degree five, that $\hat{\boldsymbol{A}}^{1,s}$ has the expansion

$$\hat{A}^{1,s}_x = (1/4)(x^2 - y^2)C^{[1]}_{1,s}(z) - (1/48)(x^4 - y^4)C^{[3]}_{1,s}(z) + \cdots , \quad (15.5.97)$$

$$\hat{A}^{1,s}_y = (1/2)xyC^{[1]}_{1,s}(z) - (1/24)(x^3y + xy^3)C^{[3]}_{1,s}(z) + \cdots , \quad (15.5.98)$$

$$\hat{A}^{1,s}_z = -xC^{[0]}_{1,s}(z)+(1/8)(x^3+xy^2)C^{[2]}_{1,s}(z)-(1/192)(x^5+2x^3y^2+xy^4)C^{[4]}_{1,s}(z)+\cdots . \quad (15.5.99)$$

This expansion should be compared with the azimuthal-free gauge expansion given by (4.27) through (4.29). Direct calculation verifies that $\hat{\boldsymbol{A}}^{1,s}$ satisfies (5.1) and (5.4) through terms of degree four, which is what is expected based on the order of the terms that have been retained in the expansion.

As a second example of the use of these relations, let us compute $\hat{\boldsymbol{A}}^{2,s}$ for the (normal) quadrupole case $m = 2$. As before, suppose all terms in (3.33) vanish save for the quadrupole terms $C^{[n]}_{2,s}(z)$. Then, again using (5.92) through (5.94), we find, through terms of degree four, that $\hat{\boldsymbol{A}}^{2,s}$ has the expansion

$$\hat{A}^{2,s}_x = (1/6)(x^3 - 3xy^2)C^{[1]}_{2,s}(z) + \cdots , \quad (15.5.100)$$

$$\hat{A}^{2,s}_y = -(1/6)(y^3 - 3x^2y)C^{[1]}_{2,s}(z) + \cdots , \quad (15.5.101)$$

$$\hat{A}^{2,s}_z = -(x^2 - y^2)C^{[0]}_{2,s}(z) + (1/12)(x^4 - y^4)C^{[2]}_{2,s}(z) + \cdots . \quad (15.5.102)$$

This expansion should be compared with the azimuthal-free gauge expansion given by (4.30) through (4.32). Direct calculation again verifies that (5.1) and (5.4) are satisfied by $\hat{\boldsymbol{A}}^{2,s}$ through the order of the terms that have been retained in the expansion. Finally, we remark that analogous results can be found for the skew case $\hat{\boldsymbol{A}}^{2,c}$.

Exercises

15.5.1. For $\hat{\boldsymbol{A}}^{0}$ given by (5.37) through (5.39), compute the curl and divergence of $\hat{\boldsymbol{A}}^{0}$ in cylindrical coordinates.

15.5.2. Verify that (5.72) and (5.73) satisfy the recursion relation (5.70) with the initial condition (5.71).

15.5.3. Verify the expansions (5.83) through (5.88) and verify that $\nabla \cdot \hat{\boldsymbol{A}}^{m,\alpha} = 0$

15.5.4. Consider the case of straight beam-line elements, such as solenoids, quadrupoles, sextupoles, octupoles, etc., for which the design orbit lies on the z axis. Suppose we wish to retain, in the expansion of the Hamiltonian H appearing in (1.3), homogeneous polynomials in x and y through degree 4. This would be required if we wished to make a Lie factorization of $\mathcal{M}$ that retained all Lie generators of degree 4 and lower,

$$\mathcal{M} = \mathcal{R}\exp(:f_3:)\exp(:f_4:). \tag{15.5.103}$$

Assuming no particular field symmetries, and working in the Coulomb gauge of this section, show that the following generalized gradients and their derivatives would then be required:

$$\begin{aligned}
&C_0^{[0]}(z),\ C_0^{[1]}(z),\ C_0^{[2]}(z),\ C_0^{[3]}(z);\\
&C_{1,\alpha}^{[0]}(z),\ C_{1,\alpha}^{[1]}(z),\ C_{1,\alpha}^{[2]}(z);\\
&C_{2,\alpha}^{[0]}(z),\ C_{2,\alpha}^{[1]}(z),\ C_{2,\alpha}^{[2]}(z);\\
&C_{3,\alpha}^{[0]}(z);\\
&C_{4,\alpha}^{[0]}(z).
\end{aligned} \tag{15.5.104}$$

Verify that in the $m = 0$ case the $C_m^{[n]}$ with n even are actually not needed. See Subsection 5.1. Also, strictly speaking, the dipole terms, the terms in the second row of (5.104), should actually vanish in order for the design orbit to lie on the z axis. A possible exception could be the case of a wiggler/undulator where the $C_{1,\alpha}^{[n]}(z)$ oscillate in z and nearly average to zero in such a way that the design orbit does not depart significantly from the z axis.

Suppose, instead, we wish to retain homogeneous polynomials through degree 8. This would be required if we wished to make a Lie factorization of $\mathcal{M}$ that retained all Lie generators of degree 8 and lower,

$$\mathcal{M} = \mathcal{R}\exp(:f_3:)\exp(:f_4:)\exp(:f_5:)\exp(:f_6:)\exp(:f_7:)\exp(:f_8:). \tag{15.5.105}$$

Assuming no particular field symmetries, and working in the Coulomb gauge of this section, show that the following generalized gradients and their derivatives would then be required:

$$\begin{aligned}
&C_0^{[0]}(z),\ C_0^{[1]}(z),\ C_0^{[2]}(z),\ C_0^{[3]}(z),\ C_0^{[4]}(z),\ C_0^{[5]}(z),\ C_0^{[6]}(z),\ C_0^{[7]}(z);\\
&C_{1,\alpha}^{[0]}(z),\ C_{1,\alpha}^{[1]}(z),\ C_{1,\alpha}^{[2]}(z),\ C_{1,\alpha}^{[3]}(z),\ C_{1,\alpha}^{[4]}(z),\ C_{1,\alpha}^{[5]}(z),\ C_{1,\alpha}^{[6]}(z);\\
&C_{2,\alpha}^{[0]}(z),\ C_{2,\alpha}^{[1]}(z),\ C_{2,\alpha}^{[2]}(z),\ C_{2,\alpha}^{[3]}(z),\ C_{2,\alpha}^{[4]}(z),\ C_{2,\alpha}^{[5]}(z),\ C_{2,\alpha}^{[6]}(z);\\
&C_{3,\alpha}^{[0]}(z),\ C_{3,\alpha}^{[1]}(z),\ C_{3,\alpha}^{[2]}(z),\ C_{3,\alpha}^{[3]}(z),\ C_{3,\alpha}^{[4]}(z);\\
&C_{4,\alpha}^{[0]}(z),\ C_{4,\alpha}^{[1]}(z),\ C_{4,\alpha}^{[2]}(z),\ C_{4,\alpha}^{[3]}(z),\ C_{4,\alpha}^{[4]}(z);\\
&C_{5,\alpha}^{[0]}(z),\ C_{5,\alpha}^{[1]}(z),\ C_{5,\alpha}^{[2]}(z);\\
&C_{6,\alpha}^{[0]}(z),\ C_{6,\alpha}^{[1]}(z),\ C_{6,\alpha}^{[2]}(z);\\
&C_{7,\alpha}^{[0]}(z);\\
&C_{8,\alpha}^{[0]}(z).
\end{aligned} \tag{15.5.106}$$

Again verify that in the $m = 0$ case the $C_m^{[n]}$ with n even are actually not needed. And again, with the possible exception of a wiggler/undulator, the dipole terms, the terms in the second row of (5.106), should actually vanish in order for the design orbit to lie on the z axis.

15.5.5. Assume that (3.77) through (3.83) hold in the *body* of a pure multipole (with $m > 0$). Let

$$\boldsymbol{B}^m = \nabla \times \hat{\boldsymbol{A}}^m \tag{15.5.107}$$

with

$$\hat{\boldsymbol{A}}^m = \hat{\boldsymbol{A}}^{m,c} + \hat{\boldsymbol{A}}^{m,s}. \tag{15.5.108}$$

Show from (5.89) through (5.94) that in this case (the symmetric Coulomb gauge case) there are the relations

$$\hat{A}_x^m = \hat{A}_y^m = 0, \tag{15.5.109}$$

and

$$\begin{aligned} \hat{A}_z^m &= C_{m,c}^{[0]}\Im[(x+iy)^m] - C_{m,s}^{[0]}\Re[(x+iy)^m] \\ &= -\Re[(C_{m,s}^{[0]} + iC_{m,c}^{[0]})(x+iy)^m] = \Im[(C_{m,c}^{[0]} - iC_{m,s}^{[0]})(x+iy)^m]. \end{aligned} \tag{15.5.110}$$

Here the quantities $C_{m,\alpha}^{[0]}$ are assumed to be *constant* (z independent).

Note that the results (5.109) and (5.110) agree with (4.66) and (4.67). The azimuthal-free and symmetric Coulomb gauges give the *same* result in the body for all terms with $m > 0$. The difference between the two gauges occurs only in the fringe-field regions.

15.5.6. As a consequence of the symmetry present in the symmetric Coulomb gauge, verify that the two real relations (5.89) and (5.90) can be combined to produce the single complex relation

$$\hat{A}_x^{m,c} + i\hat{A}_y^{m,c} = (i/2)(x+iy)^{m+1}\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,c}^{[2\ell+1]}(z)(x^2+y^2)^\ell. \tag{15.5.111}$$

Also verify that the two real relations (5.92) and (5.93) can be combined to produce the single complex relation

$$\hat{A}_x^{m,s} + i\hat{A}_y^{m,s} = (1/2)(x+iy)^{m+1}\sum_{\ell=0}^{\infty}(-1)^\ell \frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,s}^{[2\ell+1]}(z)(x^2+y^2)^\ell. \tag{15.5.112}$$

15.6 Nonuniqueness of Coulomb Gauge

There still remains the question of uniqueness. We will see that there are other Coulomb gauge vector potentials beyond the symmetric one already found.

15.6.1 The General Case

Suppose $\lambda(x, y, z)$ is any *harmonic* function,

$$\nabla^2 \lambda = 0. \tag{15.6.1}$$

If we add $\nabla\lambda$ to $\hat{\boldsymbol{A}}$ to produce a vector potential $\tilde{\boldsymbol{A}}$, it is easily verified that the result

$$\tilde{\boldsymbol{A}} = \hat{\boldsymbol{A}} + \nabla\lambda \tag{15.6.2}$$

also satisfies the desired relations

$$\nabla \times \tilde{\boldsymbol{A}} = \boldsymbol{B} \tag{15.6.3}$$

and

$$\nabla \cdot \tilde{\boldsymbol{A}} = 0. \tag{15.6.4}$$

Conversely, if we require that the Ansatz (6.2) also yield a vector potential in the Coulomb gauge, then λ must be harmonic.

We next observe that, by construction, $\hat{\boldsymbol{A}}$ falls to zero as $|z| \to \infty$ so that we should require the same of λ in order for $\tilde{\boldsymbol{A}}$ to have the same asymptotic behavior.[9] Thanks to the work already done, it easy to describe all λ satisfying (6.1) that have this property. Namely, by repeating the arguments leading to the representation of ψ in terms of generalized gradients, we may write

$$\lambda = \sum_{m=0}^{\infty} \Lambda_{m,c}(\rho, z) \cos m\phi + \sum_{m=1}^{\infty} \Lambda_{m,s}(\rho, z) \sin m\phi \tag{15.6.5}$$

and set

$$\Lambda_{m,\alpha}(\rho, z) = \sum_{\ell=0}^{\infty} (-1)^{\ell} \frac{m!}{2^{2\ell} \ell! (\ell + m)!} L_{m,\alpha}^{[2\ell]}(z) \rho^{2\ell+m}. \tag{15.6.6}$$

Here the functions $L_{m,\alpha}^{[0]}(z)$ may be specified at will save for the condition that they fall to zero for large $|z|$.

We know that $\hat{A}_x$ and $\hat{A}_y$ are harmonic functions because we may write

$$\hat{A}_x = \sum_{m=0}^{\infty} \hat{A}_x^{m,c} + \sum_{m=1}^{\infty} \hat{A}_x^{m,s}, \text{ etc.} \tag{15.6.7}$$

and we have already seen that each term in the above sums is harmonic. It is a remarkable fact that if $\sigma(x, y, z)$ is a harmonic function that falls off for large $|z|$ and thus can be written in a form analogous to (6.5), then there is another harmonic function λ with the same properties such that

$$\partial_y \lambda = \sigma. \tag{15.6.8}$$

[9] As stated earlier, This asymptotic behavior is desirable in order that the canonical and mechanical momenta be asymptotically the same. See (1.5.30). If we are working with z as the independent variable, in which case p_z is not a dynamical variable and does not appear in the Hamiltonian, we will at least want the x and y components of $\tilde{\boldsymbol{A}}$ to vanish for large $|z|$.

Or, if one prefers, there is a λ' such that

$$\partial_x \lambda' = \sigma. \tag{15.6.9}$$

See Appendix H. Let us apply this result, for example, to the case

$$\sigma = -\hat{A}_y \tag{15.6.10}$$

and then use λ to make the gauge transformation (6.2). Doing so, we find the results

$$\tilde{A}_x = \hat{A}_x + \partial_x \lambda, \tag{15.6.11}$$

$$\tilde{A}_y = \hat{A}_y + \partial_y \lambda = \hat{A}_y + \sigma = 0, \tag{15.6.12}$$

$$\tilde{A}_z = \hat{A}_z + \partial_z \lambda. \tag{15.6.13}$$

That is, we have found a gauge which is both Coulomb and for which the y component of the vector potential is zero. We call this the *vertical-free* Coulomb gauge. Similarly, by using λ', one can find a *horizontal-free* Coulomb gauge for which the x component of the vector potential is zero.

Even a bit more can be accomplished. Suppose $\tilde{\boldsymbol{A}}$ is a vector potential in the vertical-free Coulomb gauge so that $\tilde{A}_y = 0$. Let $\tau(x, z)$ be a harmonic function that depends *only* on x and z. Such a function can be written in the form

$$\begin{aligned}\tau(x,z) &= \sum_{n=0}^{\infty}(-1)^n[1/(2n+1)!]x^{2n+1}O^{[2n]}(z) + \sum_{n=0}^{\infty}(-1)^n[1/(2n)!]x^{2n}E^{[2n]}(z) \\ &= [xO^{[0]}(z) - (1/6)x^3O^{[2]}(z) + (1/120)x^5O^{[4]}(z) + \cdots] \\ &\quad + [E^{[0]}(z) - (1/2)x^2E^{[2]}(z) + (1/24)x^4E^{[4]}(z) + \cdots]\end{aligned} \tag{15.6.14}$$

where $O^{[0]}(z)$ and $E^{[0]}(z)$ are arbitrary functions of z save that they fall off for large $|z|$. See Appendix H. Now use τ to make a further gauge transformation that sends $\tilde{\boldsymbol{A}}$ to $\check{\boldsymbol{A}}$,

$$\check{\boldsymbol{A}} = \tilde{\boldsymbol{A}} + \nabla \tau. \tag{15.6.15}$$

By construction,

$$\partial_y \tau = 0 \tag{15.6.16}$$

so that $\check{\boldsymbol{A}}$ is also vertical free,

$$\check{A}_y = 0. \tag{15.6.17}$$

And for the x and z components of $\check{\boldsymbol{A}}$ we find the results

$$\begin{aligned}\check{A}_x &= \hat{A}_x + [O^{[0]}(z) - (1/2)x^2O^{[2]}(z) + (1/24)x^4O^{[4]}(z) + \cdots] \\ &\quad + [-xE^{[2]}(z) + (1/6)x^3E^{[4]}(z) + \cdots],\end{aligned} \tag{15.6.18}$$

$$\begin{aligned}\check{A}_z &= \hat{A}_z + [xO^{[1]}(z) - (1/6)x^3O^{[3]}(z) + (1/120)x^5O^{[5]}(z) + \cdots] \\ &\quad + [E^{[1]}(z) - (1/2)x^2E^{[3]}(z) + (1/24)x^4E^{[5]}(z) + \cdots].\end{aligned} \tag{15.6.19}$$

Evidently, by a suitable choice of $O^{[0]}(z)$ and $E^{[0]}(z)$, we are able to make some further adjustments to $\check{A}_x$ and $\check{A}_z$ while keeping the gauge Coulomb and vertical free.

15.6.2 Normal Dipole Example

As an example of the further gauge freedom just described, let us consider the case of a normal dipole whose Coulomb-gauge vector potential $\hat{\boldsymbol{A}}^{1,s}$ is given by (5.95) through (5.97). We will first perform a succession of gauge transformations to make the vector potential vertical free while maintaining its Coulomb nature. Then we will adjust its x component.

To begin, use a λ, which we will denote by the symbols λ^3, for which all the $L_{m,\alpha}^{[0]}(z)$ are zero save for $L_{3,c}^{[0]}(z)$. Then, from (6.6), we find through terms of degree six the result

$$\Lambda_{3,c}(\rho,z) = L_{3,c}^{[0]}(z)\rho^3 - (1/16)L_{3,c}^{[2]}(z)\rho^5 + \cdots , \tag{15.6.20}$$

from which it follows, using (6.5), that

$$\begin{aligned} \lambda^3 &= (\cos 3\phi)\Lambda_{3,c}(\rho,z) = (\cos 3\phi)[L_{3,c}^{[0]}(z)\rho^3 - (1/16)L_{3,c}^{[2]}(z)\rho^5 + \cdots] \\ &= (x^3 - 3xy^2)L_{3,c}^{[0]}(z) - (1/16)(x^5 - 2x^3y^2 - 3xy^4)L_{3,c}^{[2]}(z) + \cdots . \end{aligned} \tag{15.6.21}$$

This λ^3 has the gradients

$$(\nabla\lambda^3)_x = 3(x^2 - y^2)L_{3,c}^{[0]}(z) - (1/16)(5x^4 - 6x^2y^2 - 3y^4)L_{3,c}^{[2]}(z) + \cdots , \tag{15.6.22}$$

$$(\nabla\lambda^3)_y = -6xyL_{3,c}^{[0]}(z) + (1/16)(4x^3y + 12xy^3)L_{3,c}^{[2]}(z) + \cdots , \tag{15.6.23}$$

$$(\nabla\lambda^3)_z = (x^3 - 3xy^2)L_{3,c}^{[1]}(z) - (1/16)(x^5 - 2x^3y^2 - 3xy^4)L_{3,c}^{[3]}(z) + \cdots . \tag{15.6.24}$$

Let use employ λ^3 to produce a transformed vector potential $\boldsymbol{A}'$ using the relation

$$\boldsymbol{A}' = \hat{\boldsymbol{A}}^{1,s} + \nabla\lambda^3. \tag{15.6.25}$$

Then, from (5.95) through (5.97) and (6.22) through (6.25), we find the results

$$\begin{aligned} A'_x &= (x^2 - y^2)[(1/4)C_{1,s}^{[1]}(z) + 3L_{3,c}^{[0]}(z)] \\ &- (1/48)(x^4 - y^4)C_{1,s}^{[3]}(z) - (1/16)(5x^4 - 6x^2y^2 - 3y^4)L_{3,c}^{[2]}(z) + \cdots , \end{aligned} \tag{15.6.26}$$

$$\begin{aligned} A'_y &= xy[(1/2)C_{1,s}^{[1]}(z) - 6L_{3,c}^{[0]}(z)] \\ &- (1/24)(x^3y + xy^3)C_{1,s}^{[3]}(z) + (1/16)(4x^3y + 12xy^3)L_{3,c}^{[2]}(z) + \cdots , \end{aligned} \tag{15.6.27}$$

$$\begin{aligned} A'_z &= -xC_{1,s}^{[0]}(z) + (1/8)(x^3 + xy^2)C_{1,s}^{[2]}(z) - (1/192)(x^5 + 2x^3y^2 + xy^4)C_{1,s}^{[4]}(z) \\ &+ (x^3 - 3xy^2)L_{3,c}^{[1]}(z) - (1/16)(x^5 - 2x^3y^2 - 3xy^4)L_{3,c}^{[3]}(z) + \cdots . \end{aligned} \tag{15.6.28}$$

Observe that we can make the leading term of A'_x vanish by setting

$$[(1/4)C_{1,s}^{[1]}(z) + 3L_{3,c}^{[0]}(z)] = 0. \tag{15.6.29}$$

Or, we can make the leading term of A'_y vanish by setting

$$[(1/2)C_{1,s}^{[1]}(z) - 6L_{3,c}^{[0]}(z)] = 0. \tag{15.6.30}$$

Suppose we decide to make the leading term of A'_y vanish. Then we have the relation

$$L_{3,c}^{[0]}(z) = (1/12)C_{1,s}^{[1]}(z), \tag{15.6.31}$$

from which it follows that

$$L_{3,c}^{[1]}(z) = (1/12)C_{1,s}^{[2]}(z), \tag{15.6.32}$$

$$L_{3,c}^{[2]}(z) = (1/12)C_{1,s}^{[3]}(z), \tag{15.6.33}$$

$$L_{3,c}^{[3]}(z) = (1/12)C_{1,s}^{[4]}(z), \text{ etc.} \tag{15.6.34}$$

When this is done, $\boldsymbol{A}'$ takes the form

$$A'_x = (1/2)(x^2 - y^2)C_{1,s}^{[1]}(z) - (1/192)(9x^4 - 6x^2y^2 - 7y^4)C_{1,s}^{[3]}(z) + \cdots , \tag{15.6.35}$$

$$A'_y = -(1/48)(x^3y - xy^3)C_{1,s}^{[3]}(z) + \cdots , \tag{15.6.36}$$

$$A'_z = \; -xC_{1,s}^{[0]}(z) + (1/24)(5x^3 - 3xy^2)C_{1,s}^{[2]}(z) - (1/96)(x^5 - xy^4)C_{1,s}^{[4]}(z) + \cdots . \tag{15.6.37}$$

At this point, as a sanity check on the algebra used to yield (6.35) through (6.37), the reader should verify (through the order of the terms retained) that $\boldsymbol{A}'$ is still Coulombic and its components are still harmonic.

Let us see if we can make the next term in A'_y vanish by performing an additional gauge transformation. Suppose we make a further gauge transformation using a λ, which we will call λ^5, for which all the $L_{m,\alpha}^{[0]}(z)$ are zero save for $L_{5,c}^{[0]}(z)$. Then we find through terms of degree six the result

$$\Lambda_{5,c}(\rho, z) = L_{5,c}^{[0]}(z)\rho^5 + \cdots , \tag{15.6.38}$$

from which it follows that

$$\begin{aligned} \lambda^5 &= (\cos 5\phi)\Lambda_{5,c}(\rho, z) = (\cos 5\phi)[L_{5,c}^{[0]}(z)\rho^5 + \cdots] \\ &= (x^5 - 10x^3y^2 + 5xy^4)L_{5,c}^{[0]}(z) + \cdots . \end{aligned} \tag{15.6.39}$$

This λ has the gradients

$$(\nabla\lambda^5)_x = (5x^4 - 30x^2y^2 + 5y^4)L_{5,c}^{[0]}(z) + \cdots , \tag{15.6.40}$$

$$(\nabla\lambda^5)_y = -20(x^3y - xy^3)L_{5,c}^{[0]}(z) + \cdots , \tag{15.6.41}$$

$$(\nabla\lambda^5)_z = (x^5 - 10x^3y^2 + 5xy^4)L^{[1]}_{5,c}(z). \tag{15.6.42}$$

Correspondingly, we will define a further transformed vector potential $\boldsymbol{A}''$ by writing

$$\boldsymbol{A}'' = \boldsymbol{A}' + \nabla\lambda^5. \tag{15.6.43}$$

Then, using (6.35) through (6.37) and (6.40) through (6.43), $\boldsymbol{A}''$ takes the form

$$\begin{aligned} A''_x &= (1/2)(x^2 - y^2)C^{[1]}_{1,s}(z) - (1/192)(9x^4 - 6x^2y^2 - 7y^4)C^{[3]}_{1,s}(z) \\ &+ (5x^4 - 30x^2y^2 + 5y^4)L^{[0]}_{5,c}(z) + \cdots , \end{aligned} \tag{15.6.44}$$

$$A''_y = -(1/48)(x^3y - xy^3)C^{[3]}_{1,s}(z) - 20(x^3y - xy^3)L^{[0]}_{5,c}(z) + \cdots , \tag{15.6.45}$$

$$\begin{aligned} A''_z &= -xC^{[0]}_{1,s}(z) + (1/24)(5x^3 - 3xy^2)C^{[2]}_{1,s}(z) - (1/96)(x^5 - xy^4)C^{[4]}_{1,s}(z) \\ &+ (x^5 - 10x^3y^2 + 5xy^4)L^{[1]}_{5,c}(z) + \cdots . \end{aligned} \tag{15.6.46}$$

We see that A''_y will vanish through terms of degree four provided $L^{[0]}_{5,c}(z)$ is selected to satisfy the relation

$$L^{[0]}_{5,c}(z) = -(1/960)C^{[3]}_{1,s}(z), \tag{15.6.47}$$

from which it follows that

$$L^{[1]}_{5,c}(z) = -(1/960)C^{[4]}_{1,s}(z), \text{ etc.} \tag{15.6.48}$$

When this condition is met, $\boldsymbol{A}''$ takes the form

$$A''_x = (1/2)(x^2 - y^2)C^{[1]}_{1,s}(z) - (1/96)(5x^4 - 6x^2y^2 - 3y^4)C^{[3]}_{1,s}(z) + \cdots , \tag{15.6.49}$$

$$A''_y = 0 + \cdots , \tag{15.6.50}$$

$$\begin{aligned} A''_z &= -xC^{[0]}_{1,s}(z) + (1/24)(5x^3 - 3xy^2)C^{[2]}_{1,s}(z) \\ &- (1/960)(11x^5 - 10x^3y^2 - 5xy^4)C^{[4]}_{1,s}(z) + \cdots . \end{aligned} \tag{15.6.51}$$

(Here the reader should again perform Coulombic and harmonic sanity checks.) We have achieved, through terms of degree four, a vertical-free Coulomb gauge vector potential for the normal dipole.

There is still the possibility of adjusting the x (and correspondingly the z component) of $\boldsymbol{A}''$ by making yet another gauge transformation using the harmonic function $\tau(x, z)$ given by (6.14). We define a still further transformed vector potential $\boldsymbol{A}'''$ by writing

$$\boldsymbol{A}''' = \boldsymbol{A}'' + \nabla\tau. \tag{15.6.52}$$

So doing gives the result

$$\begin{aligned} A_x''' &= O^{[0]}(z) - xE^{[2]}(z) + (1/2)(x^2-y^2)C^{[1]}_{1,s}(z) - (1/2)x^2O^{[2]}(z) \\ &+ (1/6)x^3E^{[4]}(z) - (1/96)(5x^4-6x^2y^2-3y^4)C^{[3]}_{1,s}(z) + (1/24)x^4O^{[4]}(z) + \cdots , \end{aligned} \tag{15.6.53}$$

$$A_y''' = 0 + \cdots , \tag{15.6.54}$$

$$\begin{aligned} A_z''' &= E^{[1]}(z) - xC^{[0]}_{1,s}(z) + xO^{[1]}(z) - (1/2)x^2E^{[3]}(z) \\ &+ (1/24)(5x^3-3xy^2)C^{[2]}_{1,s}(z) - (1/6)x^3O^{[3]}(z) + (1/24)x^4E^{[5]}(z) \\ &- (1/960)(11x^5-10x^3y^2-5xy^4)C^{[4]}_{1,s}(z) + (1/120)x^5O^{[5]}(z) + \cdots . \end{aligned} \tag{15.6.55}$$

Here the functions $O^{[0]}(z)$ and $E^{[1]}(z)$ are arbitrary except that they must vanish as $|z| \to \infty$.

Exercises

15.6.1. Verify that the vector potential $\boldsymbol{A}''$ given by (6.49) through (6.51) yields the magnetic field $\boldsymbol{B}$ given by (3.58) through (3.60), and is Coulombic and harmonic.

15.6.2. Review Exercise 4.4 and, in particular, the vector potential given by (4.58) through (4.60). Show that this vector potential is in neither the azimuthal-free nor the Coulomb gauge. Let χ be the function

$$\begin{aligned} \chi(x,z) &= -\sum_{n=1}^{\infty}(-1)^n[1/(2n+1)!]x^{2n+1}O^{[2n-1]}(z) \\ &= (1/6)x^3O^{[1]}(z) - (1/120)x^5O^{[3]}(z) + \cdots . \end{aligned} \tag{15.6.56}$$

Define a vector potential $\hat{\boldsymbol{A}}^{\rm iwd}$ by the making the gauge transformation

$$\hat{\boldsymbol{A}}^{\rm iwd} = \boldsymbol{A}^{\rm iwd} + \nabla\chi. \tag{15.6.57}$$

Show that

$$\begin{aligned} \hat{A}_x^{\rm iwd} &= \sum_{n=1}^{\infty}(-1)^n[1/(2n)!]y^{2n}O^{[2n-1]}(z) - \sum_{n=1}^{\infty}(-1)^n[1/(2n)!]x^{2n}O^{[2n-1]}(z) \\ &= -(1/2)(y^2-x^2)O^{[1]}(z) + (1/24)(y^4-x^4)O^{[3]}(z) + \cdots , \end{aligned} \tag{15.6.58}$$

$$\hat{A}_y^{\rm iwd} = 0, \tag{15.6.59}$$

$$\begin{aligned} \hat{A}_z^{\rm iwd} &= -\sum_{n=0}^{\infty}(-1)^n[1/(2n+1)!]x^{2n+1}O^{[2n]}(z) \\ &= -xO^{[0]}(z) + (1/6)x^3O^{[2]}(z) - (1/120)x^5O^{[4]}(z) + \cdots . \end{aligned} \tag{15.6.60}$$

Thus, the vector potential $\hat{\boldsymbol{A}}^{\rm iwd}$ is vertical free. Show that $\hat{\boldsymbol{A}}^{\rm iwd}$ is also in the Coulomb gauge, and that all its Cartesian components are harmonic functions.

Equations (6.49) through (6.51) give the vector potential in the vertical-free Coulomb gauge corresponding to the $C_{1,s}^{[n]}$. Change notation to call this result $\bar{\boldsymbol{A}}^{1,s}$,

$$\bar{A}_x^{1,s} = (1/2)(x^2 - y^2)C_{1,s}^{[1]}(z) - (1/96)(5x^4 - 6x^2y^2 - 3y^4)C_{1,s}^{[3]}(z) + \cdots , \tag{15.6.61}$$

$$\bar{A}_y^{1,s} = 0 + \cdots , \tag{15.6.62}$$

$$\begin{aligned}\bar{A}_z^{1,s} &= -xC_{1,s}^{[0]}(z) + (1/24)(5x^3 - 3xy^2)C_{1,s}^{[2]}(z) \\ &- (1/960)(11x^5 - 10x^3y^2 - 5xy^4)C_{1,s}^{[4]}(z) + \cdots .\end{aligned} \tag{15.6.63}$$

Show, by analogous calculations, that the vector potential in the vertical-free Coulomb gauge corresponding to the $C_{3,s}^{[n]}$ is given by the relations

$$\bar{A}_x^{3,s} = (1/4)(x^4 - 6x^2y^2 + y^4)C_{3,s}^{[1]}(z) + \cdots , \tag{15.6.64}$$

$$\bar{A}_y^{3,s} = 0, \tag{15.6.65}$$

$$\bar{A}_z^{3,s} = -(x^3 - 3xy^2)C_{3,s}^{[0]}(z) + (1/80)(7x^5 - 30x^3y^2 - 5xy^4)C_{3,s}^{[2]}(z) + \cdots . \tag{15.6.66}$$

Use these results to find, through terms of degree four, the Coulombic and vertical-free vector potential for the infinite-width dipole, and show that your results agree with (6.58) through (6.60).

Note that again, as was the case for the vector potentials found in Exercise 3.4, that the vector potential is primarily in the z direction.

Study Appendix H.3.3, which finds a Coulombic and horizontal-free vector potential for the infinite-width dipole.

15.6.3. Review Exercise 4.7. Show that, under the same assumptions, (4.66) and (4.67) also hold in the Coulomb gauge.

15.6.4. The relations (5.32) through (5.34) provide expansions for the components of $\hat{\boldsymbol{A}}^0$, the $m = 0$ vector potential in the symmetric Coulomb gauge. Find the first few terms in the expansions for the components of $\tilde{\boldsymbol{A}}^0$, the vector potential for the $m = 0$ case in the vertical-free Coulomb gauge. Recall (6.11) through (6.13).

15.7 Determination of the Vector Potential: Poincaré-Coulomb Gauge

Assuming $m \neq 0$, the relations (4.15) through (4.26) provide, through all orders, formulas for the azimuthal-free gauge vector potential in terms of the on-axis gradients. And, for all values of m, the relations (5.83) through (5.94) provide, again through all orders, formulas for the symmetric Coulomb-gauge vector potential in terms of the on-axis gradients. For general m and through all orders, are there relations that provide formulas for the Poincaré-Coulomb gauge vector potential in terms of the on-axis gradients? The purpose of this section is to explore this question.

At this point it is necessary to be precise about what we wish to accomplish. Recall the vectors $\boldsymbol{R}$, $\boldsymbol{R}_0$, and $\boldsymbol{r}$ introduced in Subsection 2.1 by writing (2.3). Since the axis of any of the straight beam-line elements we are considering is supposed to lie along the z axis, we stipulate that $\boldsymbol{R}_0$ be of the form

$$\boldsymbol{R}_0 = (0, 0, Z_0). \tag{15.7.1}$$

Correspondingly, $\boldsymbol{R}$ then takes the form

$$\boldsymbol{R} = (x, y, Z_0 + z) \tag{15.7.2}$$

where x and y are assumed to be small, and z may or may not also be small depending on the choice of Z_0.

Let $\hat{\boldsymbol{A}}^{m,\alpha}$ be the symmetric Coulomb gauge vector potential of Section 5. In view of (7.2) we may write

$$\hat{\boldsymbol{A}}^{m,\alpha}(\boldsymbol{R}) = \hat{\boldsymbol{A}}^{m,\alpha}(x, y, Z_0 + z). \tag{15.7.3}$$

Assuming it exists, let us introduce the symbols ${}^P\!\boldsymbol{A}^{m,\alpha}(x, y, z; Z_0)$ to denote the Poincaré-Coulomb gauge counterpart to the vector potential $\hat{\boldsymbol{A}}^{m,\alpha}$. Since we require that these vector potentials produce the same magnetic field,

$$\nabla \times \hat{\boldsymbol{A}}^{m,\alpha}(x, y, Z_0 + z) = \nabla \times \ {}^P\!\boldsymbol{A}^{m,\alpha}(x, y, z; Z_0), \tag{15.7.4}$$

they must be related by a gauge transformation of the form

$${}^P\!\boldsymbol{A}^{m,\alpha}(x, y, z; Z_0) = \hat{\boldsymbol{A}}^{m,\alpha}(x, y, Z_0 + z) + \nabla \hat{\chi}^P_{m,\alpha} \tag{15.7.5}$$

described by the gauge function $\hat{\chi}^P_{m,\alpha}(x, y, z; Z_0)$. Here

$$\nabla = (\partial/\partial x, \partial/\partial y, \partial/\partial z), \tag{15.7.6}$$

and

$$\nabla \hat{\chi}^P_{m,\alpha} = \nabla \hat{\chi}^P_{m,\alpha}(x, y, z; Z_0). \tag{15.7.7}$$

Since both ${}^P\!\boldsymbol{A}^{m,\alpha}$ and $\hat{\boldsymbol{A}}^{m,\alpha}$ are supposed to be in the Coulomb gauge, i.e. divergence free, we see from (7.5) that the function $\hat{\chi}^P_{m,\alpha}$ must be harmonic,

$$\nabla^2 \hat{\chi}^P_{m,\alpha}(x, y, z; Z_0) = 0. \tag{15.7.8}$$

Finally if ${}^P\!\boldsymbol{A}^{m,\alpha}$ is to be in the Poincaré-Coulomb gauge, then from (7.5) we see that $\hat{\chi}^P_{m,\alpha}$ must satisfy the further condition

$$\boldsymbol{r} \cdot \nabla \hat{\chi}^P_{m,\alpha} = -\boldsymbol{r} \cdot \hat{\boldsymbol{A}}^{m,\alpha}. \tag{15.7.9}$$

Our task now is to find the functions $\hat{\chi}^P_{m,\alpha}(x, y, z; Z_0)$ in terms of the on-axis gradients.

15.7.1 The $m = 0$ Case

Observe that the $m = 0$ symmetric Coulomb gauge vector potential $\hat{\boldsymbol{A}}^0$ given by (5.37) through (5.39) has only a ϕ component. It follows, from the fact that the $\boldsymbol{e}_\rho$, $\boldsymbol{e}_\phi$, $\boldsymbol{e}_z$ form an orthonormal triad and (2.20), that there is the relation

$$\boldsymbol{r} \cdot \hat{\boldsymbol{A}}^0(\boldsymbol{R}) = 0. \tag{15.7.10}$$

Alternatively, this same relation follows from (5.32) through (5.34) and (2.5). Either way, we conclude that $\hat{\boldsymbol{A}}^0$, when evaluated with respect to any origin on the z axis, is in the Poincaré-Coulomb gauge.

Also, $\hat{\boldsymbol{A}}^0$ can be expressed in terms of on-axis gradients. Indeed, in terms of the variables employed in this section, the relations (5.32) through (5.34) and (5.36) take the form

$$\begin{aligned} \hat{A}^0_x(x, y, Z_0 + z) &= -(y/2)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{1}{2^{2\ell}\ell!(\ell+1)!} C_0^{[2\ell+1]}(Z_0 + z)(x^2 + y^2)^\ell \\ &= -(y/2)[C_0^{[1]}(Z_0 + z) - (1/8)C_0^{[3]}(Z_0 + z)(x^2 + y^2) + \cdots], \end{aligned} \tag{15.7.11}$$

$$\begin{aligned} \hat{A}^0_y(x, y, Z_0 + z) &= (x/2)\sum_{\ell=0}^{\infty}(-1)^\ell \frac{1}{2^{2\ell}\ell!(\ell+1)!} C_0^{[2\ell+1]}(Z_0 + z)(x^2 + y^2)^\ell \\ &= (x/2)[C_0^{[1]}(Z_0 + z) - (1/8)C_0^{[3]}(Z_0 + z)(x^2 + y^2) + \cdots], \end{aligned} \tag{15.7.12}$$

$$\hat{A}^0_z(x, y, Z_0 + z) = 0, \tag{15.7.13}$$

where

$$C_0^{[1]}(Z_0 + z) = B_z(0, 0, Z_0 + z). \tag{15.7.14}$$

15.7.2 The $m \geq 1$ Cases

We have seen that for the case $m = 0$ the symmetric Coulomb gauge vector potential $\hat{\boldsymbol{A}}^0$ is in the Poincaré-Coulomb gauge. What can be said about the cases $m \geq 1$? Can we construct, from the on-axis gradients, a vector potential in the Poincaré-Coulomb gauge for these cases? Here we assume that the expansion point $\boldsymbol{R}_0$ has been selected such that $\boldsymbol{r}$ is small, at least initially. Subsequently we will require that x and y remain small, but may allow z to become large.

In cylindrical coordinates the gradient operator takes the form

$$\nabla = \boldsymbol{e}_\rho(\partial/\partial\rho) + \boldsymbol{e}_\phi(1/\rho)(\partial/\partial\phi) + \boldsymbol{e}_z(\partial/\partial z). \tag{15.7.15}$$

It follows from (2.20) and (7.15) that

$$\boldsymbol{r} \cdot \nabla = \rho(\partial/\partial\rho) + z(\partial/\partial z). \tag{15.7.16}$$

Also, we conclude from (2.20) and (2.21) that

$$\boldsymbol{r} \cdot \hat{\boldsymbol{A}}^{m,\alpha} = \rho \hat{A}_\rho^{m,\alpha} + z\hat{A}_z^{m,\alpha}. \tag{15.7.17}$$

Upon combining (7.9), (7.16), and (7.17) we see that $\hat{\chi}_{m,\alpha}^P$ must satisfy the equation

$$[\rho(\partial/\partial\rho) + z(\partial/\partial z)]\hat{\chi}_{m,\alpha}^P = -(\rho\hat{A}_\rho^{m,\alpha} + z\hat{A}_z^{m,\alpha}). \tag{15.7.18}$$

Since the $\hat{\chi}_{m,\alpha}^P$ are known to be harmonic, and in view of (3.33), let us make the Ansätze

$$\hat{\chi}_{m,c}^P(x, y, z; Z_0) = -\sin(m\phi)\sum_{k=0}^{\infty}(-1)^k\frac{m!}{2^{2k}k!(k+m)!}D_{m,c}^{[2k]}(z; Z_0)\rho^{2k+m}, \tag{15.7.19}$$

$$\hat{\chi}_{m,s}^P(x, y, z; Z_0) = \cos(m\phi)\sum_{k=0}^{\infty}(-1)^k\frac{m!}{2^{2k}k!(k+m)!}D_{m,s}^{[2k]}(z; Z_0)\rho^{2k+m}, \tag{15.7.20}$$

where the functions $D_{m,\alpha}^{[0]}(z; Z_0)$ are yet to be determined. [Note that these D functions are not to be confused with those appearing in (5.53).] Recall that in Subsection 15.4.2 we found the Coulomb gauge results

$$\hat{A}_\rho^{m,c} = -(1/2)(\sin m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,c}^{[2\ell+1]}(Z_0+z)\rho^{2\ell+m+1}, \tag{15.7.21}$$

$$\hat{A}_z^{m,c} = (\sin m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,c}^{[2\ell]}(Z_0+z)\rho^{2\ell+m}; \tag{15.7.22}$$

$$\hat{A}_\rho^{m,s} = (1/2)(\cos m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,s}^{[2\ell+1]}(Z_0+z)\rho^{2\ell+m+1}, \tag{15.7.23}$$

$$\hat{A}_z^{m,s} = -(\cos m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,s}^{[2\ell]}(Z_0+z)\rho^{2\ell+m}. \tag{15.7.24}$$

[Here we have again employed the variables of this section in writing (7.21) through (7.24).] We observe that the operator appearing on the left side of (7.18) does not involve the variable ϕ. Therefore, we may cancel like trigonometric factors appearing on the right and left sides of (7.18) to find, in the case $\alpha = c$, the requirement

$$\begin{aligned}&[\rho(\partial/\partial\rho) + z(\partial/\partial z)][\sum_{k=0}^{\infty}(-1)^k\frac{m!}{2^{2k}k!(k+m)!}D_{m,c}^{[2k]}(z; Z_0)\rho^{2k+m}] = \\ &-(\rho/2)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,c}^{[2\ell+1]}(Z_0+z)\rho^{2\ell+m+1} \\ &+z\sum_{\ell=0}^{\infty}(-1)^\ell\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,c}^{[2\ell]}(Z_0+z)\rho^{2\ell+m};\end{aligned} \tag{15.7.25}$$

and, in the case $\alpha = s$, the requirement

$$[\rho(\partial/\partial\rho) + z(\partial/\partial z)][\sum_{k=0}^{\infty}(-1)^k \frac{m!}{2^{2k}k!(k+m)!} D_{m,s}^{[2k]}(z;Z_0)\rho^{2k+m}] =$$
$$-(\rho/2)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m+1)!}C_{m,s}^{[2\ell+1]}(Z_0+z)\rho^{2\ell+m+1}$$
$$+z\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,s}^{[2\ell]}(Z_0+z)\rho^{2\ell+m}. \tag{15.7.26}$$

Note the pleasant fact that the requirements (7.25) and (7.26) are identical in form. The operator on the left sides of (7.25) and (7.26) may be moved under the summation sign and allowed to work its will. For example, there is the general result

$$[\rho(\partial/\partial\rho) + z(\partial/\partial z)][D_{m,\alpha}^{[2k]}(z;Z_0)\rho^{2k+m}] = [(2k+m)D_{m,\alpha}^{[2k]}(z;Z_0) + zD_{m,\alpha}^{[2k+1]}(z;Z_0)]\rho^{2k+m}. \tag{15.7.27}$$

Also, the indicated multiplications on the right sides of (7.25) and (7.26) can be carried out. The net result of these two manipulations is the requirement

$$\sum_{k=0}^{\infty}[(-1)^k\frac{m!}{2^{2k}k!(k+m)!}][(2k+m)D_{m,\alpha}^{[2k]}(z;Z_0) + zD_{m,\alpha}^{[2k+1]}(z;Z_0)]\rho^{2k+m} =$$
$$\sum_{\ell=0}^{\infty}(-1)^{\ell+1}\frac{m!}{2^{2\ell+1}\ell!(\ell+m+1)!}C_{m,\alpha}^{[2\ell+1]}(Z_0+z)\rho^{2\ell+m+2}$$
$$+\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}zC_{m,\alpha}^{[2\ell]}(Z_0+z)\rho^{2\ell+m}. \tag{15.7.28}$$

Let us equate the coefficients of powers of ρ on both sides of (7.28) to obtain, we hope, relations that will specify the $D_{m,\alpha}^{[2k]}(z;Z_0)$ in terms of the $C_{m,\alpha}^{[2\ell]}(Z_0+z)$. The lowest power of ρ on the left side of (7.28) occurs for $k = 0$, and is ρ^m. Its coefficient is

$$\text{Coefficient of } \rho^m \text{ on left side } = mD_{m,\alpha}^{[0]}(z;Z_0) + zD_{m,\alpha}^{[1]}(z;Z_0). \tag{15.7.29}$$

The lowest power of ρ on the right side of (7.28) occurs for $\ell = 0$, and is also ρ^m. Its coefficient is

$$\text{Coefficient of } \rho^m \text{ on right side } = zC_{m,\alpha}^{[0]}(Z_0+z). \tag{15.7.30}$$

We conclude, so far, that there is the requirement that $D_{m,\alpha}^{[0]}(z;Z_0)$ must satisfy the differential equation

$$zD_{m,\alpha}^{[1]}(z;Z_0) + mD_{m,\alpha}^{[0]}(z;Z_0) = zC_{m,\alpha}^{[0]}(Z_0+z). \tag{15.7.31}$$

We now seek to solve (7.31). Begin by multiplying both sides of (7.31) by z^{m-1} to yield the result

$$z^m D_{m,\alpha}^{[1]}(z;Z_0) + z^{m-1}mD_{m,\alpha}^{[0]}(z;Z_0) = z^m C_{m,\alpha}^{[0]}(Z_0+z). \tag{15.7.32}$$

Observe that

$$z^m D^{[1]}_{m,\alpha}(z;Z_0) + z^{m-1} m D^{[0]}_{m,\alpha}(z;Z_0) = (d/dz)[z^m D^{[0]}_{m,\alpha}(z;Z_0)], \tag{15.7.33}$$

and therefore z^{m-1} is an integrating factor for (7.31). It follows that (7.31) can be rewritten in the form

$$(d/dz)[z^m D^{[0]}_{m,\alpha}(z;Z_0)] = z^m C^{[0]}_{m,\alpha}(Z_0+z) \tag{15.7.34}$$

with the immediate general solution

$$z^m D^{[0]}_{m,\alpha}(z;Z_0) = \text{constant } + \int_0^z dz'\ (z')^m C^{[0]}_{m,\alpha}(Z_0+z'), \tag{15.7.35}$$

or

$$D^{[0]}_{m,\alpha}(z;Z_0) = \text{constant} \times z^{-m} + \int_0^z dz'\ (z'/z)^m C^{[0]}_{m,\alpha}(Z_0+z'). \tag{15.7.36}$$

If we seek a particular solution that is analytic in z, then we must set the constant term to zero. Also, suppose we introduce a new variable of integration λ by writing

$$\lambda = z'/z. \tag{15.7.37}$$

When these steps are made, (7.36) takes the final form

$$D^{[0]}_{m,\alpha}(z;Z_0) = z\int_0^1 d\lambda\ \lambda^m C^{[0]}_{m,\alpha}(Z_0+\lambda z). \tag{15.7.38}$$

We arrived at the requirement (7.31) by equating the coefficients of the lowest power of ρ^m in (7.28). What happens if we equate the coefficients of the higher powers? We hope *nothing* new since $D^{[0]}_{m,\alpha}(z;Z_0)$ is already specified by (7.38). The next highest power of ρ appearing on the left side of (7.28) is ρ^{m+2}, and occurs for $k=1$. Its coefficient is

$$\text{Coefficient of } \rho^{m+2} \text{ on left side } = -[\frac{m!}{4(m+1)!}][(m+2)D^{[2]}_{m,\alpha}(z;Z_0) + zD^{[3]}_{m,\alpha}(z;Z_0)]. \tag{15.7.39}$$

The next highest power of ρ appearing on the right side of (7.28) is also ρ^{m+2}, and occurs for $\ell=0$ in the first term on the right and $\ell=1$ in the second term. Its coefficient is

$$\text{Coefficient of } \rho^{m+2} \text{ on right side } = -[\frac{m!}{2(m+1)!}]C^{[1]}_{m,\alpha}(Z_0+z) - [\frac{m!}{4(m+1)!}]zC^{[2]}_{m,\alpha}(Z_0+z). \tag{15.7.40}$$

Equating these two coefficients yields the result

$$(m+2)D^{[2]}_{m,\alpha}(z;Z_0) + zD^{[3]}_{m,\alpha}(z;Z_0) = 2C^{[1]}_{m,\alpha}(Z_0+z) + zC^{[2]}_{m,\alpha}(Z_0+z). \tag{15.7.41}$$

Is this result new? It is not. Differentiating both sides of the previous result (7.31) yields the relation

$$\partial_z[zD^{[1]}_{m,\alpha}(z;Z_0) + mD^{[0]}_{m,\alpha}(z;Z_0)] = \partial_z[zC^{[0]}_{m,\alpha}(Z_0+z)] \tag{15.7.42}$$

which, upon expansion, yields the result

$$zD^{[2]}_{m,\alpha}(z;Z_0) + (1+m)D^{[1]}_{m,\alpha}(z;Z_0) = zC^{[1]}_{m,\alpha}(Z_0+z) + C^{[0]}_{m,\alpha}(Z_0+z). \tag{15.7.43}$$

Next, differentiating both sides of (7.43) yields the relation

$$\partial_z[zD^{[2]}_{m,\alpha}(z;Z_0) + (1+m)D^{[1]}_{m,\alpha}(z;Z_0)] = \partial_z[zC^{[1]}_{m,\alpha}(Z_0+z) + C^{[0]}_{m,\alpha}(Z_0+z)] \qquad (15.7.44)$$

which, upon expansion, yields the result

$$zD^{[3]}_{m,\alpha}(z;Z_0) + (2+m)D^{[2]}_{m,\alpha}(z;Z_0)] = zC^{[2]}_{m,\alpha}(Z_0+z) + 2C^{[1]}_{m,\alpha}(Z_0+z)]. \qquad (15.7.45)$$

We see that this result agrees with (7.41). Further calculation shows that all the results obtained by equating the coefficients of like powers of ρ on both sides of (7.28) are consistent with the relation (7.31) and are identical to results that flow from it upon differentiation.

In summary, the $\hat{\chi}^P_{m,\alpha}$ are specified by (7.19) and (7.20) in terms of the $D^{[0]}_{m,\alpha}(z;Z_0)$, and the $D^{[0]}_{m,\alpha}(z;Z_0)$ are specified by (7.38) in terms of the $C^{[0]}_{m,\alpha}(Z_0+z)$. What remains, according to (7.5), is to compute $\nabla\hat{\chi}^P_{m,\alpha}$. Introduce the notation

$$\Delta\boldsymbol{A}^{m,\alpha} = {}^P\!\boldsymbol{A}^{m,\alpha} - \hat{\boldsymbol{A}}^{m,\alpha} = \nabla\hat{\chi}^P_{m,\alpha}. \qquad (15.7.46)$$

Then, from (7.15), (7.19), and (7.20), we have the relations

$$\Delta A^{m,c}_\rho = (\partial/\partial\rho)\hat{\chi}^P_{m,c} = -\sin(m\phi)\sum_{k=0}^\infty(-1)^k\frac{m!(2k+m)}{2^{2k}k!(k+m)!}D^{[2k]}_{m,c}(z;Z_0)\rho^{2k+m-1}, \qquad (15.7.47)$$

$$\Delta A^{m,c}_\phi = (1/\rho)(\partial/\partial\phi)\hat{\chi}^P_{m,c} = -m\cos(m\phi)\sum_{k=0}^\infty(-1)^k\frac{m!}{2^{2k}k!(k+m)!}D^{[2k]}_{m,c}(z;Z_0)\rho^{2k+m-1}, \qquad (15.7.48)$$

$$\Delta A^{m,c}_z = (\partial/\partial z)\hat{\chi}^P_{m,c} = -\sin(m\phi)\sum_{k=0}^\infty(-1)^k\frac{m!}{2^{2k}k!(k+m)!}D^{[2k+1]}_{m,c}(z;Z_0)\rho^{2k+m}; \qquad (15.7.49)$$

$$\Delta A^{m,s}_\rho = (\partial/\partial\rho)\hat{\chi}^P_{m,s} = \cos(m\phi)\sum_{k=0}^\infty(-1)^k\frac{m!(2k+m)}{2^{2k}k!(k+m)!}D^{[2k]}_{m,s}(z;Z_0)\rho^{2k+m-1}, \qquad (15.7.50)$$

$$\Delta A^{m,s}_\phi = (1/\rho)(\partial/\partial\phi)\hat{\chi}^P_{m,s} = -m\sin(m\phi)\sum_{k=0}^\infty(-1)^k\frac{m!}{2^{2k}k!(k+m)!}D^{[2k]}_{m,s}(z;Z_0)\rho^{2k+m-1}, \qquad (15.7.51)$$

$$\Delta A^{m,s}_z = (\partial/\partial z)\hat{\chi}^P_{m,s} = \cos(m\phi)\sum_{k=0}^\infty(-1)^k\frac{m!}{2^{2k}k!(k+m)!}D^{[2k+1]}_{m,s}(z;Z_0)\rho^{2k+m}. \qquad (15.7.52)$$

These are the results in cylindrical coordinates. Suppose results in Cartesian coordinates are desired. The relations (7.49) and (7.52) are already in Cartesian form. The remaining Cartesian-form results may be found using the relations

$$\Delta A^{m,\alpha}_x = \cos\phi\,\Delta A^{m,\alpha}_\rho - \sin\phi\,\Delta A^{m,\alpha}_\phi, \qquad (15.7.53)$$

$$\Delta A^{m,\alpha}_y = \sin\phi\,\Delta A^{m,\alpha}_\rho + \cos\phi\,\Delta A^{m,\alpha}_\phi. \qquad (15.7.54)$$

Recall (2.24) and (2.25).

There are two other points that require discussion. The first, a matter of consistency, is this: We have found formulas for the $\Delta\boldsymbol{A}^{m,\alpha}$ in the case $m > 0$. What happens when these formulas are evaluated for $m = 0$? From (7.47) through (7.49) we immediately see that

$$\Delta\boldsymbol{A}^{0,c} = 0, \tag{15.7.55}$$

and therefore

$$^{P}\!\boldsymbol{A}^{0,c} = \hat{\boldsymbol{A}}^{0,c}. \tag{15.7.56}$$

This result is consistent with previous results because we know that $\hat{\boldsymbol{A}}^{0,c} = \hat{\boldsymbol{A}}^{0}$ is already in the Poincaré-Coulomb gauge, and this gauge is unique. What about $\Delta\boldsymbol{A}^{0,s}$? From (3.36) we recall that $C^{[0]}_{0,s}(Z_0 + z)$ vanishes, and therefore according to (7.38) all the $D^{[n]}_{0,s}$ vanish. Consequently, according to (7.50) through (7.52), $\Delta\boldsymbol{A}^{0,s}$ also vanishes,

$$\Delta\boldsymbol{A}^{0,s} = 0. \tag{15.7.57}$$

Therefore, in view of (5.96), there is the result

$$^{P}\!\boldsymbol{A}^{0,s} = 0. \tag{15.7.58}$$

The second point has to do with the nature of the relation between the Poincaré-Coulomb vector potential we have found (which we know is unique from the work of Subsection 2.6) and the on-axis gradients. The relations (4.15) through (4.26) and (5.83) through (5.94) provide, at any point z, formulas for the vector potential in the azimuthal-free and Coulomb gauges in terms of the on-axis gradients $C^{[0]}_{m,\alpha}(z)$ and their first few derivatives at the *same* point z. In particular, if expansions in powers of x and y are required only through some finite order (as is the case), then only a finite number of derivatives of the $C^{[0]}_{m,\alpha}(z)$ are required. In this sense, we may say that these vector potentials depend *locally* on the $C^{[0]}_{m,\alpha}(z)$. By contrast, according to (7.38), it appears that computation of the $D^{[0]}_{m,\alpha}(z; Z_0)$, and therefore of the vector potential in the Poincaré-Coulomb gauge at this value of z, requires a knowledge of the $C^{[0]}_{m,\alpha}(Z_0 + z')$ over the full interval $z' \in [0, z]$. Thus the z dependence of the vector potential in the Poincaré-Coulomb gauge appears to be *nonlocal* in the $C^{[0]}_{m,\alpha}(Z_0 + z')$. This conclusion is correct if z is large, as it may well be. However if z is small, which will be the case in the vicinity of the expansion point $\boldsymbol{R}_0$, and if we are content with a polynomial expansion in powers of z, which is all that is required to find a polynomial expansion of the Poincaré-Coulomb gauge vector potential in the vicinity of $\boldsymbol{R}_0$, then we can do better. By Taylor's/Maclaurin's theorem we may write

$$\begin{aligned} C^{[0]}_{m,\alpha}(Z_0 + \lambda z) \quad = \quad & C^{[0]}_{m,\alpha}(Z_0) + C^{[1]}_{m,\alpha}(Z_0)(\lambda z) + (1/2!)C^{[2]}_{m,\alpha}(Z_0)(\lambda z)^2 \\ & + (1/3!)C^{[3]}_{m,\alpha}(Z_0)(\lambda z)^3 + \cdots . \end{aligned} \tag{15.7.59}$$

It follows from (7.38) that

$$\begin{aligned} D^{[0]}_{m,\alpha}(z; Z_0) \quad = \quad & \{[1/(m+1)]C^{[0]}_{m,\alpha}(Z_0)\}z + \{[1/(m+2)]C^{[1]}_{m,\alpha}(Z_0)\}z^2 \\ + \quad & \{[1/(m+3)](1/2!)C^{[2]}_{m,\alpha}(Z_0)\}z^3 + \{[1/(m+4)](1/3!)C^{[3]}_{m,\alpha}(Z_0)\}z^4 + \cdots . \end{aligned} \tag{15.7.60}$$

Correspondingly we conclude that, in order to obtain a polynomial expansion of the Poincaré-Coulomb gauge vector potential in the vicinity of $\boldsymbol{R}_0$, only a finite number of the $C^{[n]}_{m,\alpha}(Z_0)$ are required.

The fact that the relation between the Poincaré-Coulomb gauge vector potential and the $C^{[0]}_{m,\alpha}(Z_0)$ depends on the expansion point $\boldsymbol{R}_0$ should not be entirely surprising. The defining requirements (4.2) and (5.1) for the azimuthal-free and Coulomb-gauge vector potentials are required to hold for all z, and are thus *z independent.* By contrast, the defining requirement (2.72) for the Poincaré gauge involves $\boldsymbol{r}$, which in turn involves the expansion point.

15.8 Relations Between Gauges and Associated Symplectic Maps

We have found three general vector potentials specified in terms of on-axis gradients, namely the azimuthal free, symmetric Coulomb, and Poincaré-Coulomb gauge vector potentials. The purpose of this section is to find, in terms of on-axis gradients, the gauge transformation functions that interrelate these vector potentials. And, once these gauge transformation functions are known, there are associated symplectic maps given by relations of the form (6.2.79). See Exercises 6.2.8 and 6.5.3. These results will be of subsequent use. See, for example, Subsection 16.1.3.

15.8.1 Transformation Between Azimuthal Free Gauge and Symmetric Coulomb Gauge

The desired results for this subsection have already been found. The azimuthal free gauge and symmetric Coulomb gauge vector potentials are related by the gauge transformations (5.43) employing the gauge functions $\chi_{m,\alpha}$. And the gauge functions $\chi_{m,\alpha}$ are given in terms of on-axis gradients by the relations (5.75) and (5.76).

15.8.2 Transformation Between Symmetric Coulomb Gauge and Poincaré-Coulomb Gauge

The desired results for this subsection have also already been found. The symmetric Coulomb gauge vector potentials and the Poincaré-Coulomb gauge vector potentials are related by the gauge transformations (7.5) employing the gauge functions $\hat{\chi}^P_{m,\alpha}$. In turn, the gauge functions $\hat{\chi}^P_{m,\alpha}$ are given in terms of the functions $D^{[2k]}_{m,\alpha}$ by the relations (7.19) and (7.20). Finally, the functions $D^{[0]}_{m,\alpha}$ are given in terms of the on-axis gradients by the relations (7.38) or, equivalently, (7.60).

15.8.3 Transformation Between Azimuthal Free Gauge and Poincaré-Coulomb Gauge

Suppose (5.43) is added to (7.5). Doing so gives the result

$$ {}^{P}\boldsymbol{A}^{m,\alpha}(x,y,z;Z_0) = \boldsymbol{A}^{m,\alpha}(x,y,Z_0+z) + \nabla\chi_{m,\alpha} + \nabla\hat{\chi}^{P}_{m,\alpha}. \tag{15.8.1}$$

We see that there is the gauge transformation relation

$$ {}^{P}\boldsymbol{A}^{m,\alpha}(x,y,z;Z_0) = \boldsymbol{A}^{m,\alpha}(x,y,Z_0+z) + \nabla\chi^{P}_{m,\alpha} \tag{15.8.2}$$

where $\chi^{P}_{m,\alpha}$ is the gauge function

$$\chi^{P}_{m,\alpha}(x,y,z;Z_0) = \chi_{m,\alpha}(x,y,Z_0+z) + \hat{\chi}^{P}_{m,\alpha}(x,y,z;Z_0). \tag{15.8.3}$$

15.9 Magnetic Monopole Doublet Example

To validate the numerical methods to be presented in Chapters 17 through 20 and Chapters 23 and 24, it will be useful to have a test problem. One such problem is that of the field of a *monopole doublet*. This field has rapid spatial field variations, thereby posing a challenge to numerical methods, and is also exactly computable in analytic form. The monopole-doublet problem will also illustrate the methods of Sections 2 and 3 of this chapter.

15.9.1 Magnetic Scalar Potential and Magnetic Field

Specifically, suppose two magnetic monopoles having strengths $\pm 4\pi g$ are placed at the (x,y,z) locations

$$\boldsymbol{r}^{+} = (0,a,0), \tag{15.9.1}$$

$$\boldsymbol{r}^{-} = (0,-a,0). \tag{15.9.2}$$

See Figure 9.1, which also shows a circular cylinder with radius R (the surface $\rho = R$). These monopoles generate a scalar potential $\psi(x,y,z)$ described by the relation

$$\begin{aligned}\psi(x,y,z) &= -g[x^2+(y-a)^2+z^2]^{-1/2} + g[x^2+(y+a)^2+z^2]^{-1/2} \\ &= \psi^{+}(x,y,z) + \psi^{-}(x,y,z).\end{aligned} \tag{15.9.3}$$

[Here the notation is such that ψ^{+} is singular at $\boldsymbol{r}^{+}$ and ψ^{-} is singular at $\boldsymbol{r}^{-}$. We have also introduced a factor of 4π in the specification of the monopole strengths so that subsequent formulas such as (9.3) will be free of 4π factors.] Correspondingly, they produce a magnetic field $\boldsymbol{B} = \nabla\psi$ having the components

$$B_x = gx[x^2+(y-a)^2+z^2]^{-3/2} - gx[x^2+(y+a)^2+z^2]^{-3/2}, \tag{15.9.4}$$

$$B_y = g(y-a)[x^2+(y-a)^2+z^2]^{-3/2} - g(y+a)[x^2+(y+a)^2+z^2]^{-3/2}, \tag{15.9.5}$$

$$B_z = gz[x^2+(y-a)^2+z^2]^{-3/2} - gz[x^2+(y+a)^2+z^2]^{-3/2}. \tag{15.9.6}$$

This field is sketched in Figure 9.2. To provide further insight, Figure 9.3 shows the on-axis field component $B_y(x = 0, y = 0, z)$, and Figures 9.4 and 9.5 show the off-axis field components $B_x(\rho = 1/2, \phi = \pi/4, z)$ and $B_z(\rho = 1/2, \phi = \pi/4, z)$. In Cartesian coordinates, the field components B_x and B_z are shown along the line $x = y = \sqrt{2}/4$ cm $\simeq$ .353 cm, $z \in [-\infty, \infty]$. Note that the on-axis field component $B_y(x = 0, y = 0, z)$ falls off as $1/|z|^3$ for large $|z|$, as expected for a doublet of opposite strengths.

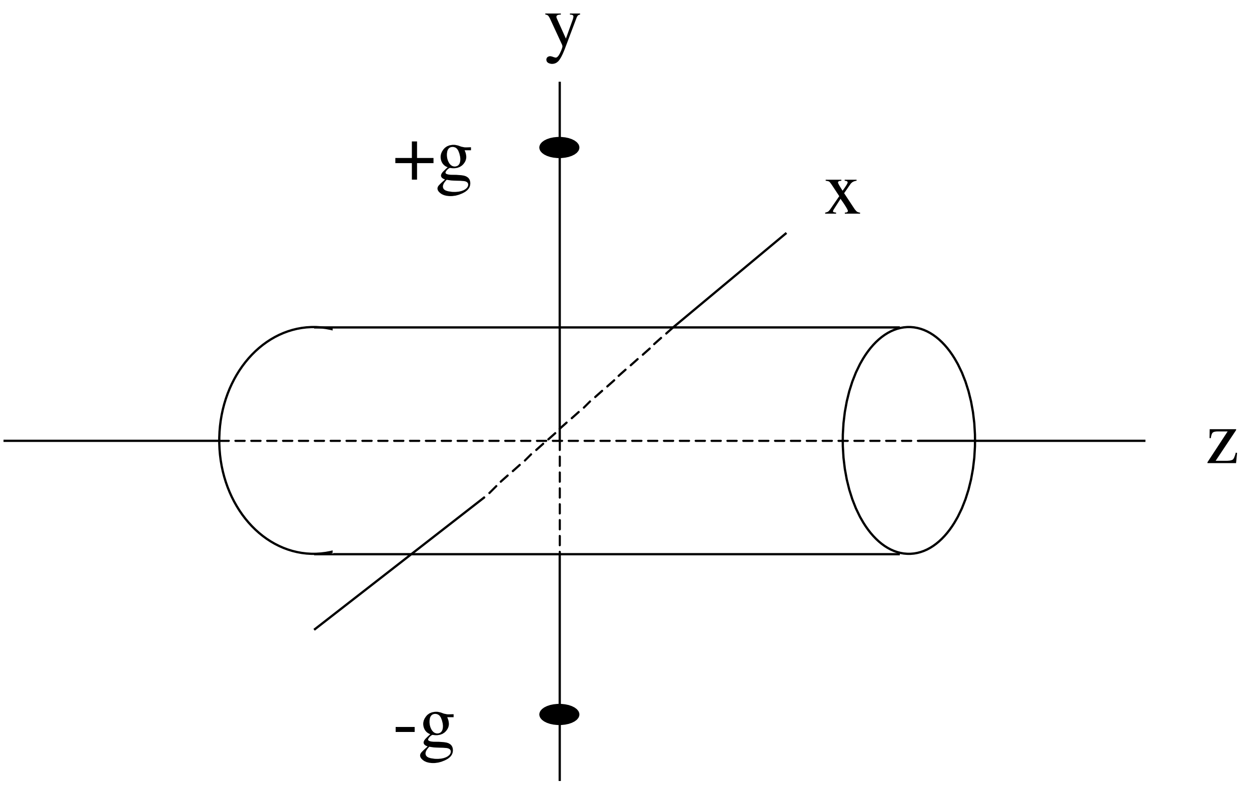

Figure 15.9.1: A monopole doublet consisting of two magnetic monopoles of equal and opposite sign placed on the y axis and centered on the origin. Also shown, for future reference, is a cylinder with circular cross section placed in the interior field.

At this point the reader might object that this field is unphysical since to this time no magnetic monopoles are known to exist. However, as far as an observer inside an interior cylinder of the kind shown in Figure 9.1 is concerned, the field he/she sees is perfectly possible because within the cylinder it obeys $\nabla \cdot \boldsymbol{B} = 0$ and $\nabla \times \boldsymbol{B} = 0$.

The radial component $B_\rho(\rho, \phi, z)$ of $\boldsymbol{B}$ is defined by the relation

$$B_\rho(\rho, \phi, z) = (\cos\phi)B_x + (\sin\phi)B_y. \tag{15.9.7}$$

Recall (2.22). Consequently, using (9.4) and (9.5), we find on the surface $\rho = R$ the result

$$\begin{aligned} B_\rho(R, \phi, z) \;=\;& gR\{[z^2 + R^2 + a^2 - 2aR\sin\phi]^{-3/2} - [z^2 + R^2 + a^2 + 2aR\sin\phi]^{-3/2}\} \\ & -ga\sin\phi\{[z^2 + R^2 + a^2 - 2aR\sin\phi]^{-3/2} + [z^2 + R^2 + a^2 + 2aR\sin\phi]^{-3/2}\}. \end{aligned} \tag{15.9.8}$$

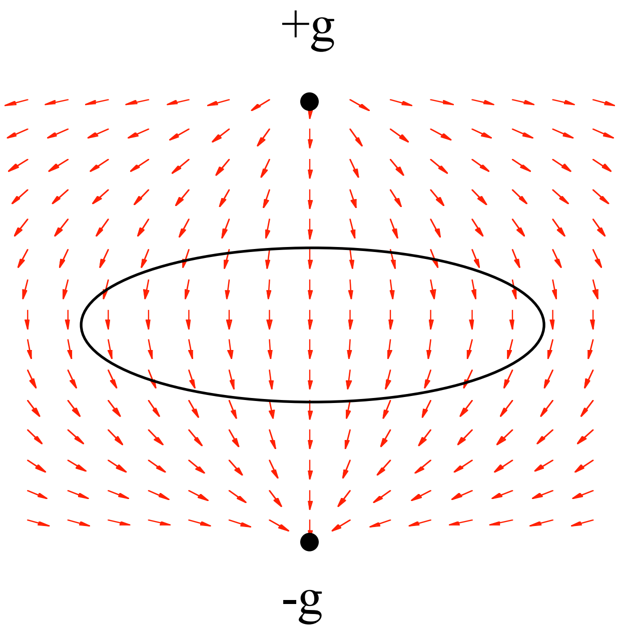

Figure 15.9.2: The interior field of a monopole doublet in the $z = 0$ plane. Also shown is an ellipse whose purpose will become clear in Sections 17.4 and 19.2.

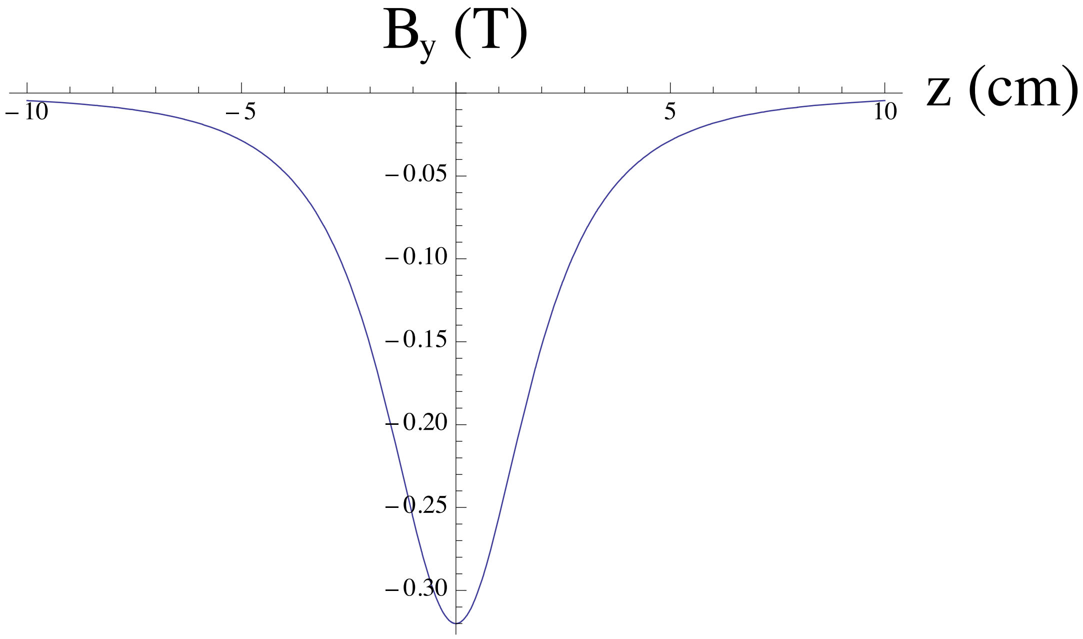

Figure 15.9.3: The on-axis field component $B_y(x = 0, y = 0, z)$ for the monopole doublet in the case that $a = 2.5$ cm and $g = 1$ Tesla-(cm)^2. The coordinate z is given in centimeters.

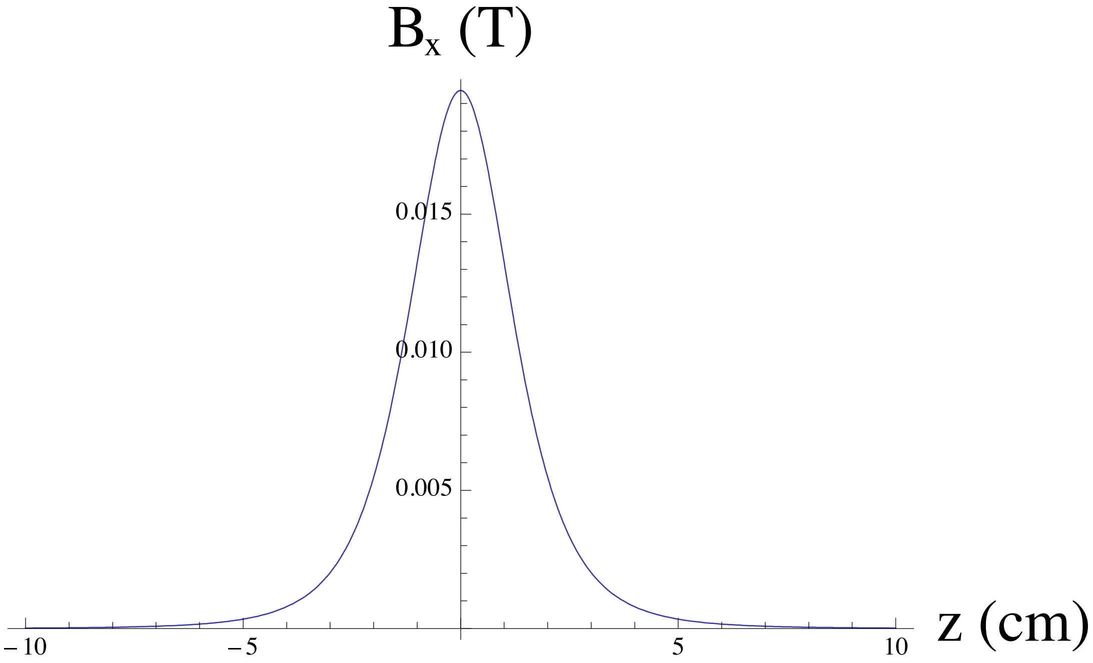

Figure 15.9.4: The field component B_x on the line $\rho = 1/2$ cm, $\phi = \pi/4$, $z \in [-\infty, \infty]$ for the monopole doublet in the case that $a = 2.5$ cm and $g = 1$ Tesla-(cm)^2. In Cartesian coordinates, this is the line $x = y \simeq .353$ cm, $z \in [-\infty, \infty]$. The coordinate z is given in centimeters.

To provide a feel for the behavior of $B_\rho(R, \phi, z)$, Figure 9.6 displays $B_\rho(R = 2, \phi, z = 0)$ as a function of ϕ, and Figure 9.7 shows $B_\rho(R = 2, \phi = \pi/2, z)$ as a function of z. We see that the surface field is rather singular. By contrast the fields shown in Figures 9.3 through 9.5, which are those at locations interior to this surface, are less singular. This is to be expected because harmonic functions take their extrema on boundaries.

15.9.2 Analytic On-Axis Gradients for Monopole Doublet

In this subsection we will find analytic expressions for the on-axis gradients for the monopole doublet. In Chapter 19, numerical results for these gradients will be compared against these analytic results.

In view of the form of the expansion (3.33) for ψ, let us seek power series expansions for $\psi^{\pm}(x, y, z)$ in the variable ρ. In the case of ψ^+, for example, we may write

$$\begin{aligned} \psi^+(x, y, z) &= -g[x^2 + (y - a)^2 + z^2]^{-1/2} = -g[(\rho\cos\phi)^2 + (\rho\sin\phi - a)^2 + z^2]^{-1/2} \\ &= -g[a^2 + z^2 - 2a\rho\sin\phi + \rho^2]^{-1/2} \\ &= -g[a^2 + z^2]^{-1/2}\{1 - [2a\rho/(a^2 + z^2)]\sin\phi + \rho^2/(a^2 + z^2)\} \\ &= -g[a^2 + z^2]^{-1/2}[1 - 2wh + h^2]^{-1/2} \end{aligned} \tag{15.9.9}$$

where

$$h = \rho/(a^2 + z^2)^{1/2} \tag{15.9.10}$$

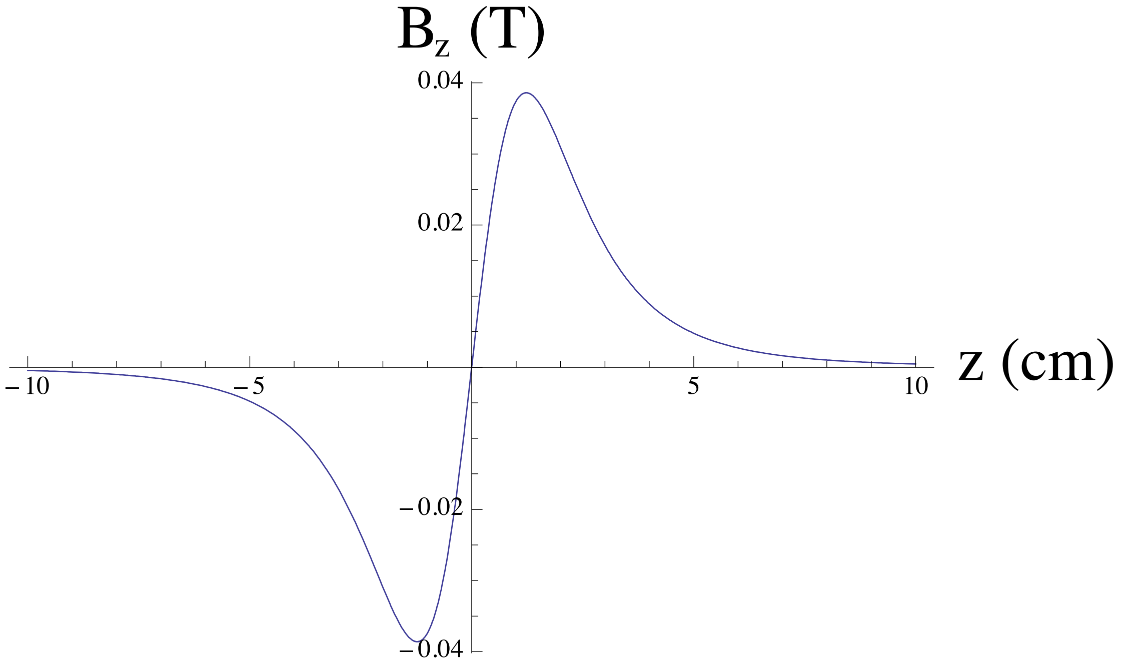

Figure 15.9.5: The field component B_z on the line $\rho = 1/2$ cm, $\phi = \pi/4$, $z \in [-\infty, \infty]$ for the monopole doublet in the case that $a = 2.5$ cm and $g = 1$ Tesla-(cm)^2. In Cartesian coordinates, this is the line $x = y \simeq .353$ cm, $z \in [-\infty, \infty]$. The coordinate z is given in centimeters.

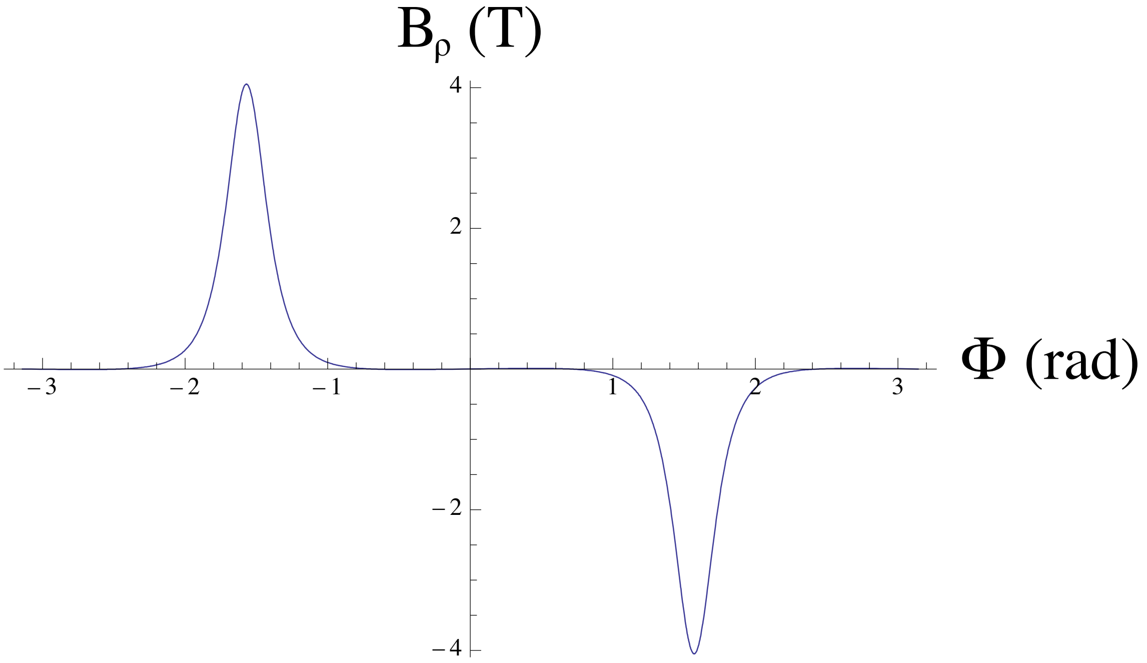

Figure 15.9.6: The quantity $B_\rho(R, \phi, z = 0)$ for the monopole doublet in the case that $R = 2$ cm, $a = 2.5$ cm, and $g = 1$ Tesla-(cm)^2.

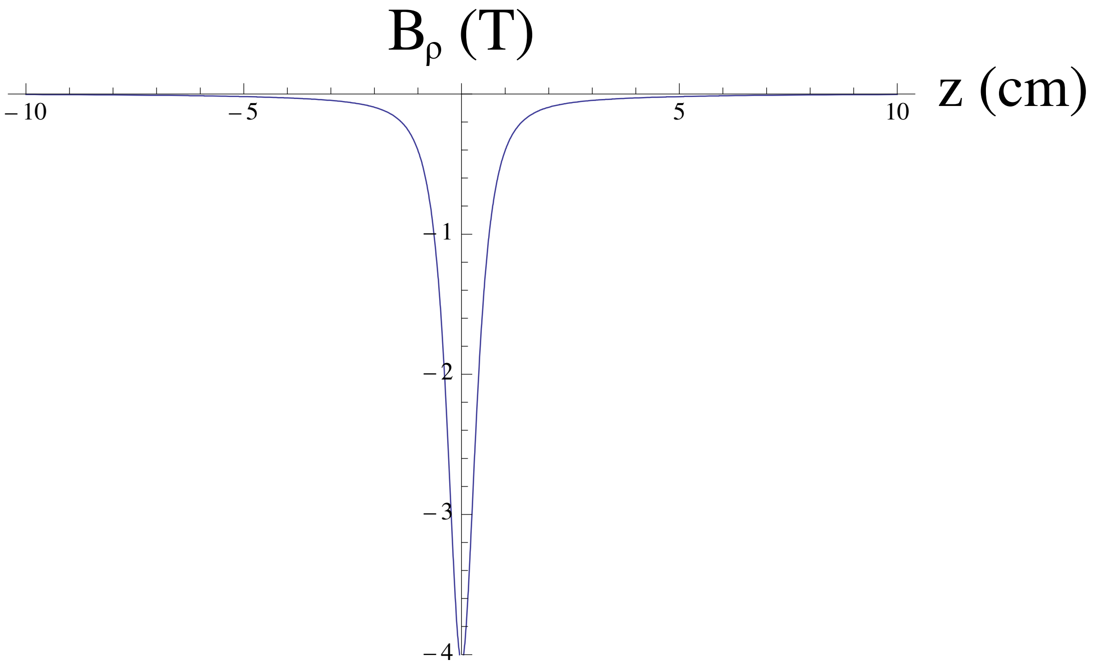

Figure 15.9.7: The quantity $B_\rho(R, \phi = \pi/2, z)$ for the monopole doublet in the case that $R = 2$ cm, $a = 2.5$ cm, and $g = 1$ Tesla-(cm)^2. The coordinate z is given in centimeters.

and

$$w = [a/(a^2 + z^2)^{1/2}] \sin\phi. \tag{15.9.11}$$

Next recall the Legendre polynomial generating function expansion

$$[1 - 2wh + h^2]^{-1/2} = \sum_{m=0}^{\infty} h^m P_m(w). \tag{15.9.12}$$

Combining (9.9) and (9.12) gives the result

$$\begin{aligned}\psi^+(x, y, z) &= -g[x^2 + (y - a)^2 + z^2]^{-1/2} \\ &= -g[a^2 + z^2]^{-1/2} \sum_{m=0}^{\infty} [\rho/(a^2 + z^2)^{1/2}]^m P_m(w).\end{aligned} \tag{15.9.13}$$

Similarly, there is the result

$$\begin{aligned}\psi^-(x, y, z) &= g[x^2 + (y + a)^2 + z^2]^{-1/2} \\ &= g[a^2 + z^2]^{-1/2} \sum_{m=0}^{\infty} [\rho/(a^2 + z^2)^{1/2}]^m P_m(-w).\end{aligned} \tag{15.9.14}$$

It follows, taking into account the parity of the the Legendre polynomials, that ψ has the expansion

$$\psi_(x, y, z) = -2g[a^2 + z^2]^{-1/2} \sum_{n=0}^{\infty} [\rho/(a^2 + z^2)^{1/2}]^{2n+1} P_{2n+1}(w). \tag{15.9.15}$$

From (3.37) through (3.43) we know there are the relations

$$\Psi_0(\rho,z) = [1/(2\pi)]\int_0^{2\pi} d\phi\, \psi(x,y,x), \tag{15.9.16}$$

$$\Psi_{m,c}(\rho,z) = (1/\pi)\int_0^{2\pi} d\phi\, \psi(x,y,x)\cos m\phi, \tag{15.9.17}$$

$$\Psi_{m,s}(\rho,z) = (1/\pi)\int_0^{2\pi} d\phi\, \psi(x,y,x)\sin m\phi. \tag{15.9.18}$$

For the case of the monopole doublet we see from (9.11) and (9.15) that ψ is an odd function of ϕ. Therefore, for the monopole doublet, we conclude that $\Psi_0(\rho,z)=0$ and $\Psi_{m,c}(\rho,z)=0$, and hence

$$C_0^{[0]}(z) = 0,$$
$$C_{m,c}^{[0]}(z) = 0. \tag{15.9.19}$$

And for $\Psi_{m,s}(\rho,z)$ we find the result

$$\Psi_{m,s}(\rho,z) = -(2g/\pi)[a^2+z^2]^{-1/2}\sum_{n=0}^{\infty}[\rho/(a^2+z^2)^{1/2}]^{2n+1}\int_0^{2\pi} d\phi\, P_{2n+1}(w)\sin m\phi. \tag{15.9.20}$$

To analyze the integral that occurs on the right side of (9.20), introduce the notation

$$\beta(z) = a/(a^2+z^2)^{1/2} \tag{15.9.21}$$

so that

$$w = \beta\sin\phi. \tag{15.9.22}$$

With this notation, we must study integrals of the form

$$c_{m',m} = \int_0^{2\pi} d\phi\, P_{m'}(\beta\sin\phi)\sin m\phi \tag{15.9.23}$$

with m' odd.

To begin, we know from the Taylor expansion for the Legendre polynomials that (for odd m')

$$P_{m'}(w) = \{[(2m')!]/[2^{m'}(m'!)^2]\}w^{m'} + \text{lower odd powers of } w. \tag{15.9.24}$$

We also know (again for odd m') that

$$(\sin\phi)^{m'} = (-1)^{(m'-1)/2}(1/2)^{m'-1}\sin m'\phi + \text{lower odd frequency sinusoidal terms.} \tag{15.9.25}$$

It follows that

$$c_{m',m} = 0 \text{ for } m \text{ even}, \tag{15.9.26}$$

$$c_{m',m} = 0 \text{ for } m' < m, \tag{15.9.27}$$

and (with m odd)

$$\begin{aligned} c_{m,m} &= (-1)^{(m-1)/2}\{[(2m)!]/[2^m(m!)^2]\}(1/2)^{m-1}\beta^m\int_0^{2\pi} d\phi\ \sin^2(m\phi) \\ &= (-1)^{(m-1)/2}\pi\{[(2m)!]/[2^{2m-1}(m!)^2]\}\beta^m. \end{aligned} \tag{15.9.28}$$

An immediate conclusion (consistent with symmetry considerations, see Subsection 3.5) is that $\Psi_{m,s}(\rho,z)=0$ for even m, and hence

$$C^{[0]}_{m,s}(z) = 0 \text{ for } m \text{ even}. \tag{15.9.29}$$

Let us insert the results obtained so far into (9.20). Doing so yields the relation

$$\begin{aligned} \Psi_{m,s}(\rho,z) &= -(2g/\pi)[a^2+z^2]^{-1/2}[\rho/(a^2+z^2)^{1/2}]^m c_{m,m} \\ &\quad -(2g/\pi)[a^2+z^2]^{-1/2}\sum_{n>n'}^{\infty}[\rho/(a^2+z^2)^{1/2}]^{2n+1}c_{2n+1,m} \end{aligned} \tag{15.9.30}$$

where (for m odd)

$$2n'+1 = m. \tag{15.9.31}$$

Also, we know from (3.39) that

$$C^{[0]}_{m,s}(z) = \lim_{\rho\to 0}(1/\rho^m)\Psi_{m,s}(\rho,z). \tag{15.9.32}$$

We conclude that (for m odd)

$$\begin{aligned} C^{[0]}_{m,s}(z) &= -(2g/\pi)(a^2+z^2)^{-1/2}(a^2+z^2)^{-m/2}c_{m,m} \\ &= -g(-1)^{(m-1)/2}\{[(2m)!]/[2^{2m-2}(m!)^2a^{m+1}]\}\beta^{2m+1}(z). \end{aligned} \tag{15.9.33}$$

Note that the $C^{[0]}_{m,s}(z)$ have the asymptotic fall off

$$|C^{[0]}_{m,s}(z)| \sim 1/|z|^{2m+1} \tag{15.9.34}$$

for large $|z|$.

Suppose we wish to retain, in the expansion of the Hamiltonian H appearing in (1.3), homogeneous polynomials through degree 8. Then, as we see from (1.4), we must retain homogeneous polynomials in the variables x,y through degree 7 in the expansions of A_x and A_y, and homogeneous polynomials in the variables x,y through degree 8 in the expansion of A_z. Inspection of (4.21) through (4.26) or (5.89) through (5.94) shows that for the cases $m=0$ or m odd we then need the $C^{[n]}_{m,\alpha}(z)$ with $(m+n)\le 7$. And for the cases of even m we need the $C^{[n]}_{m,\alpha}(z)$ with $(m+n)\le 8$. In particular, for the case of the monopole doublet, (for which only the generalized gradients with $\alpha=s$ and m odd are nonzero) we need the following functions:

$$\begin{aligned} &C^{[0]}_{1,s}(z),\ C^{[1]}_{1,s}(z),\ C^{[2]}_{1,s}(z),\ C^{[3]}_{1,s}(z),\ C^{[4]}_{1,s}(z),\ C^{[5]}_{1,s}(z),\ C^{[6]}_{1,s}(z); \\ &C^{[0]}_{3,s}(z),\ C^{[1]}_{3,s}(z),\ C^{[2]}_{3,s}(z),\ C^{[3]}_{3,s}(z),\ C^{[4]}_{3,s}(z); \\ &C^{[0]}_{5,s}(z),\ C^{[1]}_{5,s}(z),\ C^{[2]}_{5,s}(z); \\ &C^{[0]}_{7,s}(z). \end{aligned} \tag{15.9.35}$$

(See Exercise 7.1.) Graphs of a selected few of these functions, for the monopole doublet in the case that $a = 2.5$ cm and $g = 1$ Tesla-(cm)^2, are shown in Figures 9.8 through 9.15. In these plots z has units of centimeters. Evidently the $C_{m,s}^{[0]}$ become ever more highly peaked with increasing m. Fortunately, when working through some fixed degree, we need fewer derivatives with increasing m. Note that we expect that the function $C_{m,s}^{[n]}(z)$ should have n zeroes. This is indeed the case, but some of these zeroes can be hidden in the tails. Figure 9.10 is an enlargement of Figure 9.9 showing a hidden zero for the case of $C_{1,s}^{[6]}(z)$.

Exercises

15.9.1. Explain why Figures 9.3 and 9.8 should be the same.

15.10 Minimum Vector Potential for Magnetic Monopole Doublet

The purpose of this section is to find the first few terms in the expansion of the minimum (Poincaré-Coulomb gauge) vector potential for a magnetic monopole doublet. We will first find the minimum vector potential in terms of the scalar potential and its associated magnetic field using the results of Subsection 2.7. Then we will find the minimum vector potential in terms of the on-axis gradients using the results of Section 7.

In particular, we will be interested in expansions for the fringe-field regions and in the midplane. Suppose the doublet is located at the origin $\boldsymbol{R} = (0, 0, 0)$ as in Subsection 9.1, and we seek an expansion about the mid-plane point $\boldsymbol{R}_0 = (X_0, 0, Z_0)$. If $Z_0 \ll 0$, we will obtain an expansion in the leading fringe-field region, and if $Z_0 \gg 0$, we will obtain an expansion in the trailing fringe-field region. Moreover, if $X_0 = 0$, the expansion will be on axis; and setting $X_0 \neq 0$ allows for expansion about a point on the (curved) design orbit. See Section 23.3 and Figures 23.3.1 and 24.1.1.

15.10.1 Computation from the Scalar Potential and Associated Magnetic Field

We begin by specifying the scalar potential $\Psi(\boldsymbol{R})$. According to (9.3), it is given by the relation

$$\Psi(X,Y,Z) = -g[X^2+(Y-a)^2+Z^2]^{-1/2} + g[X^2+(Y+a)^2+Z^2]^{-1/2}. \qquad (15.10.1)$$

Next, according to (2.4), $\psi(\boldsymbol{r})$ is given by the relation

$$\begin{aligned}\psi(x,y,z) &= \Psi(\boldsymbol{R}_0+\boldsymbol{r})\\ &= -g[(X_0+x)^2+(y-a)^2+(Z_0+z)^2]^{-1/2}\\ &\quad +g[(X_0+x)^2+(y+a)^2+(Z_0+z)^2]^{-1/2}.\end{aligned} \qquad (15.10.2)$$

The right side of (10.2) can now be expanded in powers of the components of $\boldsymbol{r}$. Doing so yields, for the first few terms, the result

$$\begin{aligned}\psi(\boldsymbol{r};X_0,Z_0) &= [-2ga/(X_0^2+Z_0^2+a^2)^{3/2}]y\\ &\quad +[6ga/(X_0^2+Z_0^2+a^2)^{5/2}][y(X_0x+Z_0z)]\\ &\quad + \text{terms of order 3 and higher.}\end{aligned} \qquad (15.10.3)$$

Note that $\Psi(X_0,0,Z_0)$ vanishes so that there is no constant term in the expansion (10.3). We observe that the first term in (10.3) falls off as $(1/|X_0|)^3$ or $(1/|Z_0|)^3$ for large $|X_0|$ or $|Z_0|$, and the second falls off as $(1/|X_0|)^4$ or $(1/|Z_0|)^4$. In general, successive terms fall off with ever increasing powers of $(1/|X_0|)$ or $(1/|Z_0|)$.

Let us compute the magnetic field $\boldsymbol{B}$ associated with the first two terms in (10.3). We find the result

$$\begin{aligned}\boldsymbol{B}(\boldsymbol{r};X_0,Z_0) &= -[2ga/(X_0^2+Z_0^2+a^2)^{3/2}]\boldsymbol{e}_y\\ &\quad +[6ga/(X_0^2+Z_0^2+a^2)^{5/2}](X_0x+Z_0z)\boldsymbol{e}_y\\ &\quad +[6ga/(X_0^2+Z_0^2+a^2)^{5/2}][y(X_0\boldsymbol{e}_x+Z_0\boldsymbol{e}_z)].\end{aligned} \qquad (15.10.4)$$

Next let us find the minimum vector potential $\boldsymbol{A}^{\min}$ associated with the first two terms in (10.3). Begin by decomposing $\boldsymbol{B}$ into homogeneous polynomials by rewriting (10.4) in the form (2.109) with

$$\boldsymbol{B}^0(\boldsymbol{r};X_0,Z_0) = -[2ga/(X_0^2+Z_0^2+a^2)^{3/2}]\boldsymbol{e}_y \qquad (15.10.5)$$

and

$$\boldsymbol{B}^1(\boldsymbol{r};X_0,Z_0) = [6ga/(X_0^2+Z_0^2+a^2)^{5/2}][(X_0x+Z_0z)\boldsymbol{e}_y+y(X_0\boldsymbol{e}_x+Z_0\boldsymbol{e}_z)]. \quad (15.10.6)$$

The minimum vector potential associated with this magnetic field is given by the relations (2.109) through (2.111). Working out the indicated cross products yields the results

$$\boldsymbol{A}^{\min 1}(\boldsymbol{r};X_0,Z_0) = [ga/(X_0^2+Z_0^2+a^2)^{3/2}](-z\boldsymbol{e}_x+x\boldsymbol{e}_z), \qquad (15.10.7)$$

$$\boldsymbol{A}^{\min 2}(\boldsymbol{r}; X_0, Z_0) = [-2ga/(X_0^2 + Z_0^2 + a^2)^{5/2}] \times$$
$$[(Z_0y^2 - Z_0z^2 - X_0xz)\boldsymbol{e}_x + (X_0yz - Z_0xy)\boldsymbol{e}_y + (X_0x^2 + Z_0xz - X_0y^2)\boldsymbol{e}_z]. \tag{15.10.8}$$

Simple calculation verifies that there are the relations

$$\nabla \times \boldsymbol{A}^{\min 1}(\boldsymbol{r}; X_0, Z_0) = \boldsymbol{B}^0(\boldsymbol{r}; X_0, Z_0), \tag{15.10.9}$$

$$\nabla \times \boldsymbol{A}^{\min 2}(\boldsymbol{r}; X_0, Z_0) = \boldsymbol{B}^1(\boldsymbol{r}; X_0, Z_0), \tag{15.10.10}$$

as desired. We note that $\boldsymbol{A}^{\min 1}$ falls off as $(1/|X_0|)^3$ or $(1/|Z_0|)^3$ for large $|X_0|$ or $|Z_0|$, and $\boldsymbol{A}^{\min 2}$ falls off as $(1/|X_0|)^4$ or $(1/|Z_0|)^4$. In general, successive $\boldsymbol{A}^{\min n}$ fall off with ever increasing powers of $(1/|X_0|)$ or $(1/|Z_0|)$.

15.10.2 Computation from the On-Axis Gradients

The $m = 1$ and $\alpha = s$ vector potential in the symmetric Coulomb gauge of Section 5 is given in terms of on-axis gradients by the relation

$$\hat{A}_x^{1,s}(x, y, Z_0+z) = (1/4)(x^2-y^2)C_{1,s}^{[1]}(Z_0+z)-(1/48)(x^4-y^4)C_{1,s}^{[3]}(Z_0+z)+\cdots, \tag{15.10.11}$$

$$\hat{A}_y^{1,s}(x, y, Z_0+z) = (1/2)xyC_{1,s}^{[1]}(Z_0+z) - (1/24)(x^3y+xy^3)C_{1,s}^{[3]}(Z_0+z)+\cdots, \tag{15.10.12}$$

$$\begin{aligned}\hat{A}_z^{1,s}(x, y, Z_0+z) &= -xC_{1,s}^{[0]}(Z_0+z) + (1/8)(x^3+xy^2)C_{1,s}^{[2]}(Z_0+z)\\ &\quad -(1/192)(x^5+2x^3y^2+xy^4)C_{1,s}^{[4]}(Z_0+z)+\cdots.\end{aligned} \tag{15.10.13}$$

See (5.97) through (5.99). If we expand $\hat{\boldsymbol{A}}^{1,s}(x, y, Z_0+z)$ in powers of z, organize the results into homogeneous polynomials, and retain only terms of degree less than 3, we find the results

$$\hat{A}_x^{1,s}(x, y, Z_0+z) = (1/4)(x^2-y^2)C_{1,s}^{[1]}(Z_0)+\cdots, \tag{15.10.14}$$

$$\hat{A}_y^{1,s}(x, y, Z_0+z) = (1/2)xyC_{1,s}^{[1]}(Z_0)+\cdots, \tag{15.10.15}$$

$$\hat{A}_z^{1,s}(x, y, Z_0+z) = -xC_{1,s}^{[0]}(Z_0) - xzC_{1,s}^{[1]}(Z_0)+\cdots. \tag{15.10.16}$$

The gauge function $\hat{\chi}_{1,s}^P$ that relates the Coulomb-gauge vector potential $\hat{\boldsymbol{A}}^{1,s}$ and the Poincaré-Coulomb gauge vector potential ${}^P\!\boldsymbol{A}^{1,s}$ is given by the relation

$$\begin{aligned}\hat{\chi}_{1,s}^P(x, y, z; Z_0) &= \cos(\phi)\sum_{k=0}^{\infty}(-1)^k\frac{1!}{2^{2k}k!(k+1)!}D_{1,s}^{[2k]}(z; Z_0)\rho^{2k+1}\\ &= \rho\cos(\phi)[D_{1,s}^{[0]}(z; Z_0) - (1/8)\rho^2D_{1,s}^{[2]}(z; Z_0) + (*)\rho^4D_{1,s}^{[4]}(z; Z_0)+\cdots]\\ &= x[D_{1,s}^{[0]}(z; Z_0) - (1/8)\rho^2D_{1,s}^{[2]}(z; Z_0) + (*)\rho^4D_{1,s}^{[4]}(z; Z_0)+\cdots].\end{aligned} \tag{15.10.17}$$

See (7.5) and (7.20). We have also found, see (7.60), the relation

$$\begin{aligned} D^{[0]}_{1,s}(z;Z_0) &= \{[1/(1+1)]C^{[0]}_{1,s}(Z_0)\}z + \{[1/(1+2)]C^{[1]}_{1,s}(Z_0)\}z^2 \\ &\quad + \{[1/(1+3)](1/2!)C^{[2]}_{1,s}(0)\}z^3 + \{[1/(1+4)](1/3!)C^{[3]}_{1,s}(Z_0)\}z^4 + \cdots \\ &= (1/2)C^{[0]}_{1,s}(Z_0)z + (1/3)C^{[1]}_{1,s}(Z_0)z^2 + (1/8)C^{[2]}_{1,s}(Z_0)z^3 + (1/30)C^{[3]}_{1,s}(Z_0)z^4 + \cdots , \end{aligned} \tag{15.10.18}$$

from which it follows that

$$D^{[2]}_{1,s}(z;Z_0) = (2/3)C^{[1]}_{1,s}(Z_0) + (3/4)C^{[2]}_{1,s}(Z_0)z + (2/5)C^{[3]}_{1,s}(Z_0)z^2 + \cdots , \tag{15.10.19}$$

$$D^{[4]}_{1,s}(z;Z_0) = (4/5)C^{[3]}_{1,s}(Z_0) + \cdots . \tag{15.10.20}$$

Inserting these results into (10.17) and collecting terms of like degree give the final homogeneous polynomial expansion

$$\begin{aligned} \hat{\chi}^P_{1,s}(x,y,z;Z_0) &= x[(1/2)C^{[0]}_{1,s}(Z_0)z + (1/3)C^{[1]}_{1,s}(Z_0)z^2 + (1/8)C^{[2]}_{1,s}(Z_0)z^3 + \cdots] \\ &\quad - (1/8)x\rho^2[(2/3)C^{[1]}_{1,s}(Z_0) + (3/4)C^{[2]}_{1,s}(Z_0)z + (2/5)C^{[3]}_{1,s}(Z_0)z^2 + \cdots] \\ &\quad + (*)x\rho^4[(4/5)C^{[3]}_{1,s}(Z_0) + \cdots] + \cdots \\ &= \{[xz(1/2)]C^{[0]}_{1,s}(Z_0)\} + \{[xz^2(1/3) - \ (1/8)x\rho^2(2/3)]C^{[1]}_{1,s}(Z_0)\} + \cdots \\ &= \{[(1/2)xz]C^{[0]}_{1,s}(Z_0)\} + \{[(1/3)xz^2 - (1/12)x\rho^2]C^{[1]}_{1,s}(Z_0)\} + \cdots . \end{aligned} \tag{15.10.21}$$

The next step is to compute the $\Delta\boldsymbol{A}^{1,s}$ defined by (7.46). From (10.21) we find the results

$$\begin{aligned} \Delta A^{1,s}_x &= (\partial/\partial x)\hat{\chi}^P_{1,s}(x,y,z;Z_0) \\ &= \{[(1/2)z]C^{[0]}_{1,s}(Z_0)\} + \{[(1/3)z^2 - (1/12)(3x^2+y^2)]C^{[1]}_{1,s}(Z_0)\} + \cdots , \end{aligned} \tag{15.10.22}$$

$$\begin{aligned} \Delta A^{1,s}_y &= (\partial/\partial y)\hat{\chi}^P_{1,s}(x,y,z;Z_0) \\ &= +\{[-(1/6)xy]C^{[1]}_{1,s}(Z_0)\} + \cdots , \end{aligned} \tag{15.10.23}$$

$$\begin{aligned} \Delta A^{1,s}_z &= (\partial/\partial z)\hat{\chi}^P_{1,s}(x,y,z;Z_0) \\ &= \{[(1/2)x]C^{[0]}_{1,s}(Z_0)\} + \{[(2/3)xz]C^{[1]}_{1,s}(Z_0)\} + \cdots . \end{aligned} \tag{15.10.24}$$

Finally, we may obtain ${}^P\!\boldsymbol{A}^{1,s}$ with the aid of (7.46) and (10.14) through (10.16). Doing so gives the results

$$\begin{aligned} {}^P\!A^{1,s}_x(x,y,z;Z_0) &= (1/4)(x^2-y^2)C^{[1]}_{1,s}(Z_0) + \{[(1/2)z]C^{[0]}_{1,s}(Z_0)\} \\ &\quad + \{[(1/3)z^2 - (1/12)(3x^2+y^2)C^{[1]}_{1,s}(Z_0)\} + \cdots \\ &= \{[(1/2)z]C^{[0]}_{1,s}(Z_0)\} + \{[(1/3)z^2 - (1/3)y^2]C^{[1]}_{1,s}(Z_0)\} + \cdots , \end{aligned} \tag{15.10.25}$$

$$\begin{aligned}{}^{P}\!A_y^{1,s}(x,y,z;Z_0) &= (1/2)xyC_{1,s}^{[1]}(Z_0) + \{[-(1/6)xy]C_{1,s}^{[1]}(Z_0)\} + \cdots \\ &= \{[(1/3)xy]C_{1,s}^{[1]}(Z_0)\} + \cdots , \end{aligned} \qquad (15.10.26)$$

$$\begin{aligned}{}^{P}\!A_z^{1,s}(x,y,z;Z_0) &= -xC_{1,s}^{[0]}(Z_0) - xzC_{1,s}^{[1]}(Z_0) + \{[(1/2)x]C_{1,s}^{[0]}(Z_0)\} \\ &\quad + \{[(2/3)xz]C_{1,s}^{[1]}(Z_0)\} \cdots \\ &= \{[-(1/2)x]C_{1,s}^{[0]}(Z_0)\} - \{[(1/3)xz]C_{1,s}^{[1]}(Z_0)\} + \cdots . \end{aligned} \qquad (15.10.27)$$

How do the results (10.25) through (10.27) compare with the results (10.7) and (10.8) found in the previous subsection? Suppose $\boldsymbol{A}^{\min 1}(\boldsymbol{r}; X_0, Z_0)$ and $\boldsymbol{A}^{\min 2}(\boldsymbol{r}; X_0, Z_0)$ as given by (10.7) and (10.8) are evaluated at $X_0 = 0$. So doing gives the results

$$\boldsymbol{A}^{\min 1}(\boldsymbol{r}; X_0, Z_0)|_{X_0=0} = [ga/(a^2 + Z_0^2)^{3/2}](-z\boldsymbol{e}_x + x\boldsymbol{e}_z), \qquad (15.10.28)$$

$$\begin{aligned}\boldsymbol{A}^{\min 2}(\boldsymbol{r}; X_0, Z_0)|_{X_0=0} = [-2ga/(a^2 + Z_0^2)^{5/2}] \times \\ [(Z_0y^2 - Z_0z^2)\boldsymbol{e}_x + (-Z_0xy)\boldsymbol{e}_y + (Z_0xz)\boldsymbol{e}_z].\end{aligned} \qquad (15.10.29)$$

Also, from (8.21) and (8.33), we find the results

$$C_{1,s}^{[0]}(z) = -g\{[2!]/[a^2]\}\beta^3(z) = -2ga/(a^2 + z^2)^{3/2}, \qquad (15.10.30)$$

from which it follows that

$$C_{1,s}^{[0]}(Z_0) = -2ga/(a^2 + Z_0^2)^{3/2}, \qquad (15.10.31)$$

$$C_{1,s}^{[1]}(Z_0) = 6gaZ_0/(a^2 + Z_0^2)^{5/2}. \qquad (15.10.32)$$

Consequently, (10.28) and (10.29) can be rewritten in the form

$$\boldsymbol{A}^{\min 1}(\boldsymbol{r}; X_0, Z_0)|_{X_0=0} = -(1/2)C_{1,s}^{[0]}(Z_0)(-z\boldsymbol{e}_x + x\boldsymbol{e}_z), \qquad (15.10.33)$$

$$\boldsymbol{A}^{\min 2}(\boldsymbol{r}; X_0, Z_0)|_{X_0=0} = (-1/3)C_{1,s}^{[1]}(Z_0)[(y^2 - z^2)\boldsymbol{e}_x + (-xy)\boldsymbol{e}_y + (xz)\boldsymbol{e}_z]. \qquad (15.10.34)$$

Comparison of (10.33) and (10.34) with (10.25) through (10.27) reveals that (10.33) agrees with the first-degree terms in (10.25) through (10.27), and (10.34) agrees with the second-degree terms in (10.25) through (10.27). Therefore the on-axis minimum vector potential expansion computed from the scalar potential and associated magnetic field agrees with the on-axis minimum vector potential expansion computed from the on-axis gradients, as desired and required.

Finally we remind the reader that, although we have been considering the case of a monopole doublet field, the relations (10.11) through (10.13) and (10.21) through (10.27) hold for *any* $m = 1$ and $\alpha = s$ magnetic field no matter what its source. The same is true for the relation

$$C_{1.s}^{[0]}(z) = B_y(0, 0, z). \qquad (15.10.35)$$

Recall (3.59).

15.11 Calculation of Scalar and Vector Potentials from Current Data

The previous sections in this chapter have studied how magnetic fields and vector potentials may be described in terms of terms of scalar potentials and their various expansions. In this section we will explore the relation between vector and scalar potentials and the currents that produce them.

15.11.1 Calculation of Vector Potential from Current Data

15.11.1.1 Preliminary Steps

The vector potential $\boldsymbol{A}$ is a vector field with the property

$$\boldsymbol{B} = \nabla \times \boldsymbol{A} \tag{15.11.1}$$

where $\boldsymbol{B}$ is the underlying magnetic field of physical interest. In the static (no time dependence) case $\boldsymbol{B}$ is given in terms of the current density $\boldsymbol{j}(\boldsymbol{r})$ by the *Biot-Savart* law

$$\boldsymbol{B}(\boldsymbol{r}) = [\mu_0/(4\pi)] \int d^3\boldsymbol{r}'\, \boldsymbol{j}(\boldsymbol{r}') \times \{(\boldsymbol{r}-\boldsymbol{r}')/[||(\boldsymbol{r}-\boldsymbol{r}')||^3]\}. \tag{15.11.2}$$

If we define $\boldsymbol{A}$ by the rule

$$\boldsymbol{A}(\boldsymbol{r}) = [\mu_0/(4\pi)] \int d^3\boldsymbol{r}'\, \boldsymbol{j}(\boldsymbol{r}')\{1/[||(\boldsymbol{r}-\boldsymbol{r}')||]\}, \tag{15.11.3}$$

then direct computation shows that this $\boldsymbol{A}$ satisfies (11.1). Indeed, we find

$$\begin{aligned}\nabla \times \boldsymbol{A} &= -[\mu_0/(4\pi)] \int d^3\boldsymbol{r}'\, \boldsymbol{j}(\boldsymbol{r}') \times \nabla\{1/[||(\boldsymbol{r}-\boldsymbol{r}')||]\} \\ &= -[\mu_0/(4\pi)] \int d^3\boldsymbol{r}'\, \boldsymbol{j}(\boldsymbol{r}') \times \{-(\boldsymbol{r}-\boldsymbol{r}')/[||(\boldsymbol{r}-\boldsymbol{r}')||^3]\} \\ &= \boldsymbol{B}(\boldsymbol{r}).\end{aligned} \tag{15.11.4}$$

We can also verify by direct computation that this $\boldsymbol{A}$ is divergence free,

$$\begin{aligned}\nabla \cdot \boldsymbol{A} &= [\mu_0/(4\pi)] \int d^3\boldsymbol{r}'\, \boldsymbol{j}(\boldsymbol{r}') \cdot \nabla\{1/[||(\boldsymbol{r}-\boldsymbol{r}')||]\} \\ &= [\mu_0/(4\pi)] \int d^3\boldsymbol{r}'\, \boldsymbol{j}(\boldsymbol{r}') \cdot \nabla'\{1/[||(\boldsymbol{r}-\boldsymbol{r}')||]\} \\ &= -[\mu_0/(4\pi)] \int d^3\boldsymbol{r}'\, [\nabla' \cdot \boldsymbol{j}(\boldsymbol{r}')]\{1/[||(\boldsymbol{r}-\boldsymbol{r}')||]\} \\ &= 0.\end{aligned} \tag{15.11.5}$$

Here we have used integration by parts and the current conservation relation

$$\nabla' \cdot \boldsymbol{j}(\boldsymbol{r}') = 0. \tag{15.11.6}$$

See Exercise 11.2. Therefore the vector potential given by (11.3) is in a Coulomb gauge.

From (11.2) it follows that there is (in the static case) the differential relation

$$\nabla \times \boldsymbol{B} = \mu_0 \boldsymbol{j}. \tag{15.11.7}$$

Upon combining (11.1) and (11.7) we see that there is the general result

$$\nabla \times (\nabla \times \boldsymbol{A}) = -\nabla^2 \boldsymbol{A} + \nabla(\nabla \cdot \boldsymbol{A}) = \mu_0 \boldsymbol{j}. \tag{15.11.8}$$

And, when (11.5) is taken into account, we see that for the $\boldsymbol{A}$ given by (11.3) there is the result

$$-\nabla^2 \boldsymbol{A} = \mu_0 \boldsymbol{j}. \tag{15.11.9}$$

In particular, in current-free regions, the Cartesian components of this $\boldsymbol{A}$ are harmonic functions. Recall the discussion at the beginning of Section 5. We note that the result (11.9) can also be found directly from the definition (11.3),

$$\begin{aligned} -\nabla^2 \boldsymbol{A}(\boldsymbol{r}) &= -[\mu_0/(4\pi)] \int d^3\boldsymbol{r}'\, \boldsymbol{j}(\boldsymbol{r}') \nabla^2 \{1/[||(\boldsymbol{r} - \boldsymbol{r}')||]\} \\ &= -[\mu_0/(4\pi)] \int d^3\boldsymbol{r}'\, \boldsymbol{j}(\boldsymbol{r}')(-4\pi)\delta_3(\boldsymbol{r} - \boldsymbol{r}') \\ &= \mu_0 \boldsymbol{j}(\boldsymbol{r}). \end{aligned} \tag{15.11.10}$$

15.11.1.2 Use of Green Function in Cylindrical Coordinates

Suppose we attempt to compute, in cylindrical coordinates, the vector potential $\boldsymbol{A}$ in terms of $\boldsymbol{j}$ with the aid of (11.3). To do so we will need the volume element $d^3\boldsymbol{r}'$ in cylindrical coordinates,

$$d^3\boldsymbol{r}' = dz' d\phi' \rho' d\rho'. \tag{15.11.11}$$

We will also need the Green function $1/[||(\boldsymbol{r} - \boldsymbol{r}')||]$ in cylindrical coordinates. It can be shown that it is given by the relation

$$1/[||(\boldsymbol{r} - \boldsymbol{r}')||] = (2/\pi) \sum_{m=-\infty}^{\infty} \exp(im\phi) \exp(-im\phi') \int_0^\infty dk\ \cos[k(z - z')] I_m(k\rho_<) K_m(k\rho_>). \tag{15.11.12}$$

Here

$$\rho_< = \text{ the lesser of } \rho \text{ and } \rho' \tag{15.11.13}$$

and

$$\rho_> = \text{ the greater of } \rho \text{ and } \rho'. \tag{15.11.14}$$

See the books of Jackson and Arfken listed in the bibliography at the end of this chapter.

As it stands, (11.12) is not exactly in the form we need. It can be verified that there is the relation

$$\begin{aligned} &\int_0^\infty dk\ \cos[k(z - z')] I_m(k\rho_<) K_m(k\rho_>) = \\ &(1/2) \int_{-\infty}^{\infty} dk\ \exp(ikz) \exp(-ikz') I_m(|k|\rho_<) K_m(|k|\rho_>). \end{aligned} \tag{15.11.15}$$

See exercise 11.3. This relation can be employed in (11.12) to bring it to the form

$$1/[||(\boldsymbol{r}-\boldsymbol{r}')||] =$$
$$(1/\pi)\sum_{m=-\infty}^{\infty}\exp(im\phi)\exp(-im\phi')\int_{-\infty}^{\infty}dk\ \exp(ikz)\exp(-ikz')I_m(|k|\rho_<)K_m(|k|\rho_>). \tag{15.11.16}$$

We remark that (11.16) is known to appear in the literature without the absolute value signs $|*|$ about k in the arguments of I_m and K_m. Such appearances are incorrect. They are also ill defined because $K_m(w)$ is not well defined for negative values of w due to logarithmic terms at the origin.

Let us now employ (11.11) and (11.16) in (11.3) to compute $\boldsymbol{A}$ in terms of $\boldsymbol{j}$. So doing gives the result

$$\boldsymbol{A}(\boldsymbol{r}) = (1/\pi)\int dz'd\phi'\rho'd\rho'\ \boldsymbol{j}(\rho',\phi',z')\ \times$$
$$\sum_{m=-\infty}^{\infty}\exp(im\phi)\exp(-im\phi')\int_{-\infty}^{\infty}dk\ \exp(ikz)\exp(-ikz')I_m(|k|\rho_<)K_m(|k|\rho_>). \tag{15.11.17}$$

This result can be rearranged to take the form

$$\boldsymbol{A}(\boldsymbol{r}) = (1/\pi)\sum_{m=-\infty}^{\infty}\exp(im\phi)\ \times$$
$$\int_{-\infty}^{\infty}dk\ \exp(ikz)I_m(|k|\rho)\int dz'd\phi'\rho'd\rho'\ \boldsymbol{j}(\rho',\phi',z')\exp(-im\phi')\exp(-ikz')K_m(|k|\rho'). \tag{15.11.18}$$

Here we have assumed that the current $\boldsymbol{j}$ lies outside (vanishes inside) a cylinder of radius a and we are interested in the vector potential inside the cylinder. Then we have the relations $\rho \in (0,a)$ and $\rho' \in (a,\infty)$ so that $\rho_< = \rho$ and $\rho_> = \rho'$. Finally, (11.18) can be written in the more compact form

$$\boldsymbol{A}(\boldsymbol{r}) = (1/\pi)\sum_{m=-\infty}^{\infty}\exp(im\phi)\int_{-\infty}^{\infty}dk\ \exp(ikz)I_m(|k|\rho)\tilde{\boldsymbol{j}}(m,k) \tag{15.11.19}$$

where

$$\tilde{\boldsymbol{j}}(m,k) = \int dz'd\phi'\rho'd\rho'\ \boldsymbol{j}(\rho',\phi',z')\exp(-im\phi')\exp(-ikz')K_m(|k|\rho'). \tag{15.11.20}$$

15.11.1.3 Complex Cylindrical Harmonic Expansion

We observe that (11.19) is beginning to take on the appearance of a (complex) cylindrical harmonic expansion. Following the pattern of Section 15.3.1, let us work to enhance the appearance of a cylindrical harmonic expansion. Begin by rewriting (11.19) in the form

$$\boldsymbol{A} = \sum_{m=-\infty}^{\infty} \exp(im\phi)\tilde{\boldsymbol{A}}(m,\rho,z) \tag{15.11.21}$$

where

$$\tilde{\boldsymbol{A}}(m,\rho,z) = (1/\pi)\int_{-\infty}^{\infty} dk\ \exp(ikz)I_m(|k|\rho)\tilde{\boldsymbol{j}}(m,k). \tag{15.11.22}$$

Next employ the Taylor expansion (15.3.11) in (11.22). As a first step we see that

$$\begin{aligned} I_m(|k|\rho) &= (1/2)^{|m|}|k|^{|m|}\rho^{|m|}\sum_{\ell=0}^{\infty}(|k|\rho)^{2\ell}/[2^{2\ell}\ell!(\ell+|m|)!] \\ &= (1/2)^{|m|}|k|^{|m|}\rho^{|m|}\sum_{\ell=0}^{\infty}(k\rho)^{2\ell}/[2^{2\ell}\ell!(\ell+|m|)!]. \end{aligned} \tag{15.11.23}$$

Consequently, we may rewrite (11.22) in the form

$$\begin{aligned} &\tilde{\boldsymbol{A}}(m,\rho,z) = (1/\pi)\int_{-\infty}^{\infty} dk\ \tilde{\boldsymbol{j}}(m,k)\exp(ikz)I_m(|k|\rho) = \\ &(1/\pi)\int_{-\infty}^{\infty} dk\ \tilde{\boldsymbol{j}}(m,k)\exp(ikz)(1/2)^{|m|}|k|^{|m|}\rho^{|m|}\sum_{\ell=0}^{\infty}(k\rho)^{2\ell}/[2^{2\ell}\ell!(\ell+|m|)!] = \\ &\sum_{\ell=0}^{\infty}\{1/[2^{2\ell}\ell!(\ell+|m|)!]\}\rho^{2\ell+|m|}(1/\pi)(1/2)^{|m|}\int_{-\infty}^{\infty} dk\ |k|^{|m|}k^{2\ell}\tilde{\boldsymbol{j}}(m,k)\exp(ikz). \end{aligned} \tag{15.11.24}$$

Define (vector) functions $\boldsymbol{C}^{[0]}(m,z)$ by writing

$$\boldsymbol{C}^{[0]}(m,z) = (1/\pi)(1/2)^{|m|}(1/|m|!)\int_{-\infty}^{\infty} dk\ |k|^{|m|}\tilde{\boldsymbol{j}}(m,k)\exp(ikz). \tag{15.11.25}$$

Also define functions $\boldsymbol{C}^{[n]}(m,z)$ by writing

$$\boldsymbol{C}^{[n]}(m,z) = (\partial_z)^n\boldsymbol{C}^{[0]}(m,z). \tag{15.11.26}$$

Then, by differentiating under the integral sign, we have the result

$$\boldsymbol{C}^{[n]}(m,z) = i^n(1/\pi)(1/2)^{|m|}(1/|m|!)\int_{-\infty}^{\infty} dk\ |k|^{|m|}k^n\tilde{\boldsymbol{j}}(m,k)\exp(ikz) \tag{15.11.27}$$

and, in particular,

$$\boldsymbol{C}^{[2\ell]}(m,z) = (-1)^\ell(1/\pi)(1/2)^{|m|}(1/|m|!)\int_{-\infty}^{\infty} dk\ k^{2\ell}|k|^{|m|}\tilde{\boldsymbol{j}}(m,k)\exp(ikz). \tag{15.11.28}$$

Therefore we also write the relation

$$(1/\pi)(1/2)^{|m|}(1/|m|!)\int_{-\infty}^{\infty} dk\ k^{2\ell}|k|^{|m|}\tilde{\boldsymbol{j}}(m,k)\exp(ikz) = (-1)^\ell|m|!\boldsymbol{C}^{[2\ell]}(m,z). \tag{15.11.29}$$

Combining (11.24) and (11.29) gives the results

$$\tilde{\boldsymbol{A}}(m,\rho,z)=\sum_{\ell=0}^{\infty}(-1)^{\ell}|m|!\{1/[2^{2\ell}\ell!(\ell+|m|)!]\}\rho^{2\ell+|m|}\boldsymbol{C}^{[2\ell]}(m,z), \tag{15.11.30}$$

And then using (11.21) gives the final result

$$\boldsymbol{A}(\rho,\phi,z)=\sum_{m=-\infty}^{\infty}\exp(im\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}|m|!\{1/[2^{2\ell}\ell!(\ell+|m|)!]\}\rho^{2\ell+|m|}\boldsymbol{C}^{[2\ell]}(m,z). \tag{15.11.31}$$

15.11.1.4 Real Cylindrical Harmonic Expansion

Section 15.3.2

15.11.2 Calculation of Scalar Potential from Current Data

Exercises

15.11.1. Verify (11.1) through (11.4).

15.11.2. Integration by parts.

15.11.3. The aim of this exercise is to arrive at the relation (11.15). Begin by verifying the equations listed below:

$$\begin{aligned}&\int_0^{\infty}dk\ \cos[k(z-z')]I_m(k\rho_<)K_m(k\rho_>)=\\&\int_0^{\infty}dk\ (1/2)\exp[k(z-z')]I_m(k\rho_<)K_m(k\rho_>)\\&+\int_0^{\infty}dk\ (1/2)\exp[-k(z-z')]I_m(k\rho_<)K_m(k\rho_>);\end{aligned} \tag{15.11.32}$$

$$\begin{aligned}&\int_0^{\infty}dk\ \cos[k(z-z')]I_m(k\rho_<)K_m(k\rho_>)=\\&\int_0^{\infty}dk\ (1/2)\exp[k(z-z')]I_m(|k|\rho_<)K_m(|k|\rho_>)\\&+\int_0^{\infty}dk\ (1/2)\exp[-k(z-z')]I_m(|k|\rho_<)K_m(|k|\rho_>);\end{aligned} \tag{15.11.33}$$

$$\begin{aligned}&\int_0^{\infty}dk\ \cos[k(z-z')]I_m(k\rho_<)K_m(k\rho_>)=\\&\int_0^{\infty}dk\ (1/2)\exp[ik(z-z')]I_m(|k|\rho_<)K_m(|k|\rho_>)\\&+\int_{-\infty}^{0}dk\ (1/2)\exp[ik(z-z')]I_m(|k|\rho_<)K_m(|k|\rho_>);\end{aligned} \tag{15.11.34}$$

$$\int_0^\infty dk\ \cos[k(z-z')]I_m(k\rho_<)K_m(k\rho_>) =$$
$$\int_{-\infty}^\infty dk\ (1/2)\exp[ik(z-z')]I_m(|k|\rho_<)K_m(|k|\rho_>); \tag{15.11.35}$$

$$\int_0^\infty dk\ \cos[k(z-z')]I_m(k\rho_<)K_m(k\rho_>) =$$
$$\int_{-\infty}^\infty dk\ (1/2)\exp(ikz)\exp(-ikz')I_m(|k|\rho_<)K_m(|k|\rho_>). \tag{15.11.36}$$

Finally, verify that (11.15) follows from (11.28).

15.12 Closing Remarks

15.12.1 Caveat about Significance of Integrated Multipoles

Suppose the relations (3.65) and (3.66) are used to compute the integrals of the transverse field components $B_x(x,y,z)$ and $B_y(x,y,z)$ over the range $z=-\infty$ to $z=+\infty$. We observe that for $n \geq 0$ there are the relations

$$\int_{-\infty}^\infty dz\ C_0^{[n+2]}(z) = C_0^{[n+1]}(z)|_{-\infty}^\infty, \tag{15.12.1}$$

$$\int_{-\infty}^\infty dz\ C_{m,\alpha}^{[n+1]}(z) = C_{m,\alpha}^{[n]}(z)|_{-\infty}^\infty. \tag{15.12.2}$$

Also we know that the $C_0^{[n+1]}(z)$ and the $C_{m,\alpha}^{[n]}(z)$ vanish at $z=\pm\infty$. Consequently, all of the terms in the sums (3.65) and (3.66) integrate to zero save for those that involve $C_0^{[1]}(z)$ and the $C_{m,\alpha}^{[0]}(z)$. We these observations in mind, we find the results

$$\begin{aligned}\int_{-\infty}^\infty dz\ B_x(x,y,z) &= \sum_{m=0}^\infty (m+1)\rho^m\cos(m\phi)\int_{-\infty}^\infty dz\ C_{m+1,c}^{[0]}(z) \\ &\quad + \sum_{m=0}^\infty (m+1)\rho^m\sin(m\phi)\int_{-\infty}^\infty dz\ C_{m+1,s}^{[0]}(z) \\ &= \sum_{m'=1}^\infty m'\rho^{m'-1}\cos[(m'-1)\phi]\int_{-\infty}^\infty dz\ C_{m',c}^{[0]}(z) \\ &\quad + \sum_{m'=1}^\infty m'\rho^{m'-1}\sin[(m'-1)\phi]\int_{-\infty}^\infty dz\ C_{m',s}^{[0]}(z),\end{aligned} \tag{15.12.3}$$

$$\begin{aligned}\int_{-\infty}^{\infty} dz\ B_y(x,y,z) &= \sum_{m=0}^{\infty}(m+1)\rho^m\cos(m\phi)\int_{-\infty}^{\infty} dz\ C^{[0]}_{m+1,s}(z)\\ &\quad -\sum_{m=0}^{\infty}(m+1)\rho^m\sin(m\phi)\int_{-\infty}^{\infty} dz\ C^{[0]}_{m+1,c}(z)\\ &= \sum_{m'=1}^{\infty} m'\rho^{m'-1}\cos[(m'-1)\phi]\int_{-\infty}^{\infty} dz\ C^{[0]}_{m',s}(z)\\ &\quad -\sum_{m'=1}^{\infty} m'\rho^{m'-1}\sin[(m'-1)\phi]\int_{-\infty}^{\infty} dz\ C^{[0]}_{m',c}(z).\end{aligned} \tag{15.12.4}$$

Note that (11.3) and (11.4) are consistent with (3.77), (3.78), (3.80), and (3.81).

What are we to conclude from these results? The "multipole" content of a magnet is often specified, in effect, in terms of the *integrated multipole* quantities $\int_{-\infty}^{\infty} dz\ C^{[0]}_{m',\alpha}(z)$ for $m' = 1, 2, \cdots$. This is because magnet measurements are frequently made using spinning coils whose length is such that they extend beyond the ends of the magnets to include the fringe-field regions. (See Appendix K.) Hence, the use of such coils measures $\int_{-\infty}^{\infty} dz\ B_x(x,y,z)$ and $\int_{-\infty}^{\infty} dz\ B_y(x,y,z)$ which, according to (11.3) and (11.4), is equivalent to measuring the integrated multipoles. Moreover, the size of the integrated multipoles is often taken as a figure of merit for any given magnet.

Is this reasonable? We know that some terms of the form $\exp(: f_3 :)\exp(: f_4 :)\cdots$ in the transfer map can have deleterious effects on the dynamic aperture. Recall, for example, Section 1.2.3 which illustrated the effect of the term $\exp(: q^3 :)$ in the simplest nonlinear case. We also know that the generators $f_3, f_4, \cdots$ arise from $H_3, H_4, \cdots$ terms in the Hamiltonian. Finally, we know that nonzero on-axis gradients of the form $C^{[0]}_{3,\alpha}(z), C^{[0]}_{4,\alpha}(z), \cdots$ produce nonzero terms of the form $H_3, H_4, \cdots$ in the Hamiltonian.[10] Therefore, if the integrated multipoles are large for $m' = 3, 4, \cdots$, we expect that nonlinear terms in the map will be important and the dynamic aperture is likely be small. Consequently, a good rule of thumb would appear to be that the integrated $m' = 3, 4, \cdots$ multipole terms should be small to minimize possibly deleterious nonlinear terms in the transfer map.

But, while minimizing the integrated multipoles would seem to be a possible way of minimizing the nonlinear terms in the transfer map, so doing is *not necessarily sufficient.* Consider, for example, the transfer map for a composite system consisting of two identical back-to back sextuples save that they are oppositely powered. All integrated multipoles for such a system would be exactly zero. However, the transfer map for this system could still have large nonlinear terms including those with $f_3 \neq 0$.[11] Observe also that fringe-field terms

[10] However, nonzero on-axis gradients of the form $C^{[0]}_{3,\alpha}(z), C^{[0]}_{4,\alpha}(z), \cdots$ are not the only source of $H_3, H_4, \cdots$ terms in the Hamiltonian. Such terms also arise, for example, from the expansion of the square root in (1.4) and occur even if $A_x = A_y = 0$.

[11] There are at least two other instances of this apparently malevolent principle: The first involves superconducting dipoles. They are often equipped with multipole-corrector coil packages at each end. Even if these coils are powered so that the composite system (dipole plus correctors) has net integrated multipole values of zero for the first few m' values (with $m' \geq 3$), so doing does not guarantee that the net transfer map is free of f_n terms for the first few values of $n \geq 3$. The second concerns room-temperature quadrupoles.

contribute to $H_3, H_4, \cdots$, and therefore can produce nonlinear terms in the transfer map.[12] However, as noted earlier, all of the terms in the sums (3.65) and (3.66) integrate to zero save for those that involve $C_0^{[1]}(z)$ and the $C_{m,\alpha}^{[0]}(z)$. Consequently all fringe-field terms integrate to zero, and their presence is therefore undetectable solely from an examination of the values of the integrated multipoles. Note also that $m = 0$ (solenoid) terms make no contribution to the integrated multipoles. However, it can be shown that solenoid fringe-fields make nonlinear contributions to the transfer map.[13]

We conclude and emphasize that what is needed for a realistic calculation of transfer maps are the functions $C_0^{[1]}(z)$ and the $C_{m,\alpha}^{[0]}(z)$ *themselves*, and *not* just their integrals.

15.12.2 Need for Generalized Gradients and the Use of Surface Data

From the work of the previous sections, we have learned that the dynamics of a charged particle passing through a region of space occupied by a magnetic field described by the scalar potential (3.33), or the azimuthal-free vector potential $\boldsymbol{A}$ given by (4.21) through (4.26), or the symmetric Coulomb gauge vector potential $\hat{\boldsymbol{A}}$ given by (5.89) through (5.94), or their vertical-free and possibly further adjusted variants as illustrated for the normal dipole, are completely determined by a knowledge of the generalized on-axis gradient functions $C_0^{[1]}(z)$ and $C_{m,\alpha}^{[0]}(z)$ and their derivatives. In Chapter 16 we will treat cases for which the generalized gradients can be computed analytically. In Chapters 17 through 21 we will describe several general methods for computing the generalized gradients and their derivatives numerically based on the use of numerical field data on a *surface*. The surfaces employed will be those of cylinders with circular, elliptical, or rectangular cross sections. These methods are *smoothing*. That is, they have the virtue of being relatively insensitive to errors in the input data. Consequently, they are ideally suited for numerical use.

15.12.3 Limitations Imposed by Symmetry and Hamilton and Maxwell

In the introduction to this chapter we noted that there are possible limitations on what transfer maps can be achieved. The first limitation is that the transfer map must be symplectic. The second arises from the fact that, in many instances, the electric and magnetic fields within beam-line elements must arise from fields that satisfy the source-free Maxwell equations. These limitations, combined with symmetry assumptions, may place restrictions upon what can actually be achieved. For example there is a remarkable theorem, due to Scherzer, which states that any imaging system having cylindrical symmetry must have negative spherical aberration. Consequently it is impossible to design, using only electric and

Sometimes they are hand-fitted during manufacture with end shims so that the net integrated $m' = 6$ multipole (which, according to Subsection 3.5, is allowed) is in fact zero. So doing does not guarantee that the net transfer map is free of f_6 terms. For a further discussion of correction methods, see Section 12.11.

[12] For example, dipole fringe-field effects in the hard-edge limit produce an f_4 some of whose terms are infinite.

[13] For example, solenoid fringe-field effects in the hard-edge limit also produce an f_4 some of whose terms are infinite.

magnetic elements with cylindrical symmetry, an electron microscope that is free of spherical aberration. As a practical consequence, the resolution of such microscopes is limited to a few Angstroms. To achieve zero spherical aberration it is necessary to break cylindrical symmetry with the careful use of nonlinear elements such as sextuples or octupoles. This is now done in the highest resolution electron microscopes with the result that it is now possible to achieve resolution at the atomic and subatomic level. For a discussion of Scherzer's theorem, and the possible correction of spherical aberration, see the reference at the end of the bibliography for this chapter.

Exercises

15.12.1. Verify that the integrated transverse fields satisfy the transverse Laplace equation,

$$\nabla_\perp^2 \int_{-\infty}^{\infty} dz\; B_x(x,y,z) = \nabla_\perp^2 \int_{-\infty}^{\infty} dz\; B_y(x,y,z) = 0. \tag{15.12.5}$$

Hint: See Exercise 3.4.

Chapter 16

Realistic Transfer Maps for Straight Iron-Free Beam-Line Elements

Chapter 15 described cylindrical harmonic expansions for straight elements, and showed how the scalar potential, magnetic field, and various vector potentials can be described in terms of generalized on-axis gradients. In most cases these on-axis gradients must be computed numerically. How this may be done in general for straight elements is described in Chapters 17 through 21. However, in some iron-free cases the on-axis gradients can be computed analytically, including their fringe-field behavior. This chapter treats several of these cases. We remark that although our discussion is limited to magnetic beam-line elements, electrostatic beam-line elements can be treated in an analogous way.

In principle, the fringe field of any individual beam-line element at either end of the element has *infinite* extent. (This is particularly true of iron-free elements, but is also a consideration even in the case of some iron-dominated elements.) However in practice in many instances we may wish to regard a beam line as a collection of separated/isolated elements. To do this it is necessary to make an approximation in which leading and trailing end fields are "terminated" in some way. The crucial problem is how to relate canonical coordinates in the absence of a magnetic field with canonical coordinates in the presence of a magnetic field. The first part of this chapter is devoted to describing how this problem may be treated in general for straight beam-line elements. The remaining part of the chapter treats various specific straight iron-free beam-line elements.

16.1 Terminating End Fields

16.1.1 Preliminary Observations

We begin with some preliminary observations. In Cartesian coordinates the Hamiltonian describing charged-particle motion with z as the independent variable is given by the relation

$$K = -[(p_t^{\rm can})^2/c^2 - m^2c^2 - (p_x^{\rm can} - qA_x)^2 - (p_y^{\rm can} - qA_y)^2]^{1/2} - qA_z. \tag{16.1.1}$$

Here we have assumed that the electric scalar potential ψ vanishes and $\boldsymbol{A}$ is static so that there is no electric field. Also, we have used the notation $p_x^{\rm can}$, $p_y^{\rm can}$, and $p_t^{\rm can}$ to indicate that it is the components of the *canonical* momenta that are involved in a Hamiltonian description of motion. See (1.6.16).

According to Hamilton's equations of motion, the change of a coordinate, say $x(z)$, with z is given by

$$\begin{aligned} dx/dz &= \partial K/\partial p_x^{\rm can} \\ &= (p_x^{\rm can}-qA_x)/[(p_t^{\rm can})^2/c^2-m^2c^2-(p_x^{\rm can}-qA_x)^2-(p_y^{\rm can}-qA_y)^2]^{1/2} \\ &= (p_x^{\rm can}-qA_x)/[-(K+qA_z)]. \end{aligned} \tag{16.1.2}$$

Let us verify that this result agrees with what we already know. Recall that

$$K=-p_z^{\rm can}. \tag{16.1.3}$$

See (1.6.6). It follows that (1.2) can be rewritten in the form

$$dx/dz=(p_x^{\rm can}-qA_x)/(p_z^{\rm can}-qA_z). \tag{16.1.4}$$

According to (1.5.27) through (1.5.30) there is the relation

$$\boldsymbol{p}^{\rm can}-q\boldsymbol{A}=\boldsymbol{p}^{\rm mech} \tag{16.1.5}$$

where $\boldsymbol{p}^{\rm mech}$ is the *mechanical* momentum given by

$$\boldsymbol{p}^{\rm mech}=\gamma m\boldsymbol{v}. \tag{16.1.6}$$

Consequently, (1.4) can be rewritten in the form

$$dx/dz=p_x^{\rm mech}/p_z^{\rm mech}=\gamma m v_x/(\gamma m v_z)=v_x/v_z=\frac{dx/dt}{dz/dt}. \tag{16.1.7}$$

Evidently, the far left and far right sides of (1.7) agree. It is also easy to see that results analogous to those just found also hold for $y(z)$.

To complete the story we need to examine also the equation of motion for $t(z)$. In this case application of the standard Hamiltonian rules gives the result

$$\begin{aligned} dt/dz &= \partial K/\partial p_t^{\rm can} \\ &= (-p_t^{\rm can}/c^2)/[(p_t^{\rm can})^2/c^2-m^2c^2-(p_x^{\rm can}-qA_x)^2-(p_y^{\rm can}-qA_y)^2]^{1/2} \\ &= (-p_t^{\rm can}/c^2)/[-(K+qA_z)]. \end{aligned} \tag{16.1.8}$$

Now use of (1.3), (1.5), (1.6), and (1.6.17) yields the relation

$$dt/dz=(-p_t^{\rm can}/c^2)/p_z^{\rm mech}=\gamma m/(\gamma m v_z)=\frac{1}{dz/dt} \tag{16.1.9}$$

so that the far left and far right sides of (1.9) also agree.

16.1.2 Matching Conditions

We now consider what matching conditions should be imposed upon entry and exit of fringe-field regions. To proceed further it is useful to introduce some notation. Let $z^{\rm en}$ denote the z value where a transition is to be made from a region where the magnetic field is *taken* to vanish to the beginning of the leading fringe-field region. That is, any charged particle in question *enters* the leading fringe-field region when $z = z^{\rm en}$. Similarly, let $z^{\rm ex}$ denote the z value where a transition is to be made from the end of a trailing fringe-field region to a region where the magnetic field is again taken to vanish. That is, any charged particle in question *exits* the trailing fringe-field region when $z = z^{\rm ex}$. Our task is to find matching relations at $z^{\rm en}$ and $z^{\rm ex}$.

16.1.2.1 Entering a Leading Fringe-Field Region

Let us begin with a consideration of the transition between a field-free region and a leading fringe-field region. Let $K^{\rm ben}$ be the Hamiltonian *before entry* into the fringe-field region, and let $K^{\rm aen}$ be the Hamiltonian *after entry* into the fringe-field region. Then, since the magnetic field and its associated vector potential are assumed to vanish before entry, we have the relation

$$K^{\rm ben} = -[(p_t^{\rm canben})^2/c^2 - m^2c^2 - (p_x^{\rm canben})^2 - (p_y^{\rm canben})^2]^{1/2}. \tag{16.1.10}$$

And, since the magnetic field (and therefore also the vector potential) is nonzero after entry, we have the relation

$$K^{\rm aen} = -[(p_t^{\rm canaen})^2/c^2 - m^2c^2 - (p_x^{\rm canaen} - qA_x)^2 - (p_y^{\rm canean} - qA_y)^2]^{1/2} - qA_z. \tag{16.1.11}$$

Here we have added the suffixes *ben* and *aen* to the phase-space coordinates to denote their values *before entry* and *after entry.* Our task is to relate these phase-space coordinates.

As a first step, we naturally require that the coordinates be continous at $z^{\rm en}$,

$$x^{\rm aen} = x^{\rm ben}, \tag{16.1.12}$$

$$y^{\rm aen} = y^{\rm ben}, \tag{16.1.13}$$

$$t^{\rm aen} = t^{\rm ben}, \tag{16.1.14}$$

when $z = z^{\rm en}$. The next step is specify what is to be done with the momenta.

One possibility is to require that the slopes/"velocities" dx/dz, dy/dz, and dt/dz be continuous at $z^{\rm en}$. Let us work out the consequences of such a requirement. Before entry we have the result

$$\begin{aligned} & dx/dz = \partial K^{\rm ben}/\partial p_x^{\rm canben} = \\ & p_x^{\rm canben}/[(p_t^{\rm canben})^2/c^2 - m^2c^2 - (p_x^{\rm canben})^2 - (p_y^{\rm canben})^2]^{1/2}, \end{aligned} \tag{16.1.15}$$

and after entry there is the result

$$\begin{aligned} & dx/dz = \partial K^{\rm aen}/\partial p_x^{\rm canaen} = \\ & (p_x^{\rm canaen} - qA_x)/[(p_t^{\rm canaen})^2/c^2 - m^2c^2 - (p_x^{\rm canaen} - qA_x)^2 - (p_y^{\rm canaen} - qA_y)^2]^{1/2}. \end{aligned} \tag{16.1.16}$$

See (1.2). An analogous result holds for dy/dz. Finally, for dt/dz there is the before entry result

$$dt/dz = \partial K^{\rm ben}/\partial p_t^{\rm canben} = \\ (-p_t^{\rm canben}/c^2)/[(p_t^{\rm canben})^2/c^2 - m^2c^2 - (p_x^{\rm canben})^2 - (p_y^{\rm canben})^2]^{1/2}, \tag{16.1.17}$$

and the after entry result

$$dt/dz = \partial K^{\rm aen}/\partial p_t^{\rm canaen} = \\ (-p_t^{\rm canaen}/c^2)/[(p_t^{\rm canaen})^2/c^2 - m^2c^2 - (p_x^{\rm canaen} - qA_x)^2 - (p_y^{\rm canaen} - qA_y)^2]^{1/2}. \tag{16.1.18}$$

See (1.8). Now equate the far right sides of (1.15) and (1.16), the far right sides of their dy/dz counterparts, and the far right sides of (1.17) and (1.18). So doing yields the transition matching relations

$$p_x^{\rm canaen} - qA_x = p_x^{\rm canben}, \tag{16.1.19}$$

$$p_y^{\rm canaen} - qA_y = p_y^{\rm canben}, \tag{16.1.20}$$

$$p_t^{\rm canaen} = p_t^{\rm canben}. \tag{16.1.21}$$

In view of (1.5) the relations (1.19) and (1.20) can also be written in the form

$$p_x^{\rm mechaen} = p_x^{\rm mechben}, \tag{16.1.22}$$

$$p_y^{\rm mechaen} = p_y^{\rm mechben}. \tag{16.1.23}$$

Moreover, under our assumption that the electrical potential $\psi = 0$, (1.21) and (1.6.17) yield the relation

$$\boldsymbol{p}^{\rm mechaen} \cdot \boldsymbol{p}^{\rm mechaen} = \boldsymbol{p}^{\rm mechben} \cdot \boldsymbol{p}^{\rm mechben}. \tag{16.1.24}$$

This relation, when combined with (1.22) and (1.23), yields the further result

$$p_z^{\rm mechaen} = p_z^{\rm mechben}. \tag{16.1.25}$$

We conclude that imposition of the requirement that the slopes/"velocities" be continuous entails that the mechanical momenta be continuous.

The relation (1.21) is satisfactory because we would hope that the energy would not change upon entry into the leading fringe-field region. Again recall (1.6.17). However, we also desire that the phase-space transition matching relations be a symplectic transformation. Calculation shows that the transformation given by (1.12) through (1.14) and (1.19) through (1.21) is *not* symplectic. Compute the Poisson bracket of the left sides of (1.19) and (1.20) to find the result

$$\begin{aligned}[p_x^{\rm canaen} - qA_x, p_y^{\rm canaen} - qA_y] &= [p_x^{\rm canaen}, -qA_y] + [-qA_x, p_y^{\rm canaen}] \\ &= q\{\partial A_y/\partial x^{\rm aen} - \partial A_x/\partial y^{\rm aen}\} = qB_z. \end{aligned} \tag{16.1.26}$$

[Recall (1.7.40).] While hopefully small, generally $B_z(x, y, z^{\rm en})$ differs from zero at the beginning of the leading fringe-field region. On the other hand, the Poisson bracket of the right sides of (1.19) and (1.20) must vanish since $p_x^{\rm canben}$ and $p_y^{\rm canben}$ are supposed to be canonical momenta. Therefore the phase-space transformation given by (1.12) through (1.14) and (1.19) through (1.21) is generally *not* symplectic. Review, at this point, Exercise 6.4.11.

We expect that neglect of the magnetic field in the region $z < z^{\rm en}$ will lead to some error in trajectories. However, we do not want this error to violate the symplectic condition. The simplest way to maintain the symplectic condition is to retain the relations (1.12) through (1.14) and replace the relations (1.19) through (1.21) by the relations

$$p_x^{\rm canaen} = p_x^{\rm canben}, \tag{16.1.27}$$

$$p_y^{\rm canaen} = p_y^{\rm canben}, \tag{16.1.28}$$

$$p_t^{\rm canaen} = p_t^{\rm canben}. \tag{16.1.29}$$

In this case the transition matching relations (1.12) through (1.14) and (1.27) through (1.29) amount to the identity map $\mathcal{I}$, and the symplectic condition is trivially satisfied. Now, however, the error in trajectories manifests itself in that the slopes/"velocities" dx/dz, dy/dz, and dt/dz may be expected to be discontinuous at at $z^{\rm en}$. Inspection of (1.15) and (1.16), their dy/dz counterparts, and (1.17) and (1.18) shows that, in lowest approximation, these discontinuities are proportional to components of $\boldsymbol{A}(x, y, z^{\rm en})$. Indeed, again in view of (1.3) and (1.5), the transition relations (1.27) and (1.28) can be written in the form

$$\Delta p_x^{\rm mech} = p_x^{\rm mechaen} - p_x^{\rm mechben} = qA_x(x, y, z^{\rm en}), \tag{16.1.30}$$

$$\Delta p_y^{\rm mech} = p_y^{\rm mechaen} - p_y^{\rm mechben} = qA_y(x, y, z^{\rm en}). \tag{16.1.31}$$

Also, in view of (1.29), (1.24) continues to hold. Therefore, upon combining (1.29) through (1.31), we see that $p_z^{\rm mechaen}$ is given by the relation

$$\begin{aligned} p_z^{\rm mechaen} &= [(p_z^{\rm mechben})^2 + (p_x^{\rm mechben})^2 - (p_x^{\rm mechaen})^2 + (p_y^{\rm mechben})^2 - (p_y^{\rm mechaen})^2]^{1/2} \\ &= [(p_z^{\rm mechben})^2 - (\Delta p_x^{\rm mech})(\Sigma p_x^{\rm mech}) - (\Delta p_y^{\rm mech})(\Sigma p_y^{\rm mech})]^{1/2} \\ &= [(p_z^{\rm mechben})^2 - qA_x(x, y, z^{\rm en})(\Sigma p_x^{\rm mech}) - qA_y(x, y, z^{\rm en})(\Sigma p_y^{\rm mech})]^{1/2} \end{aligned} \tag{16.1.32}$$

where

$$\Sigma p_x^{\rm mech} = p_x^{\rm mechaen} + p_x^{\rm mechben} = 2p_x^{\rm mechben} + qA_x(x, y, z^{\rm en}), \tag{16.1.33}$$

$$\Sigma p_y^{\rm mech} = p_y^{\rm mechaen} + p_y^{\rm mechben} = 2p_y^{\rm mechben} + qA_y(x, y, z^{\rm en}). \tag{16.1.34}$$

We conclude that imposition of continuity in the canonical momenta as expressed by (1.27) through (1.29) entails a discontinuity in the mechanical momenta, and this discontinuity depends on the size of $\boldsymbol{A}(x, y, z^{\rm en})$. It is therefore desirable to work in a gauge where $\boldsymbol{A}(x, y, z^{\rm en})$ is as *small* as possible. Subsequently, we will explore the use of the minimum vector potential of Section 15.2.5 for this purpose.

16.1.2.2 Exiting a Trailing Fringe-Field Region

The transition between a trailing fringe-field region and a subsequent field-free region may be considered in an analogous way. We again require continuity in the coordinates and canonical momenta. As described earlier, let $z^{\rm ex}$ denote the z value where a transition is to be made from the end of a trailing fringe-field region to a region where the magnetic field is again taken to vanish. That is, any charged particle in question *exits* the trailing fringe-field region when $z = z^{\rm ex}$. We will also add the suffixes *aex* and *bex* to the phase-space coordinates to denote their values *after* and *before exit.* In terms of this notation we impose the matching conditions

$$x^{\rm aex} = x^{\rm bex}, \tag{16.1.35}$$

$$y^{\rm aex} = y^{\rm bex}, \tag{16.1.36}$$

$$t^{\rm aex} = t^{\rm bex}, \tag{16.1.37}$$

$$p_x^{\rm canaex} = p_x^{\rm canbex}, \tag{16.1.38}$$

$$p_y^{\rm canaex} = p_y^{\rm canbex}, \tag{16.1.39}$$

$$p_t^{\rm canaex} = p_t^{\rm canbex} \tag{16.1.40}$$

when $z = z^{\rm ex}$. So so doing entails discontinuities in the mechanical momenta given by the relations

$$\Delta p_x^{\rm mech} = p_x^{\rm mechaex} - p_x^{\rm mechbex} = qA_x(x, y, z^{\rm ex}), \tag{16.1.41}$$

$$\Delta p_y^{\rm mech} = p_y^{\rm mechaex} - p_y^{\rm mechbex} = qA_y(x, y, z^{\rm ex}), \tag{16.1.42}$$

$$\begin{aligned} p_z^{\rm mechaex} &= [(p_z^{\rm mechbex})^2 + (p_x^{\rm mechbex})^2 - (p_x^{\rm mechaex})^2 + (p_y^{\rm mechbex})^2 - (p_y^{\rm mechaex})^2]^{1/2} \\ &= [(p_z^{\rm mechbex})^2 - (\Delta p_x^{\rm mech})(\Sigma p_x^{\rm mech}) - (\Delta p_y^{\rm mech})(\Sigma p_y^{\rm mech})]^{1/2} \\ &= [(p_z^{\rm mechbex})^2 - qA_x(x, y, z^{\rm ex})(\Sigma p_x^{\rm mech}) - qA_y(x, y, z^{\rm ex})(\Sigma p_y^{\rm mech})]^{1/2} \end{aligned} \tag{16.1.43}$$

where

$$\Sigma p_x^{\rm mech} = p_x^{\rm mechaex} + p_x^{\rm mechbex} = 2p_x^{\rm mechbex} + qA_x(x, y, z^{\rm ex}), \tag{16.1.44}$$

$$\Sigma p_y^{\rm mech} = p_y^{\rm mechaex} + p_y^{\rm mechbex} = 2p_y^{\rm mechbex} + qA_y(x, y, z^{\rm ex}). \tag{16.1.45}$$

That is, imposition of continuity in the canonical momenta as expressed by (1.38) through (1.40) again entails discontinuities in the associated mechanical momenta. It is therefore also desirable to work in a gauge where $\boldsymbol{A}(x, y, z^{\rm ex})$ is as small as possible.

16.1.2.3 Modified Hamiltonian, Vector Potential, Magnetic Field, and Current

One way to view the symplectic matching relations (1.12) through (1.14), (1.27) through (1.29), and (1.35) through (1.40) is to replace the Hamiltonian (1.1) by a modified Hamiltonian $K^{\rm mod}$ given by

$$K^{\rm mod} = -[(p_t^{\rm can})^2/c^2 - m^2c^2 - (p_x^{\rm can} - qA_x^{\rm mod})^2 - (p_y^{\rm can} - qA_y^{\rm mod})^2]^{1/2} - qA_z^{\rm mod} \tag{16.1.46}$$

where

$$\boldsymbol{A}^{\rm mod}(x,y,z)=\theta(z-z^{\rm en})\theta(z^{\rm ex}-z)\boldsymbol{A}(x,y,z). \tag{16.1.47}$$

That is, the vector potential is taken to vanish for $z<z^{\rm en}$, turns on at $z=z^{\rm en}$, and again turns off for $z>z^{\rm ex}$. A little thought shows that integrating the equations of motion associated with this modified Hamiltonian automatically produces the matching relations (1.12) through (1.14), (1.27) through (1.29), and (1.35) through (1.40).

What is the modified magnetic field $\boldsymbol{B}^{\rm mod}$ associated with this modified vector potential? Evaluation of

$$\boldsymbol{B}^{\rm mod}=\nabla\times\boldsymbol{A}^{\rm mod} \tag{16.1.48}$$

gives the relations

$$\begin{aligned} B_x^{\rm mod}(x,y,z) &= \partial_y A_z^{\rm mod}-\partial_z A_y^{\rm mod} \\ &= \theta(z-z^{\rm en})\theta(z^{\rm ex}-z)B_x(x,y,z) \\ &\quad -[\delta(z-z^{\rm en})-\delta(z^{\rm ex}-z)]A_y(x,y,z), \end{aligned} \tag{16.1.49}$$

$$\begin{aligned} B_y^{\rm mod}(x,y,z) &= \partial_z A_x^{\rm mod}-\partial_x A_z^{\rm mod} \\ &= \theta(z-z^{\rm en})\theta(z^{\rm ex}-z)B_y(x,y,z) \\ &\quad +[\delta(z-z^{\rm en})-\delta(z^{\rm ex}-z)]A_x(x,y,z), \end{aligned} \tag{16.1.50}$$

$$\begin{aligned} B_z^{\rm mod}(x,y,z) &= \partial_x A_y^{\rm mod}-\partial_y A_x^{\rm mod} \\ &= \theta(z-z^{\rm en})\theta(z^{\rm ex}-z)B_z(x,y,z). \end{aligned} \tag{16.1.51}$$

By the construction (1.48), the modified magnetic field is divergence free,

$$\nabla\cdot\boldsymbol{B}^{\rm mod}=0, \tag{16.1.52}$$

as required. [Note that making the simple Ansatz $\boldsymbol{B}^{\rm mod}=\theta(z-z^{\rm en})\theta(z^{\rm ex}-z)\boldsymbol{B}$ violates the requirement (1.52). It is this Ansatz that would arise naturally if one were integrating the non-canonical Lorentz-force equations given in Exercise 1.6.16.]

What current $\boldsymbol{j}^{\rm mod}$ produces this modified magnetic field? It is specified by employing $\boldsymbol{B}^{\rm mod}$ as given by (1.49) through (1.51) in the relation

$$\mu_0\boldsymbol{j}^{\rm mod}=\nabla\times\boldsymbol{B}^{\rm mod}. \tag{16.1.53}$$

Doing so directly leads to considerable algebra, which can be bypassed with the use of suitable vector identities. Proceed as follows: Combining (1.48) and (1.53) gives the relation

$$\mu_0\boldsymbol{j}^{\rm mod}=\nabla\times(\nabla\times\boldsymbol{A}^{\rm mod})=\nabla(\nabla\cdot\boldsymbol{A}^{\rm mod})-\nabla^2\boldsymbol{A}^{\rm mod}. \tag{16.1.54}$$

Let us work on the first term on the right side of (1.54). From the definition (1.47) there is the result

$$\nabla\cdot\boldsymbol{A}^{\rm mod}=\boldsymbol{A}\cdot\nabla[\theta(z-z^{\rm en})\theta(z^{\rm ex}-z)]+\theta(z-z^{\rm en})\theta(z^{\rm ex}-z)\nabla\cdot\boldsymbol{A}. \tag{16.1.55}$$

Evaluation of the first term on the right in (1.55) gives the result

$$\begin{aligned} \boldsymbol{A}\cdot\nabla[\theta(z-z^{\rm en})\theta(z^{\rm ex}-z)] &= A_z\partial_z[\theta(z-z^{\rm en})\theta(z^{\rm ex}-z)] \\ &= [\delta(z-z^{\rm en})-\delta(z^{\rm ex}-z)]A_z. \end{aligned} \tag{16.1.56}$$

We also assume that $\boldsymbol{A}$ is in a Coulomb gauge, $\nabla\cdot\boldsymbol{A}=0$, so that (1.55) becomes

$$\nabla\cdot\boldsymbol{A}^{\rm mod}=[\delta(z-z^{\rm en})-\delta(z^{\rm ex}-z)]A_z, \tag{16.1.57}$$

and therefore

$$\begin{aligned} \nabla(\nabla\cdot\boldsymbol{A}^{\rm mod}) &= \boldsymbol{e}_x[\delta(z-z^{\rm en})-\delta(z^{\rm ex}-z)]\partial_x A_z \\ &\quad +\boldsymbol{e}_y[\delta(z-z^{\rm en})-\delta(z^{\rm ex}-z)]\partial_y A_z \\ &\quad +\boldsymbol{e}_z[\delta(z-z^{\rm en})-\delta(z^{\rm ex}-z)]\partial_z A_z \\ &\quad +\boldsymbol{e}_z[\delta'(z-z^{\rm en})+\delta'(z^{\rm ex}-z)]A_z. \end{aligned} \tag{16.1.58}$$

Next we turn to working out $-\nabla^2\boldsymbol{A}^{\rm mod}$, the second term on the right side of (1.54). For the x component we have the intermediate result

$$\begin{aligned} -\nabla^2 A_x^{\rm mod} &= -\nabla^2[\theta(z-z^{\rm en})\theta(z^{\rm ex}-z)A_x] \\ &= -\theta(z-z^{\rm en})\theta(z^{\rm ex}-z)(\partial_x^2+\partial_y^2)A_x-\partial_z^2[\theta(z-z^{\rm en})\theta(z^{\rm ex}-z)A_x]. \end{aligned} \tag{16.1.59}$$

By the product rule there is the relation

$$\begin{aligned} \partial_z[\theta(z-z^{\rm en})\theta(z^{\rm ex}-z)A_x] &= [\delta(z-z^{\rm en})-\delta(z^{\rm ex}-z)]A_x \\ &\quad +\theta(z-z^{\rm en})\theta(z^{\rm ex}-z)\partial_z A_x, \end{aligned} \tag{16.1.60}$$

from which it follows that

$$\begin{aligned} \partial_z^2[\theta(z-z^{\rm en})\theta(z^{\rm ex}-z)A_x] &= [\delta'(z-z^{\rm en})+\delta'(z^{\rm ex}-z)]A_x \\ &\quad +2[\delta(z-z^{\rm en})-\delta(z^{\rm ex}-z)]\partial_z A_x \\ &\quad +\theta(z-z^{\rm en})\theta(z^{\rm ex}-z)\partial_z^2 A_x. \end{aligned} \tag{16.1.61}$$

Combining (1.59) and (1.61) yields the next intermediate result

$$-\nabla^2 A_x^{\rm mod}=-2[\delta(z-z^{\rm en})-\delta(z^{\rm ex}-z)]\partial_z A_x-[\delta'(z-z^{\rm en})+\delta'(z^{\rm ex}-z)]A_x, \tag{16.1.62}$$

Here we have used the fact that $\boldsymbol{A}$ is harmonic. See (15.5.4). Similarly, there are the analogous next intermediate results

$$-\nabla^2 A_y^{\rm mod}=-2[\delta(z-z^{\rm en})-\delta(z^{\rm ex}-z)]\partial_z A_y-[\delta'(z-z^{\rm en})+\delta'(z^{\rm ex}-z)]A_y, \tag{16.1.63}$$

$$-\nabla^2 A_z^{\rm mod}=-2[\delta(z-z^{\rm en})-\delta(z^{\rm ex}-z)]\partial_z A_z-[\delta'(z-z^{\rm en})+\delta'(z^{\rm ex}-z)]A_z. \tag{16.1.64}$$

We are now able to combine the two terms on the right side of (1.54), using (1.58) and (1.62) through (1.64), to yield the desired final results

$$\begin{aligned}\mu_0 j_x^{\rm mod} &= [\delta(z-z^{\rm en})-\delta(z^{\rm ex}-z)][\partial_x A_z - 2\partial_z A_x] \\ &\quad -[\delta'(z-z^{\rm en})+\delta'(z^{\rm ex}-z)]A_x, \end{aligned}\tag{16.1.65}$$

$$\begin{aligned}\mu_0 j_y^{\rm mod} &= [\delta(z-z^{\rm en})-\delta(z^{\rm ex}-z)][\partial_y A_z - 2\partial_z A_y] \\ &\quad -[\delta'(z-z^{\rm en})+\delta'(z^{\rm ex}-z)]A_y, \end{aligned}\tag{16.1.66}$$

$$\mu_0 j_z^{\rm mod} = -[\delta(z-z^{\rm en})-\delta(z^{\rm ex}-z)]\partial_z A_z. \tag{16.1.67}$$

Evidently requiring the vector potential to vanish for $z < z^{\rm en}$, turn on at $z = z^{\rm en}$, and again turn off for $z > z^{\rm ex}$ is equivalent to introducing sheet (corresponding to the δ functions) and double-sheet (corresponding to the δ' functions) currents at $z = z^{\rm en}$ and $z = z^{\rm ex}$. And the strengths of these currents are proportional to the values of $\boldsymbol{A}$ and its first derivatives at $z = z^{\rm en}$ and $z = z^{\rm ex}$.

16.1.3 Changing Gauge

It may be useful to change gauges at various points during the course of integrating a trajectory and computing an associated transfer map. For example, to minimize end-field termination effects, it is desirable to change to minimum vector potentials at $z = z^{\rm en}$ and $z = z^{\rm ex}$. Suppose the gauge is to be *changed* at the point $z = z^c$. Let x^b, y^b, and t^b denote coordinate functions *before* the change, and let x^a, y^a, and t^a denote coordinate functions *after* the change. Also, let $\boldsymbol{A}^b(x^b, y^b; z)$ and $\boldsymbol{A}^a(x^a, y^a; z)$ be the vector potentials before ($z < z^c$) and after ($z > z^c$) the change point z^c. Finally, let $p_x^{\rm canb}$, $p_y^{\rm canb}$, $p_t^{\rm canb}$ be the canonical momentum functions before the change, and let $p_x^{\rm cana}$, $p_y^{\rm cana}$, $p_t^{\rm cana}$ be the canonical momentum functions after the change. In terms of these quantities, the before and after Hamiltonians K^b and K^a are given by the relations

$$K^b = -[(p_t^{\rm canb})^2/c^2 - m^2c^2 - (p_x^{\rm canb} - qA_x^b)^2 - (p_y^{\rm canb} - qA_y^b)^2]^{1/2} - qA_z^b \text{ for } z < z^c, \tag{16.1.68}$$

$$K^a = -[(p_t^{\rm cana})^2/c^2 - m^2c^2 - (p_x^{\rm cana} - qA_x^a)^2 - (p_y^{\rm cana} - qA_y^a)^2]^{1/2} - qA_z^a \text{ for } z > z^c. \tag{16.1.69}$$

What should be the matching relations between the phase-space quantities before and after? Since the choice of gauge should have no physical effect, there is the immediate requirement that the coordinate functions be continuous:

$$\begin{aligned} &x^a(z) = x^b(z) \text{ when } z = z^c, \\ &y^a(z) = y^b(z) \text{ when } z = z^c, \\ &t^a(z) = t^b(z) \text{ when } z = z^c. \end{aligned}\tag{16.1.70}$$

For the same reason, we require that the velocities, and hence the mechanical momenta, be continuous. From (1.5) and (1.6) we see that this requirement is equivalent to the relations

$$\boldsymbol{p}^{\rm cana} - q\boldsymbol{A^a} = \boldsymbol{p}^{\rm canb} - q\boldsymbol{A^b} \text{ when } z = z^c. \tag{16.1.71}$$

In terms of components, (1.71) yields the matching relations

$$\begin{aligned} p_x^{\text{cana}} &= p_x^{\text{canb}} + q(A_x^a - A_x^b) \text{ when } z = z^c, \\ p_y^{\text{cana}} &= p_y^{\text{canb}} + q(A_y^a - A_y^b) \text{ when } z = z^c. \end{aligned} \tag{16.1.72}$$

Finally, the total energy cannot change under a gauge transformation and therefore, since we have assumed that the electric scalar potential ψ vanishes, there is the matching relation

$$p_t^{\text{cana}} = p_t^{\text{canb}} \text{ when } z = z^c. \tag{16.1.73}$$

We note that this relation also follows from (1.6.17).

We assume there is some common overlap region where both $\boldsymbol{A}^b$ and $\boldsymbol{A}^a$ are defined. Since they both give rise to the same magnetic field, there is the relation

$$\nabla \times (\boldsymbol{A}^a - \boldsymbol{A}^b) = 0. \tag{16.1.74}$$

It follows that there is a function χ such that

$$\boldsymbol{A}^a - \boldsymbol{A}^b = \nabla\chi. \tag{16.1.75}$$

Consequently, the relations (1.72) can be rewritten in the form

$$\begin{aligned} p_x^{\text{cana}} &= p_x^{\text{canb}} + q(\partial/\partial x)\chi \text{ when } z = z^c, \\ p_y^{\text{cana}} &= p_y^{\text{canb}} + q(\partial/\partial y)\chi \text{ when } z = z^c. \end{aligned} \tag{16.1.76}$$

There is one last step. Let $\mathcal{T}^c$ be the symplectic *transformation* map defined by the relation

$$\mathcal{T}^c = \exp(q :\chi:). \tag{16.1.77}$$

With aid of this map it is easily verified that the relations (1.70), (1.72), and (1.73) can be rewritten in the form

$$\begin{aligned} x^a(z) &= \exp(q :\chi:)x^b(z) \text{ with } z = z^c, \\ y^a(z) &= \exp(q :\chi:)y^b(z) \text{ with } z = z^c, \\ t^a(z) &= \exp(q :\chi:)t^b(z) \text{ with } z = z^c; \end{aligned} \tag{16.1.78}$$

$$\begin{aligned} p_x^{\text{cana}}(z) &= \exp(q :\chi:)p_x^{\text{canb}}(z) \text{ with } z = z^c, \\ p_y^{\text{cana}}(z) &= \exp(q :\chi:)p_y^{\text{canb}}(z) \text{ with } z = z^c, \\ p_t^{\text{cana}}(z) &= \exp(q :\chi:)p_t^{\text{canb}}(z) \text{ with } z = z^c. \end{aligned} \tag{16.1.79}$$

We have determined that a change in gauge amounts to making a symplectic transformation. Review Exercises 6.2.8 and 6.5.3.

16.2 Solenoids

The remainder of this chapter is devoted to the treatment of various specific straight beam-line elements for which the on-axis gradients can be found analytically. We begin with the case of solenoids.

16.2.1 Preliminaries

A solenoid is a straight beam-line element whose field is described by a cylindrical harmonic expansion that contains (ideally) only an $m = 0$ term. Figure 2.1 illustrates a Cartesian coordinate system for the treatment of a solenoid. We recall from Section 15.3.3 that in this case the magnetic scalar potential ψ has the expansion

$$\begin{aligned}\psi(x,y,z) &= \psi_0(x,y,z) = \sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!\ell!}C_0^{[2\ell]}(z)\rho^{2\ell} \\ &= C_0^{[0]}(z) - (1/4)(x^2+y^2)C_0^{[2]}(z) + \cdots \qquad (16.2.1)\end{aligned}$$

with

$$\rho^2 = x^2 + y^2. \qquad (16.2.2)$$

See (15.3.53) and (15.5.5). Correspondingly, the associated magnetic field has the expansion

$$B_x = \partial_x\psi_0 = -(1/2)xC_0^{[2]}(z) + \cdots, \qquad (16.2.3)$$

$$B_y = \partial_y\psi_0 = -(1/2)yC_0^{[2]}(z) + \cdots, \qquad (16.2.4)$$

$$\begin{aligned}B_z &= \partial_z\psi_0 = \sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!\ell!}C_0^{[2\ell+1]}(z)\rho^{2\ell} \\ &= C_0^{[1]}(z) - (1/4)(x^2+y^2)C_0^{[3]}(z) + \cdots. \qquad (16.2.5)\end{aligned}$$

In particular, there is the result

$$\boldsymbol{B}(0,0,z) = C_0^{[1]}(z)\boldsymbol{e}_z. \qquad (16.2.6)$$

Also, according to Section 15.5.1, there is a suitable associated vector potential $\hat{\boldsymbol{A}}^0$ (in the symmetric Coulomb gauge which, in the case of a solenoid, is also the Poincaré-Coulomb gauge) given by the relation

$$\hat{A}_x^0 = -yU, \qquad (16.2.7)$$

$$\hat{A}_y^0 = xU, \qquad (16.2.8)$$

$$\hat{A}_z^0 = 0, \qquad (16.2.9)$$

where U is defined to be

$$U(\rho,z) = (1/2)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!(\ell+1)!}C_0^{[2\ell+1]}(z)\rho^{2\ell}. \qquad (16.2.10)$$

Correspondingly, the vector potential will have an expansion in x and y of the form

$$\hat{A}_x^0 = -yU = -y(1/2)[C_0^{[1]}(z) - (1/8)C_0^{[3]}(z)(x^2+y^2) + \cdots], \qquad (16.2.11)$$

$$\hat{A}_y^0 = xU = x(1/2)[C_0^{[1]}(z) - (1/8)C_0^{[3]}(z)(x^2+y^2) + \cdots], \qquad (16.2.12)$$

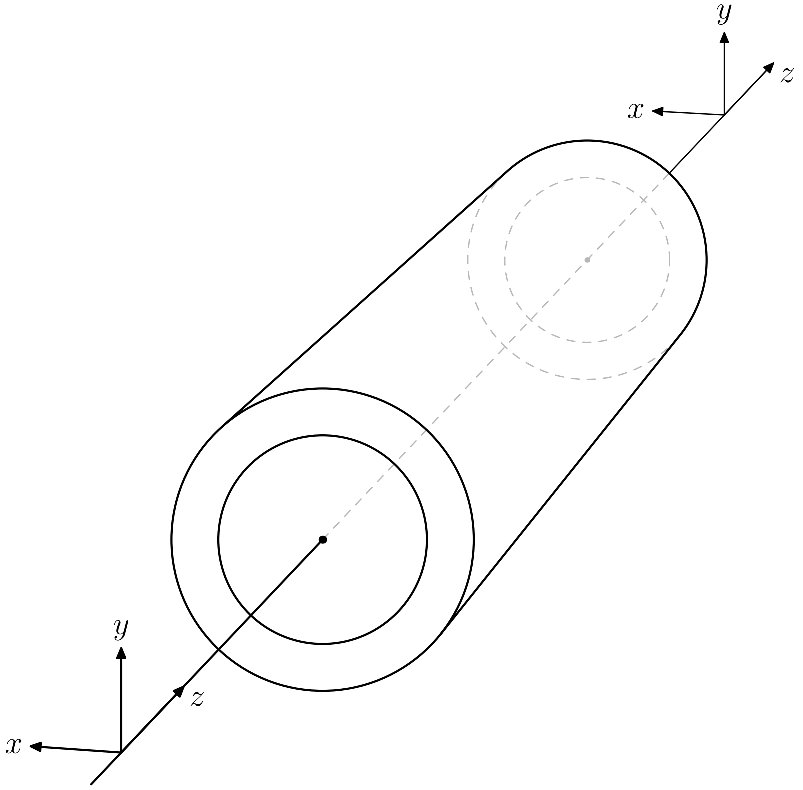

Figure 16.2.1: Coordinate system for a solenoid.

$$\hat{A}^0_z = 0, \tag{16.2.13}$$

which can be written in the vector form

$$\hat{\boldsymbol{A}}^0(\boldsymbol{r}) = -(1/2)\boldsymbol{r} \times \boldsymbol{B}(0,0,z) + \text{higher order terms.} \tag{16.2.14}$$

Note the resemblance between (2.14) and (15.2.61). This resemblance should not surprise us because we know from Section 15.7.1 that $\hat{\boldsymbol{A}}^0$ is in the Poincaré-Coulomb gauge with respect to any origin on the z axis.

From (2.3) through (2.5) and (2.7) through (2.13) we see that both $\boldsymbol{B}$ and $\hat{\boldsymbol{A}}^0$ are completely specified in terms of a single "master" function $C_0^{[1]}(z)$ and its derivatives. Moreover, according to (2.6), the function $C_0^{[1]}(z)$ is given in terms of the longitudinal on-axis field by the relation

$$C_0^{[1]}(z) = B_z(0,0,z). \tag{16.2.15}$$

We observe that for a long uniform solenoid the on-axis field $B_z(0,0,z)$ will be nearly constant in the body of the solenoid, and therefore the quantities $C_0^{[n]}(z)$ will be small in this region for $n > 1$. However, these derivatives may be large in fringe-field regions. We will next see what can be said more specifically about the master function $C_0^{[1]}(z)$ in various cases.

16.2.2 Simple Air-Core Solenoid

16.2.2.1 General Properties of the On-Axis Field

For simplicity, consider initially the case of a simple air-core solenoid consisting of a single-layer circular cylindrical winding of length L and radius $\rho = a$, and powered so that the interior field (in the infinite-length limit) is B. For such a solenoid it can be shown that the on-axis field is given by the relation

$$B_z(0,0,z) = B\{z/[z^2 + a^2]^{1/2} - (z - L)/[(z - L)^2 + a^2]^{1/2}\}/2 \tag{16.2.16}$$

where the cylinder axis is the z axis and the winding extends from $z = 0$ to $z = L$. The on-axis fields of more general air-core solenoids can be found from (2.16) by superposition. See Subsection 2.4. Here we assume that the effect of a solenoidal winding is well approximated by a uniform current sheet (or a collection of uniform current sheets) in the $\boldsymbol{e}_\phi$ direction. For a discussion of helical effects, see the book by W. Smythe cited in the references at the end of this chapter.

Suppose we define a soft-edge "bump" function bump(z, a, L) by the rule

$$\text{bump}(z, a, L) = \{z/[z^2 + a^2]^{1/2} - (z - L)/[(z - L)^2 + a^2]^{1/2}\}/2 \tag{16.2.17}$$

so that (2.16) can be written in the form

$$B_z(0,0,z) = B \ \text{bump}(z, a, L). \tag{16.2.18}$$

Then there is also the result

$$C_0^{[1]}(z) = B_z(0,0,z) = B \ \text{bump}(z, a, L). \tag{16.2.19}$$

It can be verified that the soft-edge bump function has the properties

$$\text{bump}(z, a, L) \simeq 1 \text{ for } z \in [0, L], \tag{16.2.20}$$

$$\text{bump}(z, a, L) \simeq 0 \text{ elsewhere}, \tag{16.2.21}$$

$$\text{bump}(L/2 + w, a, L) = \text{bump}(L/2 - w, a, L), \tag{16.2.22}$$

It can also be shown that

$$\int_{-\infty}^{\infty} \text{bump}(z, a, L) dz = L. \tag{16.2.23}$$

See Exercise 2.3. In particular, from the results above, it follows that for a simple air-core solenoid there is the relation

$$\int_{-\infty}^{\infty} C_0^{[1]}(z) dz = \int_{-\infty}^{\infty} B_z(0,0,z) dz = BL. \tag{16.2.24}$$

At this point two remarks are in order: The first is that we have been using the term *bump function* in a slightly different way from that often employed in mathematics. In mathematics a bump function is generally a smooth (C^∞) function with exact value 1 over some region and exact value 0 slightly outside this region. By contrast, in (2.20) and (2.21), we require only that this be approximately true. The second is that the relation (2.24) also holds in the case of a *thick* air-core solenoid. See Subsection 2.4 and Exercise 2.9.

We also observe that, according to (2.17), the soft-edge bump function can be written in the form

$$\mathrm{bump}(z,a,L) = [\mathrm{sgn}(z,a) - \mathrm{sgn}(z-L,a)]/2 \tag{16.2.25}$$

where $\mathrm{sgn}(z,a)$ is an approximating "signum" function given by the relation

$$\mathrm{sgn}(z,a) = z/[z^2+a^2]^{1/2}. \tag{16.2.26}$$

Figures 2.2 and 2.3 illustrate the behavior of the approximating signum function for two different values of a. Evidently the approximating signum function becomes the true signum function in the limit that a goes to zero,

$$\lim_{a\to 0} \mathrm{sgn}(z,a) = \mathrm{sgn}(z). \tag{16.2.27}$$

Recall that the true signum function has the definition

$$\begin{aligned}
&\mathrm{sgn}(z) = 1 \text{ if } z>0,\\
&\mathrm{sgn}(z) = 0 \text{ if } z=0,\\
&\mathrm{sgn}(z) = -1 \text{ if } z<0.
\end{aligned} \tag{16.2.28}$$

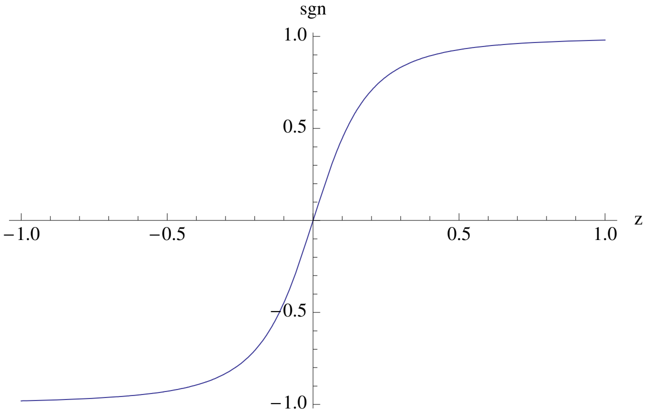

Figure 16.2.2: The approximating signum function (2.26) when $a = .2$.

In this same limit the soft-edge bump function becomes the hard-edge bump function,

$$\lim_{a\to 0} \mathrm{bump}(z,a,L) = \mathrm{bump}(z,L). \tag{16.2.29}$$

The hard-edge bump function has the properties,

$$\begin{aligned}
&\mathrm{bump}(z,L) = 1 \text{ for } z\in(0,L),\\
&\mathrm{bump}(0,L) = \mathrm{bump}(L,L) = 1/2,\\
&\mathrm{bump}(z,L) = 0 \text{ elsewhere.}
\end{aligned} \tag{16.2.30}$$

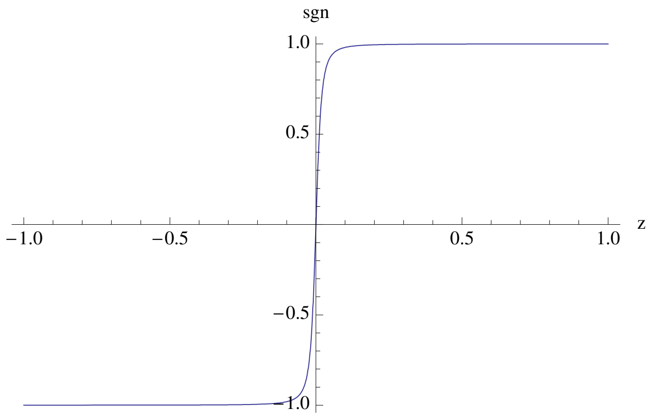

Figure 16.2.3: The approximating signum function (2.26) when $a = .02$.

Figures 2.4 and 2.5 illustrate the bump-function properties (2.20) through (2.22) for a fixed value of L and two different values of a. As expected, the simple air-core solenoid soft-edge bump function approaches a hard-edge bump function in the limit $a \to 0$. We also see that the quantity a plays the role of a *characteristic length* that controls the rate of fall off. The fringe-field region is large if a is large, and vanishes as a goes to zero. Finally, we note that $\mathrm{sgn}(z, a)$ is *analytic* as a function of z save for branch points at $z = \pm ia$. Correspondingly, $\mathrm{bump}(z, a, L)$ and hence also all the $C_0^{[n]}(z)$ are analytic in z save for branch points at $z = \pm ia$ and $z = L \pm ia$. Therefore approximating $C_0^{[1]}(z)$ by a series of straight-line segments, as is sometimes done in the literature, violates its fundamental analytic properties.

Note also that use of the term *fringe field* to describe what is going on here can be a bit misleading. It is true that the field does extend beyond/outside the solenoid boundaries $z = 0$ and $z = L$, but it is also affected/diminished *inside* the boundaries, particularly noticeably in the vicinity of the boundaries. Finally note that (2.24) holds for all a and does not depend on a. Thus, so to speak, whatever on-axis field "disappears" from inside the boundaries of the solenoid due to fringing behavior is in fact found outside the boundaries.

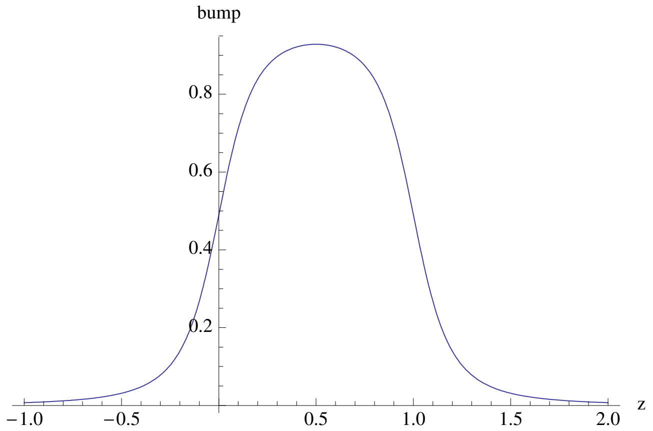

Figure 16.2.4: The soft-edge bump function (2.17) when $a = .2$ and $L = 1$.

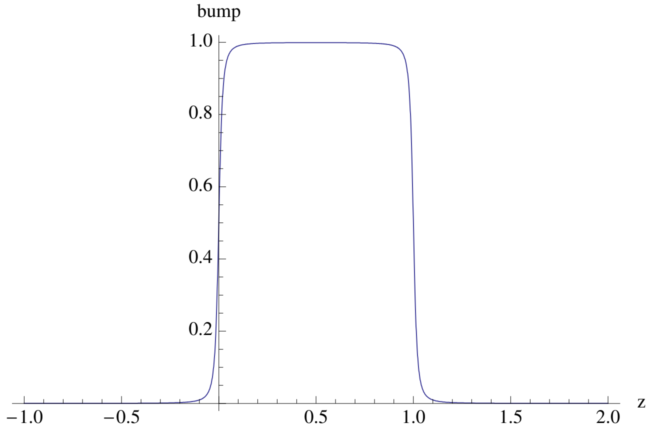

Figure 16.2.5: The soft-edge bump function (2.17) when $a = .02$ and $L = 1$.

16.2.2.2 Asymptotic Behavior of the On-Axis Field

Let us examine the behaviors of the approximating signum function and soft-edge bump function in more detail. Evidently the approximating signum function is an odd function of z,

$$\mathrm{sgn}(-z,a) = \mathrm{sgn}(z,a), \tag{16.2.31}$$

and, correspondingly, satisfies the relation

$$\mathrm{sgn}(0,a) = 0. \tag{16.2.32}$$

It is also easy to verify that

$$\mathrm{sgn}(\pm a,a) = \pm 1/\sqrt{2} = \pm .707\cdots\ . \tag{16.2.33}$$

Finally, It can be verified from (2.26) that, when $(a/z)^2 < 1$, there are the asymptotic behaviors

$$\mathrm{sgn}(z,a) = 1 - (1/2)(a/z)^2 + (3/8)(a/z)^4 - (15/48)(a/z)^6 + \cdots \text{ as } z \to +\infty, \tag{16.2.34}$$

$$\mathrm{sgn}(z,a) = -1 + (1/2)(a/z)^2 - (3/8)(a/z)^4 + (15/48)(a/z)^6 - \cdots \text{ as } z \to -\infty. \quad (16.2.35)$$

The behavior of the soft-edge bump function is a bit more complicated but, according to (2.25), follows from that of the approximating signum function. We begin with two simple observations. From (2.25) and (2.32) we see that there are the "end" ($z = 0$ and $z = L$) values

$$\mathrm{bump}(0,a,L) = \mathrm{bump}(L,a,L) = (1/2)L/(L^2 + a^2)^{1/2} \to (1/2) \text{ as } (a/L) \to 0, \quad (16.2.36)$$

and the "center" ($z = L/2$) value

$$\mathrm{bump}(L/2,a,L) = L/(L^2 + 4a^2)^{1/2} \to 1 \text{ as } (a/L) \to 0. \quad (16.2.37)$$

We will next study the soft-edge bump function's *near* leading/entering end behavior, its behavior when $z \in (-L, 0)$. [Its near trailing/exiting end behavior, its behavior when $z \in (L, 2L)$, then follows by symmetry.] For this purpose, according to (2.25), we need to know the behavior of both $\mathrm{sgn}(z,a)$ and $\mathrm{sgn}(z-L,a)$ when $z < 0$. The behavior of $\mathrm{sgn}(z,a)$ for $z < 0$ is given by (2.35). For $\mathrm{sgn}(z - L, a)$ we find (when $z \approx 0$) the expansion

$$\begin{aligned}\mathrm{sgn}(z-L,a) &= (z-L)/[(z-L)^2 + a^2]^{1/2} = -[1 + a^2/(z-L)^2]^{1/2} \\ &= -1 + (1/2)[a/(z-L)]^2 - (3/8)[a/(z-L)]^4 + \cdots \\ &= -1 + (1/2)(a/L)^2 + (a^2 z/L^3) + \cdots . \quad (16.2.38)\end{aligned}$$

(Here we assume that both z/L and a/L are small.) Consequently, for the range $z \approx 0$ but $z < -a$ so that (2.35) holds, we conclude from (2.25) there is the expansion

$$\begin{aligned}\mathrm{bump}(z,a,L) &= [\mathrm{sgn}(z,a) - \mathrm{sgn}(z-L,a)]/2 \\ &= -1/2 + (1/4)(a/z)^2 - (3/16)(a/z)^4 + \cdots \\ &\quad +1/2 - (1/4)(a/L)^2 - (1/2)(a^2 z/L^3) - \cdots \\ &= +(1/4)(a/z)^2 - (1/4)(a/L)^2 - (1/2)(a/L)^2(z/L) - \cdots . \\ &\qquad (16.2.39)\end{aligned}$$

We see that the $(a/z)^2$ term dominates for small z and therefore $\mathrm{bump}(z,a,L)$ decreases as $1/z^2$ as z becomes more negative. Upon reflection, this result should be expected. Close by the end of a solenoid the external field looks like a *monopole* field; and the field of a monopole falls off with distance as the inverse square.

Complete asymptotic behavior does not set in until $z < -L$. In that case, using (2.35), we see that $\mathrm{sgn}(z - L, a)$ has the expansion

$$\begin{aligned}\mathrm{sgn}(z-L,a) &= -1 + (1/2)[a/(z-L)]^2 - (3/8)[a/(z-L)]^4 + \cdots \\ &= -1 + (1/2)(a/z)^2 + (La^2/z^3) \\ &\quad +(3/8)(4a^2L^2 - a^4)/z^4 + \cdots \text{ when } z < -L. \quad (16.2.40)\end{aligned}$$

We now find from (2.25) the result

$$\begin{aligned}\mathrm{bump}(z,a,L) &= [\mathrm{sgn}(z,a) - \mathrm{sgn}(z-L,a)]/2 \\ &= -1/2 + (1/4)(a/z)^2 - (3/16)(a/z)^4 + \cdots \\ &\quad +1/2 - (1/4)(a/z)^2 - (1/2)(La^2/z^3) + \cdots \\ &= -(1/2)La^2/z^3 + O(1/z^4) \text{ when } z \to -\infty. \quad (16.2.41)\end{aligned}$$

Correspondingly, the on-axis gradient $C_0^{[1]}(z)$ and on-axis field $B_z(0,0,z)$ fall off for very large ($z < -L$) distances as

$$C_0^{[1]}(z) = B_z(0,0,z) = -(1/2)BLa^2/z^3 + \cdots \text{ when } z \to -\infty. \tag{16.2.42}$$

Analogous fall off occurs when $z > 2L$. This result is also to be expected. From far enough away, the end fields of a solenoid of length L look like those of two monopoles of opposite signs a distance L apart, and therefore combine to appear as the field of a *dipole* once one is more than a distance L away. Finally, at large distances, the field of a dipole falls off as $1/|z|^3$.

We close this subsection with the injunction that, although the asymptotic expansions we have examined are illuminating, there is no substitute for computing $B_z(0,0,z)$ exactly using (2.17) and (2.18).

16.2.2.3 Properties of the Vector Potential

The computation of orbits in and transfer maps for solenoids, using a Hamiltonian formulation, requires the use of a vector potential. We will employ the vector potential given by (2.11) through (2.13). Evidently, depending on the order to which we wish to work, we need the functions $C_0^{[1]}(z)$, $C_0^{[3]}(z)$, $C_0^{[5]}(z)$,$\cdots$. To get a feel for what is involved, let us examine, for example, the function $C_0^{[3]}(z)$. From (2.15) and (2.19) we see that

$$C_0^{[3]}(z) = (\partial/\partial z)^2 B_z(0,0,z) = B\ (\partial/\partial z)^2 \text{bump}(z,a,L) = B\ \text{bump}''(z,a,L). \tag{16.2.43}$$

Figures (2.6) and (2.7) illustrate the function bump$''$ for a fixed value of L and two different values of a. Evidently the function bump$''$ becomes quite singular at the ends of the solenoid in the limit $a \to 0$. Indeed it approaches the function $\delta'(z)$ at the leading end, and the function $-\delta'(z-L)$ at the trailing end. Moreover, it falls off quite rapidly beyond the fringe-field regions. From (2.39) and (2.41) we conclude that there is the near-by asymptotic behavior

$$\text{bump}''(z,a,L) = (3/2)a^2/z^4 + \cdots \text{ as } z \to -\infty, \tag{16.2.44}$$

and the far asymptotic behavior

$$\text{bump}''(z,a,L) = -6La^2/z^5 + \cdots \text{ as } z \to -\infty, \tag{16.2.45}$$

The still higher derivatives of the bump function, needed to compute the $C_0^{[n]}(z)$ for still larger values of n, are even more singular in the limit $a \to 0$, and fall off ever more rapidly as $z \to -\infty$. Analogous results hold for $z > L$ and $z > 2L$.

16.2.3 Opposing Simple Solenoid Doublet

We have seen that the on-axis field of a single simple solenoid has the *far* asymptotic behavior (2.42). A sequence of solenoids, all having the same "sign", will have the same far fall-off behavior. In this subsection we will study the far fall-off behavior for what we call an *opposing solenoid doublet*. By this term we mean a pair of solenoids, each of length L,

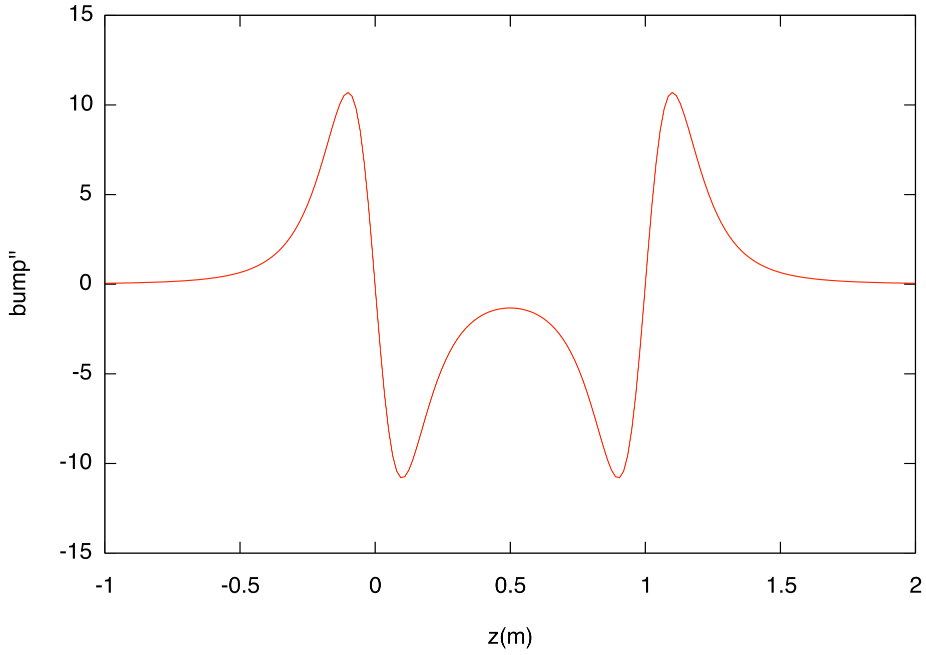

Figure 16.2.6: The function bump$''$ when $a = .2$ and $L = 1$.

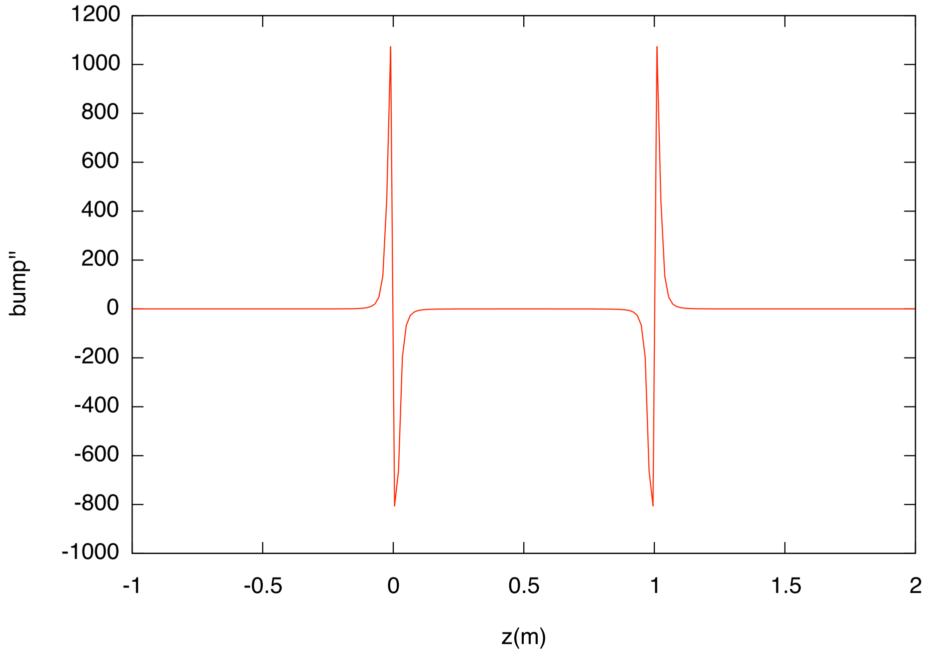

Figure 16.2.7: The function bump$''$ when $a = .02$ and $L = 1$.

separated by a space D, and having opposite strengths. By superposition, the on-axis field for such a pair of solenoids is given by the relation

$$\begin{aligned}
&B_z^{\text{osd}}(0,0,z) = B\ \text{bump}(z,a,L) - B\ \text{bump}(z-L-D,a,L)\\
&= B\{z/[z^2+a^2]^{1/2} - (z-L)/[(z-L)^2+a^2]^{1/2}\}/2\\
&-B\{(z-L-D)/[(z-L-D)^2+a^2]^{1/2} - (z-2L-D)/[(z-2L-D)^2+a^2]^{1/2}\}/2.\\
&= B[\text{sgn}(z,a) - \text{sgn}(z-L,a) - \text{sgn}(z-L-D,a) + \text{sgn}(z-2L-D,a)].
\end{aligned} \tag{16.2.46}$$

Computation using expansions such as (2.42) shows that for this opposing solenoid doublet there is the far fall-off behavior

$$C_0^{[1]}(z) = B_z^{\text{osd}}(0,0,z) = 3Ba^2L(L+D)/z^4 + O(1/z^5) \text{ when } z \to -\infty. \tag{16.2.47}$$

Comparison with (2.42) shows that this $1/z^4$ far fall-off behavior is one order higher in $1/z$ than that for a single solenoid. This result is to be expected because the end of each solenoid looks like a monopole, at a far distance the four ends of the two solenoids in the opposing solenoid doublet look like an in-line quadrupole, and the field of a quadrupole falls off as $1/z^4$.

16.2.4 More Complicated Air-Core Solenoids

The fields for more complicated air-core solenoids can be found from those of simple single-layer air-core solenoids by superposition. Consider, for example, the on-axis field of an air-core solenoid that has a multi-layer winding with inner radius a_1 and outer radius a_2. We will call such a solenoid a *thick* solenoid. We observe that there is the integral relation

$$\int_{a_1}^{a_2} da\ \{1/[z^2+a^2]^{1/2}\} = \log\Big(\{[z^2+a_2^2]^{1/2}+a_2\}/\{[z^2+a_1^2]^{1/2}+a_1\}\Big). \tag{16.2.48}$$

Correspondingly, the on-axis field of such a thick solenoid is given by the relation

$$\begin{aligned}
B_z(0,0,z) \ &= \ (B/2)[1/(a_2-a_1)]\Big[z\log\Big(\{[z^2+a_2^2]^{1/2}+a_2\}/\{[z^2+a_1^2]^{1/2}+a_1\}\Big)\\
&- \ (z-L)\log\Big(\{[(z-L)^2+a_2^2]^{1/2}+a_2\}/\{[(z-L)^2+a_1^2]^{1/2}+a_1\}\Big)\Big].
\end{aligned} \tag{16.2.49}$$

Here again the winding extends from $z=0$ to $z=L$ and the interior field (in the infinite length limit) is B.

Evidently, from this result and by superposition, analytic on-axis results can be obtained for any combination of concentric coils of various lengths, thicknesses, locations, and powerings. Note, because we have assumed cylindrical symmetry in all cases, only the $m=0$ terms are present in the expansion (15.3.33) so that (2.1) continues to hold.

16.2.5 Computation of Transfer Map

In this subsection we will compute the transfer map for a solenoid (or a collection of solenoids) including fringe-field effects. To do so we begin with the Hamiltonian (1.1) and employ the vector potential given by (2.7) through (2.10). We then introduce dimensionless scaled deviation variables and the associated scaled deviation-variable Hamiltonian. Finally, we expand the scaled deviation-variable Hamiltonian in a Taylor series, and employ this Taylor series to compute the transfer map.

16.2.5.1 Dimensionless Scaled Deviation Variables and Scaled Deviation-Variable Hamiltonian

A solenoid is an example of a straight beam-line element for which the design orbit may be taken to be the z axis (a straight line) traversed with constant velocity. According to the results of Section 13.1.5, the scaled deviation variable Hamiltonian $H(X,Y,\tau,P_x,P_y,P_\tau;z)$ for any such element is given by

$$\begin{aligned}&H(X,Y,\tau,P_x,P_y,P_\tau;z)=\\&\quad-(1/\ell)\{[1-(2P_\tau/\beta_0)+P_\tau^2-(P_x-A_x^s)^2-(P_y-A_y^s)^2]^{1/2}+(P_\tau/\beta_0)-(1/\beta_0^2)\}.\end{aligned}\tag{16.2.50}$$

Here the dimensionless scaled deviation variables $(X,Y,\tau,P_x,P_y,P_\tau)$ are defined in terms of the original variables (x,y,t,p_x,p_y,p_t) by the relations (13.1.21) through (13.1.26), and the *scaled* vector potential $\boldsymbol{A}^s$ is defined in terms of the original vector potential $\hat{\boldsymbol{A}}^0$ by the relation

$$\boldsymbol{A}^s(X,Y,z)=(q/p^0)\hat{\boldsymbol{A}}^0(\ell X,\ell Y,z).\tag{16.2.51}$$

We have also used (2.9).

The relations (2.7) through (2.10) and (2.51) can be used to find $\boldsymbol{A}^s$ for solenoids. To do so it is convenient to rewrite (2.10) in the form

$$U(\rho,z)=(1/2)\sum_{n=0}^{\infty}(-1)^n\frac{1}{2^{2n}n!(n+1)!}B^{[2n]}(z)\rho^{2n}.\tag{16.2.52}$$

Here we have introduced, in accord with (2.15), the notation

$$B^{[0]}(z)=C_0^{[1]}(z)=B_z(0,0,z),\tag{16.2.53}$$

$$B^{[2n]}(z)=(\partial/\partial z)^{2n}B^{[0]}(z)=(\partial/\partial z)^{2n}C_0^{[1]}(z)=C_0^{[2n+1]}(z).\tag{16.2.54}$$

Combining these relations yields the results

$$A_x^s=-YU^s(X,Y,z)\tag{16.2.55}$$

$$A_y^s=XU^s(X,Y,z),\tag{16.2.56}$$

$$A_z^s=0,\tag{16.2.57}$$

where

$$U^s(X,Y,z) = \ell(q/p^0)U(\ell X,\ell Y,z) = (1/2)\sum_{n=0}^{\infty}(-1)^n \frac{1}{2^{2n}n!(n+1)!}b^{[2n]}(z)(X^2+Y^2)^n. \tag{16.2.58}$$

Here we have introduced the notation

$$b^{[2n]}(z) = (q/p^0)\ell^{2n+1}B^{[2n]}(z), \tag{16.2.59}$$

and observe, in view of (1.5.81) and (2.54), that the quantities $b^{[2n]}(z)$ are dimensionless. Also, from (2.50), we conclude that the scaled deviation variable Hamiltonina H has dimensions of 1/length.

16.2.5.2 Symmetry of Scaled Deviation-Variable Hamiltonian

The Hamiltonian H given by (2.50) has a symmetry that is worth noting. Define two two-dimensional vectors $\boldsymbol{Q}$ and $\boldsymbol{P}$ by the rules

$$\boldsymbol{Q} = X\boldsymbol{e}_x + Y\boldsymbol{e}_y, \tag{16.2.60}$$

$$\boldsymbol{P} = P_x\boldsymbol{e}_x + P_y\boldsymbol{e}_y. \tag{16.2.61}$$

Also make the definitions

$$Q^2 = \boldsymbol{Q}\cdot\boldsymbol{Q} = X^2+Y^2, \tag{16.2.62}$$

$$P^2 = \boldsymbol{P}\cdot\boldsymbol{P} = P_x^2+P_y^2, \tag{16.2.63}$$

$$J_z = (\boldsymbol{Q}\times\boldsymbol{P})\cdot\boldsymbol{e}_z = XP_y - YP_x. \tag{16.2.64}$$

With the aid of these definitions we may write

$$\begin{aligned}(P_x-A_x^s)^2+(P_y-A_y^s)^2 &= (P_x)^2+(P_y)^2+(A_x^s)^2+(A_y^s)^2-2P_xA_x^s-2P_yA_y^s\\ &= \boldsymbol{P}\cdot\boldsymbol{P}+\boldsymbol{A}^s\cdot\boldsymbol{A}^s-2\boldsymbol{P}\cdot\boldsymbol{A}^s.\end{aligned} \tag{16.2.65}$$

We also observe with the aid of (2.55) and (2.56) that there are the relations

$$\boldsymbol{P}\cdot\boldsymbol{A}^s = (XP_y-YP_x)U^s = J_zU^s, \tag{16.2.66}$$

$$\boldsymbol{Q}\cdot\boldsymbol{A}^s = 0, \tag{16.2.67}$$

and

$$\boldsymbol{A}^s\cdot\boldsymbol{A}^s = Q^2(U^s)^2. \tag{16.2.68}$$

The relation (2.67) is a consequence of our decision to employ the Poincaré-Coulomb gauge. Also note that, according to (2.58), U^s depends only on Q^2 and z. With the aid of these relations we may also write

$$(P_x-A_x^s)^2+(P_y-A_y^s)^2 = P^2+Q^2(U^s)^2-2J_zU^s. \tag{16.2.69}$$

It is easily verified that J_z has the properties

$$: J_z : X = [J_z, X] = [(XP_y - YP_x), X] = Y, \tag{16.2.70}$$

$$: J_z : Y = -X, \tag{16.2.71}$$

$$: J_z : P_x = P_y, \tag{16.2.72}$$

$$: J_z : P_y = -P_x, \tag{16.2.73}$$

$$: J_z : \tau =: J_z : P_\tau = 0. \tag{16.2.74}$$

Consequently, as the notation is meant to suggest, the Lie operator $: J_z :$ is the generator of rotations about the z axis. It follows that there are the relations

$$: J_z : Q^2 =: J_z : U^s =: J_z : P^2 =: J_z : (\boldsymbol{P} \cdot \boldsymbol{Q}) = 0. \tag{16.2.75}$$

We remark that the last relation in (2.75) is consistent with the identity

$$(\boldsymbol{P} \cdot \boldsymbol{Q})^2 = Q^2 P^2 - J_z^2. \tag{16.2.76}$$

We also see from (2.55) and (2.56) that there are the relations

$$: J_z : A_x^s == [J_z, -YU^s] = -[J_z, Y]U^s = XU^s = A_y^s \tag{16.2.77}$$

and

$$: J_z : A_y^s == [J_z, XU^s] = [J_z, X]U^s = YU^s = -A_x^s. \tag{16.2.78}$$

It follows that

$$: J_z : (\boldsymbol{A}^s \cdot \boldsymbol{A}^s) =: J_z : (\boldsymbol{Q} \cdot \boldsymbol{A}^s) =: J_z : (\boldsymbol{P} \cdot \boldsymbol{A}^s) = 0. \tag{16.2.79}$$

We note that these last results can be viewed as a consequence of (2.68), (2.67), and (2.66). But they can also be viewed as consequence of the relations (2.70) through (2.73) and (2.77) and (2.78).

Based on the work so far H as given by (2.50) can be rewritten in either of the forms

$$\begin{aligned} &H(X, Y, \tau, P_x, P_y, P_\tau; z) = \\ &-(1/\ell)\{[1 - (2P_\tau/\beta_0) + P_\tau^2 - \boldsymbol{P} \cdot \boldsymbol{P} - \boldsymbol{A}^s \cdot \boldsymbol{A}^s + 2\boldsymbol{P} \cdot \boldsymbol{A}^s]^{1/2} + (P_\tau/\beta_0) - (1/\beta_0^2)\}. \end{aligned} \tag{16.2.80}$$

and

$$\begin{aligned} &H(X, Y, \tau, P_x, P_y, P_\tau; z) = \\ &-(1/\ell)\{[1 - (2P_\tau/\beta_0) + P_\tau^2 - P^2 - Q^2(U^s)^2 + 2J_z U^s]^{1/2} + (P_\tau/\beta_0) - (1/\beta_0^2)\}. \end{aligned} \tag{16.2.81}$$

From either of these forms it is evident, using (2.75) and (2.79), that

$$: J_z : H = [J_z, H] = 0. \tag{16.2.82}$$

That is, H is invariant under rotations about the z axis and, conversely, J_z is an integral of motion. (We also say that H and J_z are in involution.) Note that this invariance stems from the fact that we are dealing with the the magnetic field case described by an $m = 0$ scalar potential ψ. This scalar potential has rotational symmetry about the z axis, and the gauge for the associated vector potential has been judiciously chosen to maintain this symmetry. See Exercise 2.10.

16.2.5.3 Properties of Transfer Map and Factorization of Linear Part

Because of the J_zU^s term in (2.81) [or the $\boldsymbol{P}\cdot\boldsymbol{A}^s$ term in (2.80)] the map $\mathcal{M}$ generated by H produces rotations about the z axis as well as other effects. Consequently $\mathcal{M}$ does not preserve the X, P_x and Y, P_y planes. When performing fitting operations it is easier to understand what is happening when motion in the X, P_x and Y, P_y planes is uncoupled. Uncoupling can be accomplished by a trick. Define a Hamiltonian with no rotational parts, call it H^{nonrot}, by removing the J_zU^s term in (2.81):

$$\begin{aligned}&H^{\text{nonrot}}(X,Y,\tau,P_x,P_y,P_\tau;z) =\\ &\quad -(1/\ell)\{[1-(2P_\tau/\beta_0)+P_\tau^2-P^2-Q^2(U^s)^2]^{1/2}+(P_\tau/\beta_0)-(1/\beta_0^2)\}.\end{aligned} \tag{16.2.83}$$

The map generated by H^{nonrot}, call it $\mathcal{M}^{\text{nonrot}}$, will preserve the X, P_x and Y, P_y planes. See Exercise 2.17. To proceed, first carry out the desired fitting operation using $\mathcal{M}^{\text{nonrot}}$ in place of $\mathcal{M}$. After a fit has been achieved using $\mathcal{M}^{\text{nonrot}}$ in place of $\mathcal{M}$, continue on using the associated full $\mathcal{M}$ in subsequent calculations.

In general the maps $\mathcal{M}$ and $\mathcal{M}^{\text{nonrot}}$ do not commute. However, as shown in Exercise 2.15, the matrices M and M^{nonrot} associated with their linear parts do commute,

$$M^{\text{nonrot}}M = MM^{\text{nonrot}}. \tag{16.2.84}$$

In this case it is possible to define a matrix M^{rot} by the rule

$$M^{\text{rot}} = (M^{\text{nonrot}})^{-1}M = M(M^{\text{nonrot}})^{-1} \tag{16.2.85}$$

so that

$$M = M^{\text{rot}}M^{\text{nonrot}} = M^{\text{nonrot}}M^{\text{rot}}. \tag{16.2.86}$$

As the notation suggests, M^{rot} describes rotations about the z axis.

For example, for the matrix M^{body} displayed in Exhibit 2.11 in Subsection 2.6.2, Exhibits 2.1 and 2.2 below display the factors M^{nonrot} and M^{rot}.

```

As can be seen, the effect of $M^{\rm nonrot}$ is to produce (equal) *focussing* in both planes. (Note also that $M^{\rm nonrot}$ does not introduce any coupling between planes.) And $M^{\rm rot}$ produces a rotation about the z axis by an angle $\theta_{\rm rot}$. In the case that the entrance and exit planes are *well outside* the fringe-field regions [which, as can be seen from Figure 2.5 and (2.42), is not quite true for this example], $\theta_{\rm rot}$ is given (in radians) by the relation

$$\theta_{\rm rot} = [1/(2\ {\rm brho})]\int_{-\infty}^{+\infty} B_z(0,0,z)\,dz = BL/(2\ {\rm brho}). \tag{16.2.87}$$

Here brho is the magnetic rigidity. See Exercise 1.5.9. Note that the result (2.87) does not depend on a in the case of a simple solenoid or on a_1 and a_2 in the case of a thick solenoid.

16.2.5.4 Expansion of Scaled Deviation-Variable Hamiltonian

To find the transfer map $\mathcal{M}$ about the design orbit it is necessary to express the scaled deviation-variable Hamiltonian H as a sum of homogeneous polynomials,

$$H = \sum_{m=0}^{\infty} H_m. \tag{16.2.88}$$

Doing so for the Hamiltonian (2.50) gives, for the first few terms, the results

$$H_0 = 1/(\beta_0^2\gamma_0^2\ell), \tag{16.2.89}$$

$$H_1 = 0, \tag{16.2.90}$$

$$\begin{aligned} H_2 = {} & [1/(2\ell)](P_x^2 + P_y^2) - [b^{[0]}/(2\ell)](XP_y - YP_x) \\ & + [(b^{[0]})^2/(8\ell)](X^2 + Y^2) + [1/(2\beta_0^2\gamma_0^2\ell)]P_\tau^2, \end{aligned} \tag{16.2.91}$$

$$\begin{aligned} H_3 = {} & [1/(2\beta_0\ell)]P_\tau(P_x^2 + P_y^2) - [b^{[0]}/(2\beta_0\ell)]P_\tau(XP_y - YP_x) \\ & + [(b^{[0]})^2/(8\beta_0\ell)]P_\tau(X^2 + Y^2) + [1/(\beta_0^3\gamma_0^2\ell)]P_\tau^3, \end{aligned} \tag{16.2.92}$$

$$\begin{aligned} H_4 = {} & (1/8\ell)(P_x^4 + 2P_x^2P_y^2 + P_y^4) - [b^{[0]}/(4\ell)](P_x^2 + P_y^2)(XP_y - YP_x) \\ & + [(b^{[0]})^2/(16\ell)](X^2P_x^2 + Y^2P_y^2) + [3(b^{[0]})^2/(16\ell)](X^2P_y^2 + Y^2P_x^2) \\ & - [(b^{[0]})^2/(4\ell)](XP_xYP_y) + \{[b^{[2]} - (b^{[0]})^3]/(16\ell)\}(X^2 + Y^2)(XP_y - YP_x) \\ & + \{[(b^{[0]})^4 - 4b^{[0]}b^{[2]}]/(128\ell)\}(X^4 + 2X^2Y^2 + Y^4) - [(3 - \beta_0^3)/(4\beta_0^2\ell)]P_\tau^2(P_x^2 + P_y^2) \\ & - [b^{[0]}(3 - \beta_0^3)/(4\beta_0^2\ell)]P_\tau^2(XP_y - YP_x) + [(b^{[0]})^2(3 - \beta_0^3)/(16\beta_0^2\ell)]P_\tau^2(X^2 + Y^2) \\ & + [(5 - \beta_0)^2)/(8\beta_0^4\gamma_0^2\ell)]P_\tau^4. \end{aligned} \tag{16.2.93}$$

These are the terms required to compute $\mathcal{M}$ through third order. Note that H_1 vanishes as it should. If it did not, the phase-space path obtained by setting all deviation variables to zero (the design orbit) would not be a solution of the equations of motion. We also remark that the constant piece H_0 is irrelevant to the actual motion, and does not enter into the calculation of $\mathcal{M}$. It is presented only as an aid for those who wish to check the expansion (2.88) through (2.93).

In view of the symmetry (2.82), it is also instructive to have an expansion of H in terms of the variables P_τ, P^2, J_z, and Q^2. In terms of these variables there are the results

$$H_2 = [1/(2\ell)]P^2 - [b^{[0]}/(2\ell)]J_z + [(b^{[0]})^2/(8\ell)]Q^2 + [1/(2\beta_0^2\gamma_0^2\ell)]P_\tau^2, \tag{16.2.94}$$

$$H_3 = (1/\beta_0)P_\tau H_2, \tag{16.2.95}$$

$$\begin{aligned} H_4 = {} & [1/(8\ell)](P^2)^2 - [b^{[0]}/4\ell)]P^2 J_z + [b^{[0]}/(8\ell)]J_z^2 + [-b^{[0]}/(8\ell) + 3(b^{[0]})^2/(16\ell)]P^2 Q^2 \\ & + \{[b^{[2]} - (b^{[0]})^3]/(16\ell)\}Q^2 J_z + \{[(b^{[0]})^4 - 4b^{[0]}b^{[2]}]/(128\ell)\}(Q^2)^2 \\ & + [(3-\beta_0^2)/(4\beta_0^2\ell)]P_\tau^2 P^2 - [(3-\beta_0^2)b^{[0]}/(4\beta_0^2\ell)]P_\tau^2 J_z \\ & + [(3-\beta_0^2)(b^{[0]})^2/(16\beta_0^2\ell)]P_\tau^2 Q^2 + [(5-\beta_0)^2)/(8\beta_0^4\gamma_0^2\ell)]P_\tau^4. \end{aligned} \tag{16.2.96}$$

Note that, because H_3 as given by (2.95) is proportional to P_τ, all second-order aberrations for any solenoid transfer map are purely chromatic.

We close this subsection with the remark that the result given by (2.94) through (2.96) holds for any solenoid. For simplicity, in subsequent sections we will apply them to the case of a simple air-core solenoid, in which case (2.19) holds. But they are also applicable to more complicated air-core solenoids as described in Subsection 2.4 as well as solenoids containing iron.

16.2.6 Solenoidal Fringe-Field Effects: Attempts to Hard-Edge Model Them

16.2.6.1 Convergence and Divergence

Suppose we wish to make a *simple* model of fringe-field effects. The hope would be to find a model whose fields are not too different from those that can be attained by feasible magnet construction and for which analytic calculations can be made using simple approximations and without too much difficulty, thereby bypassing the need for detailed numerical calculation involving a detailed knowledge of the functions $b^{[n]}(z)$. One idea for doing so is to consider a model in which the bump function in (2.18) and (2.19) is replaced by a bump function having the properties (2.30). This so-called *hard-edge* model, for which the on-axis field begins and ends abruptly, has only limited utility. Here are several objections to this approach:

- Real solenoids, and in particular multi-layer solenoids as described in Subsection 2.4, have extended fringe fields. From (2.49) one sees that the on-axis field involves both the inner radius a_1 and the outer radius a_2. For a realistic/*thick* multi-layer solenoid a_2 is relatively large. Correspondingly, the fringe fields falls off only slowly. Therefore beginning and terminating the on-axis field abruptly is a poor approximation for real solenoids.

- Suppose we restrict our attention to single-layer solenoids as described in Subsection 2.2. In this case (which we have called the *simple* solenoid case), as examination of Figures 2.4 and 2.5 illustrates, it might be useful to attempt a hard-edge model. That is, we might attempt to compute the transfer map $\mathcal{M}$ when $a = 0$ because then, according to (2.29), the soft-edge bump function becomes the hard-edge bump function. In this case however, as described in Subsection 2.2.3, the on-axis gradient $C_0^{[3]}$ involves bump$''(z, a, L)$ which takes on the appearance of $\delta'(z)$ and $-\delta'(z - L)$ in the hard-edge limit. See Figure (2.7). We note that the appearance of the δ' functions is a consequence of the representation (2.1) which itself is a consequence of the Maxwell equations for $\boldsymbol{B}$. We also note that H_4 as given by (2.96) involves $b^{[2]}(z)$ which in turn, according to (2.43) and (2.59), can involve the pesky δ' functions. Therefore the differential equation (10.5.61) for f_4 is ill defined in the hard-edge case. One might hope to deal with this complication by making calculations for $a \neq 0$, including all fringe-field effects, and then taking the limit $a \to 0$. When this is done it can be shown that some of the the third- and higher-order aberrations (described by the f_n with $n \geq 4$) of the transfer map $\mathcal{M}$ for a solenoid become *infinite* in the hard-edge ($a \to 0$) limit! Thus, the hard-edge limit is unphysical for a solenoid if these aberrations are important.[1] Correspondingly, third-order solenoid aberrations can be reduced by making the fringe-field regions large. It also helps to make the solenoid weak since aberrations are proportional to B. If this is done, the solenoid must also be made long (to compensate for the small B) in order to maintain the desired paraxial properties.

- Finally we must acknowlege the obvious but irritating fact that the aperture of the simple solenoid, which must contain the beam, shrinks to zero as $a \to 0$.

To illustrate some of these points, let us examine the transfer map for the specific simple air-core solenoid we have been discussing. To do so we will employ the Lie-algebraic charged particle beam transport code MaryLie. Among the beam-line elements it treats is the simple air-core solenoid. Exhibits 2.3 through 2.5 below show (through third order) the transfer map $\mathcal{M}$ for the three cases $a = 0.2$, $a = .02$, and $a = .002$. (Here we use the indexing scheme of Table 39.2.1.) In all cases the solenoid has length $L = 1$, and the entry and exit planes are taken to be at $z = z^{\text{en}} = -1$ and $z = z^{\text{ex}} = 2$, respectively. All lengths are in meters, and we have used the terminology of Subsection 1.2. See Figures 2.4 and 2.5. The quantity B has the value $B = 1$ Tesla and the magnetic rigidity (brho) is that for 800 MeV protons. Finally, the scale length is taken to be $\ell = 1$ meter. Numerical integration of the differential equations (described in Section 10.5.2) to compute $\mathcal{M}$ was carried out employing the Adams10 routine described in Appendix B.8. Both these differential equations and the Adams10 routine are incorporated into MaryLie. The number of integrations steps was 5000 for the cases $a = 0.2$ and $a = .02$, and 10,000 for the case $a = .002$. Results are accurate to

[1] There is confusion/error on this point in the literature. Some authors give aberration results through third order and in the hard-edge limit for many common beam-line elements, but give results for simple solenoids only through second order. And their accompanying discussion can be read to imply that no difficulty is expected in extending the simple solenoid results through third order. Other authors propose formulas for the third-order aberrations of a simple solenoid in the hard-edge limit, and these formulas are independent of a and thus yield *finite* results when $a = 0$. Yet other authors correctly recognize that attempting to make the fringe-field region very small, say by adding extra coils at solenoid ends, leads to some very large third-order aberrations.

at least 10 significant figures.

Evidently the matrices for the three cases are not very different. Moreover, the f_3 Lie generators (which describe second-order aberrations), those with indices 28 through 83, are comparable for the three cases. Both these behaviors are consistent with some sort of convergence occurring for the matrix and f_3 entries as $a \to 0$. See Exercise 2.16. Examination of the equations of motion for these quantities when H_2 and H_3 are given by (2.91) and (2.92), see (10.5.32) and (10.5.60), shows that convergence is to be expected. However, the matter is delicate because the function $b^{[0]}(z)$ that appears in H_2 and hence also in H_3 [see (2.94) and (2.95)] is discontinuous at $z = 0$ and $z = L$ in the limit $a \to 0$. (See also Exercise 2.2.) Therefore the assumptions of Theorems 1.3.1 and 1.3.2 are violated in the limit $a \to 0$. (Note that in this context a is a parameter.)

What can be said about the f_4 Lie generators (which describe third-order aberrations), those with indices 84 through 209? Some of them are quite different for the three values of a. For example, the values of $f(84)$, which are the coefficients of X^4 in the f_4 Lie generators for the three cases, are quite different. Examination shows that these values are $f(84) = -3.74253654402362E - 03$, $f(84) = -3.82799704943991E - 02$, and $f(84) = -0.38235532452970$ for the cases $a = 0.2$, $a = .02$, and $a = .002$, respectively. This behavior suggests the coefficient of X^4 is *diverging* (in magnitude) to ∞ as $a \to 0$. The same is true of some of the other f_4 entries. Indeed, it can be illustrated numerically and demonstrated analytically that the divergent f_4 entries behave as $1/a$ as $a \to 0$ so that, for example, the product $af(84)$ approaches a *constant* as $a \to 0$. Table 2.1 below illustrates this divergence/behavior for the case of $f(84)$.

Table 16.2.1: Numerical behavior of $f(84)$ for small values of a.

a	$f(84)$	$af(84)$
.2	-3.7425E-3	-7.4850E-4
.02	-3.8279E-2	-7.6558E-4
.002	-3.8235E-1	-7.6470E-4

We have made a preliminary study of the $a \to 0$ behavior of the transfer map $\mathcal{M}$ for a simple solenoid. In the rest of this subsection we will examine the matter in greater detail.

16.2.6.2 Behavior of Linear Part

16.2.6.2.1 Factorization into Three a Dependent Maps/Matrices

Something more can be said about M, the matrix for the *linear* part of $\mathcal{M}$, if one attempts to form hard-edge limits/approximations. Let $\mathcal{M}_{-1\to 2}$ be the transfer map between the planes $z = -1$ and $z = 2$, respectively. It is the map displayed in Exhibits 2.3 through 2.5 for three different values of a. Also, employing analogous notation, consider the maps $\mathcal{M}_{-1\to 0}$, $\mathcal{M}_{0\to 1}$, and $\mathcal{M}_{1\to 2}$. Then we have the relation

$$\mathcal{M}_{-1\to 2} = \mathcal{M}_{-1\to 0}\mathcal{M}_{0\to 1}\mathcal{M}_{1\to 2}. \tag{16.2.97}$$

Next, let $\mathcal{D}$ be the map for a drift of length 1 meter. Employ this map to define implicitly two other maps $\mathcal{M}^{\rm lff}$ and $\mathcal{M}^{\rm tff}$ by writing

$$\mathcal{M}_{-1\to 0} = \mathcal{D}\mathcal{M}^{\rm lff} \tag{16.2.98}$$

and

$$\mathcal{M}_{1\to 2} = \mathcal{M}^{\rm tff}\mathcal{D}. \tag{16.2.99}$$

Then, particularly when a is small, we may view $\mathcal{M}^{\rm lff}$ and $\mathcal{M}^{\rm tff}$ as *leading* and *trailing fringe-field* maps. Of course, (2.98) and (2.99) can be solved to give the explicit definitions

$$\mathcal{M}^{\rm lff} = \mathcal{D}^{-1}\mathcal{M}_{-1\to 0} \tag{16.2.100}$$

$$\mathcal{M}^{\rm tff} = \mathcal{M}_{1\to 2}\mathcal{D}^{-1}. \tag{16.2.101}$$

Also, make the definition

$$\mathcal{M}^{\rm body} = \mathcal{M}_{0\to 1}. \tag{16.2.102}$$

Then we have the factorization

$$\mathcal{M}_{-1\to 2} = \mathcal{D}\mathcal{M}^{\rm lff}\mathcal{M}^{\rm body}\mathcal{M}^{\rm tff}\mathcal{D}. \tag{16.2.103}$$

Note that all these maps are symplectic. Note also that, as illustrated in Figure 2.5, when a is sufficiently small, the map $\mathcal{M}_{-1\to 2}$ essentially describes transport through a 1 meter drift followed by transport through a 1 meter solenoid followed by transport through a final 1 meter drift. We therefore expect, when a is sufficiently small, that $\mathcal{M}^{\rm lff}$ and $\mathcal{M}^{\rm tff}$ will describe leading and trailing fringe-field effects *outside* the solenoid, and $\mathcal{M}^{\rm body}$ will describe all effects occurring *within* the solenoid itself.

Finally, in view of (2.103), we make the definition

$$\mathcal{M}_{\rm solenoid} = \mathcal{M}^{\rm lff}\mathcal{M}^{\rm body}\mathcal{M}^{\rm tff}. \tag{16.2.104}$$

Note that $\mathcal{M}_{\rm solenoid}$ has been factored into *three* a dependent maps. Correspondingly for the associated linear parts there will be the relation

$$M_{\rm solenoid} = M^{\rm tff}M^{\rm body}M^{\rm lff}. \tag{16.2.105}$$

The matrix $M_{\rm solenoid}$ has also been factorized into three a dependent matrices.

From the previous discussion we expect that some of the third- and higher-order aberration parts of the maps $\mathcal{M}^{\rm lff}$, $\mathcal{M}^{\rm tff}$, and $\mathcal{M}^{\rm body}$ may diverge as $a \to 0$. But for now let us examine the linear/matrix parts of the maps $\mathcal{M}^{\rm lff}$, $\mathcal{M}^{\rm body}$, and $\mathcal{M}^{\rm tff}$ in the hard-edge limit $a \to 0$. We begin with the maps $\mathcal{M}^{\rm lff}$ and $\mathcal{M}^{\rm tff}$. Exhibits 2.6 through 2.9 show the matrices associated with these maps for the values $a = 0.2$ and $a = 0.02$.

Upon comparing Exhibits 2.6 and 2.7 we see that there appears to be the limiting behavior

$$\lim_{a\to 0} M^{\mathrm{lff}} = I. \tag{16.2.106}$$

And, upon comparing Exhibits 2.8 and 2.9, we see that there appears to be the limiting behavior

$$\lim_{a\to 0} M^{\mathrm{tff}} = I. \tag{16.2.107}$$

Thus it appears that, for a solenoid in the hard-edge limit, there are *no* effects on the *linear* part of the transfer map due to fringe fields outside the solenoid. These results can be proved analytically using the H_2 given by (2.91) to compute $M_{-1\to 0}$ and $M_{1\to 2}$ since in the hard-edge limit $b^{[0]}(z)$ vanishes for $z < 0$ and $z > L = 1$, and therefore the resulting M for such computations will simply be that for a 1 meter drift.

What can be said about the linear part of $\mathcal{M}^{\mathrm{body}}$? Exhibits 2.10 and 2.11 show the matrices associated with these maps for the values $a = 0.2$ and $a = 0.02$.

Comparison of the matrices in Exhibits 2.10 and 2.11 shows that some sort of limit also appears to be approached by M^{body} as $a \to 0$. But what is this limit? Exhibit 2.12 shows M^{uniform}, the matrix computed (numerically) using the Hamiltonian H_2 given by (2.91) with $b^{[0]}(z)$ having a *constant* value. (This matrix can be computed analytically as well as numerically. The analytic result is that quoted in Section 13.4. See Exercise 2.16.)

Examination of the matrices in the Exhibits 2.10 through 2.12 shows that there appears to be the limiting behavior

$$\lim_{a\to 0} M^{\text{body}} = M^{\text{uniform}}. \tag{16.2.108}$$

This result can be proved analytically using the H_2 given by (2.91) to compute $M_{0\to 1}$ since in the hard-edge limit $b^{[0]}(z)$ is constant for z in the *open* interval $z \in (0,1)$.

From (2.106) through (2.108) we conclude that in the hard-edge limit there are *no* fringe-field contributions to the *linear* part of the transfer map for a solenoid.That is, there is the limiting result

$$\lim_{a\to 0} M_{\text{solenoid}} = M^{\text{uniform}}. \tag{16.2.109}$$

(Curiously, this is the same result as that found by neglecting fringe fields entirely!) Some other authors have also reached the same conclusion by other methods. However we hasten to emphasize, as we have already seen, that in the hard-edge limit there are disastrous fringe-field effects for some third- and higher-order aberrations. It is therefore highly desirable, in the case of a solenoid, to treat fringe-field effects with care (which must be done numerically) using realistic profiles $b^{[n]}(z)$.

Yet other authors provide formulas for matrices M_{fringe} and $M_{\text{longitudinal}}$ which are meant to play roles analogous to M^{lff}, M^{tff}, and M^{body}. These matrices differ from those given by the linear parts of (2.100) through (2.102); and their limiting values differ from those given by (2.106) through (2.108). They are also *not* symplectic. However, when $a = 0$, their product does give the symplectic result

$$M_{\text{fringe}} M_{\text{longitudinal}} M_{\text{fringe}}^{-1} = M^{\text{uniform}}. \tag{16.2.110}$$

Based on the results of these authors one might be tempted to conclude that, at least in some way, fringe fields even in the hard-edge limit do play some role in determining the linear part of the transfer map for a solenoid. [Note however that their net effect cancels out because of the result (2.110).] The explanation for this confusing circumstance is that these authors employ in essence mechanical rather than canonical momenta in their calculations. So doing is expected to yield nonsymplectic results in the presence of magnetic fields. Recall Exercise 1.7.5. But these nonsymplectic results can ultimately cancel, as in (2.110), when a full/complete calculation is made providing the magnetic field vanishes before entry into and after exit from the solenoid. See Exercise 6.4.11.

16.2.6.2.2 Factorization Involving Only Two a Dependent Maps/Matrices

There is another variation on the theme we have been exploring. Suppose instead of (2.103) we attempt an Ansatz of the form

$$\mathcal{M}_{-1\to 2} = \mathcal{D}\mathcal{M}^{\rm LFF}\mathcal{M}^{\rm uniform}\mathcal{M}^{\rm TFF}\mathcal{D}. \tag{16.2.111}$$

Here $\mathcal{M}^{\rm uniform}$ is the map computed for a length of 1 meter using the Hamiltonian H given by (2.88) through (2.93) with $b^{[0]}$ having a *constant* value and correspondingly $b^{[n]} = 0$ for $n > 0$. (For future reference, we will call this Hamiltonian $H^{\rm uniform}$.) If the Ansatz (2.111) is successful, the maps $\mathcal{M}^{\rm LFF}$ and $\mathcal{M}^{\rm TFF}$ will describe *both* the effects arising from the depletion of the field within the body of the solenoid and the effects of the fields that extend beyond the ends of the solenoid. In view of (2.111) we make the definition

$$\mathcal{M}_{\rm solenoid} = \mathcal{M}^{\rm LFF}\mathcal{M}^{\rm uniform}\mathcal{M}^{\rm TFF}. \tag{16.2.112}$$

Assuming success of the Ansatz (2.111), we see that $\mathcal{M}_{\rm solenoid}$ has been factorized in a way that involves only *two* a dependent maps, namely $\mathcal{M}^{\rm LFF}$ and $\mathcal{M}^{\rm TFF}$, and one a independent map, namely $\mathcal{M}^{\rm uniform}$. Correspondingly for the associated linear parts there will be the relation

$$M_{\rm solenoid} = M^{\rm TFF}M^{\rm uniform}M^{\rm LFF}. \tag{16.2.113}$$

The matrix $M_{\rm solenoid}$ has been factorized in a way that involves only two a dependent matrices and one a independent matrix

Let us pause momentarily at this point to compare the factorizations (2.104) and (2.112). The map $\mathcal{M}_{\rm solenoid}$ is the same in both. [Correspondingly, the matrices $M_{\rm solenoid}$ given by (2.105) and (2.113) are the same.] But (2.104) may be viewed as a kind of *local* factorization in that it treats *separately* effects that occur before, within, and after the body of the solenoid. By contrast (2.112) may be viewed as a *nonlocal/lumped* factorization in that $\mathcal{M}^{\rm LFF}$ describes effects that occur both before and after entry into the body of the solenoid and $\mathcal{M}^{\rm TFF}$ describes effects that occur both within the body of the solenoid and after exit from the body of the solenoid. No attempt is made to describe separately what occurs only within the body of the solenoid itself.[2]

To continue, how can we determine the maps $\mathcal{M}^{\rm LFF}$ and $\mathcal{M}^{\rm TFF}$? Let $\mathcal{H}$ be the map of a uniform "half" solenoid, the map computed for a uniform solenoid with a length of 1/2 meter using the Hamiltonian H given by (2.88) through (2.93) with $b^{[0]}$ having a constant value and correspondingly $b^{[n]} = 0$ for $n > 0$. Then evidently there will be the relation

$$\mathcal{M}^{\rm uniform} = \mathcal{H}\mathcal{H} \tag{16.2.114}$$

and the Ansatz (2.111) becomes

$$\mathcal{M}_{-1\to 2} = \mathcal{D}\mathcal{M}^{\rm LFF}\mathcal{H}\mathcal{H}\mathcal{M}^{\rm TFF}\mathcal{D}. \tag{16.2.115}$$

[2] Strictly speaking, the factorization (2.104) is not completely local since, according to the definition (2.98), $\mathcal{M}^{\rm lff}$ lumps together at the end of the leading drift all the fringe-field effects that have accumulated prior to the body of the solenoid; and, according to (2.99), $\mathcal{M}^{\rm tff}$ lumps together at the beginning of the trailing drift all the fringe-field effects that will accumulate after the body of the solenoid.

Observe that there is also the factorization

$$\mathcal{M}_{-1\to 2} = \mathcal{M}_{-1\to 0.5}\mathcal{M}_{0.5\to 2}. \tag{16.2.116}$$

We are therefore led to make the implicit definitions

$$\mathcal{D}\mathcal{M}^{\rm LFF}\mathcal{H} = \mathcal{M}_{-1\to 0.5} \tag{16.2.117}$$

and

$$\mathcal{H}\mathcal{M}^{\rm TFF}\mathcal{D} = \mathcal{M}_{0.5\to 2}. \tag{16.2.118}$$

It is easily verified using (2.114) and (2.116) through (2.118) that (2.111) is then satisfied. Thus the Ansatz (2.111) has been justified. Moreover, (2.117) and (2.118) can be solved for $\mathcal{M}^{\rm LFF}$ and $\mathcal{M}^{\rm LFF}$ to give the explicit results

$$\mathcal{M}^{\rm LFF} = \mathcal{D}^{-1}\mathcal{M}_{-1\to 0.5}\mathcal{H}^{-1} \tag{16.2.119}$$

and

$$\mathcal{M}^{\rm TFF} = \mathcal{H}^{-1}\mathcal{M}_{0.5\to 2}\mathcal{D}^{-1}. \tag{16.2.120}$$

Note that, according to (2.119) and (2.120), both $\mathcal{M}^{\rm LFF}$ and $\mathcal{M}^{\rm TFF}$ are symplectic maps. Consequently the matrices $M^{\rm LFF}$ and $M^{\rm TFF}$ associated with their linear parts will be symplectic matrices.

What can be said about the nature of $M^{\rm LFF}$ and $M^{\rm TFF}$ as functions of a? Exhibits 2.13 through 2.18 display these matrices for the values $a = 0.2$, $a = .02$, and $a = .002$. For clarity of presentation, in making these calculations the rotational parts of the solenoid maps have been removed. Recall Subsection 2.5.3. In principle, because of (2.87), there should be no rotational parts in $M^{\rm LFF}$ and $M^{\rm TFF}$ in the limit that the external leading fringe field is allowed to begin at $z^{\rm en} = -\infty$ and the external trailing fringe field is allowed to extend to $z^{\rm ex} = +\infty$. In the calculations described here (and without the rotational components of the solenoid maps being removed) there are negligible but numerically noticeable rotational components in the matrices $M^{\rm LFF}$ and $M^{\rm TFF}$ associated with the maps $\mathcal{M}^{\rm LFF}$ and $\mathcal{M}^{\rm TFF}$ as defined by (2.119) and (2.120). For example, in computing (2.119) the rotational part of $\mathcal{M}_{-1\to 0.5}$ does not completely cancel the rotational part of $\mathcal{H}^{-1}$ because the leading external fringe field region is taken to begin at $z = z^{\rm en} = -1$. We have verified that if the leading external fringe field region is taken to begin at a larger negative value of z, for example $z^{\rm en} = -10$, then the cancellation of rotational parts is more nearly complete. (Of course, in this case we must also employ for $\mathcal{D}$ the map of a 10 meter drift.) The cancellation also is more nearly complete the smaller the value of a, as is to be expected from comparison of Figures 2.4 and 2.5. The subtlety of these considerations arises from the relatively slow fall off of air-core solenoid fringe fields.

From Exhibits 2.13 through 2.15 we infer that there is the limiting behavior

$$\lim_{a\to 0} M^{\rm LFF} = I. \tag{16.2.121}$$

And from Exhibits 2.16 through 2.18 we infer that there is the limiting behavior

$$\lim_{a\to 0} M^{\rm TFF} = I. \tag{16.2.122}$$

These limiting behaviors can also be verified analytically, and are to be expected. Again we conclude that in the hard-edge limit there are *no* fringe-field contributions to the *linear* part of the transfer map for a solenoid. That is, (2.109) again holds.

There is some irony here. We have seen that the matrices for the linear parts of $\mathcal{M}^{\rm LFF}$ and $\mathcal{M}^{\rm TFF}$ have the benign limiting behavior (2.121) and (2.122). We also know from (2.112) that the only a dependence in $\mathcal{M}_{\rm solenoid}$ arises from that in $\mathcal{M}^{\rm LFF}$ and $\mathcal{M}^{\rm TFF}$, and we have seen that $\mathcal{M}_{\rm solenoid}$ has some divergent third-order aberrations as $a \to 0$. We conclude that while the limiting behavior of the linear parts of $\mathcal{M}^{\rm LFF}$ and $\mathcal{M}^{\rm TFF}$ is benign, that of some of the nonlinear parts of $\mathcal{M}^{\rm LFF}$ and $\mathcal{M}^{\rm TFF}$ is pathological.

What can be said about the linear parts of $\mathcal{M}^{\rm LFF}$ and $\mathcal{M}^{\rm TFF}$ when a is small but *nonzero*? From Exhibits 2.13 through 2.15 we see that, for small a, the effect of the leading fringe field is to produce *identical defocussing* in both planes. And from Exhibits 2.16 through 2.18 we see that the same is true for the effect of the trailing fringe field.[3] The modest and small a effect of fringe fields is to *decrease* the focussing effect of a solenoid compared to that predicted by $M^{\rm uniform}$. Recall (2.113).

Moreover, as illustrated in Table 2.2 below, for small a the defocussing strength behaves linearly in a. That is, for example, the quantity $M_{21}^{\rm LFF} = M_{43}^{\rm LFF}$ is proportional to a when a is sufficiently small so that the product $(1/a)M_{21}^{\rm LFF}$ approaches a *constant* as $a \to 0$.[4] Identical results hold for $M_{21}^{\rm TFF} = M_{43}^{\rm TFF}$.

Finally, we remark that these results are consistent with those obtained by some other authors using other methods.

[3] In passing we also note that, for a given value of a and within the announced numerical accuracy, the matrices $M^{\rm LFF}$ and $M^{\rm TFF}$ differ only by permutations of various *diagonal* entries. This result is a consequence of *reversal symmetry*. That is, for a given value of a, the matrices $M^{\rm LFF}$ and $M^{\rm TFF}$ are *reverses* of each other. See Chapter 36.

[4] For modest values of a such as $a = 0.2$, and still larger values of a, there are some effects on $M_{21}^{\rm LFF}$ that arise from the approximation we have made that there are no leading external fringe-field effects before $z^{\rm en} = -1$. Similarly there are some effects on $M_{21}^{\rm TFF}$ that arise from the approximation we have made that there are no trailing external fringe-field effects after $z^{\rm ex} = 2$. These effects disappear as $a \to 0$ because then external fringe fields become more and more confined to the vicinities of the entrance and exit of the solenoid. As an indication of the size of these effects, suppose the leading external fringe field region is taken to begin at a larger negative value of z, for example $z = z^{\rm en} = -10$. (Of course, in this case we must also employ for $\mathcal{D}$ the map of a 10 meter drift.) Then, for $a = 0.2$, there are the results $M_{21}^{\rm LFF} = 1.42982$E-03 and $(1/a)M_{21}^{\rm LFF} = 7.14910$E-03, which are to be compared with those in the first line of Table 2.2. Evidently in this case the effects of the approximations we have made are small.

Table 16.2.2: Numerical behavior of $M_{21}^{\rm LFF}$ for small values of a.

a	$M_{21}^{\rm LFF}$	$(1/a)M_{21}^{\rm LFF}$
.2	1.42997E-03	7.14985E-03
.02	1.62696E-04	8.13480E-03
.002	1.64409E-05	8.22045E-03

16.2.6.3 Behavior of Nonlinear Part

We have concluded that, while the limiting behavior of the linear parts of $\mathcal{M}^{\rm LFF}$ and $\mathcal{M}^{\rm TFF}$ is benign, that of some of the nonlinear parts of $\mathcal{M}^{\rm LFF}$ and $\mathcal{M}^{\rm TFF}$ is pathological. In this subsection we will examine in more detail the behavior of the nonlinear part of $\mathcal{M}^{\rm LFF}$ in the limit $a \to 0$. For brevity, we will not present the behavior of $\mathcal{M}^{\rm TFF}$. But, as expected, it is found to be analogous to that of $\mathcal{M}^{\rm LFF}$.

Exhibits 2.19 through 2.21 display (through third order) the maps $\mathcal{M}^{\rm LFF}$ given by (2.119) for the cases $a = 0.2$, $a = 0.02$, and $a = 0.002$, respectively. For these exhibits the rotational parts of the solenoidal maps have *not* been removed.

Examination of these exhibits shows that, as expected, (2.121) continues to hold even when the rotational parts of M^{LFF} have not been removed. We reiterate that, in the hard-edge limit and when canonical coordinates are employed, there are *no* fringe-field contributions to the *linear* part of the transfer map for a solenoid.

What can be said about the exp(: f_3 :) content of $\mathcal{M}^{\rm LFF}$? Examination of the f_3 contents of these same exhibits, the generators with indices 28 through 83, shows that numerically there is the limiting behavior

$$\lim_{a\to 0} f_3^{\rm LFF} = 0. \qquad (16.2.123)$$

The same result can be obtained analytically. Consequently, in the hard-edge limit and when canonical coordinates are employed, there are also *no* fringe-field contributions to the *quadratic* part of the transfer map for a solenoid. All second-order aberrations associated with $\mathcal{M}^{\rm LFF}$ vanish in the hard-edge limit.

What can be said about the exp(: f_4 :) content of $\mathcal{M}^{\rm LFF}$? Examination of the generators with indices 84 through 209 shows that numerically some of the $f_4^{\rm LFF}$ generators *grow/diverge* in magnitude as $a \to 0$. Indeed, it can be illustrated numerically and demonstrated analytically that the divergent $f_4^{\rm LFF}$ entries behave as $1/a$ as $a \to 0$. For example, Table 2.3 below illustrates this divergence for the case of $f^{\rm LFF}(84)$.

Table 16.2.3: Numerical behavior of $f^{\rm LFF}(84)$ for small values of a.

a	$f^{\rm LFF}(84)$	$af^{\rm LFF}(84)$
.2	-1.8691E-3	-3.7382E-4
.02	-1.9315E-2	-3.8630E-4
.002	-1.9316E-1	-3.8632E-4

At this point here are two other remarks to be made. First, there are also divergent $f_n^{\rm LFF}$ generators for $n > 4$. Second, as already observed, the only a dependence in (2.112) is in the maps $\mathcal{M}^{\rm LFF}$ and $\mathcal{M}^{\rm TFF}$. We conclude that *all divergent* aberrations for a simple solenoid in the hard-edge limit arise from divergencies in the fringe-field maps.

Upon thinking in more detail, there is more that can be inferred about the a dependence of the $f_4^{\rm LFF}$ generators. We have already seen that H and J_z are in involution. Recall (2.82). Indeed, upon examination we see that all the terms in the expansion of H given in (2.94) through (2.96) are separately in involution with J_z. Therefore, since f_4 is constructed from the ingredients of H using only Lie algebraic operations, we expect that $f_4^{\rm LFF}$ and J_z will be in involution. Below we list the various possible *static* (τ independent) f_4 polynomials, call then I_j, that are in *involution* with J_z (and hence *invariant* under the action of rotations generated by : J_z :) and display their monomial content.

$$I_1 = (P^2)^2 = (P_x^2 + P_y^2)^2 = P_x^4 + 2P_x^2P_y^2 + P_y^4, \qquad (16.2.124)$$

$$\begin{aligned} I_2 &= P^2 J_z = (P_x^2 + P_y^2)(XP_y - YP_x) \\ &= XP_x^2P_y - P_x^3Y + XP_y^3 - P_xYP_y^2, \end{aligned} \qquad (16.2.125)$$

$$I_3 = J_z^2 = (XP_y - YP_x)^2 = X^2P_y^2 - 2XP_xYP_y + P_x^2Y^2, \qquad (16.2.126)$$

$$I_4 = P^2Q^2 = (P_x^2 + P_y^2)(X^2 + Y^2) = X^2P_x^2 + X^2P_y^2 + P_x^2Y^2 + Y^2P_y^2, \tag{16.2.127}$$

$$\begin{aligned} I_5 &= Q^2J_z = (X^2 + Y^2)(XP_y - YP_x) \\ &= X^3P_y - X^2P_xY + XY^2P_y - P_xY^3, \end{aligned} \tag{16.2.128}$$

$$I_6 = (Q^2)^2 = (X^2 + Y^2)^2 = X^4 + 2X^2Y^2 + Y^4, \tag{16.2.129}$$

$$I_7 = P_\tau^2P^2 = P_x^2P_\tau^2 + P_y^2P_\tau^2, \tag{16.2.130}$$

$$I_8 = P_\tau^2J_z = XP_yP_\tau^2 - P_xYP_\tau^2, \tag{16.2.131}$$

$$I_9 = P_\tau^2Q^2 = X^2P_\tau^2 + Y^2P_\tau^2, \tag{16.2.132}$$

$$I_{10} = P_\tau^4. \tag{16.2.133}$$

Note that the monomials $X^2P_y^2$ and $P_x^2Y^2$ appear in both the invariants I_3 and I_4. All other monomials appear at most once in the invariants I_j.

According to the reasoning of the previous paragraph, we expect that $f_4^{\rm LFF}$ can be expressed/expanded (in a unique way) in terms of the I_j for any value of a. This is indeed the case. The relations (2.134) through (2.136) below display this expansion for the values $a = 0.2$, $a = 0.02$, and $a = 0.002$, respectively.

$$\begin{aligned} f_4^{\rm LFF}|_{a=0.2} &= (4.36074169958001E-05)I_1 - (9.17588458782363E-04)I_2 \\ &+ (1.15770219925823E-03)I_3 - (3.06010303211954E-04)I_4 \\ &- (1.51855928877267E-04)I_5 - (1.86910737357663E-03)I_6 \\ &+ (3.39093545585142E-04)I_7 - (1.50498675709195E-05)I_8 \\ &+ (1.15254677042892E-03)I_9 + (0)I_{10}; \end{aligned} \tag{16.2.134}$$

$$\begin{aligned} f_4^{\rm LFF}|_{a=0.02} &= (5.20628154886127E-07)I_1 - (1.03168131481354E-05)I_2 \\ &+ (1.68820248937675E-04)I_3 - (9.05018682344674E-05)I_4 \\ &- (1.86391130390008E-05)I_5 - (1.93149067689109E-02)I_6 \\ &+ (5.55068286516206E-06)I_7 - (1.48898803105739E-07)I_8 \\ &+ (1.31485684215657E-04)I_9 + (0)I_{10}; \end{aligned} \tag{16.2.135}$$

$$\begin{aligned} f_4^{\rm LFF}|_{a=0.002} &= (5.33338799513228E-09)I_1 - (1.02864023718979E-07)I_2 \\ &+ (1.74499639903890E-05)I_3 - (9.71312429641274E-06)I_4 \\ &- (1.89599356992097E-06)I_5 - (0.19316037246934)I_6 \\ &+ (5.80574061863604E-08)I_7 + (1.51604383154817E-10)I_8 \\ &+ (1.33064336534576E-05)I_9 + (0)I_{10}. \end{aligned} \tag{16.2.136}$$

Inspection of (2.134) through (2.136) shows that, save for I_6, the coefficients of all the I_j *vanish* as $a \to 0$. See Exercise 2.21. By contrast, the aberrations associated with the ingredients of I_6 *grow* as $1/a$ as $a \to 0$. Recall Table 2.3 and see Exercise 2.22. Thus the behavior of f_4^{LFF} is *simple* in the hard-edge limit in that most (all but three) of its entries *vanish* in this limit. But it is also *pathological* in that the entries for the generators X^4, X^2Y^2, and Y^4, those that occur in I_6, *diverge* in this limit.[5] Finally we remark that, while we have illustrated these results numerically, they can also be proven analytically. The pathological behavior arises from the appearance of the the δ' functions that occur in the $a \to 0$ limit, and must occur in any hard-edge model.

16.2.7 Consequences of Terminating Solenoidal End Fields

Suppose we wish to find the transfer map for a solenoid with the approximation that the leading fringe-field region begins at the "entry" point $z = z^{\text{en}}$ and the trailing fringe-field region ends at the "exit" point $z = z^{\text{ex}}$. That is, we make the approximation that the vector potential is to be set to zero for $z < z^{\text{en}}$ and $z > z^{\text{ex}}$. Since $\hat{\boldsymbol{A}}^0$, the vector potential we will employ, is in the Poincaré-Coulomb gauge with respect to any origin on the z axis, we may use (following the methods of Section 1) this vector potential to terminate end fields both before entry of the leading fringe field and after exit of the trailing fringe field. That is, there is no need to make gauge transformations at these points because the vector potential is already in the minimum gauge. In this subsection we will study the consequences of terminating end fields using the Poincaré-Coulomb gauge.

Let us begin by finding the associated discontinuities in the mechanical momenta as given by (1.30), (1.31), (1.41), and (1.42). For the vector potential we use (2.7) through (2.10). So doing using (1.30) and (1.31) gives, upon entry, the results

$$\begin{aligned}
\Delta p_x^{\text{mech}} &= qA_x(x,y,z^{\text{en}}) = -qyU(\rho,z^{\text{en}}) \\
&= -qy(1/2)[C_0^{[1]}(z^{\text{en}}) - (1/8)C_0^{[3]}(z^{\text{en}})(x^2+y^2)+\cdots] \\
&= -qy(1/2)[B_z(0,0,z^{\text{en}}) - (1/8)B_z''(0,0,z^{\text{en}})(x^2+y^2)+\cdots] \\
&= -qy(B/2)[\text{bump}(z^{\text{en}},a,L) - (1/8)\text{bump}''(z^{\text{en}},a,L)(x^2+y^2)+\cdots],
\end{aligned} \tag{16.2.137}$$

$$\begin{aligned}
\Delta p_y^{\text{mech}} &= qA_y(x,y,z^{\text{en}}) = qxU(\rho,z^{\text{en}}) \\
&= qx(1/2)[C_0^{[1]}(z^{\text{en}}) - (1/8)C_0^{[3]}(z^{\text{en}})(x^2+y^2)+\cdots] \\
&= qx(1/2)[B_z(0,0,z^{\text{en}}) - (1/8)B_z''(0,0,z^{\text{en}})(x^2+y^2)+\cdots] \\
&= qx(B/2)[\text{bump}(z^{\text{en}},a,L) - (1/8)\text{bump}''(z^{\text{en}},a,L)(x^2+y^2)+\cdots].
\end{aligned} \tag{16.2.138}$$

[5] We hasten to add that the aberrations associated with $\mathcal{M}^{\text{LFF}}$ and $\mathcal{M}^{\text{TFF}}$ are not the only aberrations for $\mathcal{M}_{\text{solenoid}}$. According to (2.112) there will also be aberrations associated with $\mathcal{M}^{\text{uniform}}$. But they are always finite and, by definition, a independent. They are also relatively easy to compute because $\mathcal{M}^{\text{uniform}}$ arises from the z *independent* Hamiltonian H^{uniform}.

Here, in writing the last lines of (2.137) and (2.138), we have assumed the field profile of Subsection 2.2. Similarly, upon exit, we find from (1.41), and (1.42) the discontinuity results

$$\begin{aligned}\Delta p_x^{\text{mech}} &= qA_x(x,y,z^{\text{ex}}) = -qyU(\rho,z^{\text{ex}}) \\ &= -qy(1/2)[C_0^{[1]}(z^{\text{ex}}) - (1/8)C_0^{[3]}(z^{\text{ex}})(x^2+y^2)+\cdots] \\ &= -qy(1/2)[B_z(0,0,z^{\text{ex}}) - (1/8)B_z''(0,0,z^{\text{ex}})(x^2+y^2)+\cdots] \\ &= -qy(B/2)[\text{bump}(z^{\text{ex}},a,L) - (1/8)\text{bump}''(z^{\text{ex}},a,L)(x^2+y^2)+\cdots],\end{aligned} \tag{16.2.139}$$

$$\begin{aligned}\Delta p_y^{\text{mech}} &= qA_y(x,y,z^{\text{ex}}) = qxU(\rho,z^{\text{ex}}) \\ &= qx(1/2)[C_0^{[1]}(z^{\text{ex}}) - (1/8)C_0^{[3]}(z^{\text{ex}})(x^2+y^2)+\cdots] \\ &= qx(1/2)[B_z(0,0,z^{\text{ex}}) - (1/8)B_z''(0,0,z^{\text{ex}})(x^2+y^2)+\cdots] \\ &= qx(B/2)[\text{bump}(z^{\text{ex}},a,L) - (1/8)\text{bump}''(z^{\text{ex}},a,L)(x^2+y^2)+\cdots].\end{aligned} \tag{16.2.140}$$

We see that in all cases the discontinuities are proportional to $B_z(0,0,z)$ and its derivatives at $z = z^{\text{en}}$ or $z = z^{\text{ex}}$. See Figures 2.4 through 2.7 for examples of how these functions behave in the case of a simple air-code solenoid. Moreover, the discontinuities also vanish as the spatial deviations from the z axis (the design orbit) become small.

We close this subsection by finding, at entry and exit, the surface currents implied by our termination procedure/approximation. Since $\hat{A}_z^0 = 0$ in the Poincaré-Coulomb gauge for any solenoid or collection of solenoids, the relations (1.65) through (1.67) take the form

$$\begin{aligned}\mu_0 j_x^{\text{mod}} &= -2[\delta(z-z^{\text{en}}) - \delta(z^{\text{ex}}-z)]\partial_z\hat{A}_x^0 \\ &\quad -[\delta'(z-z^{\text{en}}) + \delta'(z^{\text{ex}}-z)]\hat{A}_x^0,\end{aligned} \tag{16.2.141}$$

$$\begin{aligned}\mu_0 j_y^{\text{mod}} &= -2[\delta(z-z^{\text{en}}) - \delta(z^{\text{ex}}-z)]\partial_z\hat{A}_y^0 \\ &\quad -[\delta'(z-z^{\text{en}}) + \delta'(z^{\text{ex}}-z)]\hat{A}_y^0,\end{aligned} \tag{16.2.142}$$

$$\mu_0 j_z^{\text{mod}} = 0. \tag{16.2.143}$$

Let us evaluate (2.141) and (2.142) using the explicit form for $\hat{\boldsymbol{A}}^0$ given by (2.7) through (2.9. Doing so gives the intermediate results

$$\begin{aligned}\mu_0 j_x^{\text{mod}} &= 2[\delta(z-z^{\text{en}}) - \delta(z^{\text{ex}}-z)]y\partial_z U \\ &\quad +[\delta'(z-z^{\text{en}}) + \delta'(z^{\text{ex}}-z)]yU,\end{aligned} \tag{16.2.144}$$

$$\begin{aligned}\mu_0 j_y^{\text{mod}} &= -2[\delta(z-z^{\text{en}}) - \delta(z^{\text{ex}}-z)]x\partial_z U \\ &\quad -[\delta'(z-z^{\text{en}}) + \delta'(z^{\text{ex}}-z)]xU.\end{aligned} \tag{16.2.145}$$

At this point it is convenient to employ cylindrical components for $\boldsymbol{j}^{\rm mod}$ using the relations

$$j_\rho^{\rm mod} = \cos\phi\, j_x^{\rm mod} + \sin\phi\, j_y^{\rm mod}, \tag{16.2.146}$$

$$j_\phi^{\rm mod} = -\sin\phi\, j_x^{\rm mod} + \cos\phi\, j_y^{\rm mod}. \tag{16.2.147}$$

Recall (15.2.22) and (15.2.23). Implementing these substitutions gives the results

$$\mu_0 j_\rho^{\rm mod} = 0, \tag{16.2.148}$$

$$\begin{aligned} \mu_0 j_\phi^{\rm mod} &= -2[\delta(z-z^{\rm en}) - \delta(z^{\rm ex}-z)]\rho\partial_z U \\ &\quad -[\delta'(z-z^{\rm en}) + \delta'(z^{\rm ex}-z)]\rho U. \end{aligned} \tag{16.2.149}$$

Here we have used the relations

$$y\cos\phi - x\sin\phi = 0, \tag{16.2.150}$$

$$y\sin\phi + x\cos\phi = \rho. \tag{16.2.151}$$

We see that $\boldsymbol{j}^{\rm mod}$, the current that is required to cancel the residual solenoidal fringe field, has only a ϕ component. This is to be expected since the current that produces the solenoidal field itself has only a ϕ component. The last step is to use the expansion (2.10) for U. With the aid of this expansion we find the final result

$$\begin{aligned} \mu_0 j_\phi^{\rm mod} &= -2[\delta(z-z^{\rm en}) - \delta(z^{\rm ex}-z)]\rho\partial_z U \\ &\quad -[\delta'(z-z^{\rm en}) + \delta'(z^{\rm ex}-z)]\rho U \\ &= [\delta(z-z^{\rm en}) - \delta(z^{\rm ex}-z)]\rho[C_0^{[2]}(z) - (1/8)C_0^{[4]}(z)(x^2+y^2) + \cdots] \\ &\quad +(1/2)[\delta'(z-z^{\rm en}) + \delta'(z^{\rm ex}-z)]\rho[C_0^{[1]}(z) - (1/8)C_0^{[3]}(z)(x^2+y^2) + \cdots] \\ &= [\delta(z-z^{\rm en}) - \delta(z^{\rm ex}-z)]\rho[B_z'(0,0,z) - (1/8)B_z'''(0,0,z)(x^2+y^2) + \cdots] \\ &\quad +(1/2)[\delta'(z-z^{\rm en}) + \delta'(z^{\rm ex}-z)]\rho[B_z(0,0,z) - (1/8)B_z''(0,0,z)(x^2+y^2) + \cdots]. \end{aligned} \tag{16.2.152}$$

Like the discontinuities in the mechanical momenta, $\boldsymbol{j}^{\rm mod}$ is also proportional to $B_z(0,0,z)$ and its derivatives at $z = z^{\rm en}$ or $z = z^{\rm ex}$, and also vanishes as the spatial deviations from the z axis (the design orbit) become small.

Exercises

16.2.1. Verify that $B_z(0,0,z)$ as given by (2.16) describes the on-axis field of a simple air-core solenoid. Verify that there is the result

$$B = \mu_0 IN/L \tag{16.2.153}$$

where I is the current in the coil, N is the number of turns in the single-layer winding, and L is the length of the coil. Hint: Use (2.24) and Ampère's law. It is of historical interest to note that the name *solenoid* was coined by Ampère.

16.2.2. Show that for the on-axis field of a simple solenoid as given by (2.16) there are, for the fields at the midpoint/center and either end, the limiting behaviors

$$\lim_{L\to\infty} B_z(0,0,L/2) = B, \tag{16.2.154}$$

$$\lim_{L\to\infty} B_z(0,0,0) = \lim_{L\to\infty} B_z(0,0,L) = B/2. \tag{16.2.155}$$

Verify that the same is true for any bump function model that is constructed from approximating signum functions.

16.2.3. The purpose of this exercise is to verify the relations (2.20) through (2.23). Show that the approximating signum function (2.26) has the properties

$$\text{sgn}(-z,a) = -\text{sgn}(z,a), \tag{16.2.156}$$

$$\lim_{z\to\pm\infty} \text{sgn}(z,a) = \pm 1. \tag{16.2.157}$$

Verify the limiting behavior (2.27). Sketch sgn(z,a), $-$sgn$(z-L,a)$, and bump(z,a,L) as given by (2.25) to verify the relations (2.20) through (2.22).

What remains is to prove the relation (2.23). Begin by writing

$$\int_{-\infty}^{\infty} \text{bump}(z,a,L)dz = \lim_{w\to\infty} \int_{-w}^{w} \text{bump}(z,a,L)dz. \tag{16.2.158}$$

Next verify from the representation (2.25) that

$$\int_{-w}^{w} \text{bump}(z,a,L)dz = (1/2)\int_{-w}^{w} \text{sgn}(z,a)dz - (1/2)\int_{-w}^{w} \text{sgn}(z-L,a)dz. \tag{16.2.159}$$

Show that the first integral on the right side of (2.159) vanishes because of (2.156). Show that by making the change of variables $x = z - L$ the second integral on the right side of (2.159) becomes

$$\begin{aligned} -(1/2)\int_{-w}^{w} \text{sgn}(z-L,a)dz &= -(1/2)\int_{-w-L}^{w-L} \text{sgn}(x,a)dx \\ &= -(1/2)\int_{-w-L}^{w+L} \text{sgn}(x,a)dx + (1/2)\int_{w-L}^{w+L} \text{sgn}(x,a)dx. \end{aligned} \tag{16.2.160}$$

Verify that the first integral in the second line of (2.160) vanishes, again because of (2.156). It follows that there is the result

$$\int_{-w}^{w} \text{bump}(z,a,L)dz = (1/2)\int_{w-L}^{w+L} \text{sgn}(x,a)dx. \tag{16.2.161}$$

Show from (2.157) that there is the result

$$\lim_{w\to\infty} (1/2)\int_{w-L}^{w+L} \text{sgn}(x,a)dx = (1/2)2L = L. \tag{16.2.162}$$

Put all your intermediate results together to obtain the final result

$$\int_{-\infty}^{\infty} \text{bump}(z,a,L)dz = L, \tag{16.2.163}$$

as desired. Note that the proof of this result has depended only on the representation (2.25) and properties (2.156) and (2.157), which are required properties of any approximating signum function.

16.2.4. Verify the fall-off relations (2.34) and (2.35) and the limiting behaviors (2.36) and (2.37).

16.2.5. Verify the expansion (2.38) and the near leading end fall-off behavior (2.39).

16.2.6. Verify the expansion (2.40) and the far fall-off behavior given by (2.41) and (2.42).

16.2.7. Verify the near-by and far asymptotic behaviors (2.44) and (2.45).

16.2.8. Verify the far fall-off behavior (2.47).

16.2.9. Verify the relation (2.49) for the on-axis field of a thick solenoid. Show that (2.24), (2.154), and (2.155) continue to hold. Show that (2.153) also holds providing that N is now the total of number of turns in the whole multilayer winding. Finally, use the notation $B_z(0,0,z;a)$ and $B_z(0,0,z;a_1,a_2)$ to denote the right sides of (2.16) and (2.49), respectively. Show that there is the limiting relation

$$\lim_{a_2 \to a} B_z(0,0,z;a,a_2) = B_z(0,0,z;a). \tag{16.2.164}$$

Hint: Use the representation (2.48).

16.2.10. Observe that (2.7) through (2.9) are the same as (15.5.7) through (15.5.9). Verify that using (15.2.22), (15.2.23), and (15.5.7) through (15.5.9) gives the results (15.5.37) through (15.5.39). That is, $\hat{\boldsymbol{A}}^0$ and hence $\boldsymbol{A}^s$ has only a ϕ component. Verify that this component manifests rotational symmetry about the z axis by having no ϕ dependence.

16.2.11. Verify that the $b^{[2n]}(z)$ as given by (2.59) are dimensionless.

16.2.12. In (2.64) the quantity J_z is defined in terms of canonical variables. What happens if mechanical momenta are employed instead? Define *scaled* mechanical momenta P_x^{mech} and P_y^{mech} by writing

$$P_x^{\text{mech}} = P_x - A_x^s, \tag{16.2.165}$$

$$P_y^{\text{mech}} = P_y - A_y^s; \tag{16.2.166}$$

from which it follows that there are the relations

$$P_x = P_x^{\text{mech}} + A_x^s, \tag{16.2.167}$$

$$P_y = P_y^{\text{mech}} + A_y^s. \tag{16.2.168}$$

[Recall the unscaled results (1.5.30).] Show that the expression for J_z in terms of mechanical momenta is given by the relation

$$J_z = XP_y^{\text{mech}} - YP_x^{\text{mech}} + XA_y^s - YA_x^s. \tag{16.2.169}$$

Verify, using (2.55), (2.56), and (2.58), that there is the result

$$\begin{aligned} XA_y^s - YA_x^s &= (X^2+Y^2)U^s(X,Y,z) \\ &= (1/2)\sum_{n=0}^{\infty}(-1)^n \frac{1}{2^{2n}n!(n+1)!} b^{[2n]}(z)(X^2+Y^2)^{n+1}. \end{aligned} \tag{16.2.170}$$

Show from (15.5.38) and (2.52) that there is the result

$$\begin{aligned} \rho\hat{A}_\phi^0 &= \rho^2 U(\rho,z) = (1/2)\sum_{n=0}^{\infty}(-1)^n \frac{1}{2^{2n}n!(n+1)!} C_0^{[2n+1]}(z)\rho^{2n+2} \\ &= (1/2)\sum_{n=0}^{\infty}(-1)^n \frac{1}{2^{2n}n!(n+1)!} B^{[2n]}(z)\rho^{2n+2}. \end{aligned} \tag{16.2.171}$$

Verify from (13.1.21) and (13.1.22) that

$$\rho^{2n+2} = \ell^{2n+2}(X^2+Y^2)^{n+1}. \tag{16.2.172}$$

Therefore (2.171) can also be written in the form

$$\rho\hat{A}_\phi^0 = (1/2)\sum_{n=0}^{\infty}(-1)^n \frac{1}{2^{2n}n!(n+1)!} B^{[2n]}(z)\ell^{2n+2}(X^2+Y^2)^{n+1}. \tag{16.2.173}$$

Verify from (2.59) that

$$B^{[2n]}(z)\ell^{2n+2} = (\ell p^0/q)b^{[2n]}(z) \tag{16.2.174}$$

so that

$$\begin{aligned} \rho\hat{A}_\phi^0 &= (\ell p^0/q)(1/2)\sum_{n=0}^{\infty}(-1)^n \frac{1}{2^{2n}n!(n+1)!} b^{[2n]}(z)(X^2+Y^2)^{n+1} \\ &= (\ell p^0/q)(X^2+Y^2)U^s(X,Y,z) = (\ell p^0/q)(XA_y^s - YA_x^s). \end{aligned} \tag{16.2.175}$$

Make the definition

$$J_z^{\text{mech}} = XP_y^{\text{mech}} - YP_x^{\text{mech}}. \tag{16.2.176}$$

Consequently, verify that (2.169) can be rewritten in the form

$$J_z = J_z^{\text{mech}} + [q/(\ell p^0)]\rho\hat{A}_\phi^0. \tag{16.2.177}$$

According to (2.82) J_z is conserved. Also, far outside a solenoid, $\hat{A}_\phi^0$ and hence $\rho\hat{A}_\phi^0$ vanish. Therefore, (2.177) shows that J_z^{mech} must have different values inside and outside a solenoid and what their difference must be. Show that if a particle enters a solenoid from a zero field region with some initial value of J_z and ultimately exits into a second zero field region, then its final value of J_z must be the same as its initial value.

16.2.13. Verify the identity (2.76). Show that (2.75) and (2.79) are a consequence of (2.70) through (2.73) and (2.77) and (2.78).

16.2.14. Compare the f_4 contents of the maps in Exhibits 2.3, 2.4, and 2.5. Which f_4 entries appear to be diverging (in magnitude) to ∞ as $a \to 0$? Why, for a given value of a, are there the relations $f(84) = f(175)$ and $f(95) = 2f(84)$? Can you find other relations of this kind? Hint: Show that the Lie generators f_n for a solenoid map must satisfy

$$: J_z : f_n = 0. \tag{16.2.178}$$

Show that the same is true for a drift map and therefore for a composite of drift and solenoid maps.

16.2.15. The purpose of this exercise is to verify the factorization of the linear part as described in Subsection 2.5.3. Begin by writing the transfer map for a solenoid in the general form

$$\mathcal{M} = \mathcal{R} \exp(: f_3 :) \exp(: f_4 :) \cdots . \tag{16.2.179}$$

Then $\mathcal{R}$ will be determined by H_2 as given by (2.94). Verify that H_2 can be written in the form

$$H_2 = H_2^{\rm nonrot} + H_2^{\rm rot} \tag{16.2.180}$$

where

$$H_2^{\rm nonrot} = [1/(2\ell)]P^2 + \{[b^{[0]}(z)]^2/(8\ell)\}Q^2 + [1/(2\beta_0^2\gamma_0^2\ell)]P_\tau^2 \tag{16.2.181}$$

and

$$H_2^{\rm rot} = -[b^{[0]}(z)/(2\ell)]J_z. \tag{16.2.182}$$

Let $\mathcal{R}$, $\mathcal{R}^{\rm nonrot}$, and $\mathcal{R}^{\rm rot}$ be the maps generated by H_2, $H_2^{\rm nonrot}$, and $H_2^{\rm rot}$, respectively. Verify that $: H_2^{\rm nonrot} :$ and $: H_2^{\rm rot} :$ commute and consequently prove, using the results of Exercise 10.2.2, that there are the relations

$$\mathcal{R} = \mathcal{R}^{\rm nonrot}\mathcal{R}^{\rm rot} = \mathcal{R}^{\rm rot}\mathcal{R}^{\rm nonrot}. \tag{16.2.183}$$

Correspondingly, there are the associated matrix relations

$$R = R^{\rm rot}R^{\rm nonrot} = R^{\rm nonrot}R^{\rm rot}. \tag{16.2.184}$$

16.2.16. Through terms of second order, the transfer map for a solenoid can be written in the general form

$$\mathcal{M} = \mathcal{R} \exp(: f_3 :). \tag{16.2.185}$$

The goal of this exercise is to compute for a simple solenoid, in the hard-edge limit $a \to 0$, both the matrix R associated with $\mathcal{R}$ and the Lie generator f_3. For a further discussion of motion in a uniform magnetic field, see Exercise 32.2.7.

Examination of H_2 and H_3 as given by (2.94) and (2.95) shows that their z dependence is given entirely in terms of $b^{[0]}(z)$. This function is bounded for all a, and in the hard-edge limit takes on a *constant* value in the open interval $z \in (0, L)$. See Figures 2.4 and 2.5. We recall that here z plays the role of the independent variable, and therefore in the hard-edge limit H_2 and H_3 do not depend on the independent variable. Consequently show that, in the hard-edge limit and through terms of second order, the transfer map for a solenoid can be written in the form

$$\mathcal{M} = \exp(-L : H_2 + H_3 :). \tag{16.2.186}$$

Recall (7.4.1). Next verify that $: H_2 :$ and $: H_3 :$ commute under the assumption that $b^{[0]}(z)$ is constant in the open interval $z \in (0, L)$. It follows that (2.186) can be rewritten in the form

$$\mathcal{M} = \exp(-L : H_2 :) \exp(-L : H_3 :). \tag{16.2.187}$$

Comparison of (2.185) and (2.187) yields the results

$$\mathcal{R} = \exp(-L : H_2 :) \tag{16.2.188}$$

and

$$f_3 = -LH_3. \tag{16.2.189}$$

What remains is to find the matrix R associated with $\mathcal{R}$. Review Exercise 2.15. The discussion there holds for all (well behaved) functions $b^{[0]}(z)$ and therefore also holds when $b^{[0]}(z)$ is constant in the open interval $z \in (0, L)$. In the case that $b^{[0]}(z)$ is constant in the open interval $z \in (0, L)$ there are the results

$$\mathcal{R}^{\text{nonrot}} = \exp(-L : H_2^{\text{nonrot}} :) \tag{16.2.190}$$

and

$$\mathcal{R}^{\text{rot}} = \exp(-L : H_2^{\text{rot}} :). \tag{16.2.191}$$

At this point we pause to observe that f_3 as given by (2.95) and (2.189) can also be decomposed into two parts whose associated Lie operators commute. We may write

$$f_3 = f_3^{\text{nonrot}} + f_3^{\text{rot}} \tag{16.2.192}$$

where

$$f_3^{\text{nonrot}} = -L(1/\beta_0)P_\tau H_2^{\text{nonrot}} \tag{16.2.193}$$

and

$$f_3^{\text{rot}} = -L(1/\beta_0)P_\tau H_2^{\text{rot}}. \tag{16.2.194}$$

To continue, your next task is to compute R^{nonrot}, the matrix associated with $\mathcal{R}^{\text{nonrot}}$. Begin by verifying that H_2^{nonrot} as given by (2.181) consists of three pieces associated with the x, P_x; y, P_y; and τ, P_τ planes, and that the Lie operators associated with different pieces all commute. Correspondingly R^{nonrot} has nonzero entries consisting only of 2×2 matrices centered on the diagonal. What are these matrices? Consider the Lie transformation

$$\exp\{: [-L/(2\ell)]P_x^2 - [L(b^{[0]})^2/(8\ell)]X^2 :\} \tag{16.2.195}$$

that is associated with the x, P_x part of $\mathcal{R}^{\text{nonrot}}$ when $b^{[0]}(z)$ is constant in the open interval $z \in (0, L)$. Let R_{XP_x} be the 2×2 matrix that describes the action of this Lie transformation on the X, P_x plane. Use the formalism and results of Section 8.7.2 to make the identifications

$$b = L/\ell, \tag{16.2.196}$$

$$a = 0, \tag{16.2.197}$$

$$c = [L/(4\ell)](b^{[0]})^2, \tag{16.2.198}$$

from which it follows that

$$\Delta = -[L/(2\ell)]^2(b^{[0]})^2 \tag{16.2.199}$$

and

$$\Delta^{1/2} = i[L/(2\ell)](b^{[0]}). \tag{16.2.200}$$

Show using (8.7.35) that there is the result

$$R_{XP_x} = \begin{pmatrix} \cosh(\Delta^{1/2}) & b[\sinh(\Delta^{1/2})]/\Delta^{1/2} \\ -c[\sinh(\Delta^{1/2})]/\Delta^{1/2} & \cosh(\Delta^{1/2}) \end{pmatrix}. \tag{16.2.201}$$

Also verify that there are the relations

$$b/\Delta^{1/2} = (L/\ell)(-i)(2\ell/L)(1/b^{[0]}) = -i(2/b^{[0]}) \tag{16.2.202}$$

and

$$c/\Delta^{1/2} = [L/(4\ell)](b^{[0]})^2(-i)(2\ell/L)(1/b^{[0]}) = -i(b^{[0]}/2). \tag{16.2.203}$$

Introduce the notation

$$k = (b^{[0]}/2) \tag{16.2.204}$$

and

$$\psi = [L/(2\ell)](b^{[0]}) = k(L/\ell) \tag{16.2.205}$$

so that (2.200), (2.202), and (2.203) take the forms

$$\Delta^{1/2} = i\psi, \tag{16.2.206}$$

$$b/\Delta^{1/2} = -i/k, \tag{16.2.207}$$

and

$$c/\Delta^{1/2} = -ik. \tag{16.2.208}$$

Verify, using this notation, that (2.201) can be written in the final form

$$R_{XP_x} = \begin{pmatrix} \cos(\psi) & (1/k)\sin(\psi) \\ -k\sin(\psi) & \cos(\psi) \end{pmatrix}. \tag{16.2.209}$$

With regard of the action of $\mathcal{R}^{\rm nonrot}$ on the Y, P_y plane, verify from symmetry considerations that

$$R_{YP_y} = R_{XP_x}. \tag{16.2.210}$$

Finally show that the the effect of the Lie transformation $\exp\{:[-L/(2\beta_0^2\gamma_0^2\ell)]P_\tau^2:\}$ on the τ, P_τ plane is given by the relations

$$\exp\{:[-L/(2\beta_0^2\gamma_0^2\ell)]P_\tau^2:\}\tau = \tau + [L/(\beta_0^2\gamma_0^2\ell)]P_\tau, \tag{16.2.211}$$

$$\exp\{:[-L/(2\beta_0^2\gamma_0^2\ell)]P_\tau^2:\}P_\tau = P_\tau. \tag{16.2.212}$$

Consequently there is the corresponding matrix

$$R_{\tau P_\tau} = \begin{pmatrix} 1 & \eta \\ 0 & 1 \end{pmatrix} \tag{16.2.213}$$

where

$$\eta = L/(\beta_0^2 \gamma_0^2 \ell). \tag{16.2.214}$$

You have shown that

$$R^{\text{nonrot}} = \begin{pmatrix} C & (1/k)S & 0 & 0 & 0 & 0 \\ -kS & C & 0 & 0 & 0 & 0 \\ 0 & 0 & C & (1/k)S & 0 & 0 \\ 0 & 0 & -kS & C & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & \eta \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix} \tag{16.2.215}$$

where we have used the short-hand notation

$$C = \cos(\psi) \tag{16.2.216}$$

and

$$S = \sin(\psi). \tag{16.2.217}$$

Note that the entries in R^{nonrot} are *even* functions of k and hence R^{nonrot} is *invariant* under the replacement $b^{[0]} \rightarrow -b^{[0]}$. This symmetry is also evident from the form of H_2^{nonrot} as given in (2.167).

Now turn to the calculation of R^{rot}, the matrix associated with $\mathcal{R}^{\text{rot}}$. Verify that $\mathcal{R}^{\text{rot}}$ can be written on the form

$$\mathcal{R}^{\text{rot}} = \exp(-L : H_2^{\text{rot}} :) = \exp(\psi : J_z :). \tag{16.2.218}$$

Use the results (2.70) and (2.71) to verify the relation

$$\begin{aligned} &\mathcal{R}^{\text{rot}} X = \exp(\psi : J_z :) X = \\ &X + \psi : J_z : X + \psi^2 (1/2!) : J_z :^2 X + \psi^3 (1/3!) : J_z :^3 X + \cdots = \\ &X + \psi Y - \psi^2 (1/2!) X - \psi^3 (1/3!) Y + \cdots = \\ &X[1 - \psi^2 (1/2!) + \cdots] + Y[\psi - \psi^3 (1/3!) + \cdots] = \\ &X \cos(\psi) + Y \sin(\psi). \end{aligned} \tag{16.2.219}$$

In a similar way verify that there is the relation

$$\mathcal{R}^{\text{rot}} Y = -X \sin(\psi) + Y \cos(\psi). \tag{16.2.220}$$

Use the results (2.72) and (2.73) to find the analogous relations

$$\mathcal{R}^{\text{rot}} P_x = P_x \cos(\psi) + P_y \sin(\psi) \tag{16.2.221}$$

and

$$\mathcal{R}^{\text{rot}} P_y = -P_x \sin(\psi) + P_y \cos(\psi). \tag{16.2.222}$$

Finally observe from (2.74) that $\mathcal{R}^{\rm rot}$ leaves τ and P_τ in peace. You have shown that

$$R^{\rm rot} = \begin{pmatrix} C & 0 & S & 0 & 0 & 0 \\ 0 & C & 0 & S & 0 & 0 \\ -S & 0 & C & 0 & 0 & 0 \\ 0 & -S & 0 & C & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{16.2.223}$$

Note that, according to (2.218), making the replacement $b^{[0]} \rightarrow -b^{[0]}$ entails the replacement $R^{\rm rot} \rightarrow (R^{\rm rot})^{-1}$.

We are almost done. According to (2.184) there will be the matrix relation

$$R = R^{\rm rot}R^{\rm nonrot} = R^{\rm nonrot}R^{\rm rot} = M^{\rm uniform}. \tag{16.2.224}$$

Verify that

$$R = M^{\rm uniform} = \begin{pmatrix} C^2 & (1/k)SC & SC & (1/k)S^2 & 0 & 0 \\ -kSC & C^2 & -kS^2 & SC & 0 & 0 \\ -SC & -(1/k)S^2 & C^2 & (1/k)SC & 0 & 0 \\ kS^2 & -SC & -kSC & C^2 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & \eta \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{16.2.225}$$

Show that (2.225) agrees with (13.4.1) when use is made of (2.59) and (1.5.81).

Verify that, if we wish, we may write

$$R = (R^{\rm rot})^{1/2}R^{\rm nonrot}(R^{\rm rot})^{1/2} \tag{16.2.226}$$

where

$$(R^{\rm rot})^{1/2} = \exp[-(L/2) : H_2^{\rm rot} :] = \exp[(\psi/2) : J_z :]. \tag{16.2.227}$$

However, there does not seem to be much point in doing so except, perhaps, to exhibit the reversibility properties of R. See Section 36.2.

16.2.17. Review Section 2.5.3. This exercise explores properties of $H^{\rm nonrot}$ and $\mathcal{M}^{\rm nonrot}$. We will employ the notation

$$\zeta = (X, P_x, Y, P_y, \tau, P_\tau). \tag{16.2.228}$$

Begin by considering *initial* conditions with the property

$$\zeta_1^{\rm in} = X^{\rm in} = 0, \tag{16.2.229}$$

$$\zeta_2^{\rm in} = P_x^{\rm in} = 0, \tag{16.2.230}$$

$$\zeta_3^{\rm in} = Y^{\rm in} = \text{anything}, \tag{16.2.231}$$

$$\zeta_4^{\rm in} = P_y^{\rm in} = \text{anything}, \tag{16.2.232}$$

$$\zeta_5^{\rm in} = \tau^{\rm in} = \text{anything}, \tag{16.2.233}$$

$$\zeta_6^{\rm in} = P_\tau^{\rm in} = \text{anything}. \tag{16.2.234}$$

These are the initial conditions for motion that is, at least initially, in the vertical plane. Show that the resulting subsequent motion, when governed by $H^{\rm nonrot}$, remains in the vertical plane. In particular, show that then the associated *final* conditions under the action of $\mathcal{M}^{\rm nonrot}$ have the property

$$X^{\rm fin} = 0, \tag{16.2.235}$$

$$P_x^{\rm fin} = 0. \tag{16.2.236}$$

Next show that

$$: J_z : \mathcal{M}^{\rm nonrot} = \mathcal{M}^{\rm nonrot} : J_z :, \tag{16.2.237}$$

and consequently

$$\mathcal{R}^{\rm rot}\mathcal{M}^{\rm nonrot} = \mathcal{M}^{\rm nonrot}\mathcal{R}^{\rm rot}. \tag{16.2.238}$$

Suppose we summarize the results (2.229) through (2.236) by writing

$$\zeta^{\rm fin} = \mathcal{M}^{\rm nonrot}\zeta^{\rm fn}. \tag{16.2.239}$$

Use (2.238) and (2.239) to show that

$$\mathcal{M}^{\rm nonrot}\mathcal{R}^{\rm rot}\zeta^{\rm in} = \mathcal{R}^{\rm rot}\zeta^{\rm fin}. \tag{16.2.240}$$

You have shown that $\mathcal{M}^{\rm nonrot}$ preserves *all* planes obtained by rotating, by any angle ψ, the vertical plane about the z axis. This includes, of course, the horizontal plane.

16.2.18. Review the discussion of Section 15.11.1. Using (2.3) through (2.6), show that for a solenoid the transverse components of its magnetic field have the integral property

$$\int_{-\infty}^{\infty} dz\ B_x(x,y,z) = \int_{-\infty}^{\infty} dz\ B_y(x,y,z) = 0. \tag{16.2.241}$$

16.2.19. Review Exercise 2.1. Consider a "one-turn" solenoid consisting of a single circular loop of radius a lying in the $z=0$ plane, centered on the origin, and carrying a current I. Show that in this case

$$B_z^{\rm one\ turn}(0,0,z)) = \mu_0 I\delta(z,a) \tag{16.2.242}$$

where $\delta(z,a)$ is an approximating delta function defined by

$$\delta(z,a) = (a^2/2)/(z^2+a^2)^{3/2}. \tag{16.2.243}$$

See the discussion following (3.13). See also Section 3.3. Show that

$$\int_{-\infty}^{\infty} dz\ \delta(z,a) = 1. \tag{16.2.244}$$

Show also that there is the relation

$$\text{bump}(z,a,L) = \int_0^L dz'\ \delta(z-z',a). \tag{16.2.245}$$

Show that (2.23) follows from (2.244) and (2.245).

16.2.20. Verify that (2.134) through (2.136) reproduce the f_4 content of Exhibits 2.19 through 2.21.

16.2.21. The purpose of this exercise is to study how the coefficients of the I_i, save for I_6, in the relations (2.134) through (2.136) tend to zero as $a \to 0$. Let us write relations of this kind in the general form

$$f_4^{\text{LFF}}(a) = \sum_{i=1}^{10} c_i^{\text{LFF}}(a) I_i \tag{16.2.246}$$

where we have indicated that f_4^{LFF} is a dependent. Verify that for the case of $c_1^{\text{LFF}}(a)$ one may make the Table 2.4 below, and conclude that $c_1^{\text{LFF}}(a)$ vanishes as a^2 when a goes to zero. Verify that the same is true for $c_2^{\text{LFF}}(a)$, $c_7^{\text{LFF}}(a)$, and $c_8^{\text{LFF}}(a)$. By contrast, verify that $c_3^{\text{LFF}}(a)$, $c_4^{\text{LFF}}(a)$, $c_5^{\text{LFF}}(a)$, and $c_9^{\text{LFF}}(a)$ vanish as a^1 when a goes to zero. Evidently $c_{10}^{\text{LFF}}(a)$ vanishes for all values of a.

Table 16.2.4: Numerical behavior of $c_1^{\text{LFF}}(a)$ for small values of a.

a	c_1^{LFF}	$(1/a^2)c_1^{\text{LFF}}$
.2	4.3607E-5	1.09019E-3
.02	5.2063E-7	1.30158E-3
.002	5.3334E-9	1.33335E-3

16.2.22. By making a suitable table, illustrate that $c_6^{\text{LFF}}(a)$ diverges as $1/a$ when a goes to zero.

16.2.23. Show that H_4 as given by (2.96) can be written in the form

$$H_4 = \sum_{i=1}^{10} d_i(z) I_i, \tag{16.2.247}$$

and verify that it is d_5 and d_6 that contain the pesky δ' functions. In particular, verify that d_5 contains $b^{[2]}$ (which involves δ' functions) and d_6 contains the product $b^{[0]}b^{[2]}$. Reason that the latter is more singular than the former because $b^{[0]}$ is discontinuous in the hard-edge limit. Show that there are the results

$$\text{sgn}'(z,a) = \partial_z \text{sgn}(z,a) = 2\delta(z,a) \tag{16.2.248}$$

and

$$\begin{aligned}\int_{-\infty}^{\infty} dz\ \text{sgn}(z,a)\delta'(z,a) &= [\text{sgn}(z,a)\delta(z,a)]|_{z=-\infty}^{z=+\infty} - \int_{-\infty}^{\infty} dz\ \text{sgn}'(z,a)\delta(z,a) \\ = 0 - 2\int_{-\infty}^{\infty} dz\ \delta(z,a)\delta(z,a) &= -2\int_{-\infty}^{\infty} dz\ \delta^2(z,a) = -(3\pi/16)(1/a).\end{aligned} \tag{16.2.249}$$

Review and, if you have not already done so, perform Exercise 2.22. In agreement with the results of this exercise, make the small a Ansatz

$$c_6^{\rm LFF}(a) \simeq e^{\rm LFF}/a \tag{16.2.250}$$

where $e^{\rm LFF}$ is a coefficient to be determined. Find a formula for $e^{\rm LFF}$ in terms of beam parameters and the parameters for a simple solenoid.

16.2.24. Exercise on the vector spherical harmonic decomposition of the vector potential for the magnetic field of a simple solenoid.

16.3 Iron-Free Dipoles

16.3.1 Preliminaries

A *straight* dipole is a straight beam-line element whose field is described by a cylindrical harmonic expansion that contains primarily an $m = 1$ term.[6] We recall from Section 15.3.3 that for the $m = 1$ case the magnetic scalar potential ψ has the expansion

$$\psi(x, y, z) = \psi_{1,s}(x, y, z) = y[C_{1,s}^{[0]}(z) - (1/8)(x^2 + y^2)C_{1,s}^{[2]}(z) + \cdots]. \tag{16.3.1}$$

See (15.3.57). [Here we have retained only the *normal* $m = 1$ term, but a skew ($\psi_{1,c}$) term is also possible. See (15.3.40) and Exercise 15.4.1.] Correspondingly, the associated magnetic field has the expansion

$$B_x = \partial_x\psi_{1,s} = -(1/4)xyC_{1,s}^{[2]}(z) + \cdots\ , \tag{16.3.2}$$

$$B_y = \partial_y\psi_{1,s} = C_{1,s}^{[0]}(z) - (1/8)(x^2 + 3y^2)C_{1,s}^{[2]}(z) + \cdots\ , \tag{16.3.3}$$

$$B_z = \partial_z\psi_{1,s} = y[C_{1,s}^{[1]}(z) - (1/8)(x^2 + y^2)C_{1,s}^{[3]}(z) + \cdots]. \tag{16.3.4}$$

From (3.2) through (3.4) we see that $\boldsymbol{B}$ is completely specified in terms of a single "master" function $C_{1,s}^{[0]}(z)$ and its derivatives. Moreover, according to (3.3), the on-axis field has only a B_y component, and it is given by the relation

$$B_y(0, 0, z) = C_{1,s}^{[0]}(z). \tag{16.3.5}$$

See Exercise 1.5.7.

There is also a suitable associated vector potential $\hat{\boldsymbol{A}}^{1,s}$ given (in symmetric Coulomb gauge) by the relations

$$\hat{A}_x^{1,s} = (1/4)(x^2 - y^2)C_{1,s}^{[1]}(z) - (1/48)(x^4 - y^4)C_{1,s}^{[3]}(z) + \cdots\ , \tag{16.3.6}$$

$$\hat{A}_y^{1,s} = (1/2)xyC_{1,s}^{[1]}(z) - (1/24)(x^3y + xy^3)C_{1,s}^{[3]}(z) + \cdots\ , \tag{16.3.7}$$

[6] In practice dipoles are often *bent* because the design orbit in a dipole is bent. In this case a cylindrical harmonic expansion is of limited use. See Subsection 3.7.

$$\hat{A}_z^{1,s} = -xC_{1,s}^{[0]}(z) + (1/8)(x^3+xy^2)C_{1,s}^{[2]}(z) - (1/192)(x^5+2x^3y^2+xy^4)C_{1,s}^{[4]}(z) + \cdots . \quad (16.3.8)$$

Recall (15.5.97) through (15.5.99). We observe that $\hat{\boldsymbol{A}}^{1,s}$, like $\boldsymbol{B}$, is also completely specified in terms of $C_{1,s}^{[0]}(z)$ and its derivatives. Vector potentials in other gauges are also possible, in particular the azimuthal-free gauge, and they too are completely specified in terms of $C_{1,s}^{[0]}(z)$ and its derivatives. Recall Sections 15.4 through 15.7.

We will next examine what can be said about the master function $C_{1,s}^{[0]}(z)$ in various cases.

16.3.2 Single Monopole Doublet

The simplest way to *mathematically* model a dipole field, as the name suggests, is to properly locate and assign strengths to two monopoles. Suppose two monopoles having strengths $\mp 4\pi g$ are placed at the (x, y, z) locations $(0, a, 0)$ and $(0, -a, 0)$. Note that these locations lie on a cylinder of radius a. A pair of monopoles of opposite sign is what we have called a *monopole doublet*. Recall Section 15.9. Note, however, that in this section we have *interchanged* the strengths of the two monopoles so as to produce an on-axis $\boldsymbol{B}$ field that points in the $+\boldsymbol{e}_y$ direction.

We will verify, as expected, that this monopole doublet produces an interior field whose cylindrical multipole expansion begins with an $m = 1$ term. From the symmetry of this array we expect that, in addition to the leading $m = 1$ term, there may also be $m = 3, 5, \cdots$ terms. Recall Subsection 15.3.5 for explicit results.

Define a *unit* monopole to be a monopole for which $g = 1$. Let $\chi(\boldsymbol{r}; \boldsymbol{r}')$ be the scalar potential for a unit monopole located at the point $\boldsymbol{r}'$,

$$\begin{aligned} \chi(\boldsymbol{r}; \boldsymbol{r}') &= \chi(x, y, z; x', y', z') = -1/||\boldsymbol{r} - \boldsymbol{r}'|| \\ &= -1/[(x-x')^2 + (y-y')^2 + (z-z')^2]^{1/2}. \end{aligned} \quad (16.3.9)$$

Then the potential ψ^{doub} for the monopole doublet we are considering here is given by the relation

$$\begin{aligned} \psi^{\text{doub}}(x, y, z) &= g\chi(x, y, z; 0, a, 0) - g\chi(x, y, z; 0, -a, 0) \\ &= g[x^2 + (y-a)^2 + z^2]^{-1/2} - g[x^2 + (y+a)^2 + z^2]^{-1/2}, \end{aligned} \quad (16.3.10)$$

in agreement with (15.9.1) through (15.9.3) save for a sign.

Next expand $\psi^{\text{doub}}(x, y, z)$ as a power series in x and y. So doing yields the result

$$\psi^{\text{doub}}(x, y, z) = 2gay/(z^2 + a^2)^{3/2} + \text{higher order terms}. \quad (16.3.11)$$

Comparison of (3.11) with (3.1) reveals that, for the monopole doublet we are considering here, the $m = 1$ on-axis gradient is given by the relation

$$C_{1,s}^{[0]}(z) = 2ga/(z^2 + a^2)^{3/2} = (4g/a)\delta(z, a) \quad (16.3.12)$$

where $\delta(z, a)$ is the approximating delta function already introduced in Exercise 2.19,

$$\delta(z, a) = (a^2/2)/(z^2 + a^2)^{3/2}. \quad (16.3.13)$$

The result (3.12) agrees, save for the expected sign difference, with (15.9.21) and (15.9.33) evaluated at $m = 1$.

Calculation shows that the approximating delta function (3.13) has the properties

$$\delta(-z, a) = \delta(z, a), \tag{16.3.14}$$

$$\delta(0, a) = 1/(2a), \tag{16.3.15}$$

$$\delta(z, a) = (a^2/2)/|z|^3 + O(1/|z|^5) \text{ as } |z| \to \infty, \tag{16.3.16}$$

$$\int_{-\infty}^{\infty} dz\ \delta(z, a) = 1. \tag{16.3.17}$$

Figures 3.1 and 3.2 illustrate the behavior of this approximating delta function for two different values of a. Evidently the approximating delta function (3.13) becomes the true delta function in the limit $a \to 0$,

$$\lim_{a\to 0} \delta(z, a) = \delta(z), \tag{16.3.18}$$

and a controls the fall-off rate. From (3.12) we see that the $m = 1$ on-axis gradient for a monopole doublet has the fall-off behavior

$$C_{1,s}^{[0]}(z) = 2ga/|z|^3 + O(1/|z|^5) \text{ as } |z| \to \infty. \tag{16.3.19}$$

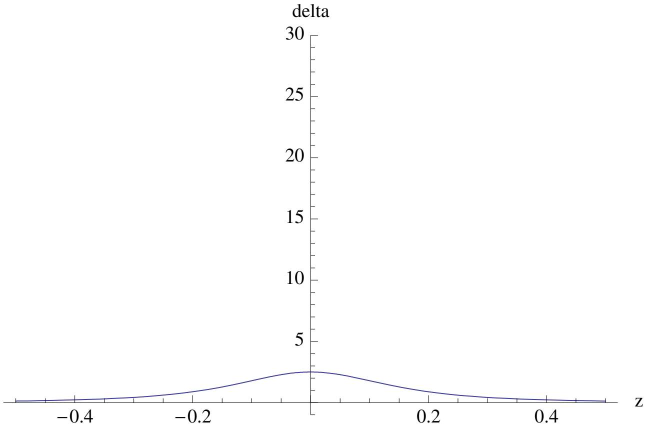

Figure 16.3.1: The approximating delta function (3.13) when $a = .2$.

16.3.3 Line of Monopole Doublets

Next consider, as a second mathematical model, the case of a *line* of monopole doublets extending from $z = 0$ to $z = L$. Associated with a line of monopole doublets will be a soft-edge bump function described by the relation

$$\text{bump}(z, a, L) = \int_0^L dz'\ \delta(z - z', a). \tag{16.3.20}$$

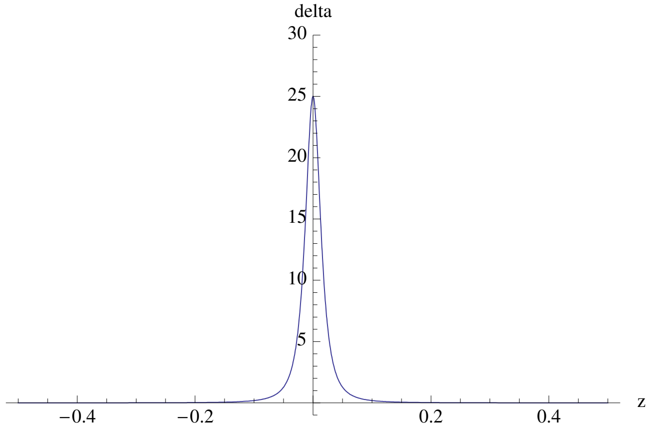

Figure 16.3.2: The approximating delta function (3.13) when $a = .02$.

In terms of this soft-edge bump function the $m = 1$ on-axis field gradient $C^{[0]}_{1,s}(z)$ for a line of monopole doublets can be written in the form

$$C^{[0]}_{1,s}(z) = B \operatorname{bump}(z, a, L) \tag{16.3.21}$$

where B is the dipole strength in the infinite length limit. Recall Exercise 1.5.7 and (3.2) through (3.5). It is given in terms of the doublet parameters by the relation

$$B = 4G/a \tag{16.3.22}$$

where $4\pi G$ is the monopole strength per unit length.

To evaluate (3.20), make the change of variables $\zeta = z - z'$ so that (3.20) becomes

$$\operatorname{bump}(z, a, L) = -\int_{z}^{z-L} d\zeta\ \delta(\zeta, a) = \int_{z-L}^{z} d\zeta\ \delta(\zeta, a). \tag{16.3.23}$$

The approximating delta function (3.13) has as an indefinite integral the result

$$\int d\zeta\ \delta(\zeta, a) = (1/2)\zeta/(\zeta^2 + a^2)^{1/2} = (1/2)\operatorname{sgn}(\zeta, a) \tag{16.3.24}$$

where $\operatorname{sgn}(\zeta, a)$ is the approximating signum function (2.26). It follows from (3.23) and (3.24) that

$$\operatorname{bump}(z, a, L) = [\operatorname{sgn}(z, a) - \operatorname{sgn}(z - L, a)]/2, \tag{16.3.25}$$

a result identical to (2.25). We conclude that the soft-edge bump function for the $m = 1$ on-axis gradient arising from a line of monopole doublets is the same as the soft-edge bump function for a simple air-core solenoid. In particular, the fall off for the $m = 1$ on-axis gradient arising from a line of monopole doublets goes as $1/|z|^3$, just as it does for a single monopole doublet.

16.3.4 Current Windings for two Air-Core Dipoles

The work of the previous Subsections 3.2 and 3.3 is deficient in at least two ways. First, according to Section 15.9.2, a monopole doublet has nonzero on-axis gradients for all odd values of m. See also Section 15.3.5. Moreover, even the integrated on-axis gradients for a monopole doublet are nonzero for all odd values of m,

$$\int_{-\infty}^{\infty} dz\, C_{m,s}^{[0]}(z) \neq 0 \text{ for } m \text{ odd.} \tag{16.3.26}$$

[See (15.9.21) and (15.9.33), and, for graphic examples, Figures 15.9.8, 15.9.11, 15.19.13, and 15.9.15.] The same is true for a line of monopole doublets.

Second, unlike the case of a solenoid, no prescription has been given of current windings/distributions that could be fabricated to produce the field of a line of multipole doublets or, better yet, the field of a reasonably "pure dipole". The aim of this subsection is to describe two commonly used (or contemplated) thin-shell windings on a straight circular cylinder of radius a and length L such that the magnetic field produced within the bore has *primarily* an $m = 1$ component.

Then, in the next two subsections, we will consider windings such that *only* the $m = 1$ on-axis gradient is nonzero for the field produced by such windings. We will call such a winding an *ideal* air-core dipole. However it is not the case, even for an ideal air-core dipole, that the field is that of a *perfect* dipole, a field, say, only in the $\boldsymbol{e}_y$ direction. According to (15.2.61) through (15.2.64) there are additional components in the fringe-field regions at the ends of the dipole where $C_{1,s}^{[0]}(z)$ is changing.

As already stated, we will consider air-core dipoles that consist of a thin-shell winding placed on a circular cylinder of radius $\rho = a$ and length L. We will also arrange the coordinate system so that the winding begins at $z = 0$ and ends at $z = L$.

There are two commonly used or considered approaches as to what the nature of this winding should be. One approach is to arrange to have most of the winding running on straight lines parallel to the cylinder axis to form what are called *saddle* coils. See Figure 3.3. Moreover, the spacing between successive straight lines is arranged so that the cross-sectional current density for the straight-line portion of the winding has (effectively on average) a $\cos(\theta)$ distribution. [Here suppose the coordinate system shown in Figure 2.1 is also employed in part c of Figure 3.3 above. Then, following customary nomenclature, θ is the angle ϕ defined by (15.2.12) through (15.2.14). From now on we will refer to a $\cos(\phi)$ distribution.] This can be accomplished by placing the winding in grooves machined into the underlying cylinder or by placing appropriate sized variable width spacers (not depicted) between successive straight wires.

It can be shown that for a $\cos(\phi)$ current distribution for the straight-line portion of the winding, and assuming the coils are long so that L is large, the field in the vicinity of $z = L/2$ is that of a reasonably pure dipole. See Exercise 3.5. That is, we already know from symmetry considerations, see Section 15.3.5, that only the $C_{m,s}^{[0]}(z)$ for odd m can be nonzero. And for a $\cos(\phi)$ current distribution for the straight-line portion of the winding it can be shown that $C_{1,s}^{[0]}(z)$ is substantial, and the remaining $C_{m,s}^{[0]}(z)$ are small, in the vicinity of $z = L/2$.

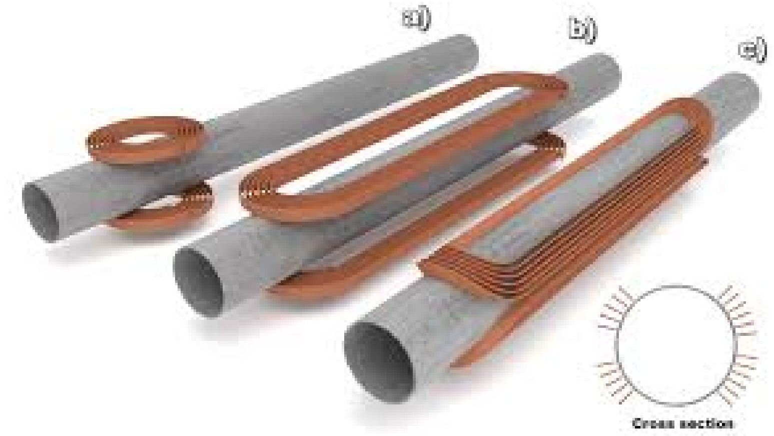

Figure 16.3.3: Coils and cylinders: Part c of this figure shows coils draped like saddles, above and below, over a circular cylinder. Apart from the coil ends, most of the winding runs along straight lines parallel to the cylinder axis.

What can be said about the field *away* from the central region $z \simeq L/2$? There the $C^{[0]}_{3,s}(z)$, $C^{[0]}_{5,s}(z)$, $\cdots$ can be substantial due to the currents flowing around the cylinder at the coil ends. Thus, an air-core dipole made with saddle $\cos(\phi)$ coils is not ideal as defined above. Moreover, in general there will be the integral results

$$\int_{-\infty}^{\infty} dz\, C^{[0]}_{m,s}(z) \neq 0 \text{ for } m \text{ odd}. \tag{16.3.27}$$

In particular the undesired $m = 3$, $m = 5$, $\cdots$ integrated multipole strengths will in general be nonzero.

But it is in principle possible to drive various undesired integrated multipole strengths to zero by placing and appropriately powering suitable multipole corrector windings at or near the ends of the main coil. Of course, when this is done, the net $C^{[0]}_{3,s}(z)$, $C^{[0]}_{5,s}(z)$, $\cdots$ remain nonzero. Only their integrals vanish.

A second approach, variously called "canted $\cos(\theta)$", "double helix", or "tilted solenoid", is based on a simple configuration where a conductor is wound around a cylinder as two oppositely *tilted* solenoids. Figure 3.4 illustrates such a winding.[7] See the Ph.D. thesis of *Brouwer* cited at the end of this chapter for an extensive treatment of canted $\cos(\theta)$ dipoles.

It can be shown that two tilted solenoids when powered as shown produce what is primarily a dipole field. Each layer produces a combination of vertical and solenoidal fields. If the currents are directed as shown, the vertical components add to produce a primarily dipole field and the solenoidal components cancel (save for end effects which are modest and also integrate to zero).[8] (And if the current in one of the layers is directed as shown and the other is reversed, the vertical components essentially cancel and the solenoidal components

[7] The use of the term "$\cos(\theta)$" in this context may seem slightly confusing since each tilted solenoid is wound *uniformly* with no variable width spacers between turns. However, as study of Figure 3.4 suggests, it can be shown that the net effect of the two tilted layers is to produce, in the overlap region and in the z direction, a $\cos(\phi)$ current distribution.

[8] Here we assume the layers have infinitesimal thickness so that they both have the same radii. If not,

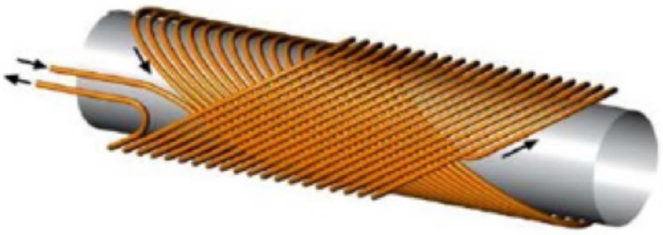

Figure 16.3.4: A winding composed of two oppositely tilted solenoids to form a canted $\cos(\theta)$ dipole.

add to produce a primarily solenoidal field.) Figure 3.5 shows, in Tesla, the solenoidal field component $B_z(0,0,z) = C_0^{[1]}(z)$ for the individual layers as well as the net $C_0^{[1]}(z)$ for a two-layer canted $\cos(\theta)$ dipole. Note that, due to the advertised cancellation, the net solenoidal field is small save for end effects. The solenoidal field at the center location $z = L/2$ is 0.003 Tesla and arises from the layers having slightly different radii.

With regard to the dipole and higher multipole fields, and again from symmetry considerations, only the $C_{m,s}^{[0]}(z)$ for odd m can be nonzero. And, if L is large, it can be shown that $C_{1,s}^{[0]}(z)$ is substantial, and the remaining $C_{m,s}^{[0]}(z)$ are small, in the vicinity of $z = L/2$. Figure 3.6 shows, for example, $C_{1,s}^{[0]}(z)$; and Figure 3.7 shows $C_{3,s}^{[0]}(z)$ and $C_{5,s}^{[0]}(z)$. But note that the $C_{3,s}^{[0]}(z)$, $C_{5,s}^{[0]}(z)$, $\cdots$ are *not* zero for all z, and therefore this air-core dipole is also not ideal.

Nevertheless, this air-core dipole does have a remarkable property: It can be shown that $\int_{-\infty}^{\infty} dz\, C_{1,s}^{[0]}(z)$ is substantial, and for all the remaining $C_{m,s}^{[0]}(z)$ there is the relation

$$\int_{-\infty}^{\infty} dz\, C_{m,s}^{[0]}(z) = 0. \tag{16.3.28}$$

That is, the *integrated* strengths of all undesired multipoles vanish for this air-core winding! Again see Figure 3.7.[9]

cancellation is not perfect so that there is a small residual solenoidal field even apart from end effects. In any event the effect of solenoidal fields can presumably be compensated if desired by the addition of other windings or the use of skew quadrupoles. For example, the x, y coupling effect of the strong solenoidal fields associated with some detectors in storage rings/colliders is routinely compensated by the use of skew quadrupoles.

[9] Windings (for air-core magnets) which have the property that all integrated multipoles vanish save for some desired multipole are sometimes called *Lambertson* windings. See the references at the end of this chapter.

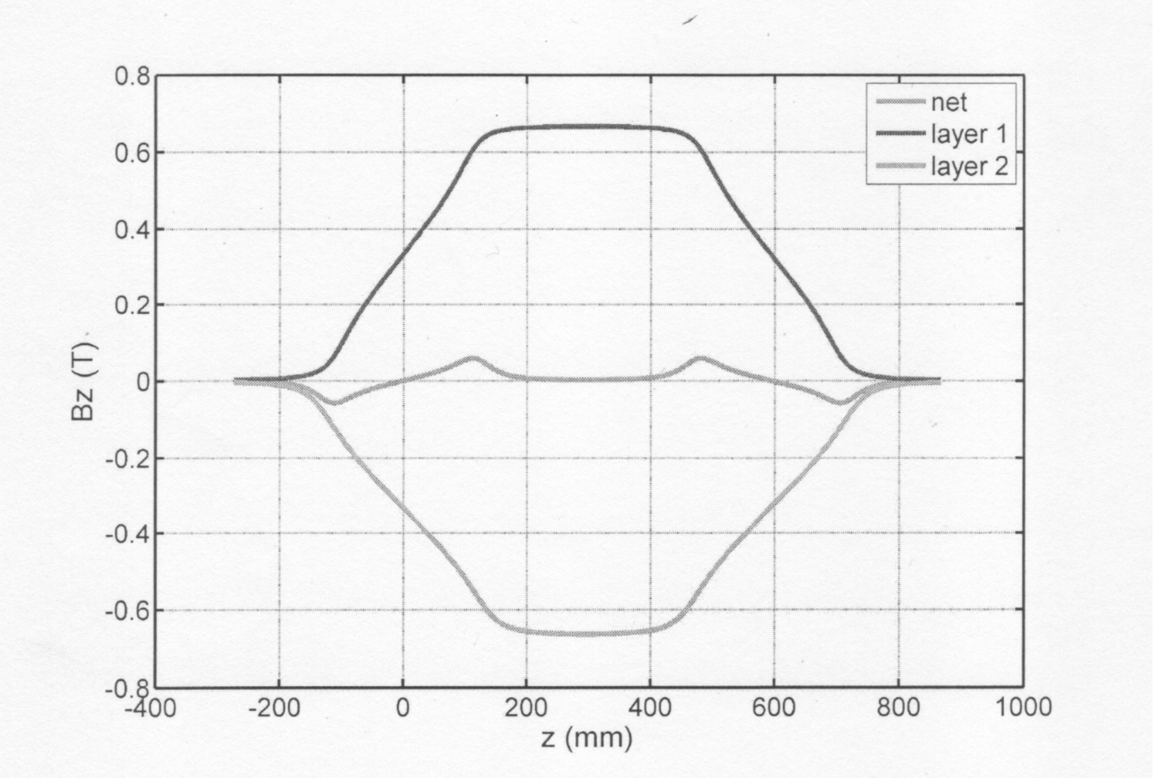

Figure 16.3.5: The individual and net $C_0^{[1]}(z)$ for a canted $\cos(\theta)$ dipole.

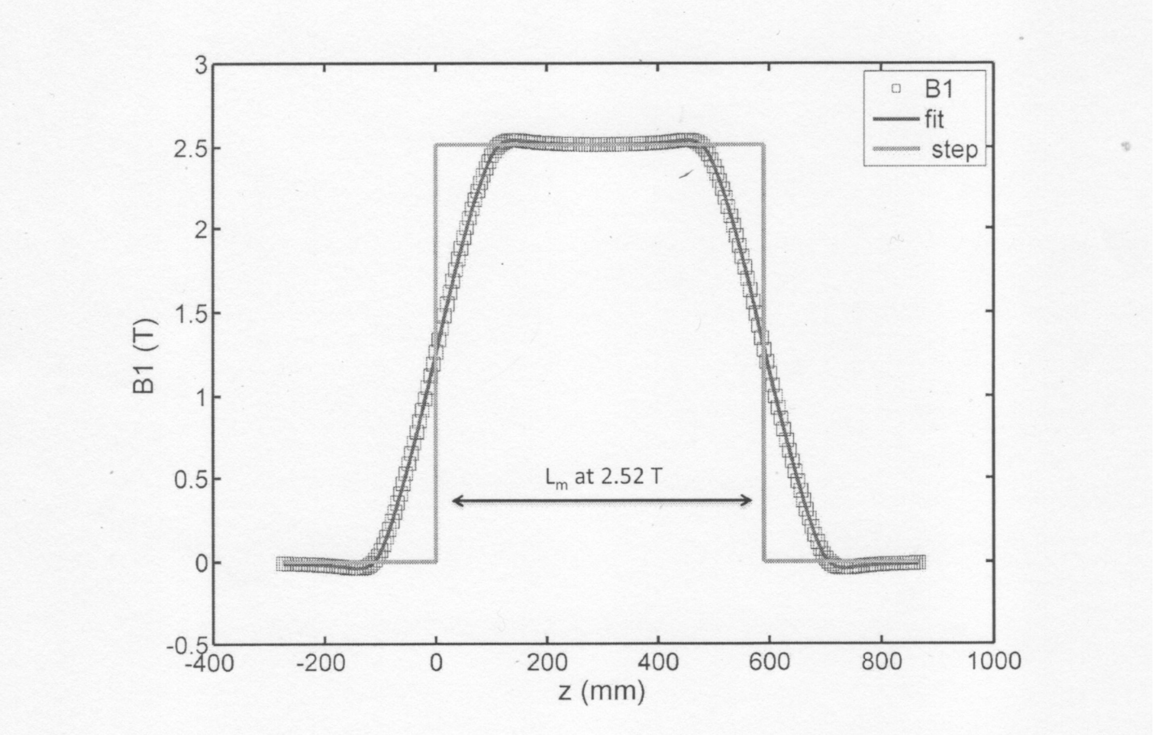

Figure 16.3.6: The on-axis gradient $C_{1,s}^{[0]}(z)$ in Tesla for a canted $\cos(\theta)$ dipole. Also shown is a hard-edge bump function approximation.

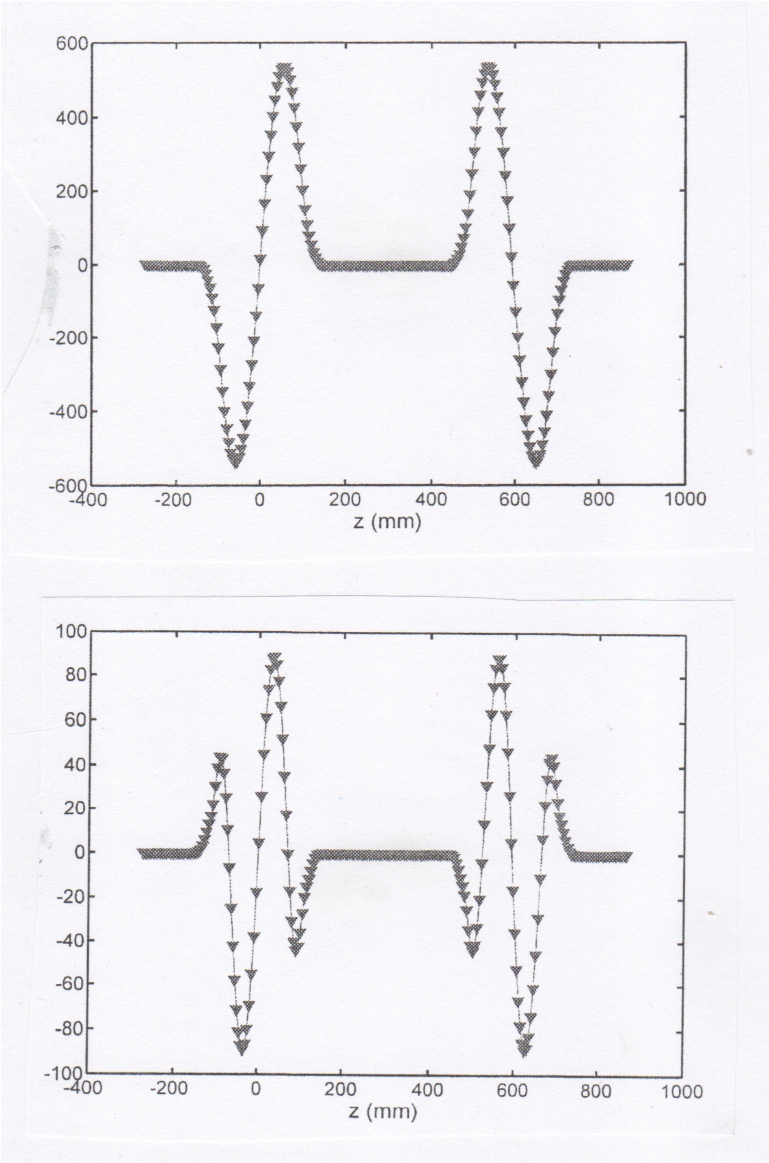

Figure 16.3.7: The on-axis gradient $C_{3,s}^{[0]}(z)$ (above) and on-axis gradient $C_{5,s}^{[0]}(z)$ (below) in dimensionless units for a canted $\cos(\theta)$ dipole. They are small for $z \simeq L/2$, but do not vanish everywhere. Nevertheless their integrated strengths do vanish.

16.3.5 Current Winding for an Ideal Air-Core Dipole

We have seen two examples of windings that fail to produce ideal air-core dipoles. Is there a winding that succeeds? Yes, there are several. This subsection will describe one that is easy to visualize and for which it is possible to compute $C_{1,s}^{[0]}(z)$ analytically.

Figure 3.8 shows a net of coils placed on a circular cylinder. Figure 3.9 shows a top view of the right end of the cylinder and illustrates the sign convention for describing the current flow in the right ($+z$) end of each coil and the currents as they flow along the long sides of each coil. A dot denotes the tip of an arrow as it comes up from below the plane of the figure, and a cross denotes the feather of an arrow as it goes down below the plane of the figure. In this figure $n = 12$ coils are displayed with the circular arc of each I_k current subtending an angle of $\Delta = 2\pi/n = 30°$. We also define angles ϕ_k by the rule

$$\phi_k = k\Delta. \tag{16.3.29}$$

Thus, at each angular location ϕ_k there is an upward and downward current pair so that, for example, there is a *net* current $(I_1 - I_n)$ along the side of the cylinder in the z direction at the location $\phi_0 = 0$.

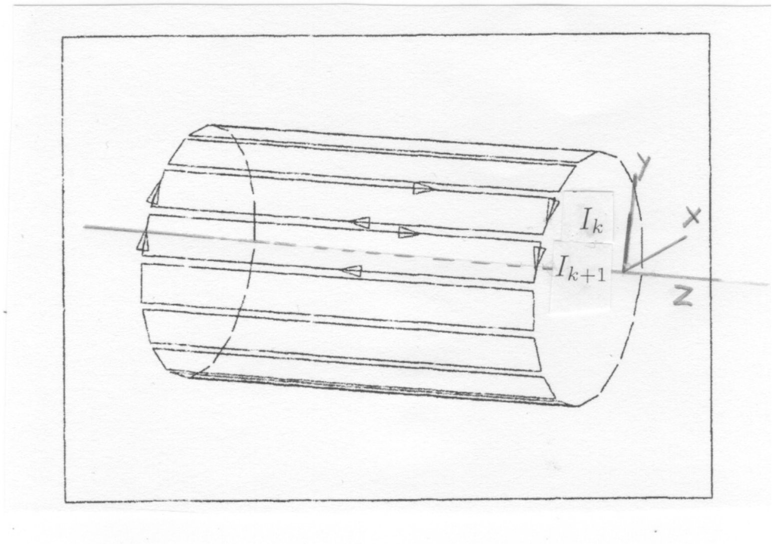

Figure 16.3.8: A net of coils draped over a cylinder. The k^{th} coil carries a current I_k.

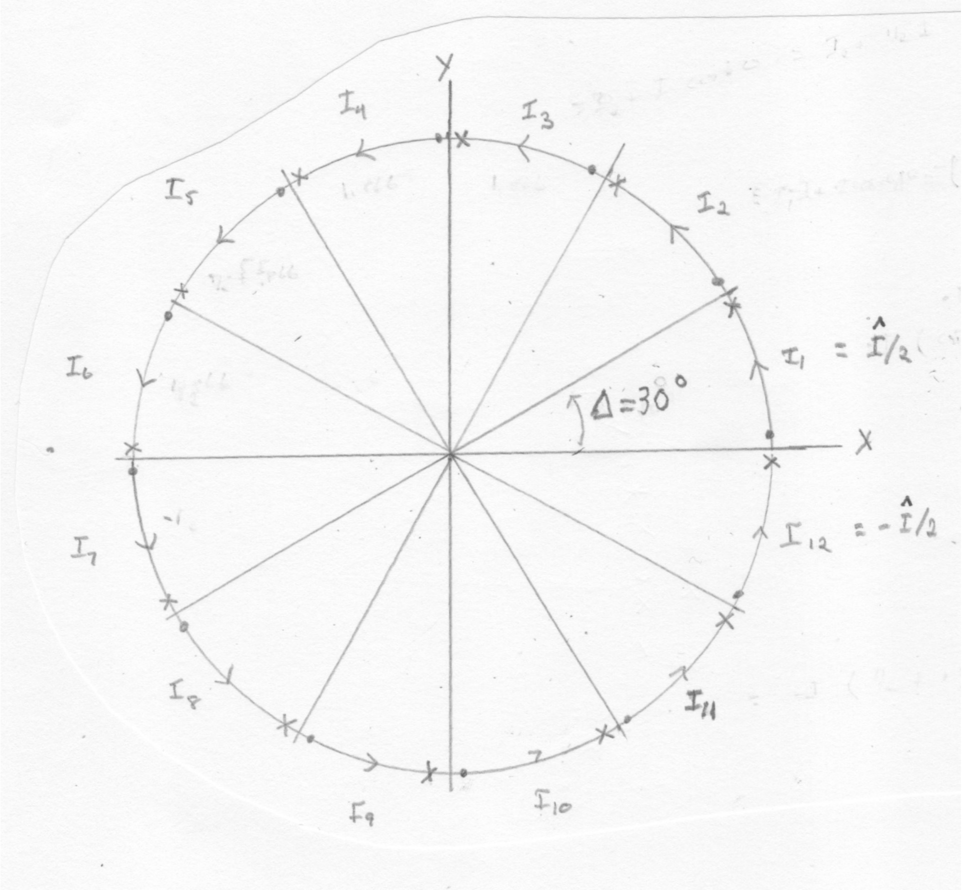

Figure 16.3.9: Top view of the right ends of the coils shown in Figure 3.8. The z axis comes out of the plane of the paper.

In order to achieve an effective $\cos\phi$ current distribution along the *length* of the cylinder, the currents in adjacent coils are required to be related by the rules

$$\begin{aligned}
&I_2 - I_1 = \hat{I}\cos\phi_1,\\
&I_3 - I_2 = \hat{I}\cos\phi_2,\\
&I_{k+1} - I_k = \hat{I}\cos\phi_k,\\
&\cdots\cdots\cdots\cdots\cdots\cdots\ ,
\end{aligned}\qquad (16.3.30)$$

$$\begin{aligned}
&I_n - I_{n-1} = \hat{I}\cos\phi_{n-1},\\
&I_1 - I_n = \hat{I}\cos\phi_0 = \hat{I},
\end{aligned}\qquad (16.3.31)$$

where $\hat{I}$ is some amount of current yet to be determined. As a sanity check, we observe that the sum of the left sides of (3.30) through (3.31) vanishes. And for the right sides computation shows that the sum also vanishes, as desired,

$$\begin{aligned}
&\hat{I}[1+\cos\phi_1+\cos\phi_2+\cdots+\cos\phi_{n-1}] = \hat{I}\Re\{\sum_{k=0}^{n-1}\exp(ik\Delta)\}\\
&= \hat{I}\Re\{[1-\exp(in\Delta)]/[1-\exp(i\Delta)]\}\\
&= \hat{I}\Re\{[1-\exp(2\pi i)]/[1-\exp(i2\pi/n)]\} = 0. \qquad (16.3.32)
\end{aligned}$$

Observe that the left sides of (3.30) through (3.31) only involve current differences, and therefore the currents themselves still need to be determined. This can be done by specifying that

$$I_1 = \hat{I}/2. \qquad (16.3.33)$$

Note that this specification, when employed with the last equation in (3.31), produces the pleasant result

$$I_n = -\hat{I}/2. \qquad (16.3.34)$$

It can be shown that (3.30) through (3.31) and (3.33), when taken together, yield the relations

$$I_k = (\hat{I}/2)[\sin(\Delta/2)]^{-1}\sin\psi_k \qquad (16.3.35)$$

where

$$\psi_k = (k-1/2)\Delta. \qquad (16.3.36)$$

See Exercise *. Note that ψ_k is the angular location of the *midpoint* of the arc that carries the current I_k. For example, $\psi_1 = \Delta/2$.

Consider cases for which n has a value of the form $n = 4\ell$ where ℓ is an integer. Then, in the *continuum* large ℓ limit (and with $\hat{I}$ adjusted accordingly), it can be shown that the collection of coils of the kind shown schematically in Figure 3.8 and more precisely in Figure 3.9 (for the case $\ell = 3$) with the I_k described by (3.35) and (3.36) produces an ideal dipole field. That is, $C_{1,s}^{[0]}(z)$ is substantial, and the remaining $C_{m,s}^{[0]}(z)$ *all vainsh*. See Exercise *.

Moreover, in this case $C_{1,s}^{[0]}(z)$ can be computed analytically. (See the work of *Bassetti* and *Biscari* cited in the references at the end of this chapter.) If the winding is on a cylinder of radius a that begins at $z = 0$ and extends to $z = L$, then the on-axis gradient for such an air-core dipole, as is the case for the on-axis field for a simple air-core solenoid and the on-axis gradient for a line of monopole doublets, can be described in terms of a soft-edge bump function which we will again call bump(z, a, L). That is, the on-axis gradient $C_{1,s}^{[0]}(z)$ can be written in the form

$$C_{1,s}^{[0]}(z) = B\ \text{bump}(z, a, L) \qquad (16.3.37)$$

where B is again the dipole strength in the infinite length limit.

Like the soft-edge bump function for a simple air-core solenoid and a line of monopole doublets, the soft-edge bump function for this ideal air-core dipole can be written in terms of an associated approximating signum function in the form

$$\text{bump}(z, a, L) = [\text{sgn}(z, a) - \text{sgn}(z - L, a)]/2. \qquad (16.3.38)$$

It can be shown that for this ideal air-core dipole the approximating signum function sgn(z, a) is given by the relation

$$\mathrm{sgn}(z,a) = z(z^2 + 2a^2)/(z^2 + a^2)^{3/2}. \tag{16.3.39}$$

Figures 3.10 and 3.11 illustrate the behavior of this approximating signum function for two different values of a. Evidently the approximating signum function (3.39) becomes the true signum function in the limit $a \to 0$.

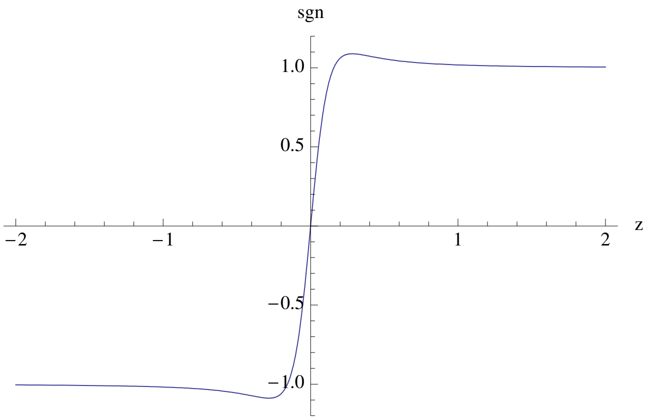

Figure 16.3.10: The approximating signum function (3.39) when $a = .2$.

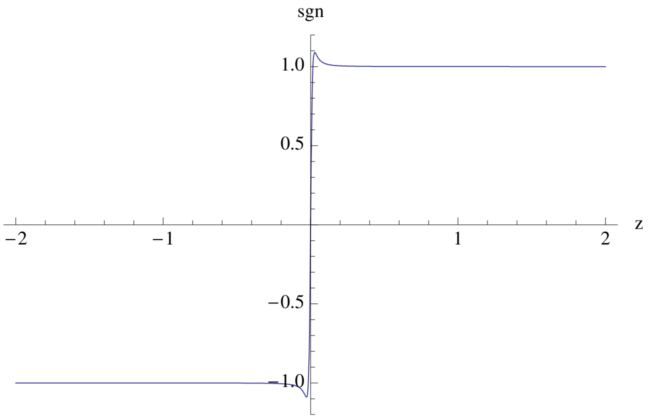

Figure 16.3.11: The approximating signum function (3.39) when $a = .02$.

It follows from (3.38) and (3.39) that, like the soft-edge bump function for a simple air-core solenoid and a line of monopole doublets, the soft-edge bump function for this ideal air-core dipole satisfies the relations (2.20 through (2.22). Recall Exercise 2.3. We see from (2.23) and (3.37) that for this ideal air-core dipole there is the relation

$$\int_{-\infty}^{\infty} C_{1,s}^{[0]}(z)dz = BL. \tag{16.3.40}$$

Figures 3.12 and 3.13 illustrate the properties (2.20) through (2.22) for a fixed value of L and two different values of the radius a. Evidently the ideal air-core dipole soft-edge bump function given by (3.38) and (3.39) becomes a hard-edge bump function in the limit $a \to 0$. The radius a plays the role of a characteristic length that controls the rate of fall off. The fringe-field region is large if a is large, and vanishes as a goes to zero.

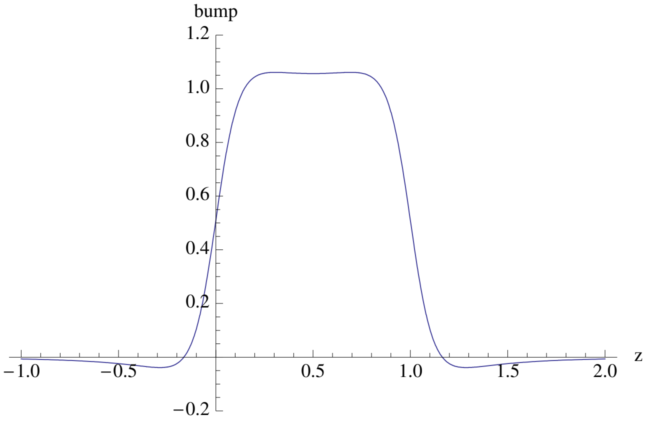

Figure 16.3.12: The soft-edge bump function bump(z, a, L) given by (3.38) and (3.39) when $a = 0.2$ and $L = 1$.

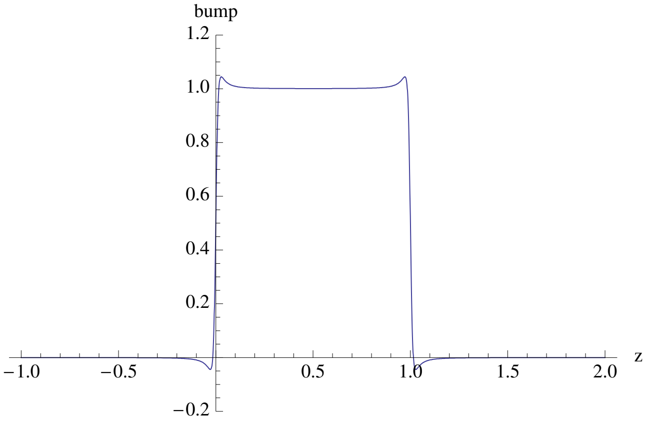

Figure 16.3.13: The soft-edge bump function bump(z, a, L) given by (3.38) and (3.39) when $a = 0.02$ and $L = 1$.

From (3.39) and (3.38) we find the asymptotic behaviors

$$\mathrm{sgn}(z, a) = 1 + (1/2)a^2/z^2 + O(1/z^4) \text{ as } z \to +\infty, \tag{16.3.41}$$

$$\mathrm{bump}(z, a, L) = -(1/2)La^2/|z|^3 + O(1/|z|^4) \text{ as } |z| \to \infty. \tag{16.3.42}$$

Consequently $C^{[0]}_{1,s}(z)$ falls off for large distances as

$$C^{[0]}_{1,s}(z) = -(1/2)BLa^2/|z|^3 + O(1/|z|^4) \text{ as } |z| \to \infty. \tag{16.3.43}$$

We see that the fall off goes as $1/|z|^3$, just as it does for the simple air-core solenoid, a single monopole doublet, and a line of monopole doublets. Compare (2.42) and (3.43). Note, however, that the approximating signum functions (2.26) and (3.39) are different. Compare, for example, Figures 2.2 and 3.10. Also, compare (2.34) with (3.41). Correspondingly, the bump functions for a line of monopole doublets and this idealized air-core dipole are different, and the relations (2.42) and (3.43) differ in sign. Finally we observe, for example from Figures 3.12 and 3.13, that for an ideal air-core dipole the bump function bump(z, a, L), while positive in the center of the dipole, can be *negative* outside the dipole. This change in sign *cannot* be modeled by an *Enge* function profile.[10]

Our discussion of dipole fringe fields so far has treated the iron-free case, and we have found a $1/|z|^3$ fall off in all cases susceptible to easy analysis. When iron is present, and the coils are buried in iron or field clamps are employed, the fall off can in principle be much faster including the possibility of essentially exponential fall off.

16.3.6 Current Windings for other Ideal Air-Core Dipoles

16.3.7 Limited Utility of Cylindrical Harmonic Expansions for Dipoles

Strictly speaking, and as already alluded to in a previous footnote, cylindrical harmonic expansions for the field of a dipole are of limited use. First, there is this observation: If it is desired that the bore be much smaller than the length of the dipole, as is frequently the case, then the dipole must be bent to accommodate the design orbit. In this case a cylindrical harmonic analysis of the field is no longer possible.[11] Second, cylindrical harmonic expansions are expected to be valid (rapidly convergent) only in the vicinity of the z axis. But the orbit in a dipole is bent and therefore cannot be confined to the vicinity of the z axis unless the bend angle is suitably small. Thus there is a conflict between the desire to have a simple model of the design orbit accompanied by a practical dipole design (an essentially circular arc reasonably closely surrounded by coil windings/iron), and the desire for a simple model (cylindrical harmonic expansion) of the dipole field. This conflict occurs both for iron-free dipoles and dipoles with iron. Chapter 22, which does not presuppose a cylindrical harmonic expansion, treats the problem of finding realistic transfer maps for curved beam-line elements with significant sagitta.

At this point we pause to note that there is one area where this conflict does not occur, of at least may be less significant: the modeling of a wiggler/undulator which may be viewed as a string of short dipoles and for which the design orbit throughout the length of the element does not differ much from a straight line. In this case a cylindrical harmonic analysis of the field is appropriate and useful providing the amplitude of the wiggles in the design orbit is modest compared to the half gap of the dipoles. See Section 4 of this chapter. Finally, wigglers/undulators may be treated using the methods of Chapter 22 without the use of

[10] Note that for a canted $\cos(\theta)$ dipole, see Figure 3.6, the field can also be negative outside the dipole.

[11] Often, in the case of large storage rings/colliders, long superconducting dipoles with small bores are initially built as straight rectangular magnets with windings (essentially $\cos\phi$) and iron designed in such a way as to produce as far as practical a pure $m = 1$ field. These magnets are then *mechanically* bent to accommodate a curved design orbit, thereby producing a sector bend with normal entry and exit. The hope, partially verified by experience, is that the transfer map for such a bent dipole will not have unacceptable nonlinearities.

cylindrical harmonic expansions.

Let us return to the main discussion: instances where the conflict must be addressed. Consider the case of a straight (unbent) rectangular dipole of length L with equal entry and exit angles. Make the approximation that the design orbit is a circular arc within the dipole and straight lines outside the dipole in the fringe-field regions. Assume the bend angle is θ. Then, by simple geometry, in order to *just accommodate* the design trajectory the dipole (without bending) must have a bore radius a given by the relation

$$a/L = (1 - \cos\theta/2)/(4\sin\theta/2) = \theta/(16) + O(\theta^3). \tag{16.3.44}$$

See Exercise *. Figure 3.14 displays the ratio a/L as a function of θ.[12] Suppose, for example, that $\theta = 9$ degrees and $L = 1$ meter. Then use of (3.44) gives the result $a/L = .0098$ and therefore $a = .98$ cm.

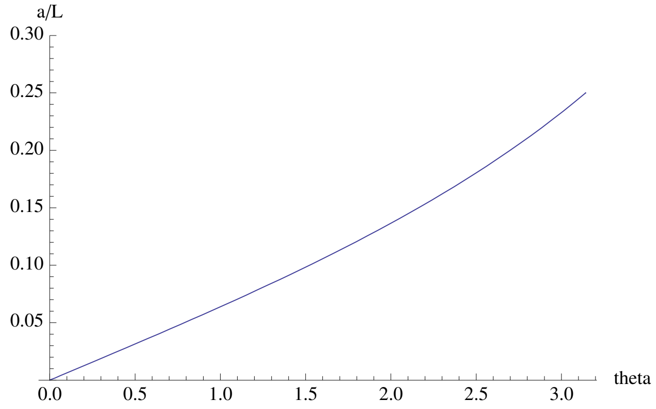

Figure 16.3.14: The ratio a/L as a function of θ.

Next, beyond the simple geometric considerations we have just explored, we must acknowledge that a cylindrical harmonic expansion is expected to be valid only in the vicinity of the z axis. Suppose we assume that the actual bore should be at least twice the geometrically needed bore in order for the cylindrical harmonic expansion to be reasonably accurate in the region traversed by the design orbit. In this case we should, say for convenience, make the Ansatz $a = 2$ cm $= .02$ meters. When $a = .02$ and $L = 1$ the field profile is that of Figure 3.13, from which we see that the fringe-field region appears to be relatively small. Specifically, from (3.38) and (3.39), we find the result

$$\text{bump}(z = -.3, a = .02, L = 1) = \text{bump}(z = 1.3, a = .02, L = 1) = -1.04 \times 10^{-3}. \tag{16.3.45}$$

Consequently, in this case one must be a distance of about 30 cm from the ends of the dipole for the on-axis field value to fall to 10^{-3} of its central on-axis value. Thus, in this case and with a 10^{-3} fall-off criterion, the fringe-field region on either end of the dipole is about 1/3 the length of the dipole.

Evidently, a more detailed analysis of this case would involve numerical integration to determine the design orbit accurately. And computation of the transfer map about this

[12] Note that, for an unbent dipole with fixed design-orbit bend angle, the bore is proportional to the length.

design orbit would require integration of the map equations of Section 10.5 using a Hamiltonian based on the vector potential given by (3.6) through (3.8). Note that in this case, according to (3.5) and (3.37) there are the relations

$$C_{1,s}^{[1]}(z) = B \text{ bump}'(z, a, L), \tag{16.3.46}$$

$$C_{1,s}^{[2]}(z) = B \text{ bump}''(z, a, L), \text{ etc.} \tag{16.3.47}$$

These functions are shown in Figures 3.15 and 3.16 below. Like its counterpart shown in Figure 2.7 for a solenoid of the same geometry, the function bump$''$ for the ideal air-core dipole of Section 3.5 is quite singular in the case $a = 0.02$ and $L = 1$. We may therefore expect that the transfer map for this ideal air-core dipole will have substantial higher-order aberrations.

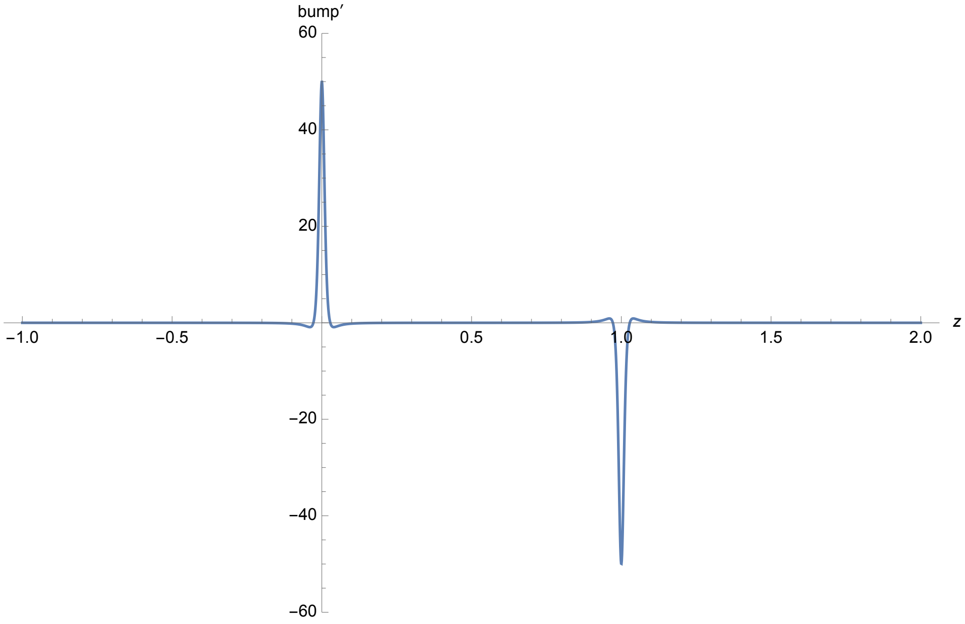

Figure 16.3.15: The function bump$'(z, a = 0.02, L = 1)$ associated with (3.38).

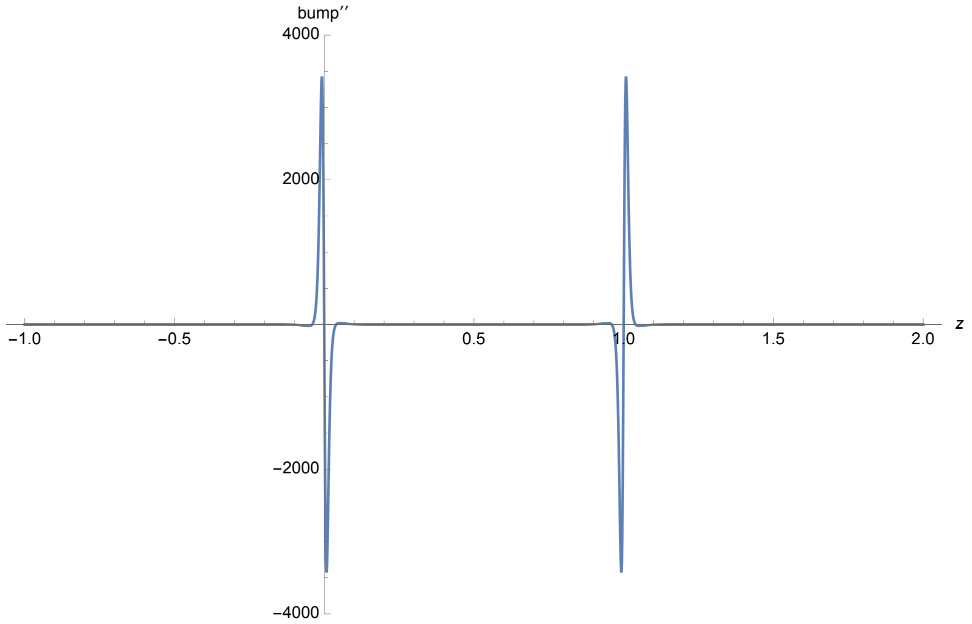

Figure 16.3.16: The function bump$''(z, a = 0.02, L = 1)$ associated with (3.38).

16.3.8 Terminating Dipole End Fields

As already described, cylindrical harmonic expansions are of limited use for dipoles because the design orbit in a dipole is bent. Correspondingly, it is generally not useful to describe the termination of dipole end fields in terms of cylindrical harmonic expansions. For the special case of wigglers/undulators, where the use of cylindrical harmonic expansions may be appropriate for describing the termination of end fields, see Subsection 4.3. For a treatment of dipole end-field termination in the general case without the use of cylindrical harmonic expansions, see Section 22.8.

16.3.9 Limited Utility of Hard-Edge Models for Dipole Fringe Fields

Exercises

16.3.1. Verify (3.11) and (3.12). Verify that (3.12) also follows from (15.8.21) and (15.8.33).

16.3.2. Verify (3.14) through (3.17).

16.3.3. Verify (3.20) through (3.22).

16.3.4. Verify (3.24) by shoing that

$$\partial_\zeta \mathrm{sgn}(\zeta, a) = 2\delta(\zeta, a). \tag{16.3.48}$$

Verify (3.25).

16.3.5. Material re $\cos(\phi)$ current distribution.

16.3.6. Verify $\cdots$.

16.3.7. Verify the relation (3.33).

16.4 Air-Core Wiggler/Undulator Models

16.4.1 Simple Air-Core Wiggler/Undulator Model

The fields of individual monopole doublets or lines of monopole doublets or idealized air-core dipoles may be used to create model fields for wigglers/undulators. We will consider the simplest case where individual monopole doublet fields are employed.

A possible simple three-pole model of a wiggler/undulator may be taken to be a string of three equally spaced monopole doublets having relative strengths $+1/2, -1, +1/2$. That is we may define a three-pole wiggler/undulator profile function $\text{wig}(3, z, a, L)$ by the rule

$$\text{wig}(3, z, a, L) = (1/2)\delta(z + L, a) - \delta(z, a) + (1/2)\delta(z - L, a) \tag{16.4.1}$$

where $2L$ is the wiggler/undulator period. Here $\delta(z, a)$ is the approximating delta function given by (3.13). The sum of the pole strengths is zero so that the wiggler/undulator produces no net bending, and the end poles are given half strengths so that the wiggler/undulator produces no net translation in x. For this profile there is the asymptotic fall off

$$\text{wig}(3, z, a, L) = (3a^2L^2)/|z|^5 + O(1/|z|^6) \text{ as } |z| \to \infty. \tag{16.4.2}$$

Figure 4.1 displays the profile function $\text{wig}(3, z, a, L)$ for the case $a = .1$ and $L = .5$. Evidently in this case, as expected from (4.2), the fringe field falls off quite rapidly. For example, at a distance of one wiggler/undulator period from the end, there is the result

$$\text{wig}(3, 1.5, .1, .5)/\text{wig}(3, 0, .1, .5) = -2.6 \times 10^{-4}. \tag{16.4.3}$$

At this point $C_{1,s}^{[0]}$ has fallen from its peak value by almost four orders of magnitude.

Another simple model is a string of five equally spaced monopole doublets having relative strengths $+1/2, -1, +1, -1, +1/2$. In this model we define a five-pole wiggler/undulator profile function $\text{wig}(5, z, a, L)$ by the rule

$$\text{wig}(5, z, a, L) = (1/2)\delta(z + 2L, a) - \delta(z + L, a) + \delta(z, a) - \delta(z - L, a) + (1/2)\delta(z - 2L, a). \tag{16.4.4}$$

For this profile there is the asymptotic fall off

$$\text{wig}(5, z, a, L) = (6a^2L^2)/|z|^5 + O(1/|z|^6) \text{ as } |z| \to \infty. \tag{16.4.5}$$

Note that the fall off for both the three-pole and five-pole wiggler/undulator goes as $1/|z|^5$, which is two orders higher in $1/|z|$ than that for a single monopole doublet. Compare (3.19), (4.2), and (4.5). This higher fall-off rate arises from cancellations that occur between the doublets because the sum of the pole strengths is zero. That is, we have enforced the relation

$$\int_{-\infty}^{\infty} dz \, \text{wig}(n, z, a, L) = 0. \tag{16.4.6}$$

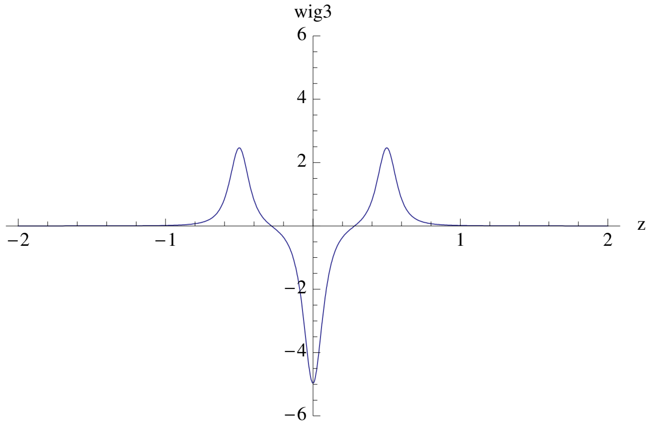

Figure 16.4.1: The three-pole wiggler/undulator profile function (4.1) when $a = 0.1$ and $L = 0.5$.

Figure 4.2 displays the five-pole profile function for the case $a = .1$ and $L = .5$. Evidently the fringe field again falls off quite rapidly. For example, at a distance of one wiggler/undulator period from the end, there is the result

$$\mathrm{wig}(5, 2, .1, .5)/\mathrm{wig}(5, 0, .1, .5) = 2.8 \times 10^{-4}. \tag{16.4.7}$$

At this point $C^{[0]}_{1,s}$ has again fallen from its peak value by almost four orders of magnitude.

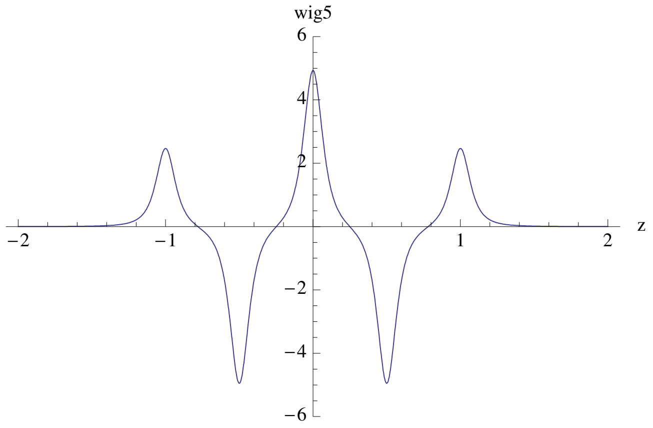

Figure 16.4.2: The five-pole wiggler/undulator profile function (4.4) when $a = 0.1$ and $L = 0.5$.

16.4.2 Iron-Free Rare Earth Cobalt (REC) Wiggler/Undulator

16.4.3 Terminating Wiggler/Undulator End Fields

Preliminaries

There is an application for which expansions employing $m = 1$ cylindrical harmonics may be useful, namely the case of wigglers/undulators when the excursion of the design orbit from the axis may be treated as small. That is, it is assumed that the design orbit enters and exits the wiggler/undulator on axis and nearly along the axis, and the excursions of the design orbit from the axis while within the wiggler/undulator may be treated as small.

At this point it is necessary to make a change of notation. In the discussion of most of the preceding sections and subsections, save for that of Sections 15.2, 15.7 and 15.9, we have used the coordinates x, y, z as global coordinates. For this subsection, as described in Section 15,2, we will use

$$\boldsymbol{R} = (X, Y, Z) \tag{16.4.8}$$

as global coordinates and

$$\boldsymbol{r} = (x, y, z) \tag{16.4.9}$$

as local coordinates. In analogy with the notation of Subsection 1.2, we assume the leading wiggler/undulator fringe field begins at $Z = Z^{\rm en}$ and the trailing wiggler/undulator fringe field ends at $Z = Z^{\rm ex}$. In the interval $[Z^{\rm en}, Z^{\rm ex}]$ the design orbit and map integrations will be carried out using the vector potential in the Coulomb gauge of Section 15.5. The entering transition at $Z^{\rm en}$ from the leading no-field region to the leading fringe-field region, and the exiting transition at $Z^{\rm ex}$ from the trailing fringe-field region to the trailing no-field region, will be made using the minimum vector potential, namely the Poincaré-Coulomb gauge vector potential.

Entering a Leading Fringe-Field Region

If we wish to make the transition from the leading no-field region to the leading fringe-field region using the minimum vector potential (the vector potential in the Poincaré-Coulomb gauge), and also wish to carry out the design orbit and map integrations using the vector potential in the Coulomb gauge of Section 15.5.2, then we need to find at $Z = Z^{\rm en}$ the gauge transformation that relates the Poincaré-Coulomb gauge and the Coulomb gauge of Section 15.5.2. The general problem of changing gauges has already been discussed in Subsection 1.3, the general relation between the Poincaré-Coulomb gauge vector potential and the Coulomb gauge vector potential of Section 15.5 has been described in Section 15.7, and the specific $m = 1$ and $\alpha = s$ relation has been treated in Section 15.9.2.

We seek relations in the vicinity of the point $(0, 0, Z^{\rm en})$. Let us recapitulate some of what we have learned. In the vicinity of this point, and for the $\alpha = s$ component of the magnetic field, the Poincaré-Coulomb gauge vector potential and the Coulomb gauge vector potential of Section 15.5 are related by the gauge transformation

$$^{P}\boldsymbol{A}^{1,s}(x, y, z; Z^{\rm en}) = \hat{\boldsymbol{A}}^{1,s}(x, y, Z^{\rm en} + z) + \nabla\chi_{1,s}. \tag{16.4.10}$$

Recall (15.7.5). Also, we found that the gauge term $\chi_{1,s}$ is related to the $m = 1$ and $\alpha = s$ on-axis gradient by the expansion

$$\chi_{1,s}(x, y, z; Z^{\rm en}) = \{[(1/2)xz]C^{[0]}_{1,s}(Z^{\rm en})\} + \{[(1/3)xz^2 - (1/12)x\rho^2]C^{[1]}_{1,s}(Z^{\rm en})\} + \cdots\ . \tag{16.4.11}$$

See (15.9.21).

Next, see (1.75), we recall the relation

$$\boldsymbol{A}^a - \boldsymbol{A}^b = \nabla\chi, \tag{16.4.12}$$

and compare it with the relation (4.10) rewritten in the form

$$\hat{\boldsymbol{A}}^{1,s}(x,y,Z^{\rm en}+z)\ -\ {}^{P}\!\boldsymbol{A}^{1,s}(x,y,z;Z^{\rm en}) = -\nabla\chi_{1,s}. \tag{16.4.13}$$

We conclude that if we wish to identify $\hat{\boldsymbol{A}}^{1,s}$ with $\boldsymbol{A}^{a}$, and identify ${}^{P}\!\boldsymbol{A}^{1,s}$ with $\boldsymbol{A}^{b}$, then we should require the relation

$$\chi = -\chi_{1,s}. \tag{16.4.14}$$

Finally, define the function $\chi^{\rm en}$ by the rule

$$\chi^{\rm en}(x,y;Z^{\rm en}) = \chi(x,y,0;Z^{\rm en}). \tag{16.4.15}$$

With this definition we see from (4.11) and (4.14) that there is the result

$$\chi^{\rm en}(x,y;Z^{\rm en}) = \{[(1/12)x\rho^2]C^{[1]}_{1,s}(Z^{\rm en})\} - \cdots . \tag{16.4.16}$$

We are now ready to invoke the results (1.77) through (1.79). So doing, we find that the canonical coordinates $(x,y,t;p_x^{\rm can},p_y^{\rm can},p_t^{\rm can})$ *after* and *before* $Z^{\rm en}$ are connected by the symplectic map $\mathcal{T}^{\rm en}$,

$$\begin{aligned}
x^a(Z) &= \mathcal{T}^{\rm en}x^b(Z) \text{ with } Z = Z^{\rm en},\\
y^a(Z) &= \mathcal{T}^{\rm en}y^b(Z) \text{ with } Z = Z^{\rm en},\\
t^a(Z) &= \mathcal{T}^{\rm en}t^b(Z) \text{ with } Z = Z^{\rm en};
\end{aligned} \tag{16.4.17}$$

$$\begin{aligned}
p_x^{\rm cana}(Z) &= \mathcal{T}^{\rm en}p_x^{\rm canb}(Z) \text{ with } Z = Z^{\rm en},\\
p_y^{\rm cana}(Z) &= \mathcal{T}^{\rm en}p_y^{\rm canb}(Z) \text{ with } Z = Z^{\rm en},\\
p_t^{\rm cana}(Z) &= \mathcal{T}^{\rm en}p_t^{\rm canb}(Z) \text{ with } Z = Z^{\rm en},
\end{aligned} \tag{16.4.18}$$

where

$$\mathcal{T}^{\rm en} = \exp(q : \chi^{\rm en} :). \tag{16.4.19}$$

Exiting a Trailing Fringe-Field Region

The general considerations for the transition associated with exiting a trailing fringe-field region are similar to those employed earlier for entering a leading fringe-field region. If we wish to make the transition from the trailing fringe-field region to the trailing no-field region using the minimum vector potential (the vector potential in the Poincaré-Coulomb gauge), and also wish to carry out the design orbit and map integrations using the vector potential in the Coulomb gauge of Section 15.5.2, then we need to find at $Z = Z^{\rm ex}$ the gauge transformation that relates the Poincaré-Coulomb gauge and the Coulomb gauge of Section 15.5.2.

We now seek relations in the vicinity of the point $(0,0,Z^{\rm ex})$. Let us again recapitulate some of what we have learned. In the vicinity of this point, and for the $\alpha = s$ component of the magnetic field, the Poincaré-Coulomb gauge vector potential and the Coulomb gauge vector potential of Section 15.5 are related by the gauge transformation

$${}^{P}\!\boldsymbol{A}^{1,s}(x,y,z;Z^{\rm ex}) = \hat{\boldsymbol{A}}^{1,s}(x,y,Z^{\rm ex}+z) + \nabla\chi_{1,s}. \tag{16.4.20}$$

Also, the gauge term $\chi_{1,s}$ is related to the $m = 1$ and $\alpha = s$ on-axis gradient by the expansion

$$\chi_{1,s}(x, y, z; Z^{\rm ex}) = \{[(1/2)xz]C^{[0]}_{1,s}(Z^{\rm ex})\} + \{[(1/3)xz^2 - (1/12)x\rho^2]C^{[1]}_{1,s}(Z^{\rm ex})\} + \cdots . \quad (16.4.21)$$

Next we again recall the relation

$$\boldsymbol{A}^a - \boldsymbol{A}^b = \nabla\chi, \quad (16.4.22)$$

and compare it with the relation (4.20) rewritten in the form

$${}^P\!\boldsymbol{A}^{1,s}(x, y, z; Z^{\rm ex}) - \hat{\boldsymbol{A}}^{1,s}(x, y, Z^{\rm ex} + z) = \nabla\chi_{1,s}. \quad (16.4.23)$$

We conclude that if we wish to identify ${}^P\!\boldsymbol{A}^{1,s}$ with $\boldsymbol{A}^a$, and identify $\hat{\boldsymbol{A}}^{1,s}$ with $\boldsymbol{A}^b$, then we should now require the relation

$$\chi = \chi_{1,s}. \quad (16.4.24)$$

Finally, define the function $\chi^{\rm ex}$ by the rule

$$\chi^{\rm ex}(x, y; Z^{\rm ex}) = \chi(x, y, 0; Z^{\rm ex}). \quad (16.4.25)$$

With this definition we see from (4.21) and (4.24) that there is the result

$$\chi^{\rm ex}(x, y; Z^{\rm ex}) = -\ \{[(1/12)x\rho^2]C^{[1]}_{1,s}(Z^{\rm ex})\} + \cdots . \quad (16.4.26)$$

We are again ready to invoke the results (1.77) through (1.79). So doing, we find that the canonical coordinates $(x, y, t; p^{\rm can}_x, p^{\rm can}_y, p^{\rm can}_t)$ after and before $Z^{\rm ex}$ are connected by the symplectic map $\mathcal{T}^{\rm ex}$,

$$\begin{aligned} x^a(Z) &= \mathcal{T}^{\rm ex}x^b(Z) \text{ with } Z = Z^{\rm ex},\\ y^a(Z) &= \mathcal{T}^{\rm ex}y^b(Z) \text{ with } Z = Z^{\rm ex},\\ t^a(Z) &= \mathcal{T}^{\rm ex}t^b(Z) \text{ with } Z = Z^{\rm ex}; \end{aligned} \quad (16.4.27)$$

$$\begin{aligned} p^{\rm cana}_x(Z) &= \mathcal{T}^{\rm ex}p^{\rm canb}_x(Z) \text{ with } Z = Z^{\rm ex},\\ p^{\rm cana}_y(Z) &= \mathcal{T}^{\rm ex}p^{\rm canb}_y(Z) \text{ with } Z = Z^{\rm ex},\\ p^{\rm cana}_t(Z) &= \mathcal{T}^{\rm ex}p^{\rm canb}_t(Z) \text{ with } Z = Z^{\rm ex}, \end{aligned} \quad (16.4.28)$$

where

$$\mathcal{T}^{\rm ex} = \exp(q : \chi^{\rm ex} :). \quad (16.4.29)$$

Behavior of $C^{[1]}_{1,s}(Z)$

According to (4.16) and (4.26) both $\chi^{\rm en}$ and $\chi^{\rm ex}$ are proportional to $C^{[1]}_{1,s}(Z)$. Let us explore the behavior of $C^{[1]}_{1,s}(Z)$ for the simplest wiggler/undulator models described in Subsection 4.1. In accord with (3.13), (4.1), and (4.4) we may write for these models

$$C^{[0]}_{1,s}(Z) = -(4g/a){\rm wig}(3, Z, a, L) \quad (16.4.30)$$

and

$$C^{[0]}_{1,s}(Z) = -(4g/a)\mathrm{wig}(5, Z, a, L) \tag{16.4.31}$$

for the three-pole and five-pole cases, respectively. It follows that for the three-pole model there is the relation

$$C^{[1]}_{1,s}(Z) = -(4g/a)(\partial/\partial Z)\mathrm{wig}(3, Z, a, L) = -(4g/a)\mathrm{wig}'(3, Z, a, L), \tag{16.4.32}$$

and there is an analogous relation for the five-pole model. Figure 4.3 displays the profile function $\mathrm{wig}'(3, z, a, L)$ for the case $a = 0.1$ and $L = 0.5$. Evidently $\mathrm{wig}'(3, z, a, L)$ falls of quite rapidly for large $|Z|$. From (4.2) we expect the asymptotic fall off behavior to go as $1/|Z|^6$ for large $|Z|$. For example, at a distance of one wiggler/undulator period from the end, there is the result

$$\mathrm{wig}'(3, 1.5, .1, .5)/\mathrm{wig}(3, 0, .1, .5) = *. \tag{16.4.33}$$

And, at a distance of two wiggler/undulator periods from the end, there is the result

$$\mathrm{wig}'(3, 1.5, .1, .5)/\mathrm{wig}(3, 0, .1, .5) = *. \tag{16.4.34}$$

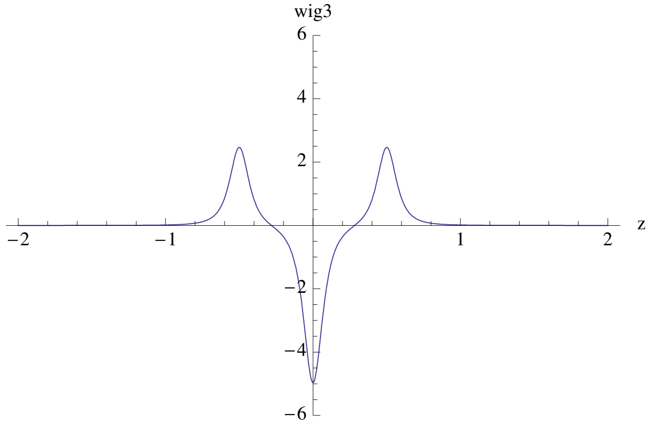

Figure 16.4.3: (Place Holder) The three-pole wiggler/undulator profile function $\mathrm{wig}'(3, z, a, L)$ when $a = 0.1$ and $L = 0.5$.

Net Total Map

Let $\mathcal{M}_{\mathrm{en}\to\mathrm{ex}}$ denote the map obtained by integrating for a wiggler/undulator the design orbit and map equations from $Z = Z^{\mathrm{en}}$ to $Z = Z^{\mathrm{ex}}$ using the Coulomb gauge vector potential of Section 15.5. Then the full net map $\mathcal{M}$ for the wiggler/undulator, including end-field termination effects, is given by the product

$$\mathcal{M} = \mathcal{T}^{\mathrm{en}}\mathcal{M}_{\mathrm{en}\to\mathrm{ex}}\mathcal{T}^{\mathrm{ex}}. \tag{16.4.35}$$

Discontinuities in Mechanical Momenta Associated with Termination Approximation

As described in Subsection 1.2, there are discontinuities in the mechanical momenta associated with the use of a symplectic termination procedure. Recall (1.30), (1.31), (1.41), and (1.42). Here, for our simple wiggler/undulator models, we will study the consequences of terminating end fields using the minimum (Poincaré-Coulomb gauge) vector potential.

The $m = 1$ and $\alpha = s$ Poincaré-Coulomb gauge vector potential about the expansion point $(0, 0, Z_0)$ is given in terms of on-axis gradients by (15.9.25) through (15.9.27). And, for our simple wiggler/undulator models, the on-axis gradients are given by relations of the form (4.30) through (4.32). Combining these relations with (1.30) and (1.31) gives, upon entry and for the 3-pole case, the discontinuity results

$$\begin{aligned}\Delta p_x^{\rm mech} &= q[{}^PA_x^{1,s}(x,y,0;Z^{\rm en})]\\ &= q\{[-(1/3)y^2]C_{1,s}^{[1]}(Z^{\rm en})+\cdots\}\\ &= q\{[-(1/3)y^2](-4g/a){\rm wig}'(3,Z^{\rm en},a,L)+\cdots\},\end{aligned} \tag{16.4.36}$$

$$\begin{aligned}\Delta p_y^{\rm mech} &= q[{}^PA_y^{1,s}(x,y,0;Z^{\rm en})]\\ &= q\{[(1/3)xy]C_{1,s}^{[1]}(Z^{\rm en})+\cdots\}\\ &= q\{[(1/3)xy](-4g/a){\rm wig}'(3,Z^{\rm en},a,L)+\cdots\}.\end{aligned} \tag{16.4.37}$$

Similarly, upon exit, we find from (15.9.25) through (15.9.27), (1.40), and (1.41) the discontinuity results

$$\begin{aligned}\Delta p_x^{\rm mech} &= q[{}^PA_x^{1,s}(x,y,0;Z^{\rm ex})]\\ &= q\{[-(1/3)y^2]C_{1,s}^{[1]}(Z^{\rm ex})+\cdots\}\\ &= q\{[-(1/3)y^2](-4g/a){\rm wig}'(3,Z^{\rm en},a,L)+\cdots\},\end{aligned} \tag{16.4.38}$$

$$\begin{aligned}\Delta p_y^{\rm mech} &= q[{}^PA_y^{1,s}(x,y,0;Z^{\rm ex})]\\ &= q\{[(1/3)xy]C_{1,s}^{[1]}(Z^{\rm ex})+\cdots\}\\ &= q\{[(1/3)xy](-4g/a){\rm wig}'(3,Z^{\rm ex},a,L)+\cdots\}.\end{aligned} \tag{16.4.39}$$

Recall the relation (15.9.35) which we rewrite in the form

$$C_{1,s}^{[0]}(Z) = B_y(0,0,Z). \tag{16.4.40}$$

We see from (4.36) through (4.39) and (4.40) that in all cases the discontinuities are proportional to $B_y'(0,0,Z)$ and its derivatives at $Z = Z^{\rm en}$ or $Z = Z^{\rm ex}$. Recall (4.32) and see Figure 4.3 for an example of how these functions behave (fall off) in the case of the simplest 3-pole wiggler/undulator model. Moreover, the discontinuities also vanish as the spatial deviations from the z axis (the design orbit) become small.

Exercises

16.4.1. Verify (4.11) and (4.12). Verify that (4.12) also follows from (15.8.21) and (15.8.33).

16.4.2. Verify (4.14) through (4.17).

16.4.3. Verify (4.20) through (4.22).

16.4.4. Verify (4.24) and (4.25).

16.4.5. Verify $\cdots$.

16.4.6. Verify the relation (4.33).

16.5 Iron-Free Quadrupoles

16.5.1 Preliminaries

A quadrupole is a straight beam-line element whose field is described by a cylindrical harmonic expansion that contains primarily an $m = 2$ term. We recall from Section 15.2.3 that in this case the magnetic scalar potential ψ has the expansion

$$\psi(x, y, z) = \psi_{2,s}(x, y, z) = 2xy[C_{2,s}^{[0]}(z) - (1/24)(x^2 + y^2)C_{2,s}^{[2]}(z) + \cdots]. \tag{16.5.1}$$

(Here we have retained only the *normal* term, but a skew term is also possible.) See (15.2.65). Correspondingly, the associated magnetic field has the expansion

$$B_x = \partial_x \psi_{2,s} = 2yC_{2,s}^{[0]}(z) - (1/12)(3x^2y + y^3)C_{2,s}^{[2]}(z) + \cdots , \tag{16.5.2}$$

$$B_y = \partial_y \psi_{2,s} = 2xC_{2,s}^{[0]}(z) - (1/12)(x^3 + 3xy^2)C_{2,s}^{[2]}(z) + \cdots , \tag{16.5.3}$$

$$B_z = \partial_z \psi_{2,s} = 2xy[C_{2,s}^{[1]}(z) - (1/24)(x^2 + y^2)C_{2,s}^{[3]}(z) + \cdots]. \tag{16.5.4}$$

From (6.2) through (6.4) we see that $\boldsymbol{B}$ is completely specified in terms of a single "master" function $C_{2,s}^{[0]}(z)$ and its derivatives. Moreover, according to (6.2) and (6.3), the on-axis field is characterized by a quadrupole strength Q given by the relation

$$Q(0, 0, z) = 2C_{2,s}^{[0]}(z). \tag{16.5.5}$$

See Exercise 1.5.9. We will next examine what can be said about the master function $C_{2,s}^{[0]}(z)$ in various cases.

16.5.2 Single Monopole Quartet

The simplest way to produce a quadrupole field, as the name again suggests, is to properly locate and assign strengths to four monopoles. Suppose two monopoles with strengths g are placed at the diametrically opposed (x,y,z) locations $(a\sqrt{2},a\sqrt{2},0)$ and $(-a\sqrt{2},-a\sqrt{2},0)$. Suppose two more monopoles of strength $-g$ are placed at the diametrically opposed locations $(a\sqrt{2},-a\sqrt{2},0)$ and $(-a\sqrt{2},a\sqrt{2},0)$. Note that all these locations lie on a cylinder of radius a and are spaced 90° apart. Such an array of monopoles will be called a monopole *quartet*. (For a discussion of the case of a monopole *half quartet*, which is what we will call two diametrically opposed monopoles of the same strength, see Exercise *.)

We will now see that a monopole quartet produces an interior field whose cylindrical multipole expansion begins with an $m=2$ term. From the symmetry of this array we expect that, in addition to the leading $m=2$ term, there may also be $m=6,10,\cdots$ terms. Recall Subsection 15.2.5. As before, let $\chi(\boldsymbol{r};\boldsymbol{r}')$ be the potential for a monopole having strength g and located at the point $\boldsymbol{r}'$. Recall (4.9). Then the potential $\psi^{\rm quart}$ for a monopole quartet centered on the origin is given by the relation

$$\begin{aligned}\psi^{\rm quart}(x,y,z) \;\;=\;\; & g\chi(x,y,z;a\sqrt{2},a\sqrt{2},0)+g\chi(x,y,z;-a\sqrt{2},-a\sqrt{2},0)\\ & -g\chi(x,y,z;a\sqrt{2},-a\sqrt{2},0)-g\chi(x,y,z;-a\sqrt{2},a\sqrt{2},0). \qquad (16.5.6)\end{aligned}$$

Next expand $\psi^{\rm quart}(x,y,z)$ as a power series in x and y. So doing yields the result

$$\psi^{\rm quart}(x,y,z)=-6ga^2xy/(z^2+a^2)^{5/2}+\text{higher order terms}. \qquad (16.5.7)$$

Comparison of (6.1) with (6.10) reveals that for a monopole quartet centered on the origin its $m=2$ on-axis gradient is given by the relation

$$C_{2,s}^{[0]}(z)=-3ga^2/(z^2+a^2)^{5/2}=-4(g/a^2)\delta(z,a) \qquad (16.5.8)$$

where $\delta(z,a)$ is an approximating delta function defined by the relation

$$\delta(z,a)=(3/4)a^4/(z^2+a^2)^{5/2}. \qquad (16.5.9)$$

Calculation shows that this approximating delta function has the properties

$$\delta(-z,a)=\delta(z,a), \qquad (16.5.10)$$

$$\delta(0,a)=3/(4a) \qquad (16.5.11)$$

$$\delta(z,a)=(3a^4/4)/|z|^5+O(1/|z|^7) \text{ as } |z|\to\infty, \qquad (16.5.12)$$

$$\int_{-\infty}^{\infty} dz\;\delta(z,a)=1. \qquad (16.5.13)$$

Figures 5.1 and 5.2 illustrate the behavior of this approximating delta function for two different values of a. Evidently this approximating delta function (5.9) becomes the true delta function in the limit $a\to 0$,

$$\lim_{a\to 0}\delta(z,a)=\delta(z), \qquad (16.5.14)$$

and a controls the fall-off rate. From (5.11) we see that the $m=2$ on-axis gradient for a monopole quartet has the fall-off behavior

$$C_{2,s}^{[0]}(z)=-3ga^2/|z|^5+O(1/|z|^7) \text{ as } |z|\to\infty. \qquad (16.5.15)$$

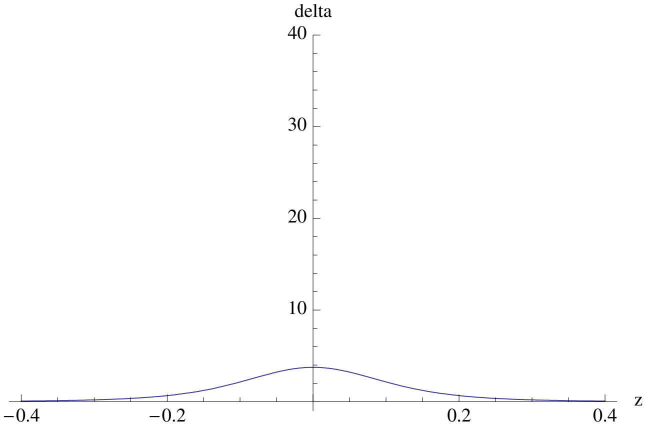

Figure 16.5.1: The approximating delta function (5.9) when $a = .2$.

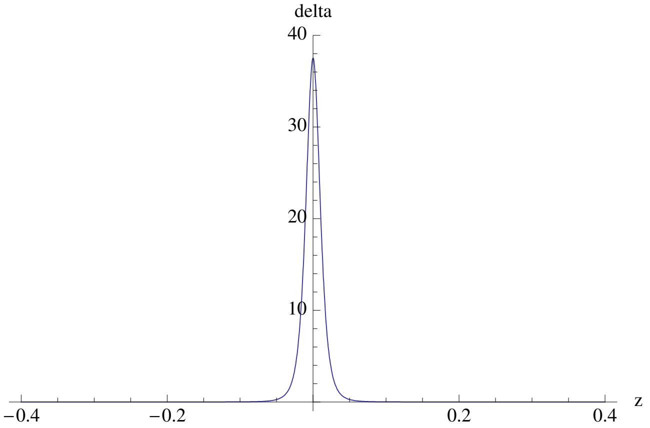

Figure 16.5.2: The approximating delta function (5.9) when $a = .02$.

16.5.3 Line of Monopole Quartets

Next consider the case of a *line* of monopole quartets extending from $z = 0$ to $z = L$. It can be treated analogously to the treatment of a line of monopole doublets provided in Subsection 4.3. A line of monopole quartets will produce a profile function described by the relation

$$\text{bump}(z, a, L) = \int_0^L dz' \, \delta(z - z', a) \tag{16.5.16}$$

where now $\delta(z, a)$ is the approximating delta function given by (5.9). In terms of this soft-edge bump function the $m = 1$ on-axis field gradient $C_{2,s}^{[0]}(z)$ for a line of monopole quartets can be written in the form

$$C_{2,s}^{[0]}(z) = (Q/2)\text{bump}(z, a, L) \tag{16.5.17}$$

where Q is the quadrupole strength in the infinite length limit. Recall Exercise 1.5.9 and (15.2.66) through (15.2.68). It is given in terms of the quartet parameters by the relation

$$Q = -8G/a^2. \tag{16.5.18}$$

Here again G is the monopole strength per unit length.

To evaluate (5.16) again make make the change of variables $\zeta = z - z'$ so that (5.16) becomes

$$\text{bump}(z, a, L) = -\int_z^{z-L} d\zeta \; \delta(\zeta, a) = \int_{z-L}^{z} d\zeta \; \delta(\zeta, a). \tag{16.5.19}$$

The approximating delta function (5.9) has as an indefinite integral the result

$$\int d\zeta \; \delta(\zeta, a) = [(1/2)\zeta^3 + (3/4)a^2\zeta]/(\zeta^2 + a^2)^{3/2} \tag{16.5.20}$$

so that we may now define an associated approximating signum function by the rule

$$\text{sgn}(z, a) = z[z^2 + (3/2)a^2]/(z^2 + a^2)^{3/2}. \tag{16.5.21}$$

We conclude from (5.19) and (5.20) that, in terms of the approximating signum function (5.21), there is the relation.

$$\text{bump}(z, a, L) = [\text{sgn}(z, a) - \text{sgn}(z - L, a)]/2. \tag{16.5.22}$$

It follows from (5.21) and (5.22) that, like the soft-edge bump functions already discussed, the soft-edge bump function for a line of monopole quartets satisfies the relations (1.15) through (1.18). Recall Exercise 1.2. We see from (1.18) and (5.17) that for line of monopole quartets there is the relation

$$\int_{-\infty}^{\infty} C_{2,s}^{[0]}(z)dz = (Q/2)L. \tag{16.5.23}$$

Figures 5.3 and 5.4 illustrate the behavior of the approximating signum function (5.21) for two different values of a. Evidently it becomes the true signum function in the limit

$a \to 0$. Figures 5.5 and 5.6 illustrate the behavior of the corresponding soft-edge bump function (5.22). It becomes the true bump function in the limit $a \to 0$. These sigum and bump functions have the asymptotic behaviors

$$\mathrm{sgn}(z,a) = 1 - (3/8)(a/z)^4 + O(1/z^6) \text{ as } z \to \infty, \tag{16.5.24}$$

$$\mathrm{bump}(z,a,L) = (3/4)La^4/|z|^5 + O(1/|z|^6) \text{ as } |z| \to \infty. \tag{16.5.25}$$

It follows that

$$C_{2,s}^{[0]}(z) = (3/8)QLa^4/|z|^5 + O(1/|z|^6) \text{ as } |z| \to \infty. \tag{16.5.26}$$

The fall off for the $m = 2$ on-axis gradient arising from a line of monopole quartets goes as $1/|z|^5$, just as it does for a single monopole quartet.

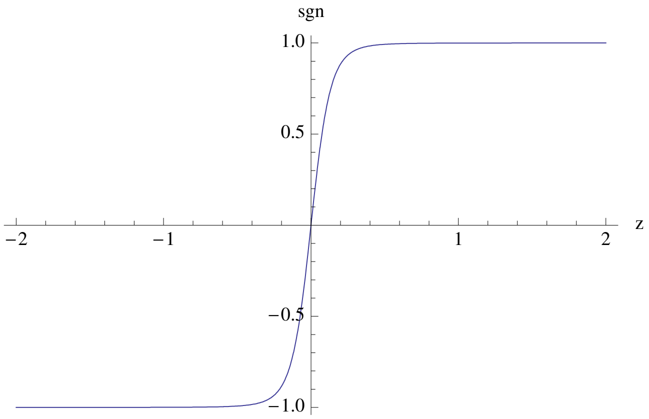

Figure 16.5.3: The approximating signum function (5.21) when $a = .2$.

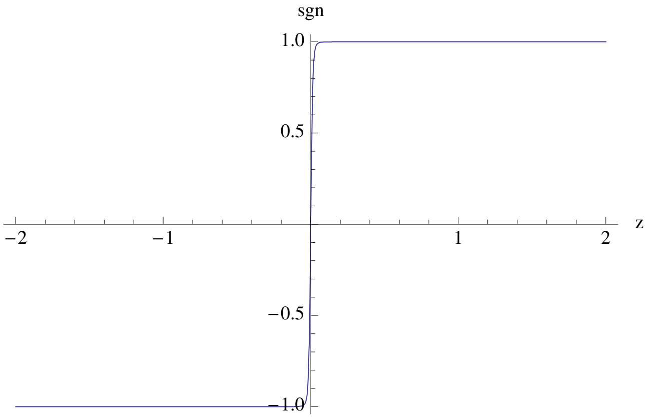

Figure 16.5.4: The approximating signum function (5.21) when $a = .02$.

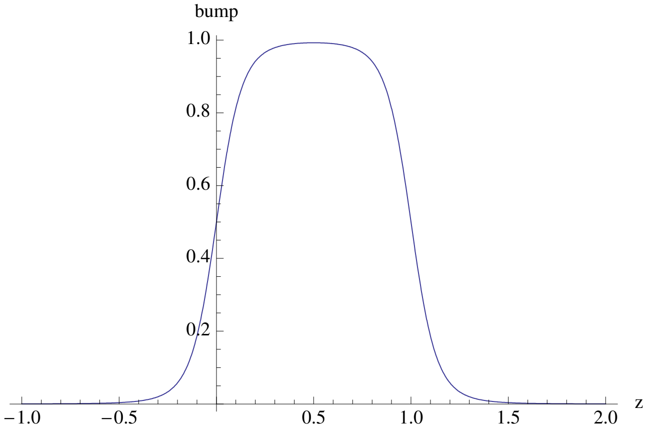

Figure 16.5.5: The soft-edge bump function (5.22) when $a = .2$.

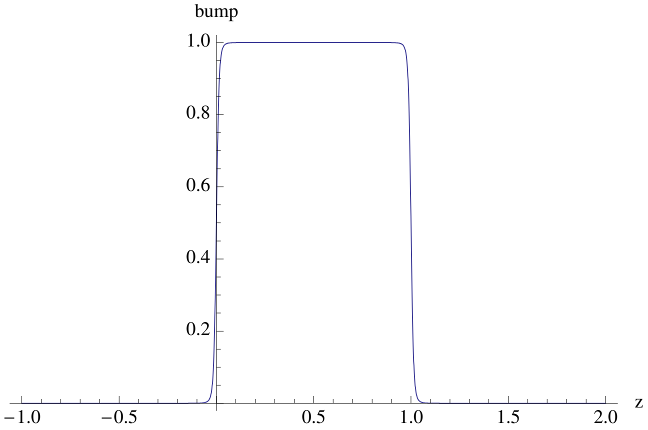

Figure 16.5.6: The soft-edge bump function function (5.22) when $a = .02$.

16.5.4 Idealized Air-Core Quadrupole

According to Subsection 15.2.5 we expect that a single monopole quartet may have nonzero on-axis gradients for the values $m = 6, 10, \cdots$ as well as the value $m = 2$. The same is true for a line of monopole quartets. An idealized air-core quadrupole consists of a thin-shell winding having a circular cross section of radius $\rho = a$ and length L. The current in the winding ideally has a $\cos(2\phi)$ dependence, which results in a "pure" quadrupole field within the bore. That is, *only* the $m = 2$ on-axis gradient is nonzero for the field produced by such a winding. However, it is not the case that the field is that of a *perfect* quadrupole. According to (15.2.65) through (15.2.68) there are additional components in the fringe-field regions at the ends of the quadrupole where $C_{2,s}^{[0]}(z)$ is changing.

If the winding begins at $z = 0$ and extends to $z = L$, then the on-axis field gradient for such a quadrupole can again be described in terms of a soft-edge bump function which we will again call $\text{bump}(z, a, L)$. That is, the on-axis field gradient $C_{2,s}^{[0]}(z)$ can again be written in the form

$$C_{2,s}^{[0]}(z) = (Q/2)\text{bump}(z, a, L) \tag{16.5.27}$$

where Q is again the quadrupole strength in the infinite length limit.

Like the previous examples of soft-edge bump functions, the soft-edge bump function for an idealized air-core quadrupole can be written in terms of an associated approximating signum function in the form

$$\text{bump}(z, a, L) = [\text{sgn}(z, a) - \text{sgn}(z - L, a)]/2. \tag{16.5.28}$$

It can be shown that for an idealized air-core quadrupole the approximating signum function $\text{sgn}(z, a)$ is given by the relation

$$\begin{aligned} \text{sgn}(z, a) &= [z^5 + (5/2)z^3a^2 + (9/4)za^4]/(z^2 + a^2)^{5/2} \\ &= z[z^4 + (5/2)z^2a^2 + (9/4)a^4]/(z^2 + a^2)^{5/2}. \end{aligned} \tag{16.5.29}$$

Figures 5.7 and 5.8 illustrate the behavior of this approximating signum function for two different values of a. Evidently the approximating signum function (5.29) becomes the true signum function in the limit $a \to 0$.

It follows from (5.28) and (5.29) that, like the previous soft-edge bump functions, the soft-edge bump function for an idealized air-core quadrupole satisfies the relations (1.15) through (1.18). Recall Exercise 1.2. Also, the relation (5.23) continues to hold.

Figures 5.9 and 5.10 illustrate the properties (1.15) through (1.17) for a fixed value of L and two different values of the radius a. Evidently the ideal air-core quadrupole soft-edge bump function becomes a hard-edge bump function in the limit $a \to 0$. The radius a plays the role of a characteristic length that controls the rate of fall off. The fringe-field region is large if a is large, and vanishes as a goes to zero. From (5.29) and (5.28) we find the asymptotic behaviors

$$\text{sgn}(z, a) = 1 + (3/8)(a/z)^4 + O(1/z^6) \text{ as } z \to \infty, \tag{16.5.30}$$

$$\text{bump}(z, a, L) = -(3/4)La^4/|z|^5 + O(1/|z|^6) \text{ as } |z| \to \infty. \tag{16.5.31}$$

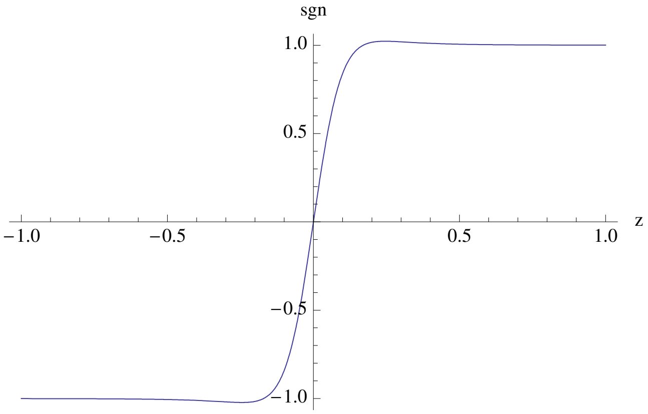

Figure 16.5.7: The approximating signum function (5.29) when $a = .2$.

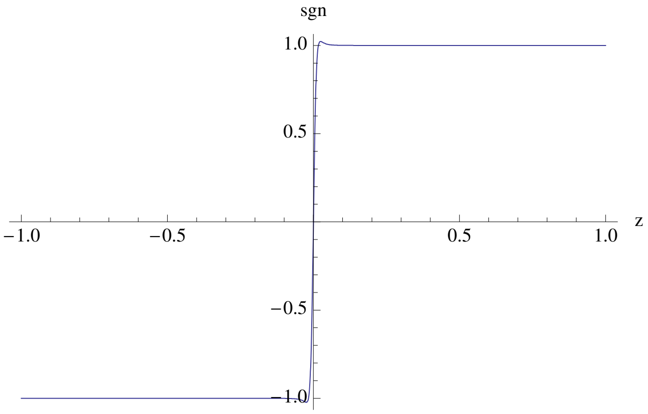

Figure 16.5.8: The approximating signum function (5.29) when $a = .02$.

Consequently $C^{[0]}_{2,s}(z)$ falls off for large distances as

$$C^{[0]}_{2,s}(z) = -(3/4)(Q/2)La^4/|z|^5 + O(1/|z|^6) \text{ as } |z| \to \infty. \tag{16.5.32}$$

We see that the fall off goes as $1/|z|^5$, which is the same rate as that for a monopole quartet and a line of monopole quartets. Note, however, that the sign on the right side of (5.31) is negative just as it is for the right side of (3.31). Therefore, the bump function for an idealized air-core quadrupole also cannot be modeled by an Enge function profile.

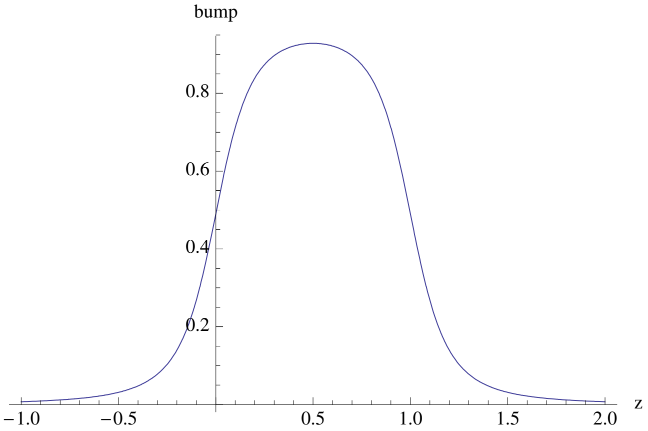

Figure 16.5.9: The soft-edge bump function given by (5.28) and (5.29) when $a = .2$ and $L = 1$.

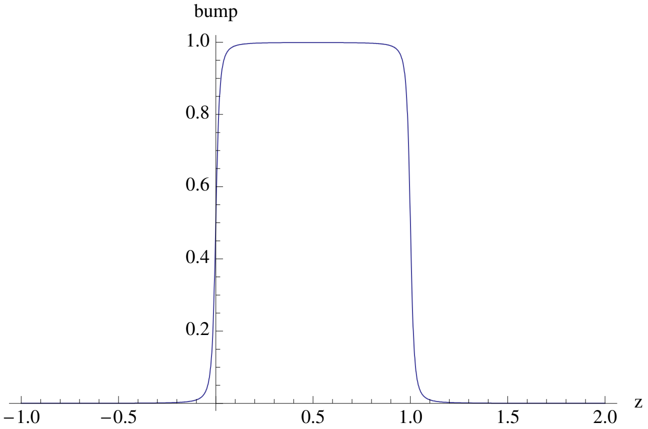

Figure 16.5.10: The soft-edge bump function given by (5.28) and (5.29) when $a = .02$ and $L = 1$.

Our discussion of quadrupole fringe fields so far has treated the iron-free case, and we have found a $1/|z|^5$ fall off in all cases. When iron is present, and the coils are buried in iron, the fall off can in principle be much faster including the possibility of essentially exponential fall off.

16.5.5 Rare Earth Cobalt (REC) Quadrupoles

A rare earth cobalt (REC) quadrupole typically has a circular annular cross section with outer radius r_2 and inner/bore radius r_1. The space between r_1 and r_2 is filled with REC material magnetized and arranged so as to produce a pure quadrupole magnetic field within the bore. That is, ideally *only* the $m = 2$ on-axis gradient is nonzero for the field produced by such an arrangement of REC material.

It can be shown that the on-axis gradient can again be described in terms of a soft-edge bump function which we will call bump(z, r_1, r_2, L) where L is the quadrupole length. That is, the on-axis field gradient $C_{2,s}^{[0]}(z)$ can be written in the form

$$C_{2,s}^{[0]}(z) = (Q/2)\text{bump}(z, r_1, r_2, L) \tag{16.5.33}$$

where Q is the strength of the REC quadrupole in the infinite length limit. Moreover, as before, the soft-edge bump function for a REC quadrupole can be written in terms of an associated approximating signum function in the form

$$\text{bump}(z, r_1, r_2, L) = [\text{sgn}(z, r_1, r_2) - \text{sgn}(z - L, r_1, r_2)]/2. \tag{16.5.34}$$

Finally, it can be shown that for the REC quadrupole the approximating signum function sgn(z, r_1, r_2) is given by the relation

$$\text{sgn}(z, r_1, r_2) = z[(r_1 + r_2)/(r_1 r_2)][(v_1 v_2)/(v_1 + v_2)][1 + (1/8)v_1 v_2(4 + v_1^2 + v_1 v_2 + v_2^2)] \tag{16.5.35}$$

where v_1 and v_2 are defined by the relations

$$v_1 = 1/\sqrt{1 + (z/r_1)^2}, \tag{16.5.36}$$

$$v_2 = 1/\sqrt{1 + (z/r_2)^2}. \tag{16.5.37}$$

It can be easily checked that the approximating signum function sgn(z, r_1, r_2) becomes the true signum function in the limit $r_1 \to 0$. See Exercise 5.4. For example, Figures 5.11 and 5.12 illustrate the behavior of this approximating signum function for two different values of r_1 and fixed values of r_2 and L.

It follows from (5.34) that the soft-edge bump function for a REC quadrupole also satisfies relations analogous to (1.15) through (1.18) and (5.23) remains true. Figures 5.13 and 5.14 illustrate the properties (1.15) through (1.17) for fixed values of r_2 and L and two different values of the inner radius r_1. Evidently the REC soft-edge bump function becomes a hard-edge bump function in the limit $r_1 \to 0$. The inner radius r_1 (as well as r_2) plays the role of a characteristic length that controls the rate of fall off. The fringe-field region is large if r_1 is large, and vanishes as r_1 goes to zero. From (5.34) through (5.37) we find the asymptotic behaviors

$$\begin{aligned}\text{sgn}(z, r_1, r_2) &= 1 - (1/16)r_1 r_2[(r_1^5 - r_2^5)/(r_1 - r_2)](1/z)^6 + O(1/z^8) \\ &= 1 - (1/16)r_1 r_2(r_1^4 + r_1^3 r_2 + r_1^2 r_2^2 + r_1 r_2^3 + r_2^4)(1/z^6) + O(1/z^8) \\ &\quad \text{as } z \to \infty,\end{aligned} \tag{16.5.38}$$

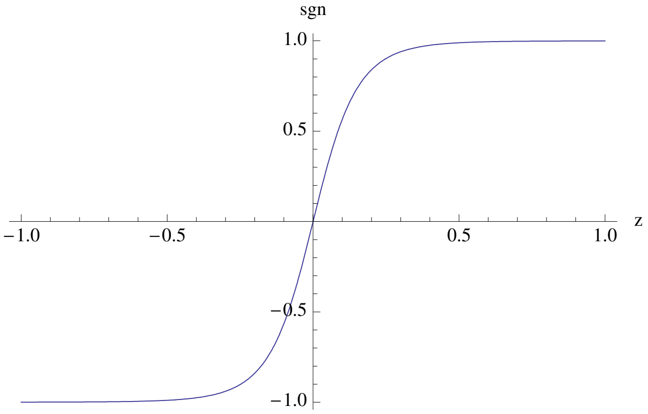

Figure 16.5.11: The approximating signum function (5.35) when $r_1 = .2$ and $r_2 = .5$.

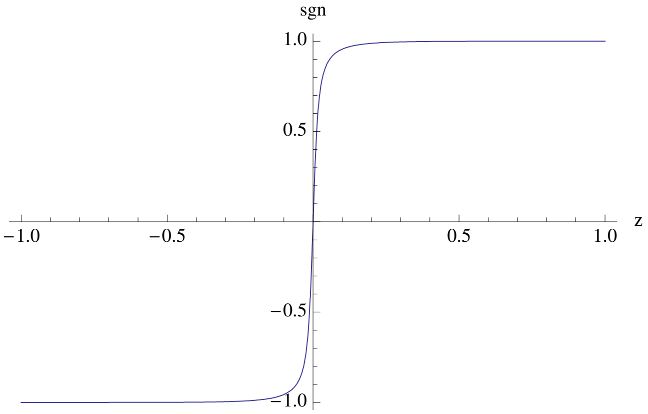

Figure 16.5.12: The approximating signum function (5.35) when $r_1 = .02$ and $r_2 = .5$.

$$\begin{aligned}\text{bump}(z,r_1,r_2,L) &= (3/16)Lr_1r_2[(r_1^5-r_2^5)/(r_1-r_2)](1/|z|^7)+O(1/|z|^8)\\ &= (3/16)Lr_1r_2(r_1^4+r_1^3r_2+r_1^2r_2^2+r_1r_2^3+r_2^4)(1/|z|^7)+O(1/|z|^8)\\ &\quad \text{as } |z|\to\infty. \qquad (16.5.39)\end{aligned}$$

Consequently $C_{2,s}^{[0]}(z)$ falls off for large distances as

$$\begin{aligned}C_{2,s}^{[0]}(z) &= (3/16)(Q/2)Lr_1r_2[(r_1^5-r_2^5)/(r_1-r_2)](1/|z|^7)+O(1/|z|^8)\\ &= (3/16)(Q/2)Lr_1r_2(r_1^4+r_1^3r_2+r_1^2r_2^2+r_1r_2^3+r_2^4)(1/|z|^7)+O(1/|z|^8).\end{aligned} \qquad (16.5.40)$$

We see that the fall off goes as $1/|z|^7$, which is pleasantly rapid. Remarkably, this rate of fall off for a REC quadrupole is two orders higher in $1/|z|$ than that for an idealized air-core quadrupole. Compare (5.32) and (5.40).

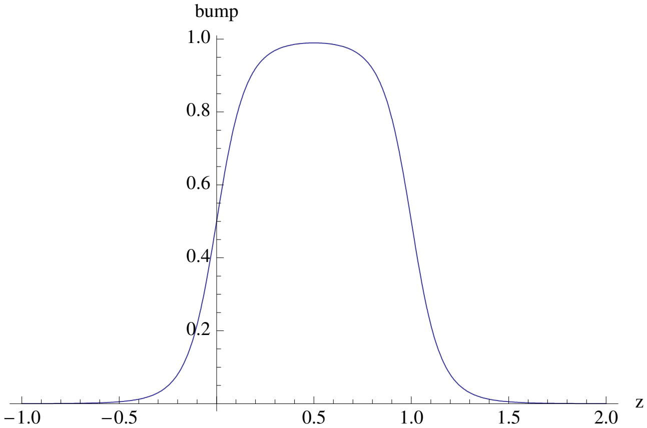

Figure 16.5.13: The soft-edge bump function (5.34) when $r_1 = .2$, $r_2 = .5$, and $L = 1$.

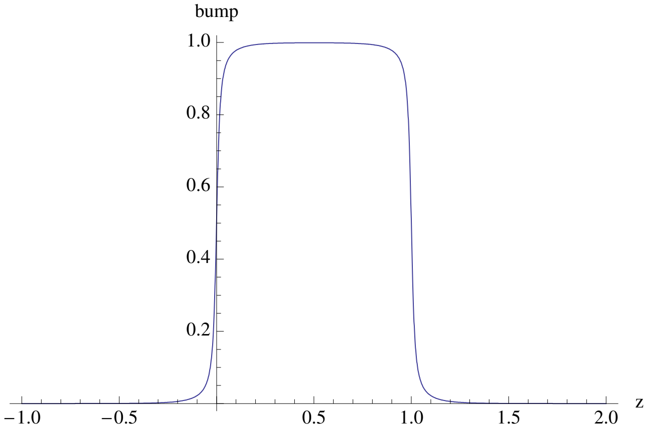

Figure 16.5.14: The soft-edge bump function (5.34) when $r_1 = .02$, $r_2 = .5$, and $L = 1$.

16.5.6 Overlapping Fringe Fields

16.5.7 Terminating Quadrupole End Fields

Preliminaries

For this subsection, as we did in Subsection 4.3, we will use the global coordinates $\boldsymbol{R}$ and local coordinates $\boldsymbol{r}$ as given by (4.8) and (4.9). Following previous notation, we assume the leading quadruple fringe field begins at $Z = Z^{\rm en}$ and the trailing quadrupole fringe field ends at $Z = Z^{\rm ex}$. In the interval $[Z^{\rm en}, Z^{\rm ex}]$ the design orbit and map integrations will be carried out using the vector potential in the Coulomb gauge of Section 15.5. The entering transition at $Z^{\rm en}$ from the leading no-field region to the leading fringe-field region, and the exiting transition at $Z^{\rm ex}$ from the trailing fringe-field region to the trailing no-field region, will be made using the minimum vector potential, namely the Poincaré-Coulomb gauge vector potential.

If we wish to make the transition from the leading no-field region to the leading fringe-field region using the minimum vector potential (the vector potential in the Poincaré-Coulomb gauge), and also wish to carry out the design orbit and map integrations using the vector potential in the Coulomb gauge of Section 15.5.2, then we need to find at $Z = Z^{\rm en}$ the gauge transformation that relates the Poincaré-Coulomb gauge and the Coulomb gauge of Section 15.5.2. Similarly, If we wish to make the transition from the trailing fringe-field region to the trailing no-field region using the minimum vector potential (the vector potential in the Poincaré-Coulomb gauge), and also wish to carry out the design orbit and map integrations using the vector potential in the Coulomb gauge of Section 15.5.2, then we need to find at $Z = Z^{\rm ex}$ the gauge transformation that relates the Poincaré-Coulomb gauge and the Coulomb gauge of Section 15.5.2. For simplicity, we will continue to assume that we are dealing with the case of a *normal* quadrupole; namely $\alpha = s$.

For both transitions there is a relation of the form

$$ {}^{P}\!\boldsymbol{A}^{2,s}(x, y, z; Z^\beta) = \hat{\boldsymbol{A}}^{2,s}(x, y, Z^\beta + z) + \nabla\chi_{2,s} \tag{16.5.41}$$

where $\beta = $ en or $\beta = $ ex. See (15.7.5). There is also the relation

$$\begin{aligned} \chi_{2,s}(x, y, z; Z^\beta) &= \cos(2\phi)\sum_{k=0}^{\infty}(-1)^k \frac{2!}{2^{2k}k!(k+2)!} D^{[2k]}_{2,s}(z; Z^\beta)\rho^{2k+2} \\ &= \rho^2\cos(2\phi)[D^{[0]}_{2,s}(z; Z^\beta) - (1/6)\rho^2 D^{[2]}_{2,s}(z; Z^\beta) + (*)\rho^4 D^{[4]}_{2,s}(z; Z^\beta) + \cdots] \\ &= (x^2 - y^2)[D^{[0]}_{2,s}(z; Z^\beta) - (1/6)\rho^2 D^{[2]}_{2,s}(z; Z^\beta) + (*)\rho^4 D^{[4]}_{2,s}(z; Z^\beta) + \cdots]. \end{aligned} \tag{16.5.42}$$

See (15.7.20). Moreover we have found, see (15.7.60), the relation

$$\begin{aligned} D^{[0]}_{2,s}(z; Z^\beta) &= \{[1/(2+1)]C^{[0]}_{2,s}(Z^\beta)\}z + \{[1/(2+2)]C^{[1]}_{2.s}(Z^\beta)\}z^2 \\ &+ \{[1/(2+3)](1/2!)C^{[2]}_{2,s}(Z^\beta)\}z^3 + \{[1/(2+4)](1/3!)C^{[3]}_{2,s}(Z^\beta)\}z^4 + \cdots \\ &= (1/3)C^{[0]}_{2,s}(Z^\beta)z + (1/4)C^{[1]}_{2,s}(Z^\beta)z^2 + (1/10)C^{[2]}_{2,s}(Z^\beta)z^3 + (1/36)C^{[3]}_{2,s}(Z^\beta)z^4 + \cdots , \end{aligned} \tag{16.5.43}$$

from which it follows that

$$D_{2,s}^{[0]}(0;Z^\beta)=0, \tag{16.5.44}$$

$$D_{2,s}^{[2]}(0;Z^\beta)=(1/2)C_{2,s}^{[1]}(Z^\beta), \tag{16.5.45}$$

$$D_{2,s}^{[4]}(0;Z^\beta)=(2/3)C_{2,s}^{[3]}(Z^\beta). \tag{16.5.46}$$

Inserting these results in (5.42) gives the expansion

$$\begin{aligned}\chi_{2,s}(x,y,0;Z^\beta) &= (x^2-y^2)[(*)\rho^2C_{2,s}^{[1]}(Z^\beta)+(*)\rho^4C_{2,s}^{[3]}(Z^\beta)+\cdots]\\ &= (x^4-y^4)[(*)C_{2,s}^{[1]}(Z^\beta)+(*)\rho^2C_{2,s}^{[3]}(Z^\beta)+\cdots].\end{aligned} \tag{16.5.47}$$

Finally there is the relation (4.12), which we repeat below:

$$\boldsymbol{A}^a-\boldsymbol{A}^b=\nabla\chi, \tag{16.5.48}$$

Entering a Leading Fringe-Field Region

Compare (5.48) with the relation (5.41) evaluated for the case $\beta=\text{en}$ and rewritten in the form

$$\hat{\boldsymbol{A}}^{2,s}(x,y,Z^{\text{en}}+z)\ -\ {}^P\!\boldsymbol{A}^{2,s}(x,y,z;Z^{\text{en}})=-\nabla\chi_{2,s}. \tag{16.5.49}$$

We conclude that if we wish to identify $\hat{\boldsymbol{A}}^{2,s}$ with $\boldsymbol{A}^a$, and identify ${}^P\!\boldsymbol{A}^{2,s}$ with $\boldsymbol{A}^b$, then we should require the relation

$$\chi=-\chi_{2,s}. \tag{16.5.50}$$

Next define the function χ^{en} by the rule

$$\chi^{\text{en}}(x,y;Z^{\text{en}})=\chi(x,y,0;;Z^{\text{en}}). \tag{16.5.51}$$

With this definition we see from (5.47), (5.50), and (5.51) that there is the result

$$\chi^{\text{en}}(x,y;Z^{\text{en}})=-(x^4-y^4)[(*)C_{2,s}^{[1]}(Z^{\text{en}})+(*)\rho^2C_{2,s}^{[3]}(Z^{\text{en}})+\cdots]. \tag{16.5.52}$$

We are now ready to invoke the results (1.77) through (1.79). So doing, we find that the canonical coordinates $(x,y,t;p_x^{\text{can}},p_y^{\text{can}},p_t^{\text{can}})$ *after* and *before* Z^{en} are connected by the symplectic map $\mathcal{T}^{\text{en}}$,

$$\begin{aligned}x^a(Z)&=\mathcal{T}^{\text{en}}x^b(Z)\text{ with }Z=Z^{\text{en}},\\ y^a(Z)&=\mathcal{T}^{\text{en}}y^b(Z)\text{ with }Z=Z^{\text{en}},\\ t^a(Z)&=\mathcal{T}^{\text{en}}t^b(Z)\text{ with }Z=Z^{\text{en}};\end{aligned} \tag{16.5.53}$$

$$\begin{aligned}p_x^{\text{cana}}(Z)&=\mathcal{T}^{\text{en}}p_x^{\text{canb}}(Z)\text{ with }Z=Z^{\text{en}},\\ p_y^{\text{cana}}(Z)&=\mathcal{T}^{\text{en}}p_y^{\text{canb}}(Z)\text{ with }Z=Z^{\text{en}},\\ p_t^{\text{cana}}(Z)&=\mathcal{T}^{\text{en}}p_t^{\text{canb}}(Z)\text{ with }Z=Z^{\text{en}},\end{aligned} \tag{16.5.54}$$

where

$$\mathcal{T}^{\text{en}}=\exp(q:\chi^{\text{en}}:). \tag{16.5.55}$$

Exiting a Trailing Fringe-Field Region

Compare (5.48) with the relation (5.41) evaluated for the case $\beta = \text{ex}$ and rewritten in the form

$$^{P}\boldsymbol{A}^{2,s}(x,y,z) - \hat{\boldsymbol{A}}^{2,s}(x,y,Z^{\text{ex}}+z) = \nabla\chi_{2,s}. \tag{16.5.56}$$

We conclude that if we wish to identify $^{P}\boldsymbol{A}^{2,s}$ with $\boldsymbol{A}^{a}$, and identify $\hat{\boldsymbol{A}}^{2,s}$ with $\boldsymbol{A}^{b}$, then we should now require the relation

$$\chi = \chi_{2,s}. \tag{16.5.57}$$

Next define the function χ^{ex} by the rule

$$\chi^{\text{ex}}(x,y) = \chi(x,y,0). \tag{16.5.58}$$

With this definition we see from (5.47), (5.57), and (5.58) that there is the result

$$\chi^{\text{ex}}(x,y) = (x^4 - y^4)[(*)C_{2,s}^{[1]}(Z^{\text{ex}}) + (*)\rho^2 C_{2,s}^{[3]}(Z^{\text{ex}}) + \cdots]. \tag{16.5.59}$$

We are again ready to invoke the results (1.77) through (1.79). So doing, we find that the canonical coordinates $(x,y,t;p_x^{\text{can}},p_y^{\text{can}},p_t^{\text{can}})$ after and before Z^{ex} are connected by the symplectic map $\mathcal{T}^{\text{ex}}$,

$$\begin{aligned}
x^a(Z) &= \mathcal{T}^{\text{ex}} x^b(Z) \text{ with } Z = Z^{\text{ex}},\\
y^a(Z) &= \mathcal{T}^{\text{ex}} y^b(Z) \text{ with } Z = Z^{\text{ex}},\\
t^a(Z) &= \mathcal{T}^{\text{ex}} t^b(Z) \text{ with } Z = Z^{\text{ex}};
\end{aligned} \tag{16.5.60}$$

$$\begin{aligned}
p_x^{\text{cana}}(Z) &= \mathcal{T}^{\text{ex}} p_x^{\text{canb}}(Z) \text{ with } Z = Z^{\text{ex}},\\
p_y^{\text{cana}}(Z) &= \mathcal{T}^{\text{ex}} p_y^{\text{canb}}(Z) \text{ with } Z = Z^{\text{ex}},\\
p_t^{\text{cana}}(Z) &= \mathcal{T}^{\text{ex}} p_t^{\text{canb}}(Z) \text{ with } Z = Z^{\text{ex}},
\end{aligned} \tag{16.5.61}$$

where

$$\mathcal{T}^{\text{ex}} = \exp(q : \chi^{\text{ex}} :). \tag{16.5.62}$$

Behavior of $C_{2,s}^{[1]}(Z)$

According to (5.52) and (5.59) both χ^{en} and χ^{ex} involve $C_{2,s}^{[1]}(Z)$ and its derivatives. Let us explore the behavior of $C_{2,s}^{[1]}(Z)$ for the cases of idealized air-core quadrupoles and REC quadrupoles, which are described in Subsections 5.4 and 5.6, respectively. In both cases $C_{2,s}^{[0]}(Z)$ is proportional to an associated bump function. See (5.27) and (5.33). Therefore, in both cases we are interested in the Z dependence of bump′, the derivative of the bump function. Figures 5.15 and 5.16 display the derivative of the soft-edge bump functions shown in Figures 5.9 and 5.10 for two idealized air-core quadrupoles; and Figures 5.17 and 5.18 display the derivative of the soft-edge bump functions shown in Figures 5.13 and 5.14 for two REC quadrupoles.

Evidently bump′, the derivative of the bump function, falls of quite rapidly beyond the quadrupole body. For example we expect, according to (5.31), that in the case of an idealized air-core quadrupole the function bump′ will fall off like $1/|z|^6$ as $z \to -\infty$. And, according to (5.39), we expect a fall off like $1/|z|^8$ for the case of a REC quadrupole.

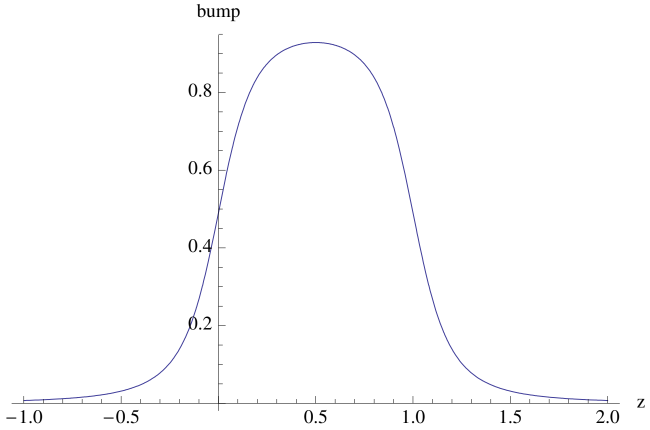

Figure 16.5.15: (Place Holder) Derivative of the soft-edge bump function given by (5.28) and (5.29) when $a = .2$ and $L = 1$, and shown in Figure 5.9.

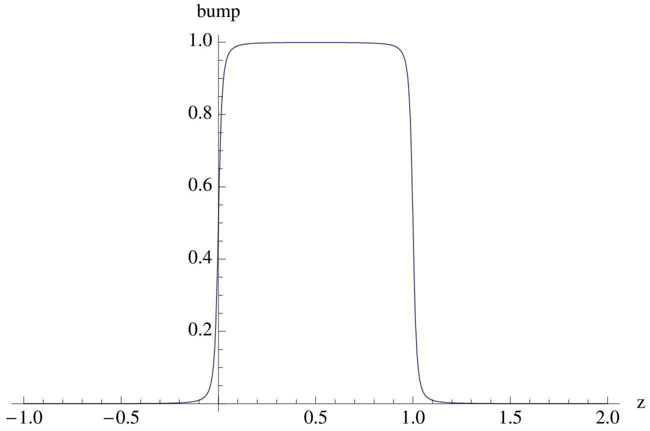

Figure 16.5.16: (Place Holder) Derivative of the soft-edge bump function given by (5.28) and (5.29) when $a = .02$ and $L = 1$, and shown in Figure 5.10.

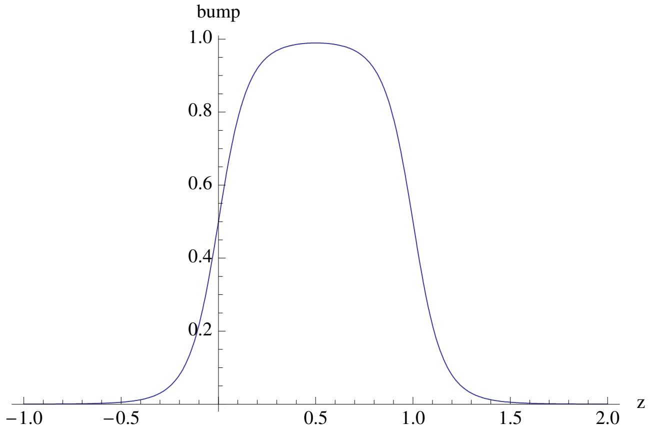

Figure 16.5.17: (Place Holder) Derivative of the soft-edge bump function (5.34) when $r_1 = .2$, $r_2 = .5$, and $L = 1$, and shown in Figure 5.13.

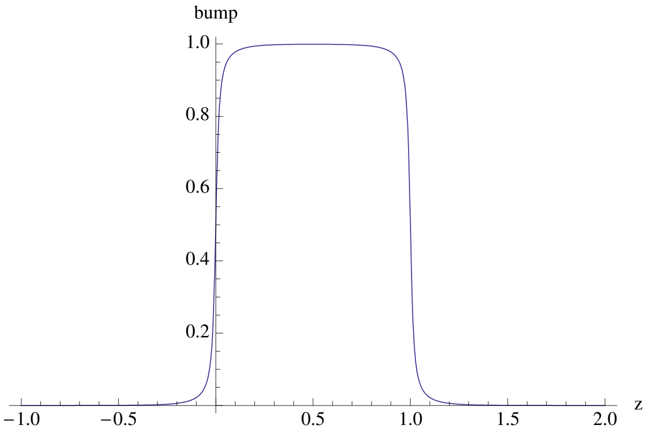

Figure 16.5.18: (Place Holder) Derivative of the soft-edge bump function (5.34) when $r_1 = .02$, $r_2 = .5$, and $L = 1$, and shown in Figure 5.14.

Net Total Map

Let $\mathcal{M}_{\text{en}\rightarrow\text{ex}}$ denote the map obtained by integrating for a quadrupole the design orbit and map equations from $Z = Z^{\text{en}}$ to $Z = Z^{\text{ex}}$ using the Coulomb gauge vector potential of Section 15.5. Then the full net map $\mathcal{M}$ for the quadrupole, including end-field termination effects, is given by the product

$$\mathcal{M} = \mathcal{T}^{\text{en}}\mathcal{M}_{\text{en}\rightarrow\text{ex}}\mathcal{T}^{\text{ex}}. \tag{16.5.63}$$

Discontinuities in Mechanical Momenta Associated with Termination Approximation

As described in Subsection 1.2, there are discontinuities in the mechanical momenta associated with the use of a symplectic termination procedure. Recall (1.30), (1.31), (1.41), and (1.42). Here we will study for quadrupoles the consequences of terminating end fields using the minimum (Poincaré-Coulomb gauge) vector potential. To do so we will need the $m = 2$ and $\alpha = s$ Poincaré-Coulomb gauge vector potential about the expansion point $(0, 0, Z_0)$.

For fun let us compute ${}^{P}\boldsymbol{A}^{2,s}(x, y, z)$ from scratch starting with $\psi_{2,s}(x, y, Z_0 + z)$. From (5.1) we have the result

$$\psi_{2,s}(x, y, Z_0 + z) = 2xy[C^{[0]}_{2,s}(Z_0 + z) - (1/24)(x^2 + y^2)C^{[2]}_{2,s}(Z_0 + z) + \cdots]. \tag{16.5.64}$$

Let $\boldsymbol{B}(\boldsymbol{r}; Z_0)$ be the associated magnet field and employ the notation

$$\boldsymbol{B}(\boldsymbol{r}; Z_0) = \boldsymbol{B}(x, y, z; Z_0) = \boldsymbol{B}(x, y, Z_0 + z). \tag{16.5.65}$$

We then have the relations

$$B_x(x, y, z; Z_0) = \partial_x\psi_{2,s} = 2yC^{[0]}_{2,s}(Z_0 + z) - (1/12)(3x^2y + y^3)C^{[2]}_{2,s}(Z_0 + z) + \cdots , \tag{16.5.66}$$

$$B_y(x, y, z; Z_0) = \partial_y\psi_{2,s} = 2xC^{[0]}_{2,s}(Z_0 + z) - (1/12)(x^3 + 3xy^2)C^{[2]}_{2,s}(Z_0 + z) + \cdots , \tag{16.5.67}$$

$$B_z(x,y,z;Z_0) = \partial_z \psi_{2,s} = 2xy[C_{2,s}^{[1]}(Z_0+z) - (1/24)(x^2+y^2)C_{2,s}^{[3]}(Z_0+z) + \cdots]. \quad (16.5.68)$$

Next expand $\boldsymbol{B}(x,y,Z_0+z)$ in homogeneous polynomials by writing,

$$\boldsymbol{B}(\boldsymbol{r};Z_0) = \boldsymbol{B}^1(\boldsymbol{r};Z_0) + \boldsymbol{B}^2(\boldsymbol{r};Z_0) + \boldsymbol{B}^3(\boldsymbol{r};Z_0) + \cdots . \quad (16.5.69)$$

From (5.65) through (5.67) we see that there are the relations

$$\boldsymbol{B}^1(\boldsymbol{r};Z_0) = 2C_{2,s}^{[0]}(Z_0)(y\boldsymbol{e}_x + x\boldsymbol{e}_y), \quad (16.5.70)$$

$$\boldsymbol{B}^2(\boldsymbol{r};Z_0) = 2C_{2,s}^{[1]}(Z_0)(yz\boldsymbol{e}_x + xz\boldsymbol{e}_y + xy\boldsymbol{e}_z). \quad (16.5.71)$$

Now we may use (15.2.111) to find the results

$$\begin{aligned}\boldsymbol{A}^2(\boldsymbol{r};Z_0) &= -(1/3)[\boldsymbol{r}\times\boldsymbol{B}^1(\boldsymbol{r};Z_0)] \\ &= (-2/3)C_{2,s}^{[0]}(Z_0)[-zx\boldsymbol{e}_x + zy\boldsymbol{e}_y + (x^2-y^2)\boldsymbol{e}_z], \quad (16.5.72)\end{aligned}$$

$$\begin{aligned}\boldsymbol{A}^3(\boldsymbol{r};Z_0) &= -(1/4)[\boldsymbol{r}\times\boldsymbol{B}^2(\boldsymbol{r};Z_0)] \\ &= (-1/2)C_{2,s}^{[1]}(Z_0)[(xy^2-xz^2)\boldsymbol{e}_x + (yz^2-yx^2)\boldsymbol{e}_y + (zx^2-zy^2)\boldsymbol{e}_z]. \quad (16.5.73)\end{aligned}$$

[Note that, in view of the relation(5.5), (5.72) agrees with (15.2.165), as it should.] Finally, we write

$$^{P}\boldsymbol{A}^{2,s}(\boldsymbol{r};Z_0) = \boldsymbol{A}^2(\boldsymbol{r};Z_0) + \boldsymbol{A}^3(\boldsymbol{r};Z_0) + \cdots . \quad (16.5.74)$$

Let us find what this knowledge of $^{P}\boldsymbol{A}^{2,s}$ entails for discontinuities in mechanical momenta. Observe that, according to (5.72) and (5.73), there are the results

$$\boldsymbol{A}^2(x,y,0;Z_0) = 0, \quad (16.5.75)$$

$$\boldsymbol{A}^3(x,y,0;Z_0) = (-1/2)C_{2,s}^{[1]}(Z_0)[(xy^2)\boldsymbol{e}_x + (-yx^2)\boldsymbol{e}_y], \quad (16.5.76)$$

so that

$$^{P}\boldsymbol{A}^{2,s}(x,y,0;Z_0) = (-1/2)C_{2,s}^{[1]}(Z_0)[(xy^2)\boldsymbol{e}_x + (-yx^2)\boldsymbol{e}_y] + \cdots . \quad (16.5.77)$$

We conclude from * that upon entry there are the discontinuity results

$$\begin{aligned}\Delta p_x^{\rm mech} &= q[^{P}A_x^{2,s}(x,y,0;Z^{\rm en})] \\ &= q\{[-(1/2)xy^2]C_{2,s}^{[1]}(Z^{\rm en}) + \cdots\}, \quad (16.5.78)\end{aligned}$$

$$\begin{aligned}\Delta p_y^{\rm mech} &= q[^{P}A_y^{2,s}(x,y,0;Z^{\rm en})] \\ &= q\{[(1/2)x^2y]C_{2,s}^{[1]}(Z^{\rm en}) + \cdots\}. \quad (16.5.79)\end{aligned}$$

Similarly, upon exit, we find from * the discontinuity results

$$\begin{aligned}\Delta p_x^{\rm mech} &= q[^{P}A_x^{2,s}(x,y,0;Z^{\rm ex})] \\ &= q\{[-(1/2)xy^2]C_{2,s}^{[1]}(Z^{\rm ex}) + \cdots\}, \quad (16.5.80)\end{aligned}$$

$$\begin{aligned}\Delta p_y^{\rm mech} &= q[{}^P A_y^{2,s}(x,y,0;Z^{\rm ex})] \\ &= q\{[(1/2)x^2y]C_{2,s}^{[1]}(Z^{\rm ex})+\cdots\}.\end{aligned} \tag{16.5.81}$$

Recall the relations (5.5), (5.27), and (5.33). We see that in all cases the discontinuities are proportional to $Q'(0,0,Z)$, or, equivalently bump$'$, and its derivatives at $Z = Z^{\rm en}$ or $Z = Z^{\rm ex}$. We have already seen examples, in Figures 15 through 18, of how these functions behave (fall off) in the cases of idealized air-core and REC quadrupoles. Moreover, the discontinuities also vanish as the spatial deviations from the z axis (the design orbit) become small.

Exercises

16.5.1. Verify the relations (7.32) through (7.39).

16.5.2. Evidently the second-order portion of $\psi^e(\boldsymbol{r}^d;x_0,z_0)$ as given in (7.61) is composed of the monomials $\xi\eta$ and $\eta\zeta$. Show that these are the only monomials allowed at this order based on symmetry considerations. Verify that each monomial is an harmonic polynomial. Indeed, making the usual correspondence between ξ,η,ζ and x,y,z show, following the harmonic polynomial labeling scheme (U.2.9), that there are the relations

$$\xi\eta = [1/(4i)][\sqrt{32\pi/15}][H_2^2(\boldsymbol{r}) - H_2^{-2}(\boldsymbol{r})], \tag{16.5.82}$$

$$\eta\zeta = [-1/(2i)][\sqrt{8\pi/15}][H_2^1(\boldsymbol{r}) + H_2^{-1}(\boldsymbol{r})]. \tag{16.5.83}$$

Would these relations have been simpler had the polar axis, used to set up spherical polar coordinates, been taken to be the y axis instead of the z axis?

16.5.3. Verify (6.13) through (6.16.

16.5.4. Verify (6.19) through (6.24).

16.5.5. Verify that sgn(z,r) as given by (6.24) becomes the true signum function in the limit $r \to 0$. Verify the relations (6.27) through (6.29).

16.5.6. The purpose of this exercise is to verify that the approximating signum function sgn(z,r_1,r_2) becomes the true signum function in the limit that r_1 goes to zero,

$$\lim_{r_1\to 0} \mathrm{sgn}(z,r_1,r_2) = \mathrm{sgn}(z). \tag{16.5.84}$$

Along the way we will also verify some other expected properties of sgn(z,r_1,r_2).

16.5.7. Verify (6.41) through (6.43).

16.6 Sextupoles and Beyond

A sextupole is a beam-line element whose field is described by a cylindrical harmonic expansion that contains primarily an $m = 3$ term. The simplest way to produce a sextupole field, as the name again suggests, is to properly locate and assign strengths to six monopoles. In the case of a sextupole the sextet of monopoles can be taken to be three doublets rotated successively by 60 degrees. We already know from the work of Section 15.8.2 that a monopole doublet produces an $m = 3$ term. See (15.8.33). And (15.8.34) evaluated with $m = 3$ describes how this term falls off for large $|z|$. We conclude that the on-axis gradient for a monopole sextet falls off as $1/|z|^7$ for large $|z|$. In analogy with the case of dipoles and quadrupoles, we expect that the on-axis gradients for a line of monopole sextets and an idealized air-core sextupole will also fall off as $1/|z|^7$ for large $|z|$.

Moreover, the general pattern is now clear. We expect that the on-axis gradient for an idealized air-core $2m$-pole magnet will fall off for large $|z|$ as $1/|z|^{2m+1}$.

Chapter 17

Surface Methods for General Straight Beam-Line Elements

17.1 Introduction

Section 15.1 described the need for Taylor expansions of the vector potential $\boldsymbol{A}$ in order to determine the transfer map $\mathcal{M}$. As illustrated in Chapter 16, there are cases in which these Taylor expansions can be found analytically. However, for most cases, all that we can hope to have are magnetic field values determined numerically at points on some regular 3-dimensional grid with the aid of some electromagnetic code.[1] This places us in what might appear to be a hopeless position: it is well known that it is generally difficult to extract reliable information about derivatives from numerical data on a grid. And we want to know about high derivatives! Hildebrand, author of *Introduction to Numerical Analysis*, writes

> *Once an interpolating polynomial $y(x)$ has been determined so that it satisfactorily approximates a given function $f(x)$ over a certain interval I, it may be hoped that the results of differentiating $y(x)$ $\cdots$ will also satisfactorily approximate the corresponding derivative $\cdots$ of $f(x)$. However $\cdots$ we may anticipate the fact that, even though the deviation between $y(x)$ and $f(x)$ will be small throughout the interval, still the slopes of the two curves representing them may differ quite appreciably. Further, it is seen that roundoff errors (or errors of observation) of alternating sign in consecutive ordinates could affect the calculation of the derivative quite strongly if those ordinates were fairly closely spaced $\cdots$. In particular, numerical differentiation should be avoided whenever possible, particularly when the data are empirical and subject to appreciable errors of observation.*

Remarkably, we will find that this problem can be overcome to some satisfactory aberration order with the use of *surface* data.[2] We will fit field data onto some surface, and then use

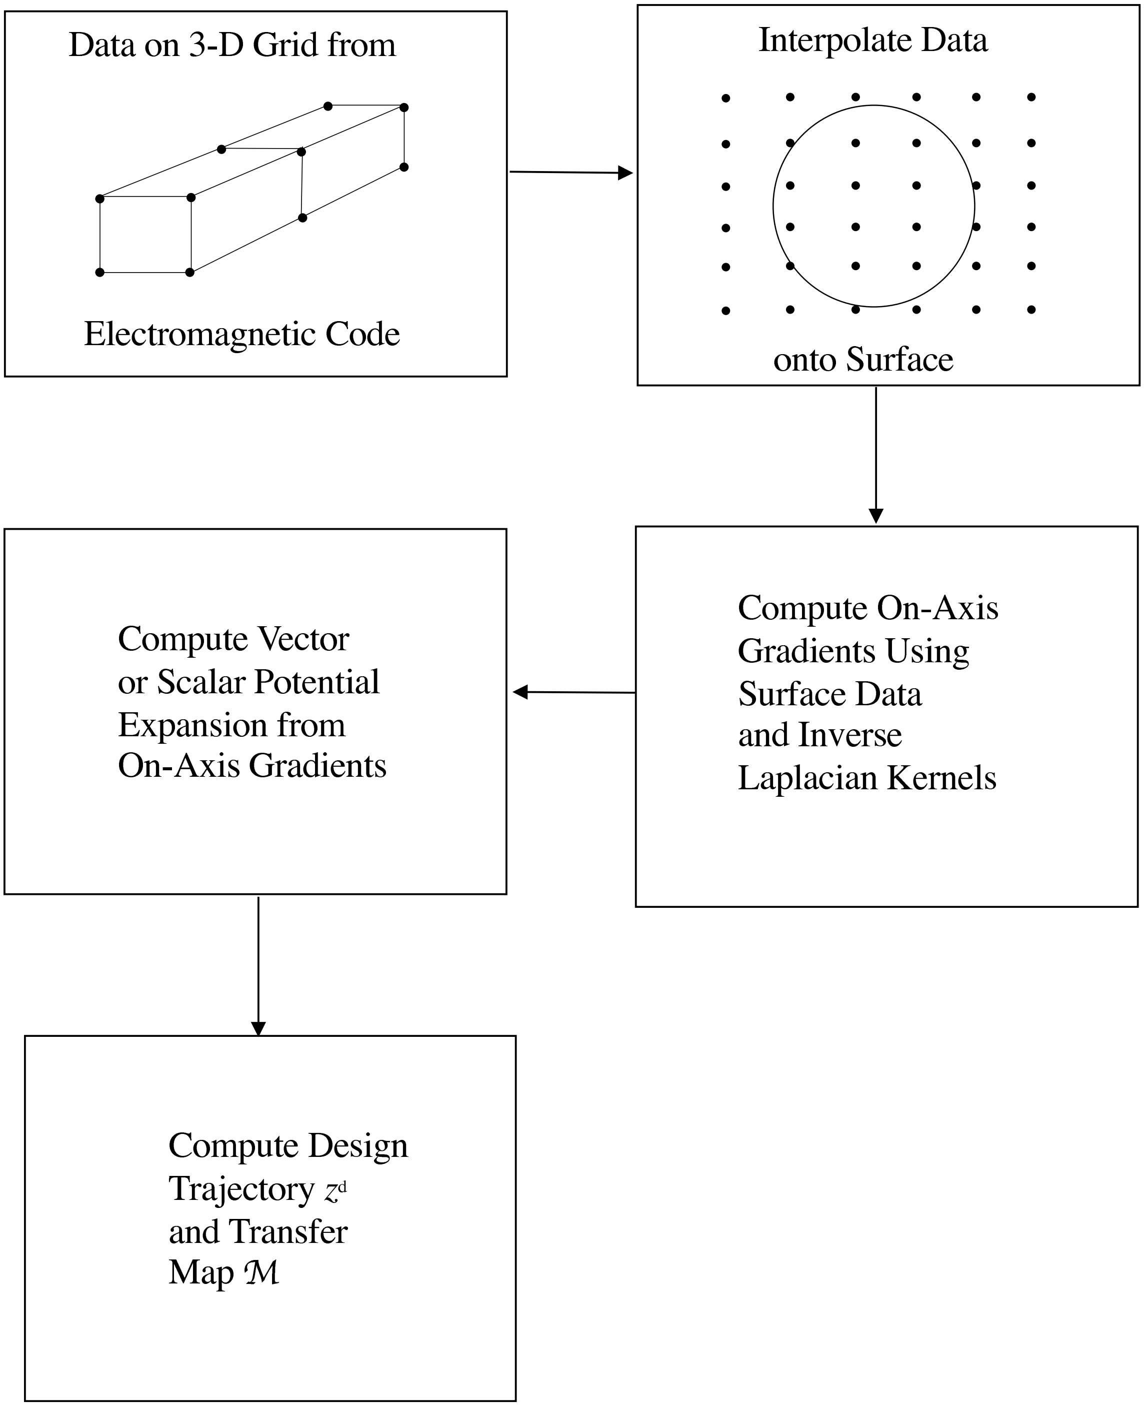
[1] Alternatively, see Section 17.2, we may have numerically-determined values of the magnetic scalar potential.

[2] The determination of the solution of Laplace's equation in terms of surface data is called the *Dirichlet* (1805-1859) problem. Dirichlet was the thesis advisor of, among others, Kronecker and Lipschitz. It is also interesting to note that he married Rebecka Mendelssohn, one of the sisters of Felix Mendelssohn.

this surface data to compute interior fields. Specifically, and in summary, we will find that surface methods have the following virtues:

- Only functions with known (orthonormal) completeness properties and known (optimal) convergence properties are employed.
- The Maxwell equations are exactly satisfied.
- The results are manifestly analytic in all variables.
- The error is globally controlled. Fields that satisfy the Laplace equation take their extrema on boundaries. Both the exact and computed fields satisfy the Laplace equation. Therefore their difference, the error field, also satisfies the Laplace equation, and must take its extrema on the boundary. But this is precisely where a controlled fit is made. Thus, the error on the boundary is controlled, and the interior error must be even smaller.
- Because fields take their extrema on boundaries, interior values inferred from surface data are relatively insensitive to errors/noise in the surface data. Put another way, the inverse Laplacian (Laplace Green function), which relates interior data to surface data, is *smoothing*. It is this smoothing that we seek to exploit. We will find that the sensitivity to noise in the data decreases rapidly (as some high inverse power of distance) with increasing distance from the surface, and this property improves the accuracy of the high-order interior derivatives needed to compute high-order transfer maps.

In this chapter, devoted to the case of straight beam-line elements, we will develop methods for computing high-order transfer maps based on data provided on a 3-dimensional grid. See Figure 1.1. These methods make it possible to compute realistic transfer maps for real (straight) beam-line elements including all fringe-field and higher-order multipole effects. In Chapter 15 we learned how to characterize magnetic fields in terms of cylindrical harmonics described by on-axis gradients, and also how to determine vector potentials in terms of on-axis gradients. In this chapter we will see how on-axis gradients can in turn be computed from numerical data provided on a 3-dimensional grid. Chapters 18 through 21 will elaborate on these methods and apply them to a variety of straight beam-line elements. In Chapters 22 through 25 we will consider realistic transfer maps for curved beam-line elements.



Data on 3-D Grid from
Electromagnetic Code
Interpolate Data
onto Surface
Compute On-Axis Gradients Using Surface Data and Inverse Laplacian Kernels
Compute Vector or Scalar Potential Expansion from On-Axis Gradients
Compute Design Trajectory z^d and Transfer Map $\mathcal{M}$

Figure 17.1.1: Calculation of realistic design trajectory z^d and its associated realistic transfer map $\mathcal{M}$ based on data provided on a 3-dimensional grid for a real beam-line element. Only a few points on the 3-dimensional grid are shown. In this illustration, data from the 3-dimensional grid is interpolated onto the surface of a cylinder with circular cross section, and this surface data is then processed to compute the design trajectory and the transfer map. The use of other surfaces is also possible, and may offer various advantages.

At this point one might wonder about a seemingly simpler approach: Suppose some fine grid of possible initial conditions is laid out in phase space. Next suppose the final conditions associated with these initial conditions are computed numerically, say by integrating Newton's equations with a Lorentz force, using volume magnetic field data interpolated off a three-dimensional grid. Based on the collection of initial and final conditions, make a polynomial expansion of the final conditions in terms of the initial conditions. Announce that these truncated Taylor series, generally six in number assuming a six-dimensional phase space, constitute a (Taylor) transfer map. What could be wrong with that?

There are three reasons why such an approach is problematic:

1. After some reflection, we see that this procedure essentially amounts to high-order numerical differentiation, and therefore Hildebrand's warning still holds. The problem of error associated with high-order numerical differentiation remains.

2. If Newton's equations are integrated, the symplectic symmetry inherent in a Hamiltonian formulation cannot be exploited.

3. Again assuming Newton's equations are integrated, and even in the absence of the error associated with high-order numerical differentiation, the result will not be symplectic if there is a residual magnetic field at the beginning or end of the integration region. See Exercise 6.4.11. Therefore the result may not be suitable for long-term tracking. Perhaps this possible lack of symplecticity could in principle be handled by factorizing the resulting Taylor map into symplectic and nonsymplectic parts, and then using only the symplectic part for any subsequent calculations. See Section 29.1. As a bonus, examination of the size of the nonsymplectic part might give some indication of the error involved in the calculation.

There are also some other approaches that have sometimes been attempted to obtain transfer maps based on 3-d field data on a grid. They are described in Section 17.6. They too involve high-order numerical differentiation, and therefore are unlikely to succeed beyond modest order, at best.

Finally, we mention that there are two other possible ways of determining on-axis gradients that warrant exploration. The first is to infer on-axis gradients from experimental spinning coil data. The second, applicable in the case of air-core magnets, is to compute on-axis gradients based on data describing coil winding geometry and currents flowing in the windings. See Appendix K.

Exercises

17.1.1. This exercise explores some aspects of the Laplace/Poisson equation. We will consider solutions $\psi(x, y, z)$ about some point which, without loss of generality, may be taken to be the origin $\boldsymbol{r} = 0$.

Suppose that ψ is analytic in the Cartesian components of $\boldsymbol{r}$, has at the origin the value

$$\psi(0) = \psi_0, \tag{17.1.1}$$

and is harmonic is some volume V surrounding the origin,

$$\nabla^2\psi(\boldsymbol{r}) = 0. \tag{17.1.2}$$

Introduce spherical coordinates in the usual way and let $Q_{\ell,m,c}(\theta,\phi)$ and $Q_{\ell,m,s}(\theta,\phi)$ denote the functions

$$Q_{\ell,m,c}(\theta,\phi) = \Re[Y_{\ell,m}(\theta,\phi)] = O_{\ell,m}(\theta)\cos(m\phi), \tag{17.1.3}$$

$$Q_{\ell,m,s}(\theta,\phi) = \Im[Y_{\ell,m}(\theta,\phi)] = O_{\ell,m}(\theta)\sin(m\phi). \tag{17.1.4}$$

Here we impose the requirement $m \geq 0$ and make the definitions

$$Q_{\ell,0,s}(\theta,\phi) = 0, \tag{17.1.5}$$

$$O_{\ell,m}(\theta) = (-1)^m\sqrt{[(2\ell+1)(\ell-m)!]/[(4\pi)(\ell+m)!]}P_\ell^m(\cos\theta). \tag{17.1.6}$$

Expand $\psi(x,y,z)$ in a Taylor series about the origin and group terms of like degree so as to yield an expansion in homogeneous polynomials. Show that rewriting this expansion in spherical coordinates gives the result

$$\psi = \psi_0 + \sum_{\ell=1}^{\infty}\sum_{m=0}^{\ell}\sum_{\alpha=c,s} d_{\ell,m,\alpha}[r^\ell Q_{\ell,m,\alpha}(\theta,\phi)]. \tag{17.1.7}$$

Here the quantities $d_{\ell,m,\alpha}$ are arbitrary coefficients and we have enforced the conditions (1.1) and (1.2).

Next, integrate ψ over the surface of a sphere of radius R centered on the origin. Show, recalling the orthogonality properties of the $Y_{\ell,m}$, that using the expansion (1.7) yields the result

$$\int_S \psi dS = 4\pi R^2\psi_0. \tag{17.1.8}$$

Consequently, there is the relation

$$[1/(4\pi R^2]\int_S \psi dS = \psi_0. \tag{17.1.9}$$

The average of ψ over the surface of a sphere equals it value at the center of the sphere. It follows that if $\psi > \psi_0$ at some point on the surface of the sphere, then it must be the case that $\psi < \psi_0$ at some other point on the surface of the sphere, and vice versa, in order for (1.9) to hold. Finally, an analogous result must be true for any expansion point within V. Consequently, ψ has no local minima or maxima, and must take its extrema on the boundary of V.

Suppose we replace the harmonic requirement (1.2) by the condition

$$\nabla^2\psi|_{\boldsymbol{r}=0} = \rho_0. \tag{17.1.10}$$

What happens now? In this case expand $\psi(x,y,z)$ in a Taylor series about the origin through terms of degree 2 and group terms of like degree so as to again yield an expansion in homogeneous polynomials. Show that rewriting this expansion in spherical coordinates gives, through terms of degree 2, the result

$$\psi = \psi_0 + \sum_{m=0}^{1} \sum_{\alpha=c,s} d_{1,m,\alpha}[rQ_{1,m,\alpha}(\theta,\phi)] + (\rho_0/6)r^2 + \sum_{m=0}^{2} \sum_{\alpha=c,s} d_{2,m,\alpha}[r^2 Q_{2,m,\alpha}(\theta,\phi)] + \cdots . \tag{17.1.11}$$

Here the quantities $d_{\ell,m,\alpha}$ are again arbitrary coefficients and we have enforced the conditions (1.1) and (1.10).

Again integrate ψ over the surface of a sphere of radius R centered on the origin. Show that using the expansion (1.11) yields the result

$$\int_S \psi dS = 4\pi R^2 \psi_0 + 4\pi(\rho_0/6)R^4 + O(R^6). \tag{17.1.12}$$

Consequently, there is the relation

$$[1/(4\pi R^2)] \int_S \psi dS = \psi_0 + (\rho_0/6)R^2 + O(R^4). \tag{17.1.13}$$

The average of ψ over the surface of a small sphere equals it value at the center of the sphere, plus a correction of order R^2 that involves ρ_0, plus corrections of order R^4. In lowest order, the difference between the spherical average of ψ and its central value ψ_0 involves ρ_0. For this reason, the quantity ρ_0 is called the *concentration* of ψ at $\boldsymbol{r} = 0$.

17.2 Use of Potential Data on Surface of Circular Cylinder

We will begin our discussion with the use of the surface of a cylinder with circular cross section, and the use of scalar potential data on this surface. This is conceptually the simplest case, and will give us opportunity to develop various needed concepts. Moreover, some electromagnetic codes calculate directly the scalar potential on some regular three-dimensional grid, and this data can be interpolated onto the surface of a cylinder. Therefore, this method can also be of practical use.

Consider a circular cylinder of radius R, centered on the z-axis, fitting within the bore of the beam-line element in question, and extending beyond the fringe-field regions at the ends of the beam-line element. The beam-line element could be any straight element such as a solenoid, quadrupole, sextupole, octupole, etc., or it could be wiggler with no net bending. See Figure 2.1, which illustrates the case of a wiggler. Write

$$\psi(x,y,z) = \psi(\rho,\phi,z), \tag{17.2.1}$$

and suppose $\psi(R,\phi,z)$ is known. Here we have used the coordinates (15.2.12) through (15.2.16). In general, determination of $\psi(R,\phi,z)$ will require interpolation onto a circle of data on a square (or rectangular) grid in x and y for each z value on the grid. See the second frame of Figure 1.1 which depicts a square or rectangular grid in the x,y plane for a fixed z

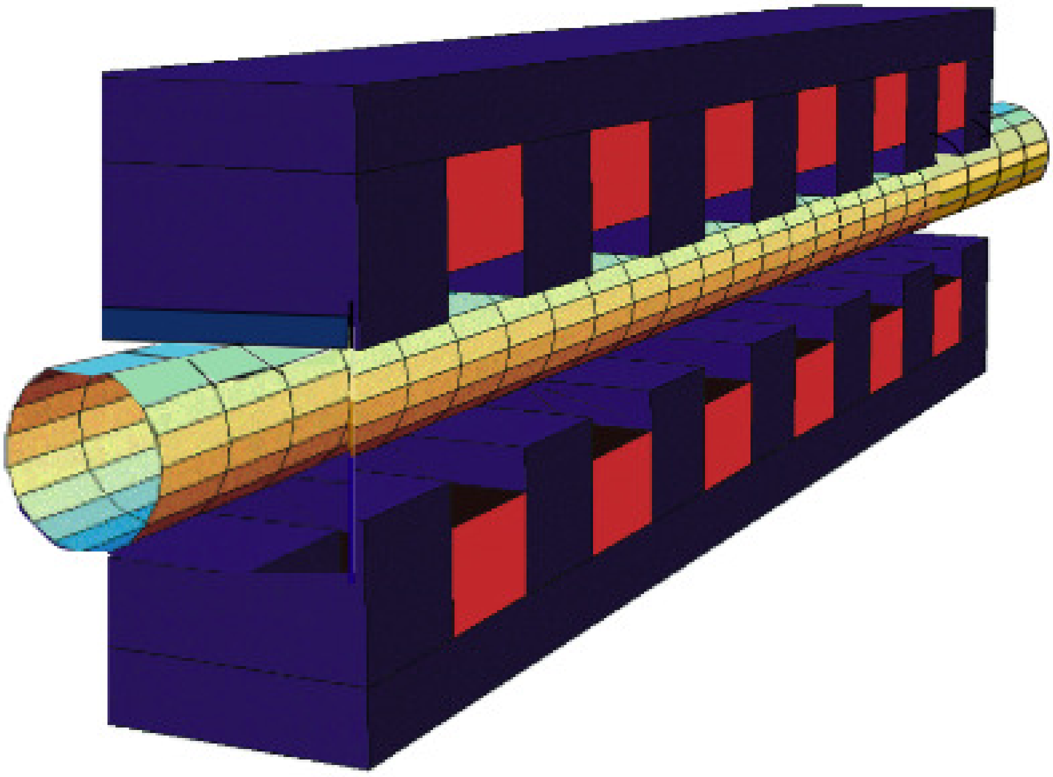


Figure 17.2.1: A circular cylinder of radius R, centered on the z-axis, fitting within the bore of a beam-line element, in this case a wiggler, and extending beyond the fringe-field regions at the ends of the beam-line element.

value on the 3-dimensional grid. Values at data points near the circle are to be interpolated onto the circle.

From this given function $\psi(R,\phi,z)$, obtained by interpolation, form/define the function $\tilde{\tilde{\psi}}(R,m',k')$ by the rule

$$\tilde{\tilde{\psi}}(R,m',k') = [1/(2\pi)]^2 \int_{-\infty}^{\infty} dz \exp(-ik'z) \int_0^{2\pi} d\phi \exp(-im'\phi)\psi(R,\phi,z). \tag{17.2.2}$$

Here we pause a moment to describe our nomenclature and notation: We will refer to the operation of Fourier transforming over the *line* $[-\infty,\infty]$ as performing a *linear* Fourier transform, and the result of this transform will be labeled by a continuous variable usually called k. We will refer to the operation of Fourier transforming over the angular domain $[0,2\pi]$ as performing an *angular* Fourier transform.[3] Moreover, the result of performing an angular Fourier transform will be called a Fourier coefficient, and these coefficients will be labeled by integers such as m and n. Finally, we have used the symbol $\tilde{}$ to denote a linear or angular Fourier transform, and the symbol $\tilde{\tilde{}}$ to denote that both have been performed.

To continue, we know from (15.3.7) that $\psi(R,\phi,z)$ has the representation

$$\psi(R,\phi,z) = \sum_{m=-\infty}^{\infty} \int_{-\infty}^{\infty} dk G_m(k) \exp(ikz) \exp(im\phi) I_m(kR). \tag{17.2.3}$$

Employing this representation in (2.2) and performing the indicated integrations give the result

$$\tilde{\tilde{\psi}}(R,m',k') = G_{m'}(k') I_{m'}(k'R), \tag{17.2.4}$$

from which we conclude that

$$G_m(k) = \tilde{\tilde{\psi}}(R,m,k)/I_m(kR). \tag{17.2.5}$$

This relation for $G_m(k)$ can now be employed in (15.3.15) to give the result

$$C_m^{[n]}(z) = i^n (1/2)^{|m|} (1/|m|!) \int_{-\infty}^{\infty} dk [k^{n+|m|}/I_m(kR)] \tilde{\tilde{\psi}}(R,m,k) \exp(ikz). \tag{17.2.6}$$

We have found an expression for the generalized on-axis gradients in terms of potential data on the surface of the cylinder. Equation (2.6) may be viewed as the convolution of Fourier surface data $\tilde{\tilde{\psi}}(R,m,k)$ with the *inverse Laplacian* kernel $[k^{n+|m|}/I_m(kR)]$. Moreover, this kernel has a very desirable property. The Bessel functions $I_m(kR)$ have the asymptotic behavior

$$|I_m(kR)| \sim \exp(|k|R)/\sqrt{2\pi|k|R} \text{ as } |k| \to \infty. \tag{17.2.7}$$

[3] Joseph Fourier (1768-1830) was a student of Lagrange. Fourier was the first to make extensive use of the trigonometric series that bear his name, and to make the claim that they could be used to represent arbitrary functions. This claim his elders and contemporaries found hard to believe. In reviewing one of his fundamental papers on the theory of heat that employed these series the referees Lagrange, Laplace, Legendre, and others complained that $\cdots$ *the manner in which the author arrives at these equations is not exempt of difficulties and that his analysis to integrate them still leaves something to be desired on the score of generality and even rigor.* As a result, the paper was not published.

Since $I_m(kR)$ appears in the denominator of (2.6), we see that the integrand is exponentially damped for large $|k|$. Now suppose there is uncorrelated point-to-point noise in the surface data. Such noise will result in anomalously large $|k|$ contributions to the $\tilde{\tilde{\psi}}(R, m, k)$. But, because of the exponential damping arising from $I_m(kR)$ in the denominator, the effect of this noise is effectively filtered out. Moreover, this filtering action is improved by making R as large as possible. This filtering, or *smoothing*, feature will be discussed in more detail in Chapter 18.

17.3 Use of Field Data on Surface of Circular Cylinder

All three-dimensional electromagnetic codes calculate all three components of the field on some three-dimensional grid. Also, such data is in principle available from actual field measurements. In this section we will describe how to compute the on-axis gradients from field data.

Again we will employ a cylinder of radius R centered on the z axis. Suppose the magnetic field $\boldsymbol{B}(x, y, z)$ is interpolated onto the surface of the cylinder using values at the grid points near the surface. Next, from the values on the surface, compute $B_\rho(x, y, z) = B_\rho(R, \phi, z)$, the component of $\boldsymbol{B}(x, y, z)$ *normal* to the surface. We will now see how to compute the generalized gradients from a knowledge of $B_\rho(x, y, z) = B_\rho(R, \phi, z)$.

From this known function form the functions $\tilde{B}_\rho(R, m', z)$ and $\tilde{\tilde{B}}_\rho(R, m', k')$ by the rules

$$\tilde{B}_\rho(R, m', z) = [1/(2\pi)] \int_0^{2\pi} d\phi \exp(-im'\phi) B_\rho(R, \phi, z), \tag{17.3.1}$$

$$\tilde{\tilde{B}}_\rho(R, m', k') = [1/(2\pi)] \int_{-\infty}^{\infty} dz \exp(-ik'z) \tilde{B}_\rho(R, m', z). \tag{17.3.2}$$

Note that we may also directly write that

$$\tilde{\tilde{B}}_\rho(R, m', k') = [1/(2\pi)]^2 \int_{-\infty}^{\infty} dz \exp(-ik'z) \int_0^{2\pi} d\phi \exp(-im'\phi) B_\rho(R, \phi, z), \tag{17.3.3}$$

and the indicated integrations may be performed in either order. We also know that

$$B_\rho(R, \phi, z) = [\partial_\rho \psi(\rho, \phi, z)]|_{\rho=R}, \tag{17.3.4}$$

from which it follows, using the representation (15.3.7), that

$$B_\rho(R, \phi, z) = \sum_{m=-\infty}^{\infty} \int_{-\infty}^{\infty} dk G_m(k) \exp(ikz) \exp(im\phi) k I'_m(kR). \tag{17.3.5}$$

Now substitute (3.5) into the right side of (3.3) and perform the indicated integrations to get the result

$$\tilde{\tilde{B}}_\rho(R, m', k') = G_{m'}(k') k' I'_{m'}(k'R), \tag{17.3.6}$$

from which it follows that

$$G_m(k) = \tilde{\tilde{B}}_\rho(R, m, k)/[kI'_m(kR)]. \tag{17.3.7}$$

This relation for $G_m(k)$ can be employed in (15.3.15) to give the result

$$C_m^{[n]}(z) = i^n(1/2)^{|m|}(1/|m|!)\int_{-\infty}^{\infty} dk[k^{n+|m|-1}/I'_m(kR)]\tilde{\tilde{B}}_\rho(R, m, k)\exp(ikz). \tag{17.3.8}$$

We have found an expression for the generalized on-axis gradients in terms of field data (normal component) on the surface of the cylinder. Moreover, this expression again has the smoothing property since the denominator functions $I'_m(kR)$ also have the asymptotic behavior (2.7) and therefore also provide exponential damping,

$$|I'_m(kR)| \sim \exp(|k|R)/\sqrt{2\pi|k|R} \text{ as } |k| \to \infty. \tag{17.3.9}$$

For future use it is also convenient to have explicit formulas for the $C_{m,\alpha}^{[n]}(z)$. Motivated by (15.3.28) and (15.3.31), define quantities $\tilde{\tilde{B}}_\rho^\alpha(R, m', k')$ and $\tilde{B}_\rho^\alpha(R, m', z)$ with $m' \geq 1$ by the rules

$$\tilde{\tilde{B}}_\rho^s(R, m', k') = i[\tilde{\tilde{B}}_\rho(R, m', k') - \tilde{\tilde{B}}_\rho(R, -m', k')], \tag{17.3.10}$$

$$\tilde{\tilde{B}}_\rho^c(R, m', k') = [\tilde{\tilde{B}}_\rho(R, m', k') + \tilde{\tilde{B}}_\rho(R, -m', k')], \tag{17.3.11}$$

$$\tilde{B}_\rho^s(R, m', z) = i[\tilde{B}_\rho(R, m', z) - \tilde{B}_\rho(R, -m', z)], \tag{17.3.12}$$

$$\tilde{B}_\rho^c(R, m', z) = [\tilde{B}_\rho(R, m', z) + \tilde{B}_\rho(R, -m', z)]. \tag{17.3.13}$$

Then we have the results

$$\tilde{\tilde{B}}_\rho^\alpha(R, m', k') = [1/(2\pi)]\int_{-\infty}^{\infty} dz\exp(-ik'z)\tilde{B}_\rho^\alpha(R, m', z) \tag{17.3.14}$$

with

$$\tilde{B}_\rho^s(R, m', z) = (1/\pi)\int_0^{2\pi} d\phi\sin(m'\phi)B_\rho(R, \phi, z), \tag{17.3.15}$$

$$\tilde{B}_\rho^c(R, m', z) = (1/\pi)\int_0^{2\pi} d\phi\cos(m'\phi)B_\rho(R, \phi, z). \tag{17.3.16}$$

And, in accord with (15.3.35) and (15.3.36), for $m' = 0$ make the definitions

$$\tilde{\tilde{B}}_\rho^s(R, m' = 0, k') = 0, \tag{17.3.17}$$

$$\tilde{\tilde{B}}_\rho^c(R, m' = 0, k') = \tilde{\tilde{B}}_\rho(R, m' = 0, k'), \tag{17.3.18}$$

$$\tilde{B}_\rho^s(R, m' = 0, z) = 0, \tag{17.3.19}$$

$$\tilde{B}_\rho^c(R, m' = 0, z) = \tilde{B}_\rho(R, m' = 0, z). \tag{17.3.20}$$

Then we have the further results

$$\tilde{\tilde{B}}_\rho^c(R, m' = 0, k') = [1/(2\pi)]\int_{-\infty}^{\infty} dz\exp(-ik'z)\tilde{B}_\rho^c(R, m' = 0, z), \tag{17.3.21}$$

$$\tilde{B}^c_\rho(R, m' = 0, z) = \tilde{B}_\rho(R, m' = 0, z) = [1/(2\pi)] \int_0^{2\pi} d\phi B_\rho(R, \phi, z). \tag{17.3.22}$$

Note that the quantities $\tilde{B}^\alpha_\rho(R, m', z)$ are real. Correspondingly, we see form (3.14) that the real part of $\tilde{\tilde{B}}^\alpha_\rho(R, m', k')$ is even in k and the imaginary part is odd in k.

With these definitions in hand, we are ready to state the final results:

$$C^{[n]}_{m,\alpha}(z) = i^n(1/2)^m(1/m!) \int_{-\infty}^{\infty} dk[k^{n+m-1}/I'_m(kR)]\tilde{\tilde{B}}^\alpha_\rho(R, m, k)\exp(ikz) \tag{17.3.23}$$

for $m > 0$, and

$$C^{[n]}_{m=0,s}(z) = 0, \tag{17.3.24}$$

$$C^{[n]}_{m=0,c}(z) = C^{[n]}_0(z) = i^n \int_{-\infty}^{\infty} dk[k^{n-1}/I'_0(kR)]\tilde{\tilde{B}}^c_\rho(R, m = 0, k)\exp(ikz). \tag{17.3.25}$$

We close this section with the remark that if one wishes to extract the $C^{[n]}_0(z)$ (monopole) on-axis gradients from field data, it may be preferable to use the longitudinal component $B_z(R, \phi, z)$ on the surface of the cylinder rather than the normal component $B_\rho(R, \phi, z)$.[4] See Section 19.2.

17.4 Use of Field Data on Surface of Elliptical Cylinder

17.4.1 Background

In the previous two sections we employed a cylinder with circular cross section, and observed mathematically that it is desirable for error insensitivity to use a cylinder with a large radius R. Physically, this is because we want the data points to be as far from the axis as possible since the effect of inhomogeneities (noise) in the data decays with distance from the inhomogeneity. Evidently the use of a large circular cylinder is optimal for beam-line elements with a circular bore. However, for dipoles or wigglers with small gaps and wide pole faces, use of a cylinder with elliptical cross section should give improved error insensitivity. See Figure 4.1. In this section we will set up the machinery required for the use of elliptical cylinders, and apply it to the calculation of on-axis gradients based on field data.

We will see that the use of elliptic cylinders requires a knowledge of Mathieu functions. Since these functions may well be relatively unfamiliar to the reader, considerable effort will be devoted to describing their properties.

For brevity, we will omit treatment of the related case where potential data is used on the surface of the elliptic cylinder. The reader should be able to solve this simpler problem based on the work of the current section and what was done in Section 14.2.

[4] Note that in any case we only need the $C^{[n]}_0(z)$ with $n \geq 1$ because they are what is required to compute the vector potential. See (15.5.32) through (15.5.34). Thus, (3.6) is well defined for all values of m and n of physical interest.

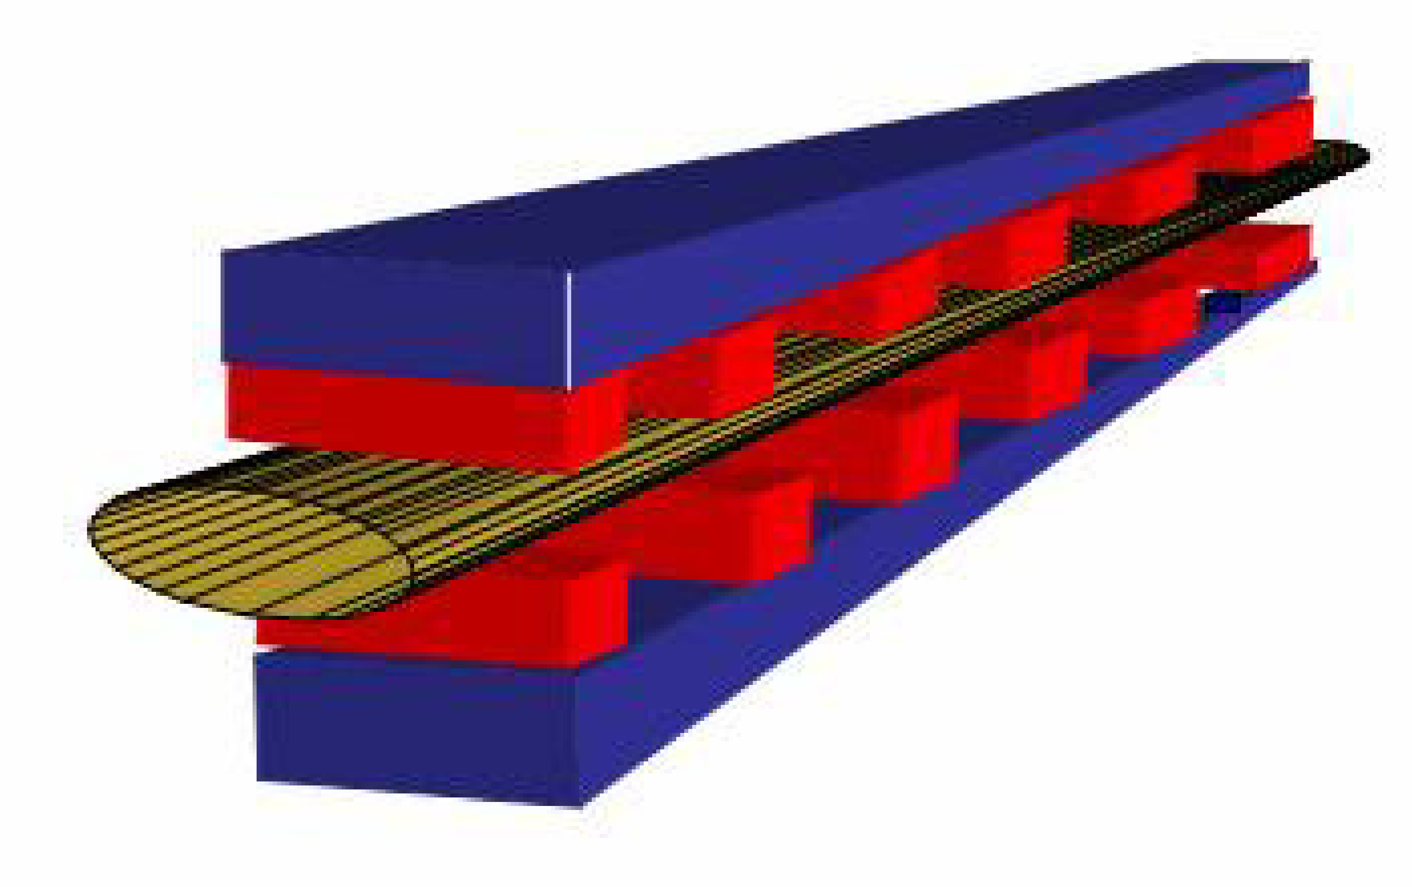

Figure 17.4.1: An elliptical cylinder, centered on the z-axis, fitting within the bore of a wiggler, and extending beyond the fringe-field regions at the ends of the wiggler.

17.4.2 Elliptic Coordinates

Elliptic coordinates in the x, y plane are described by the relations

$$x = f\cosh(u)\cos(v), \tag{17.4.1}$$

$$y = f\sinh(u)\sin(v). \tag{17.4.2}$$

Contours of constant u, with $u \in [0, \infty]$, are nested ellipses with common foci located at $(x; y) = (\pm f; 0)$. Contours of constant v, with $v \in [0, 2\pi]$, are hyperbolae. Together these contours form an orthogonal coordinate system. See Figure 4.2. Data is to be interpolated onto the ellipse whose cross section is that of the elliptical cylinder of Figure 4.1. See Figure 4.3.

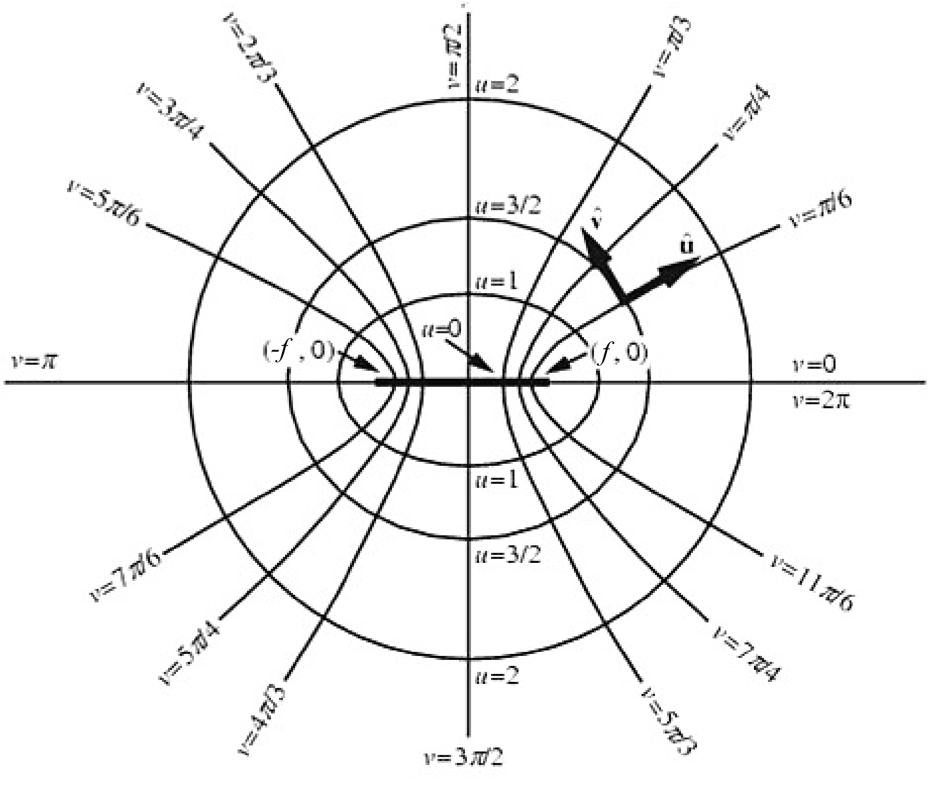

Figure 17.4.2: Elliptical coordinates showing contours of constant u and constant v.

For our work we will need the unit vector $\hat{\boldsymbol{e}}_u$, the unit vector (outwardly) normal to the surface of the elliptical cylinder. Write

$$\begin{aligned}\boldsymbol{r} &= x\hat{\boldsymbol{e}}_x + y\hat{\boldsymbol{e}}_y + z\hat{\boldsymbol{e}}_z \\ &= f\cosh(u)\cos(v)\hat{\boldsymbol{e}}_x + f\sinh(u)\sin(v)\hat{\boldsymbol{e}}_y + z\hat{\boldsymbol{e}}_z.\end{aligned} \tag{17.4.3}$$

Then, by definition, we have the result

$$\begin{aligned}\hat{\boldsymbol{e}}_u &= (\partial\boldsymbol{r}/\partial u)/||(\partial\boldsymbol{r}/\partial u)|| \\ &= [\sinh(u)\cos(v)\hat{\boldsymbol{e}}_x + \cosh(u)\sin(v)\hat{\boldsymbol{e}}_y]/[\cosh^2(u) - \cos^2(v)]^{1/2}.\end{aligned} \tag{17.4.4}$$

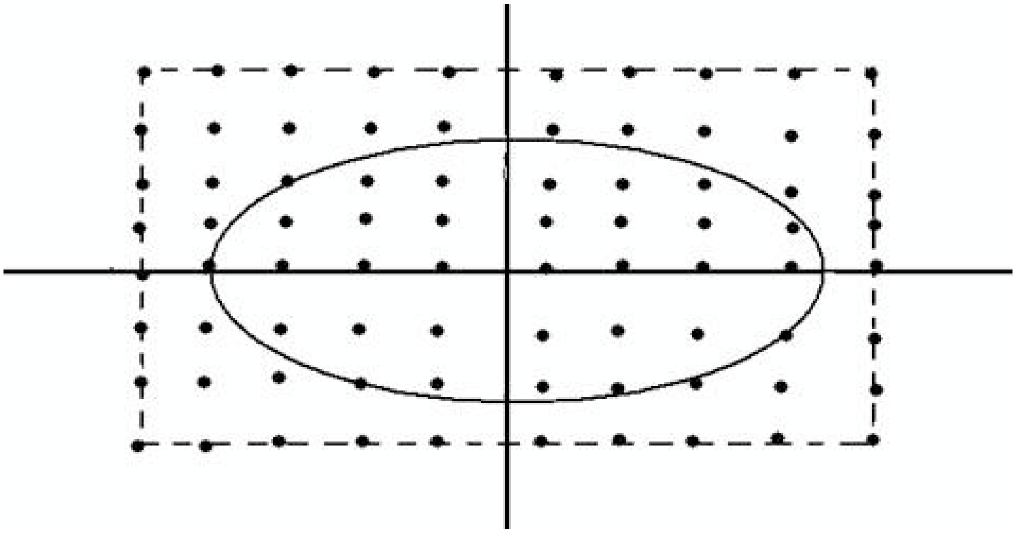

Figure 17.4.3: A square or rectangular grid in the x,y plane for a fixed z value on the 3-dimensional grid. Values at data points near the ellipse are to be interpolated onto the ellipse.

It is also convenient to employ the complex variables

$$\zeta = x + iy, \tag{17.4.5}$$

and

$$w = u + iv. \tag{17.4.6}$$

In these variables, the relations (4.1) and (4.2) can be written in the more compact form

$$\zeta = f\cosh(w). \tag{17.4.7}$$

[For a discussion of the analytic properties of $\zeta(w)$ and its inverse $w(\zeta)$, see Exercise 4.2.] Form differentials of both sides of (4.7). Doing so gives the result

$$dx + idy = f\sinh(w)(du + idv) \tag{17.4.8}$$

and the complex conjugate result

$$dx - idy = f\sinh(\bar{w})(du - idv). \tag{17.4.9}$$

Now form the product of (4.8) and (4.9) to get the transverse line-element relation

$$\begin{aligned} ds_\perp^2 &= dx^2 + dy^2 = f^2\sinh(u+iv)\sinh(u-iv)(du^2+dv^2) \\ &= f^2[\cosh^2(u) - \cos^2(v)](du^2+dv^2). \end{aligned} \tag{17.4.10}$$

From this relation we infer the results

$$B_u = \hat{\boldsymbol{e}}_u \cdot \boldsymbol{B} = (\nabla\psi)_u = (1/f)[\cosh^2(u) - \cos^2(v)]^{-1/2}(\partial\psi/\partial u), \tag{17.4.11}$$

$$\nabla^2\psi = (1/f^2)[\cosh^2(u) - \cos^2(v)]^{-1}[(\partial_u)^2 + (\partial_v)^2]\psi + (\partial_z)^2\psi. \tag{17.4.12}$$

17.4.3 Mathieu Equations

Let us seek to construct harmonic functions of the form

$$\psi \sim P(u)Q(v)\exp(ikz) \tag{17.4.13}$$

where the functions P and Q are yet to be determined. Employing the Ansatz (4.13) in Laplace's equation and use of (4.12) yields the requirement

$$[(\partial_u)^2 + (\partial_v)^2][P(u)Q(v)] = k^2 f^2[\cosh^2(u) - \cos^2(v)]P(u)Q(v). \tag{17.4.14}$$

We also observe that there is the trigonometric identity

$$\cosh^2(u) - \cos^2(v) = (1/2)[\cosh(2u) - \cos(2v)] \tag{17.4.15}$$

so that the requirement (4.14) can be rewritten in the form

$$[(\partial_u)^2 + (\partial_v)^2][P(u)Q(v)] = (k^2 f^2/4)[2\cosh(2u) - 2\cos(2v)]P(u)Q(v). \tag{17.4.16}$$

Upon dividing both sides by PQ, (4.16) becomes

$$(1/P)(\partial_u)^2 P + (1/Q)(\partial_v)^2 Q = (k^2 f^2/4)[2\cosh(2u) - 2\cos(2v)], \tag{17.4.17}$$

from which it follows that

$$(1/P)(\partial_u)^2 P - (k^2 f^2/4)[2\cosh(2u)] = -(1/Q)(\partial_v)^2 Q - (k^2 f^2/4)[2\cos(2v)]. \tag{17.4.18}$$

Therefore, there is a common *separation* constant a such that

$$(1/P)(\partial_u)^2 P - (k^2 f^2/4)[2\cosh(2u)] = a \tag{17.4.19}$$

and

$$-(1/Q)(\partial_v)^2 Q - (k^2 f^2/4)[2\cos(2v)] = a. \tag{17.4.20}$$

Correspondingly, P and Q must satisfy the ordinary and linear differential equations

$$d^2P/du^2 - [a - 2q\cosh(2u)]P = 0, \tag{17.4.21}$$

$$d^2Q/dv^2 + [a - 2q\cos(2v)]Q = 0, \tag{17.4.22}$$

where

$$q = -k^2 f^2/4. \tag{17.4.23}$$

Equation (4.22) for Q is called the *Mathieu* equation, and Equation (4.21) for P is called the *modified Mathieu* equation.[5]

[5] We remark that many, and probably the majority, of the special functions ordinarily encountered in Mathematical Physics are particular cases of the hypergeometric function. The Mathieu functions do not fall in this category. In some sense, they are *more transcendental* than the hypergeometric function.

17.4.4 Periodic Mathieu Functions and Separation Constants

For our purposes, we will need solutions $Q(v)$ of (4.22) that are *periodic* with period 2π. See Figure 4.2. Such solutions exist only for certain specific values of the separation constant a. These values are called $a_n(q)$ for $n = 0, 1, 2, 3, \cdots$ and $b_n(q)$ for $n = 1, 2, 3, \cdots$.[6] The functions $a_n(q)$ and $b_n(q)$ are all *real* for real values of q. As the notation indicates, their values depend on q (and on n). For small q they have expansions of the form

$$a_0(q) = -(1/2)q^2 + (7/128)q^4 + \cdots\,, \tag{17.4.24}$$

$$a_1(q) = 1 + q - (1/8)q^2 - (1/64)q^3 - (1/1536)q^4 + \cdots\,, \tag{17.4.25}$$

$$a_2(q) = 4 + (5/12)q^2 - (763/13824)q^4 + \cdots\,, \text{ etc.;} \tag{17.4.26}$$

$$b_1(q) = 1 - q - (1/8)q^2 + (1/64)q^3 - (1/1536)q^4 + \cdots\,, \tag{17.4.27}$$

$$b_2(q) = 4 - (1/12)q^2 + (5/13824)q^4 + \cdots\,, \text{ etc.} \tag{17.4.28}$$

In each case the leading (the q independent) term is n^2.

Note that, according to (4.23), for our purposes we are interested in negative, and possibly quite negative, values of q.[7] Figures 4.4 and 4.5 display the first few $a_n(q)$ and $b_n(q)$ for negative values of q. Observe that, as $q \to -\infty$, the quantities $a_{2m}(q)$ and $a_{2m+1}(q)$, for $m = 0, 1, 2, 3, \cdots$, tend to agree. Similarly, for large negative q, the quantities $b_{2m+1}(q)$ and $b_{2m+2}(q)$, for $m = 0, 1, 2, 3, \cdots$, tend to agree. Indeed, it can be shown that there is the asymptotic behavior

$$\begin{aligned}
&a_{2m}(q) \sim a_{2m+1}(q)\\
&\sim 2q + (8m+2)(-q)^{1/2} - (1/4)(8m^2 + 4m + 1)\\
&-(1/32)(4m^2 + 2m + 1)(4m + 1)(-q)^{-1/2} + O(1/q)\\
&\text{ as } q \to -\infty \text{ for } m = 0, 1, 2, 3, \cdots\,,
\end{aligned} \tag{17.4.29}$$

$$\begin{aligned}
&b_{2m+1}(q) \sim b_{2m+2}(q)\\
&\sim 2q + (8m+6)(-q)^{1/2} - (1/4)(8m^2 + 12m + 5)\\
&-(1/32)(4m^2 + 6m + 3)(4m + 3)(-q)^{-1/2} + O(1/q)\\
&\text{ as } q \to -\infty \text{ for } m = 0, 1, 2, 3, \cdots\,.
\end{aligned} \tag{17.4.30}$$

We also remark, in passing, that there are the relations

$$a_n(-q) = a_n(q) \text{ for } n \text{ even,} \tag{17.4.31}$$

$$b_n(-q) = b_n(q) \text{ for } n \text{ even,} \tag{17.4.32}$$

$$a_n(-q) = b_n(q) \text{ for } n \text{ odd,} \tag{17.4.33}$$

$$b_n(-q) = a_n(q) \text{ for } n \text{ odd.} \tag{17.4.34}$$

[6] The reader might find confusing the use of the symbols a, a_n, and b_n to denote separation constants. We agree, but it is standard in the Mathieu-equation literature.

[7] Unfortunately for our purposes, the Mathieu function literature treats primarily the $q > 0$ case because this is the case that arises in the solution of the wave equation. See Exercise 4.1.

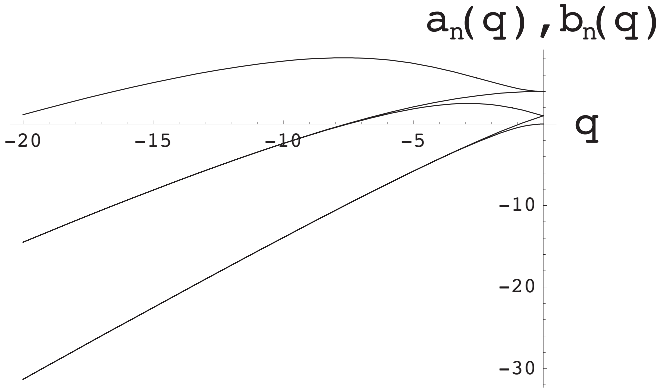

Figure 17.4.4: The functions $a_0(q)$ through $a_2(q)$ and $b_1(q)$ and $b_2(q)$ for negative values of q.

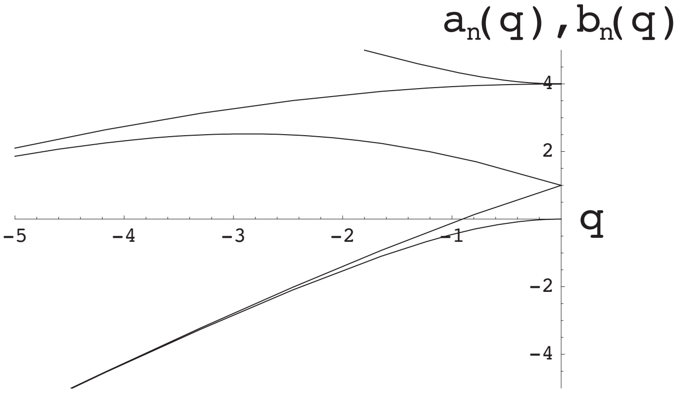

Figure 17.4.5: An enlargement of a portion of Figure 4.4. For q fixed and slightly negative, the curves, in order of increasing value, are $a_0(q)$, $a_1(q)$, $b_1(q)$, $b_2(q)$, and $a_2(q)$. See (4.24) through (4.28). Note that the pair $a_0(q)$ and $a_1(q)$ tends to merge for large negative q, as does the pair $b_1(q)$ and $b_2(q)$. Similarly, although not shown in this figure, the pair $a_2(q)$ and $a_3(q)$ tends to merge as does the pair $b_3(q)$ and $b_4(q)$, etc. See (4.29) and (4.30).

The solutions associated with the separation constants $a = a_n(q)$ are called $\mathrm{ce}_0(v,q)$, $\mathrm{ce}_1(v,q)$, $\mathrm{ce}_2(v,q)$, $\mathrm{ce}_3(v,q)$ $\cdots$. They are *even* functions of v and, in the small q limit, are proportional to the functions 1, $\cos(v)$, $\cos(2v)$, $\cos(3v)$, $\cdots$. The solutions associated with the separation constants $a = b_n(q)$ are called $\mathrm{se}_1(v,q)$, $\mathrm{se}_2(v,q)$, $\mathrm{se}_3(v,q)$, $\cdots$. They are *odd* functions of v and, in the small q limit, are proportional to the functions $\sin(v)$, $\sin(2v)$, $\sin(3v)$, $\cdots$.[8] Indeed, the $\mathrm{ce}_n(v,q)$ and $\mathrm{se}_n(v,q)$ are normalized so that in the limit $q \to 0$ there are the relations

$$\mathrm{ce}_0(v,0) = 1/\sqrt{2}, \tag{17.4.35}$$

$$\mathrm{ce}_n(v,0) = \cos(nv) \text{ for } n \geq 1, \tag{17.4.36}$$

$$\mathrm{se}_n(v,0) = \sin(nv) \text{ for } n \geq 1. \tag{17.4.37}$$

Moreover, like their trigonometric counterparts, the functions $\mathrm{ce}_n(v,q)$ and $\mathrm{se}_n(v,q)$ form a complete set over the interval $[0, 2\pi]$. In fact, they form a complete orthogonal set and are normalized so that

$$\int_0^{2\pi} dv\ \mathrm{ce}_m(v,q)\ \mathrm{ce}_n(v,q) = \pi\delta_{mn}, \tag{17.4.38}$$

$$\int_0^{2\pi} dv\ \mathrm{se}_m(v,q)\ \mathrm{se}_n(v,q) = \pi\delta_{mn}, \tag{17.4.39}$$

$$\int_0^{2\pi} dv\ \mathrm{ce}_m(v,q)\ \mathrm{se}_n(v,q) = 0. \tag{17.4.40}$$

Apart from $\mathrm{ce}_0(v,q)$, this normalization is like that of their trigonometric counterparts. See (4.35) through (4.37). Finally, again like their trigonometric counterparts, it can be shown that the functions $\mathrm{ce}_n(v,q)$ and $\mathrm{se}_n(v,q)$ have n zeroes in the half-open interval $v \in [0, \pi)$.

As noted earlier, we are primarily interested in the case $q \leq 0$. However we note for the record that, in concert with the relations (4.31) through (4.34), there are the relations

$$ce_{2n}(v,-q) = (-1)^n ce_{2n}(\pi/2 - v, q), \tag{17.4.41}$$

$$ce_{2n+1}(v,-q) = (-1)^n se_{2n+1}(\pi/2 - v, q), \tag{17.4.42}$$

$$se_{2n+1}(v,-q) = (-1)^n ce_{2n+1}(\pi/2 - v, q), \tag{17.4.43}$$

$$se_{2n+2}(v,-q) = (-1)^n se_{2n+2}(\pi/2 - v, q). \tag{17.4.44}$$

We will shortly present figures that display the first few $\mathrm{ce}_n(v,q)$ and $\mathrm{se}_n(v,q)$ as functions of v. Before doing so it is useful to look more closely at the terms appearing in the Mathieu equations. Inspired by both the analogy to Schrödinger's equation and the harmonic oscillator, rewrite (4.22) in the form

$$d^2Q/dv^2 - \lambda(v,q)Q = 0 \tag{17.4.45}$$

where

$$\lambda(v,q) = -[a - 2q\cos(2v)]. \tag{17.4.46}$$

[8] Note that, unlike their trigonometric counterparts $\cos(nv)$ and $\sin(nv)$, the functions $\mathrm{ce}_n(v,q)$ and $\mathrm{se}_n(v,q)$ do not satisfy the *same* differential equation. This is because $a_n(q) \neq b_n(q)$.

From a Schrödinger perspective, we may view $Q(v)$ as the wave function and $\lambda(v, q)$ as the 'potential'. In the harmonic oscillator analogy, we may view Q as the oscillator coordinate and $-\lambda(v, q)$ as the instantaneous square of the time (v) dependent frequency. With this background in mind, Figure 4.6 shows $\lambda(v, q = -2)$ for various n values with $a = a_n(q)$. These are the potentials appropriate to the $\text{ce}_n(v, q)$. Similarly, Figure 4.7 shows $\lambda(v, q = -2)$ for various n values with $a = b_n(q)$. These are the potentials appropriate to the $\text{se}_n(v, q)$. According to (4.45), understood in the harmonic oscillator analogy, when $\lambda < 0$ we expect oscillatory behavior; and when $\lambda > 0$ we expect exponentially growing or decaying behavior. From the Schrödinger perspective, the region where $\lambda < 0$ is an allowed region, and the region where $\lambda > 0$ is a forbidden or tunneling region. Inspection of Figures 4.6 and 4.7 shows that (when $q = -2$) part of the v axis is forbidden for small n values, but that all of it is allowed once n becomes sufficiently large.

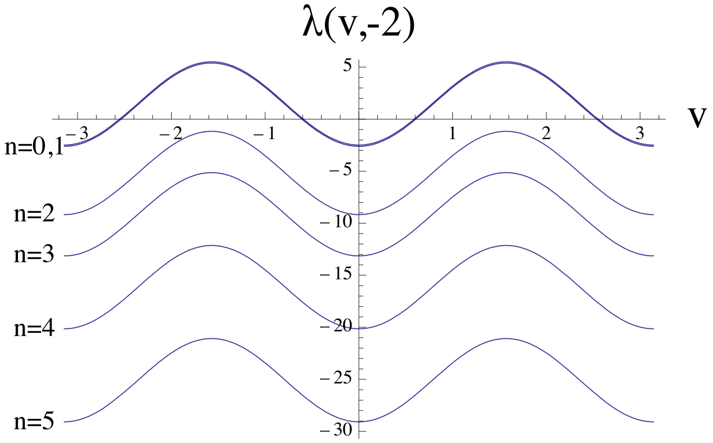

Figure 17.4.6: The effective potentials $\lambda(v, q)$ for the $\text{ce}_n(v, q)$ in the case $q = -2$. They are displayed as a function of v, over the interval $[-\pi, \pi]$, for various n values with $a = a_n(q)$. The top two curves, which very nearly coincide so as to almost look identical on the scale of the figure, are for the cases $n = 0$ and $n = 1$. According to Figure 4.5, the curve for $n = 0$ lies just slightly above that for $n = 1$. The bottom curve is that for $n = 5$. The curves in between are for $n = 2, 3, 4$ in that order.

Figures 4.8 through 4.10 display the first few $\text{ce}_n(v, q)$ as a function of v for $q = -2$. Figures 4.11 and 4.12 do the same for $\text{se}_1(v, q)$ and $\text{se}_2(v, q)$. It can be shown, as a consequence of Poincaré's theorem (see Section 1.3), that the $\text{ce}_n(v, q)$ and $\text{se}_n(v, q)$ are *entire* functions (analytic everywhere in the complex plane except at infinity) of v. Also, since the differential equation (4.22) has real coefficients for q real, the solutions $\text{ce}_n(v, q)$ and $\text{se}_n(v, q)$ are taken to be real for real q and real v.[9]

Observe from Figure 4.10 that $\text{ce}_2(v, q)$ is freely oscillating. This is to be expected from Figure 4.6 because we see that for $n \geq 2$ all of the v axis allowed. By contrast, Figure

[9] Since (4.22) is a second-order differential equation, there will also be second solutions that are linearly independent of the $\text{ce}_n(v, q)$ when $a = a_n(q)$, and second solutions that are linearly independent of the $\text{se}_n(v, q)$ when $a = b_n(q)$. Since the differential equation is invariant under parity (it is even in v), these solutions could, for example, be taken to have the opposite parity of the $\text{ce}_n(v, q)$ and the $\text{se}_n(v, q)$. They will not have period 2π.

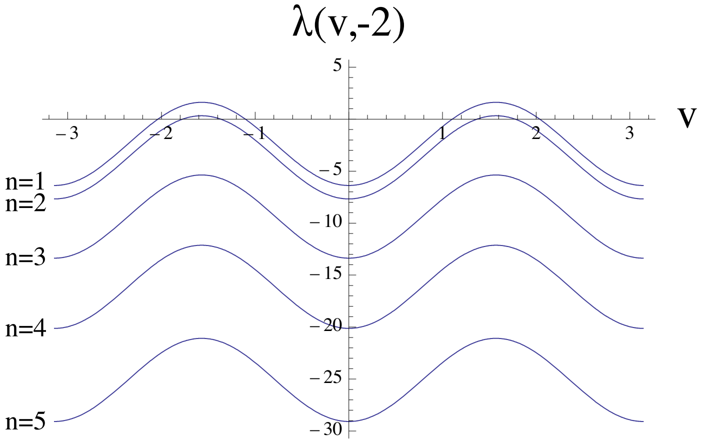

Figure 17.4.7: The effective potentials $\lambda(v,q)$ for the $\mathrm{se}_n(v,q)$ in the case $q=-2$. They are displayed as a function of v, over the interval $[-\pi,\pi]$, for various n values with $a=b_n(q)$. The top curve is that for $n=1$, and the bottom that for $n=5$. The curves in between are for $n=2,3,4$ in that order.

4.8 shows that $\mathrm{ce}_0(v,q)$ does not change sign. This is because (as v increases) this solution enters a forbidden region for $v \approx .6$ and at this point the function begins to decay. Again see Figure 4.6. Moreover, in the forbidden region, there is also a small exponentially growing part, with *positive* coefficient, that eventually dominates the solution by the time $v=\pi/2$ so that the solution begins to grow beyond this point. Finally, for $v >\approx 2.5$ the solution again enters an allowed region and begins to oscillate so that it has zero slope by the time $v=\pi$.

The case of $\mathrm{ce}_1(v,q)$ is more delicate. As has already been noted in the caption to Figure 4.6, when $q=-2$ the potentials λ for $a=a_0$ and for $a=a_1$ are almost the same. Yet, inspection of Figures 4.8 and 4.9 shows that $\mathrm{ce}_0(v,q)$ and $\mathrm{ce}_1(v,q)$ are very different! Because $\lambda|_{a_1} < \lambda|_{a_0}$, the forbidden region for $\mathrm{ce}_1(v,q)$ is somewhat smaller than for $\mathrm{ce}_0(v,q)$. Therefore $\mathrm{ce}_1(v,q)$ 'oscillates' a bit more before entering the forbidden region, and does so in such a way that the exponentially growing part in the forbidden region now has a negative sign. This exponentially growing part, although initially small in magnitude, eventually dominates at $v=\pi/2$ so that $\mathrm{ce}_1(v,q)$ crosses through zero and continues on to become negative. Eventually v again reaches an allowed region and $\mathrm{ce}_1(v,q)$ begins to oscillate so that it has zero slope by the time $v=\pi$.

What about the behavior of the $\mathrm{se}_n(v,q)$? Figure 4.7 shows their effective potentials for the case $q=-2$. Evidently these potentials are all completely negative when $n \geq 3$ and therefore the $\mathrm{se}_n(v,q)$ will be freely oscillatory when $n \geq 3$. Moreover, for $n=1$ the forbidden region is small, and for $n=2$ it is smaller yet. Therefore we expect the effects of the forbidden regions will be small. For example, the dips in $\mathrm{se}_1(v,q)$ at $v=\pm\pi/2$, see Figure 4.11, arise from the solution momentarily tunneling in forbidden regions. And examination of Figure 4.12 shows that, for $\mathrm{se}_2(v,q)$, passage through the forbidden regions has little noticeable effect.

It is also instructive to examine the behavior of the $\mathrm{ce}_n(v,q)$ and $\mathrm{se}_n(v,q)$ when q has a much more negative value. Figures 4.13 and 4.14 show their effective potentials for the case

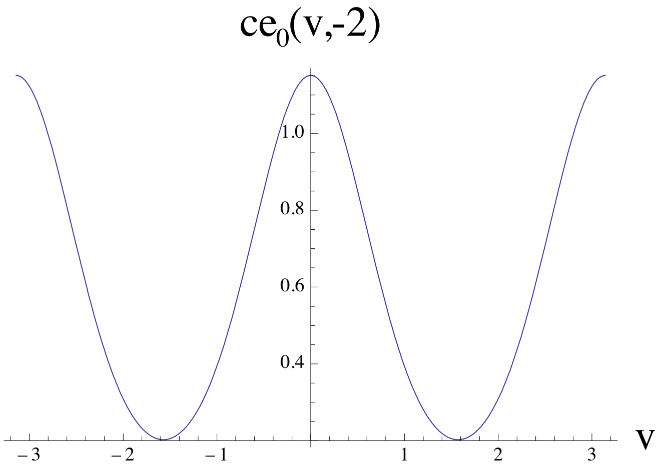

Figure 17.4.8: The function $\mathrm{ce}_0(v,q)$ as a function of v, over the interval $[-\pi,\pi]$, for $q=-2$. High magnification of this figure would reveal that the graph of $\mathrm{ce}_0(v,q)$ never touches or crosses, but always lies above, the v axis so that $\mathrm{ce}_0(v,q)$ has no zeroes.

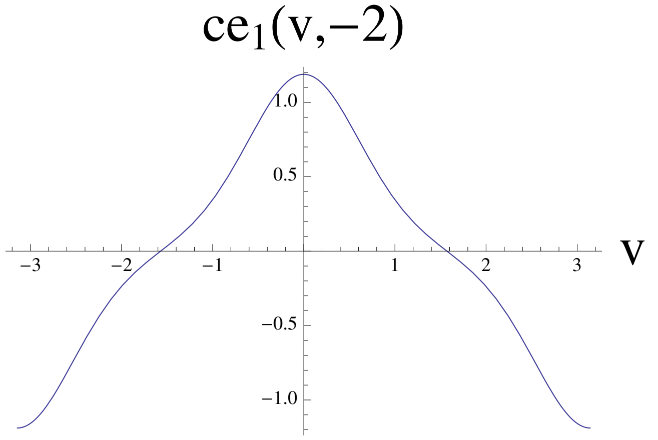

Figure 17.4.9: The function $\mathrm{ce}_1(v,q)$ as a function of v, over the interval $[-\pi,\pi]$, for $q=-2$.

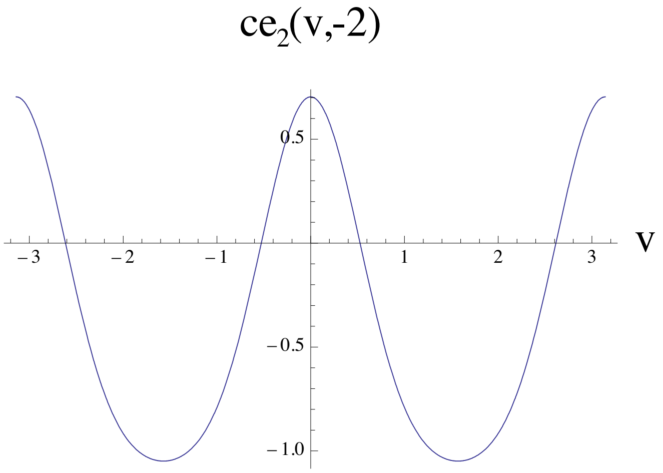

Figure 17.4.10: The function $\mathrm{ce}_2(v,q)$ as a function of v, over the interval $[-\pi,\pi]$, for $q=-2$.

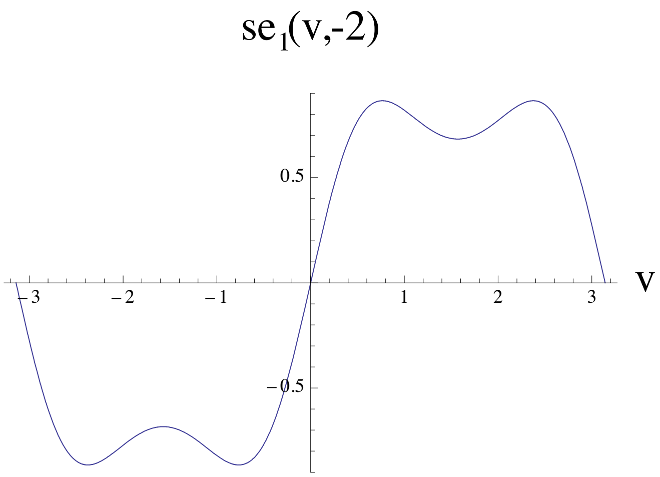

Figure 17.4.11: The function $\mathrm{se}_1(v,q)$ as a function of v, over the interval $[-\pi,\pi]$, for $q=-2$. The small dips at $v=\pm\pi/2$ arise from passage through forbidden regions.

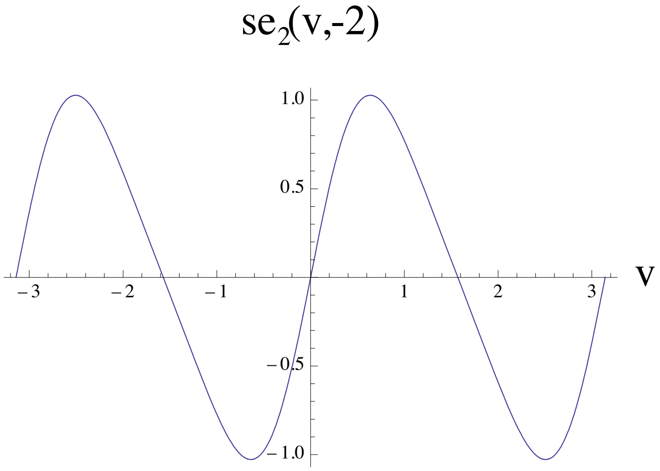

Figure 17.4.12: The function $\mathrm{se}_2(v,q)$ as a function of v, over the interval $[-\pi,\pi]$, for $q=-2$.

$q = -300$. Now we see that, for modest values of n, the potentials are *positive* for most values of v save for small intervals where they are negative. Therefore large portions of the v axis are forbidden regions. Consequently, for modest n values, the functions $\mathrm{ce}_n(v,q)$ and $\mathrm{se}_n(v,q)$ contain exponentially decaying terms for most values of v, and are oscillatory only over small intervals. On the other hand, as n is increased, the forbidden regions become smaller and the allowed regions become larger until for sufficiently large n the entire v axis becomes an allowed region. Therefore, for sufficiently large n, the functions $\mathrm{ce}_n(v,q)$ and $\mathrm{se}_n(v,q)$ are fully oscillatory.

As an illustration of this expected behavior, Figures 4.15 through 4.17 display the $\mathrm{ce}_n(v,q)$ for $q = -300$ and $n = 0, 1, 2$. We see that these functions begin bravely in the small allowed region about $v = 0$, rapidly decay to very nearly zero values in the forbidden regions centered about $v = \pm\pi/2$, and then rapidly revive in the allowed region centered about the (equivalent, due to periodicity) points $v = \pm\pi$. Compare these figures with their $q = -2$ counterparts, Figures 4.8 through 4.10. By contrast, Figure 4.18 shows $\mathrm{ce}_{22}(v,q)$ for $q = -300$. It can be shown that in this case the effective potential $\lambda(v, q = -300)$ is negative for all v. Therefore, in accord with Figure 4.18, $\mathrm{ce}_{22}(v,q)$ is fully oscillatory.

Similarly, Figures 4.19 and 4.20 display the $\mathrm{se}_n(v,q)$ for $q = -300$ and $n = 1, 2$. Again we see these functions are very nearly zero in the forbidden regions. For example, the dips in Figure 4.11 have become, in Figure 4.19, *canyons* with very steep walls and very flat floors. By contrast, Figure 4.21 shows $\mathrm{se}_{23}(v,q)$ for $q = -300$. It can be shown that in this case the effective potential $\lambda(v, q = -300)$ is negative for all v. Therefore, in accord with Figure 4.21, $\mathrm{se}_{23}(v,q)$ is fully oscillatory.

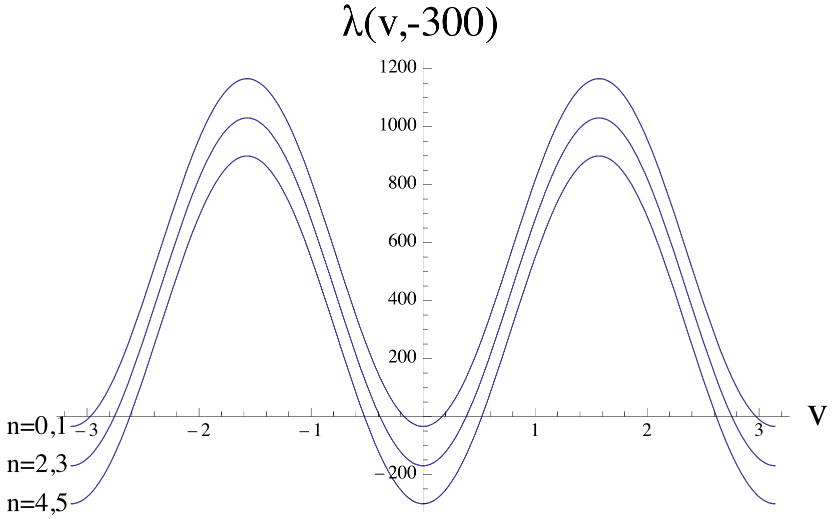

Figure 17.4.13: The effective potentials $\lambda(v,q)$ for the $\mathrm{ce}_n(v,q)$ in the case $q = -300$. They are displayed as a function of v, over the interval $[-\pi, \pi]$, for the n values $n = 0, 1, 2, 3, 4, 5$ with $a = a_n(q)$. The top two curves, which very nearly coincide so as to almost look identical on the scale of the figure, are for the cases $n = 0$ and $n = 1$. The next two curves, which also nearly coincide, are for $n = 2$ and $n = 3$. Finally, the bottom two curves also nearly coincide and are for the cases $n = 4$ and $n = 5$. As in Figure 4.6, the higher the n value, the lower the curve.

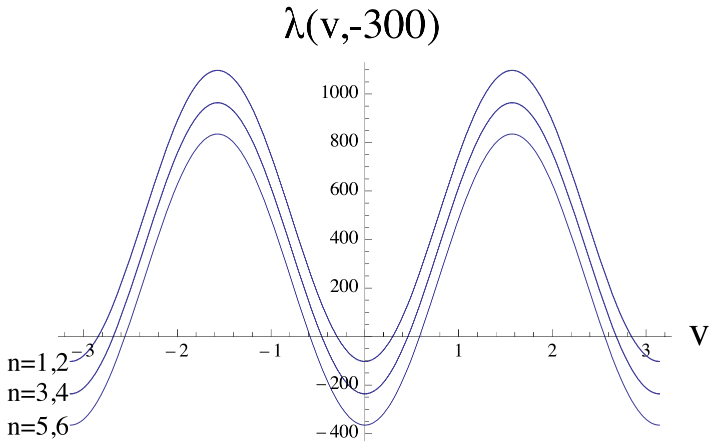

Figure 17.4.14: The effective potentials $\lambda(v,q)$ for the $\mathrm{se}_n(v,q)$ in the case $q=-300$. They are displayed as a function of v, over the interval $[-\pi,\pi]$, for the n values $n=1,2,3,4,5,6$ with $a=b_n(q)$. The top two curves, which very nearly coincide so as to almost look identical on the scale of the figure, are for the cases $n=1$ and $n=2$. The next two curves, which also nearly coincide, are for $n=3$ and $n=4$. Finally, the bottom two curves also nearly coincide and are for the cases $n=5$ and $n=6$. As in Figure 4.7, the higher the n value, the lower the curve.

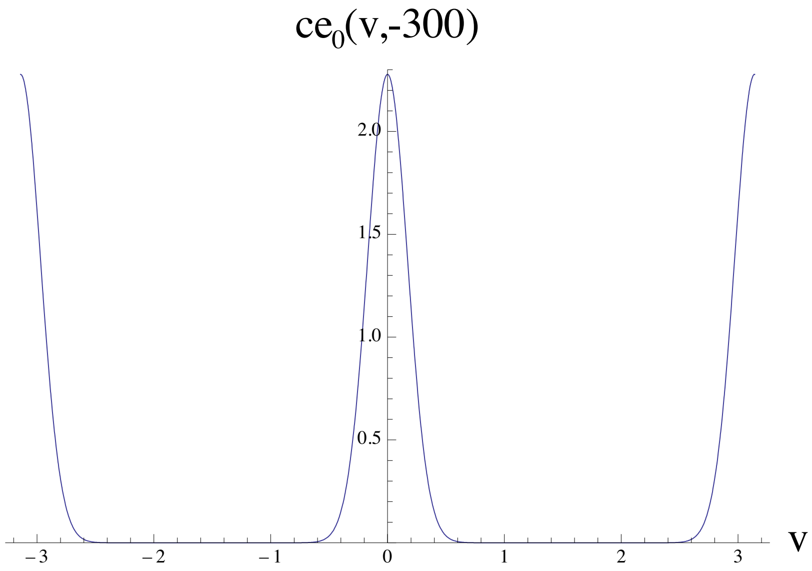

Figure 17.4.15: The function $\mathrm{ce}_0(v,q)$ as a function of v, over the interval $[-\pi,\pi]$, for $q=-300$. Most of the v axis is forbidden.

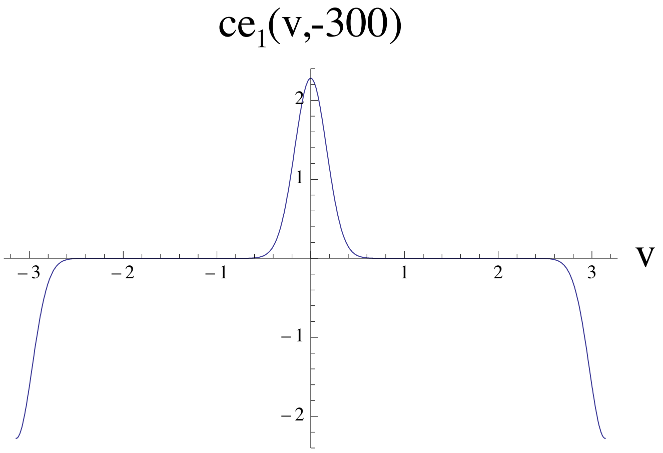

Figure 17.4.16: The function $\mathrm{ce}_1(v, q)$ as a function of v, over the interval $[-\pi, \pi]$, for $q = -300$. Most of the v axis is forbidden.

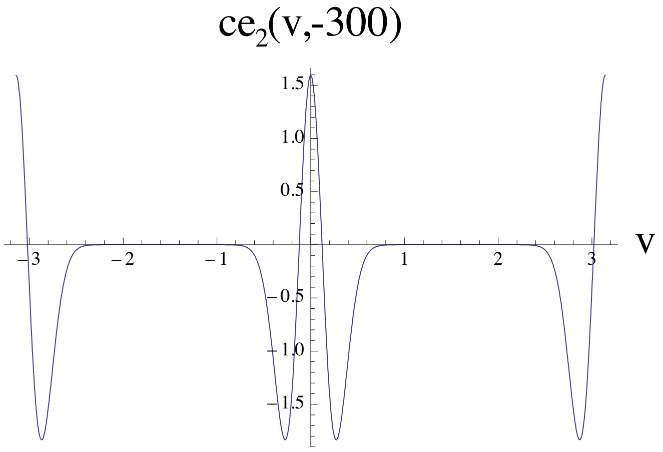

Figure 17.4.17: The function $\mathrm{ce}_2(v, q)$ as a function of v, over the interval $[-\pi, \pi]$, for $q = -300$. Most of the v axis is forbidden.

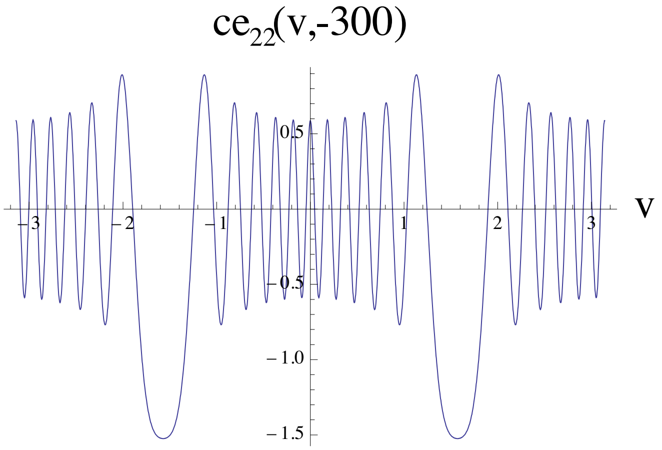

Figure 17.4.18: The function $\text{ce}_{22}(v, q)$ as a function of v, over the interval $[-\pi, \pi]$, for $q = -300$. For these q and n values all of the v axis is allowed, and the function is fully oscillatory.

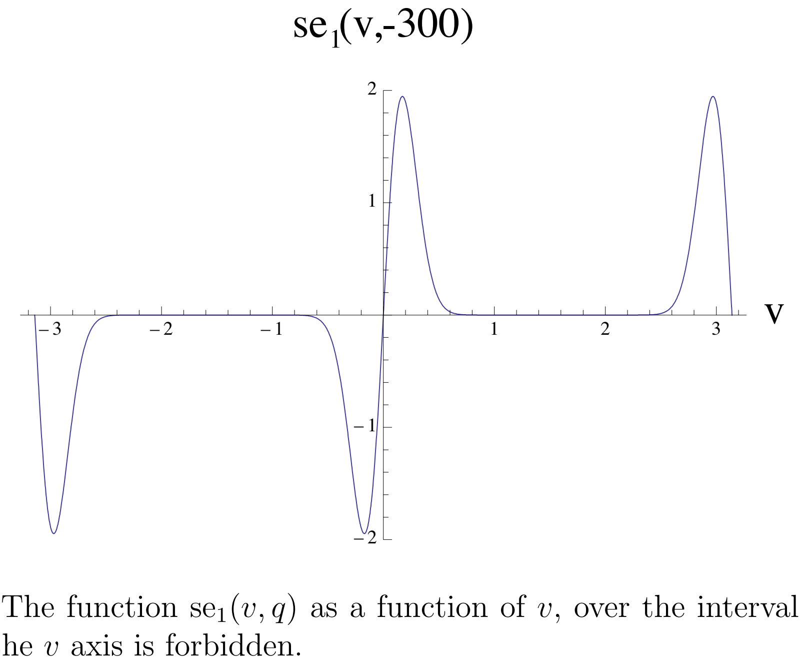

Figure 17.4.19: The function $\text{se}_1(v, q)$ as a function of v, over the interval $[-\pi, \pi]$, for $q = -300$. Most of the v axis is forbidden.

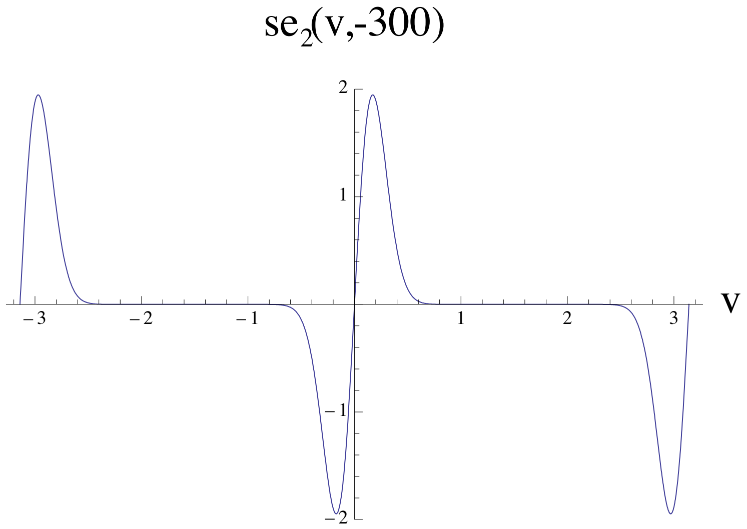

Figure 17.4.20: The function $\mathrm{se}_2(v, q)$ as a function of v, over the interval $[-\pi, \pi]$, for $q = -300$. Most of the v axis is forbidden.

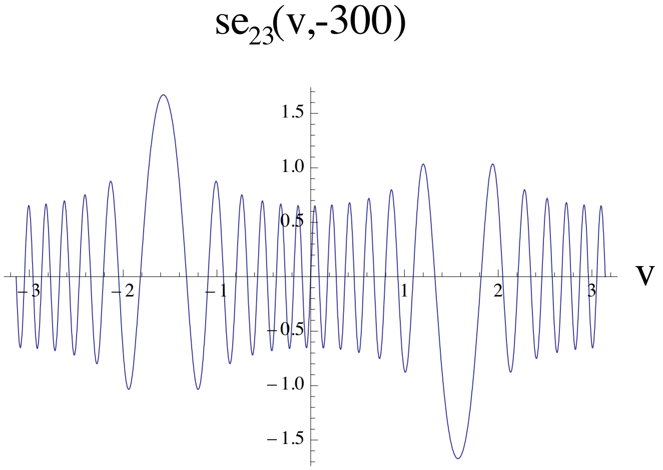

Figure 17.4.21: The function $\mathrm{se}_{23}(v, q)$ as a function of v, over the interval $[-\pi, \pi]$, for $q = -300$. For these q and n values all of the v axis is allowed, and the function is fully oscillatory.

Look again at the potentials $\lambda(v,q)$ shown in Figures 4.6, 4.7, 4.13, and 4.14. We see, as is also evident from (4.46), that they have maxima at $v = \pm\pi/2$, and at these points they have the maximum values

$$\lambda_{\max}(q) = \lambda(\pm\pi/2, q) = -a - 2q. \tag{17.4.47}$$

Figure 4.22 shows $\lambda_{\max}(q)$ for various n values in the case $a = a_n(q)$, and Figure 4.23 does the same in the case $a = b_n(q)$. From (4.29) and (4.30) we have the asymptotic formulas

$$\begin{aligned}&\lambda_{\max}(q) \sim -4q - (8m+2)(-q)^{1/2} + \cdots\\ &\text{as } q \to -\infty \text{ for } a = a_{2m}(q) \sim a_{2m+1}(q) \text{ and } m = 0,1,2,3,\cdots,\end{aligned} \tag{17.4.48}$$

$$\begin{aligned}&\lambda_{\max}(q) \sim -4q - (8m+6)(-q)^{1/2} + \cdots\\ &\text{as } q \to -\infty \text{ for } a = b_{2m+1}(q) \sim b_{2m+2}(q) \text{ and } m = 0,1,2,3,\cdots.\end{aligned} \tag{17.4.49}$$

We know that all of the interval $v \in [-\pi, \pi]$ is allowed when $\lambda_{\max}(q) < 0$, and part of it becomes forbidden when $\lambda_{\max}(q) > 0$. Thus, for each n value and each alternative $a = a_n(q)$ or $a = b_n(q)$, there is a *critical* value $q_{\rm cr}$ such that $\lambda_{\max}(q_{\rm cr}) = 0$. From (4.47) we see that these critical values, in the two alternatives, are given (implicitly) by the relations

$$q_{\rm cr}(n) = -(1/2)a_n[q_{\rm cr}(n)], \tag{17.4.50}$$

$$q_{\rm cr}(n) = -(1/2)b_n[q_{\rm cr}(n)]. \tag{17.4.51}$$

These critical values, which can be read off from the 'x' intercepts of the curves in Figures 4.22 and 4.23, are listed in Table 4.1. For a given value of n, all of the v axis is allowed and $\mathrm{ce}_n(v,q)$ is fully oscillatory if $q > q_{\rm cr}(n)$, and otherwise part of the v axis is forbidden. Here $q_{\rm cr}(n)$ is to be calculated using (4.50). An analogous statement holds for $\mathrm{se}_n(v,q)$ where now $q_{\rm cr}(n)$ is to be calculated using (4.51).

At this point we are prepared to comment on the symmetry properties of the $\mathrm{ce}_n(v,q)$ and $\mathrm{se}_n(v,q)$. We begin with the $\mathrm{ce}_n(v,q)$. We know they are even and periodic with period 2π. They therefore have Fourier series expansions consisting only of cosine terms. Also, consistent with the behavior of $\mathrm{ce}_0(v,q)$ and $\mathrm{ce}_2(v,q)$ displayed in Figures 4.8, 4.10, 4.15, and 4.17, it can be shown that the $\mathrm{ce}_n(v,q)$ for *even n* are *symmetric* about the point $v = \pi/2$. Specifically, the $\mathrm{ce}_n(v,q)$ for even n have Fourier expansions of the form

$$\mathrm{ce}_n(v,q) = *1 + *\cos(2v) + *\cos(4v) + \cdots \text{ for even } n \tag{17.4.52}$$

where the *'s denote q and n dependent coefficients. That is, there is the relation

$$\mathrm{ce}_n(\pi/2 + \Delta, q) = \mathrm{ce}_n(\pi/2 - \Delta, q) \text{ for even } n. \tag{17.4.53}$$

It follows that the $\mathrm{ce}_n(v,q)$ for even n have vanishing first derivative at $v = \pi/2$,

$$\mathrm{ce}_n'(\pi/2, q) = 0 \text{ for even } n. \tag{17.4.54}$$

By contrast, as illustrated in Figures 4.9 and 4.16, the $\mathrm{ce}_n(v,q)$ for *odd n* are *antisymmetric* about the point $v = \pi/2$ and have Fourier expansions of the form

$$\mathrm{ce}_n(v,q) = *\cos(v) + *\cos(3v) + *\cos(5v) + \cdots \text{ for odd } n. \tag{17.4.55}$$

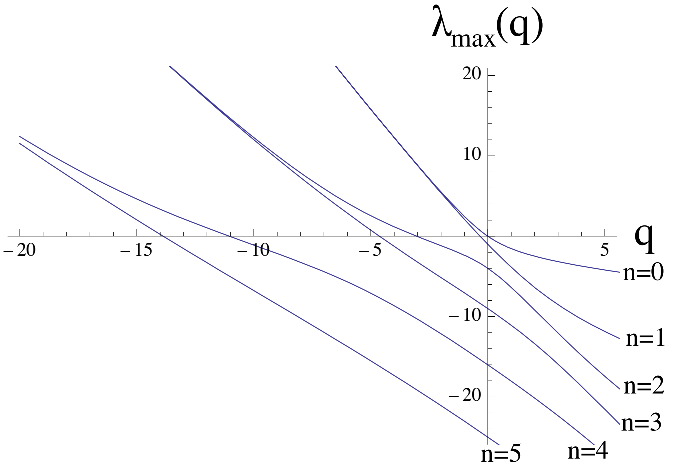

Figure 17.4.22: The function $\lambda_{\max}(q)$ for the n values 0 through 5 in the case $a = a_n(q)$. When $\lambda_{\max}(q) < 0$, all of the v axis is allowed, and the function $\mathrm{ce}_n(v, q)$ is fully oscillatory. When $\lambda_{\max}(q) > 0$, part of the v axis is forbidden. The higher the n value, the lower the curve. Note that the 'y' intercepts have the values $-n^2$ in accord with (4.24) through (4.26) and (4.47). The 'x' intercepts are the values $q_{\mathrm{cr}}(n)$. Note also that the values of $\lambda_{\max}(q)$ for $n = 0$ and $n = 1$ tend to merge for large negative q, as do the values for $n = 2$ and $n = 3$, etc. See Figure 4.5 and (4.48).

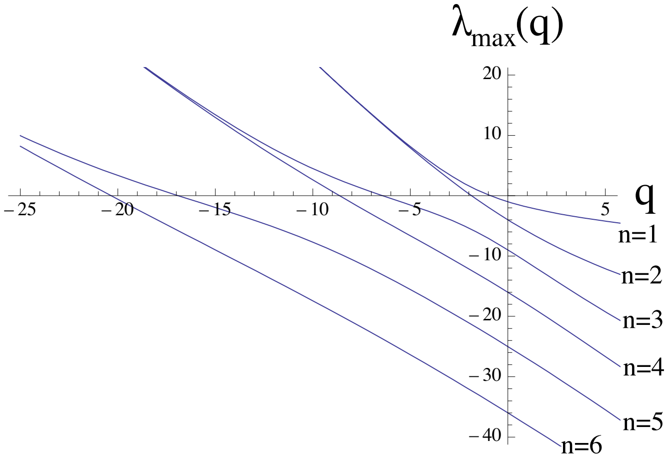

Figure 17.4.23: The function $\lambda_{\max}(q)$ for the n values 1 through 6 in the case $a = b_n(q)$. When $\lambda_{\max}(q) < 0$, all of the v axis is allowed, and the function $\mathrm{se}_n(v, q)$ is fully oscillatory. When $\lambda_{\max}(q) > 0$, part of the v axis is forbidden. The higher the n value, the lower the curve. Note that the 'y' intercepts have the values $-n^2$ in accord with (4.27), (4.28), and (4.47). The 'x' intercepts are the values $q_{\mathrm{cr}}(n)$. Note also that the values of $\lambda_{\max}(q)$ for $n = 1$ and $n = 2$ tend to merge for large negative q, as do the values for $n = 3$ and $n = 4$, etc. See Figure 4.5 and (4.49).

Table 17.4.1: The quantity $q_{\rm cr}(n)$ for various values of n.

n	$q_{\rm cr}(n)$ when $a = a_n(q)$	$q_{\rm cr}(n)$ when $a = b_n(q)$
0	0	*
1	-0.329005727826915	-0.889819993831662
2	-3.039073671630782	-1.8582116914842934

6	-23.995780230075020	-20.345062417526364
7	-28.0531793998642485	-32.320930596434941
8	-41.880084880521011	-36.995345508020719
9	-47.171475670427398	-52.673172894843788
10	-64.7001463432813892	-58.581512590132760

That is, there is the relation

$$\mathrm{ce}_n(\pi/2 + \Delta, q) = -\mathrm{ce}_n(\pi/2 - \Delta, q) \text{ for odd } n. \tag{17.4.56}$$

It follows that the $\mathrm{ce}_n(v, q)$ for odd n vanish at $v = \pi/2$,

$$\mathrm{ce}_n(\pi/2, q) = 0 \text{ for odd } n. \tag{17.4.57}$$

Next consider the symmetry properties of the $\mathrm{se}_n(v, q)$. We know they are odd and periodic with period 2π. They therefore have Fourier series expansions consisting only of sine terms. Also, consistent with the behavior of $\mathrm{se}_2(v, q)$ displayed in Figures 4.12 and 4.20, it can be shown that the $\mathrm{se}_n(v, q)$ for even n are antisymmetric about the point $v = \pi/2$. Specifically, the $\mathrm{se}_n(v, q)$ for even n have Fourier expansions of the form

$$\mathrm{se}_n(v, q) = * \sin(2v) + * \sin(4v) + * \sin(6v) + \cdots \text{ for even } n. \tag{17.4.58}$$

That is, there is the relation

$$\mathrm{se}_n(\pi/2 + \Delta, q) = -\mathrm{se}_n(\pi/2 - \Delta, q) \text{ for even } n, \tag{17.4.59}$$

from which it follows that

$$\mathrm{se}_n(\pi/2, q) = 0 \text{ for even } n. \tag{17.4.60}$$

By contrast, as ilustrated in Figures 4.11 and 4.19 for $\mathrm{se}_1(v, q)$, the $\mathrm{se}_n(v, q)$ for odd n are symmetric about the point $v = \pi/2$ and have Fourier expansions of the form

$$\mathrm{se}_n(v, q) = * \sin(v) + * \sin(3v) + * \sin(5v) + \cdots \text{ for odd } n. \tag{17.4.61}$$

That is, there is the relation

$$\mathrm{se}_n(\pi/2 + \Delta, q) = \mathrm{se}_n(\pi/2 - \Delta, q) \text{ for odd } n, \tag{17.4.62}$$

from which it follows that

$$\mathrm{se}_n'(\pi/2, q) = 0 \text{ for odd } n. \tag{17.4.63}$$

Finally, it follows from (4.52) and (4.58) that

$$\mathrm{ce}_n(v + \pi, q) = \mathrm{ce}_n(v, q) \text{ for even } n \tag{17.4.64}$$

and

$$\mathrm{se}_n(v + \pi, q) = \mathrm{se}_n(v, q) \text{ for even } n. \tag{17.4.65}$$

Thus the $\mathrm{se}_n(v, q)$ and $\mathrm{se}_n(v, q)$ for even n have period π as well as period 2π. By contrast, we see from (4.55) and (4.61) that there are the relations

$$\mathrm{ce}_n(v + \pi, q) = -\mathrm{ce}_n(v, q) \text{ for odd } n \tag{17.4.66}$$

and

$$\mathrm{se}_n(v + \pi, q) = -\mathrm{se}_n(v, q) \text{ for odd } n. \tag{17.4.67}$$

The relations (4.64) through (4.67) can be written more succinctly in the form

$$\mathrm{ce}_n(v + \pi, q) = (-1)^n \mathrm{ce}_n(v, q), \tag{17.4.68}$$

$$\mathrm{se}_n(v + \pi, q) = (-1)^n \mathrm{se}_n(v, q). \tag{17.4.69}$$

From a computational perspective, an important consequence of these symmetry properties of the $\mathrm{ce}_n(v, q)$ and $\mathrm{se}_n(v, q)$ is that they only need to be computed over the interval $v \in [0, \pi/2]$. Their values elsewhere are then determined by their symmetry properties. Moreover, if q and n are such that a value of v is deep within a strongly forbidden region, then we may set the associated value of $\mathrm{ce}_n(v, q)$ or $\mathrm{se}_n(v, q)$ to zero for these values of v. Recall that the forbidden regions are centered about the values $v = \pm\pi/2$. Thus, if there are such strongly forbidden regions, we only need to compute $\mathrm{ce}_n(v, q)$ or $\mathrm{se}_n(v, q)$ over the smaller interval $v \in [0, v_{\text{deep}}]$ where v_{deep} is the smallest v value deep within the strongly forbidden region.

17.4.5 Modified Mathieu Functions

Now that the possible values of the separation constant a have been determined by the periodicity requirement, these values of a can be employed in (4.21) to determine the functions $P(u)$. The so-called solutions of the *first kind* for (4.21), when $a = a_n(q)$, are denoted as $\mathrm{Ce}_n(u, q)$; and the solutions of the first kind, when $a = b_n(q)$, are denoted as $\mathrm{Se}_n(u, q)$. The functions $\mathrm{Ce}_n(u, q)$ are even functions of u and the functions $\mathrm{Se}_n(u, q)$ are odd functions of u. They can be conveniently arranged to satisfy the relations

$$\mathrm{Ce}_n(u, q) = \mathrm{ce}_n(iu, q), \tag{17.4.70}$$

$$\mathrm{Se}_n(u, q) = -i\mathrm{se}_n(iu, q). \tag{17.4.71}$$

Evidently, they are also entire functions, and they are also real for q and u real. Since the $\mathrm{ce}_n(v, q)$ and $\mathrm{se}_n(v, q)$ are analogous to cosines and sines, see (4.52), (4.55), (4.58), and

(4.61), the relations (4.70) and (4.71) indicate that the $\mathrm{Ce}_n(u,q)$ and $\mathrm{Se}_n(u,q)$ are analogous to hyperbolic cosines and hyperbolic sines.

Suppose we write (4.21) in the form

$$d^2P/du^2 - \Lambda(u,q)P = 0 \tag{17.4.72}$$

where

$$\Lambda(u,q) = a - 2q\cosh(2u). \tag{17.4.73}$$

Figure 4.24 shows these $\Lambda(u,q)$ for various n values with $a = a_n(q)$ and $q = -2$. These are the potentials appropriate to the $\mathrm{Ce}_n(u,q)$. The potentials for the $\mathrm{Se}_n(u,q)$ computed with $a = b_n(q)$ are similar. Inspection of these $\mathrm{Ce}_n(u,q)$ potentials shows that they are all *positive* for *all* u. The same can be shown to be true for the $\mathrm{Se}_n(v,q)$ potentials.

In fact, more can be said. From (4.73) it is evident that, when $q < 0$ (which is what we have assumed), Λ has a minimum at $u = 0$ and, at this point has the value

$$\Lambda(0,q) = a - 2q. \tag{17.4.74}$$

Therefore, if we can show that

$$\Lambda(0,q) = a - 2q > 0 \tag{17.4.75}$$

for all $q < 0$ and all n with $a = a_n(q)$ or $a = b_n(q)$, then we will have shown that all Λ are positive for all u. Figure 4.25 displays $\Lambda(0,q)$ for various n values when $a = a_n(q)$, and Figure 4.26 does the same for the case $a = b_n(q)$. Note also that from (4.29) and (4.30) there is the asymptotic behavior

$$\begin{aligned}&\Lambda(0,q) \sim (8m+2)(-q)^{1/2} + \cdots\\ &\text{as } q \to -\infty \text{ for } a = a_{2m}(q) \sim a_{2m+1}(q) \text{ and } m = 0,1,2,3,\cdots,\end{aligned} \tag{17.4.76}$$

$$\begin{aligned}&\Lambda(0,q) \sim (8m+6)(-q)^{1/2} + \cdots\\ &\text{as } q \to -\infty \text{ for } a = b_{2m+1}(q) \sim b_{2m+2}(q) \text{ and } m = 0,1,2,3,\cdots.\end{aligned} \tag{17.4.77}$$

Evidently (4.75) is always satisfied when $q < 0$. We conclude that for $q \le 0$ the $\mathrm{Ce}_n(u,q)$ and $\mathrm{Se}_n(u,q)$ are non-oscillatory and must all be exponentially growing.[10]

As examples, Figures 4.27 and 4.28 display the first few $\mathrm{Ce}_n(u,q)$ and $\mathrm{Se}_n(u,q)$ as a function of u for $q = -2$.[11] We see that, as predicted, they are non-oscillatory and their magnitudes do indeed become large for large values of $|u|$.

[10] Also, as Figures 4.25 and 4.26 illustrate, oscillatory behavior for the $\mathrm{Ce}_n(u,q)$ and $\mathrm{Se}_n(u,q)$ is possible if $q > 0$. See Exercise 4.1.

[11] Since the modified Mathieu equation (4.21) is also of second order, it will also have second solutions that are linearly independent of the $\mathrm{Ce}_n(u,q)$ and $\mathrm{Se}_n(u,q)$. Because it too is invariant under parity, these solutions could be constructed to have parities opposite to those of the $\mathrm{Ce}_n(u,q)$ and $\mathrm{Se}_n(u,q)$.

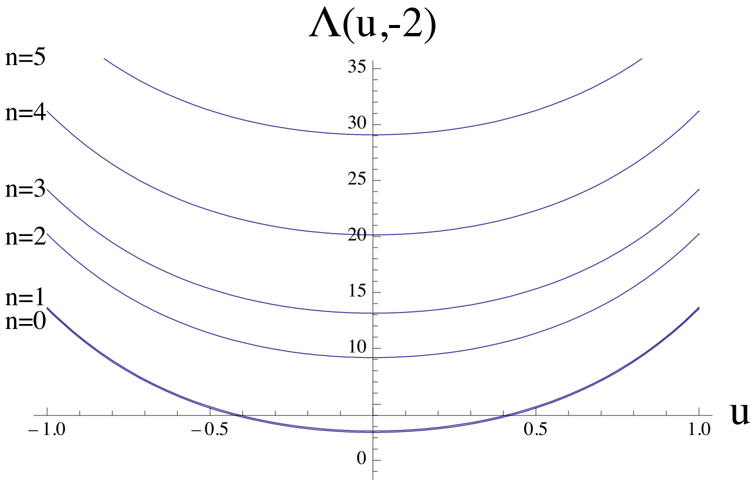

Figure 17.4.24: The effective potentials $\Lambda(u, q)$ for the $\mathrm{Ce}_n(v, q)$ in the case $q = -2$. They are displayed as a function of u for the n values $n = 0, 1, 2, 3, 4, 5$ with $a = a_n(q)$. As in Figure 4.6, the curves for $n = 0$ and $n = 1$ nearly coincide. Now, because of the difference in sign between (4.46) and (4.73), the higher the n value the higher the curve.

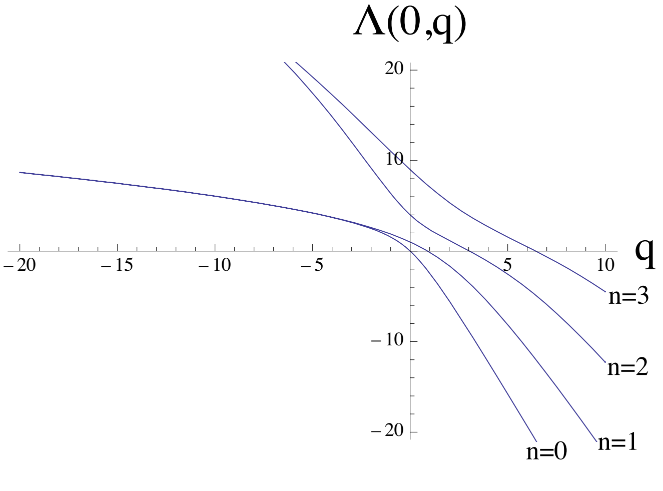

Figure 17.4.25: The quantities $\Lambda(0, q)$ with $a = a_n(q)$ and $n = 0, 1, 2, 3$. The higher the n value, the higher the curve. Note that the 'y' intercepts have the values n^2 in agreement with (4.24) through (4.26). Also, values of $\Lambda(0, q)$ for $n = 0$ and $n = 1$ tend to merge for large negative q, as do the values for $n = 2$ and $n = 3$, etc. See Figure 4.5 and (4.76).

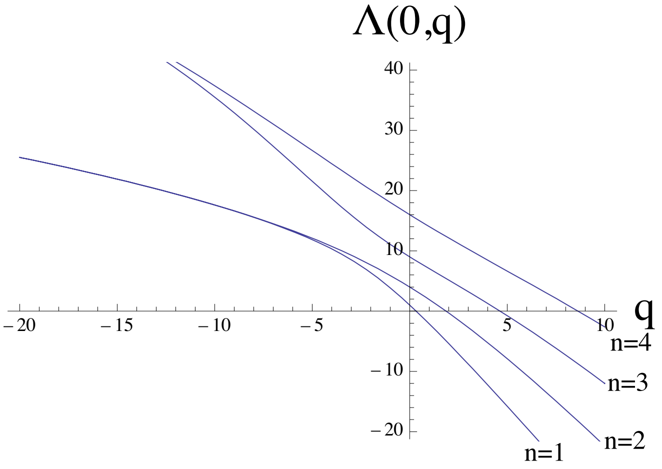

Figure 17.4.26: The quantities $\Lambda(0, q)$ with $a = b_n(q)$ and $n = 1, 2, 3, 4$. The higher the n value, the higher the curve. Note that the 'y' intercepts have the values n^2 in agreement with (4.27) and (4.28). Also, values of $\Lambda(0, q)$ for $n = 1$ and $n = 2$ tend to merge for large negative q, as do the values for $n = 3$ and $n = 4$, etc. See Figure 4.5 and (4.77).

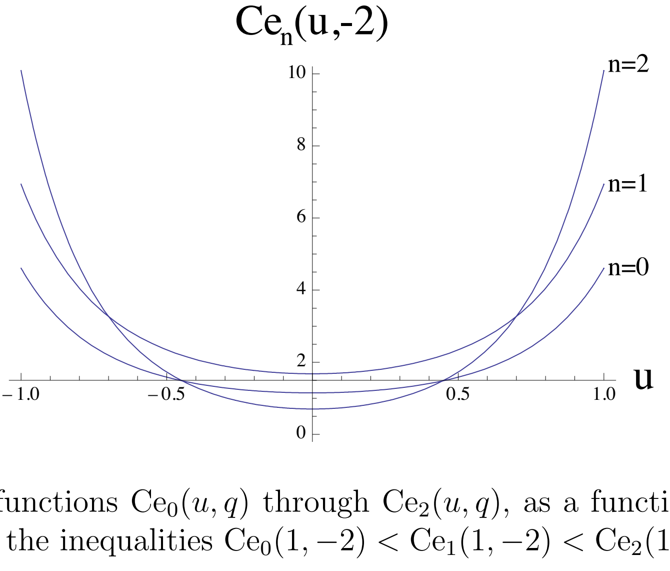

Figure 17.4.27: The functions $\mathrm{Ce}_0(u, q)$ through $\mathrm{Ce}_2(u, q)$, as a function of u, for $q = -2$. At $u = 1$ they satisfy the inequalities $\mathrm{Ce}_0(1, -2) < \mathrm{Ce}_1(1, -2) < \mathrm{Ce}_2(1, -2)$.

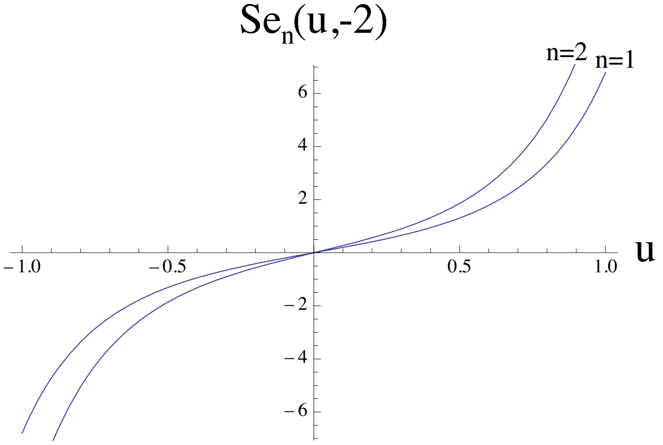

Figure 17.4.28: The functions $\mathrm{Se}_1(u,q)$ and $\mathrm{Se}_2(u,q)$, as a function of u, for $q=-2$. At $u=1$ they satisfy the inequality $\mathrm{Se}_1(1,-2)<\mathrm{Se}_2(1,-2)$.

17.4.6 Analyticity in x and y

So far we have described the functions $\mathrm{ce}_n(v,q)$ and $\mathrm{se}_n(v,q)$, and the functions $\mathrm{Ce}_n(u,q)$ and $\mathrm{Se}_n(u,q)$, and have seen that they are entire functions of the variables u and v. But this does not mean that they are entire functions of the variables x and y because the relation (4.7) that connects u,v to x,y has singularities. See Exercise 4.2. Remarkably, however, the products $[\mathrm{Ce}_n(u,q)\times\mathrm{ce}_n(v,q)]$ and $[\mathrm{Se}_n(u,q)\times\mathrm{se}_n(v,q)]$, which according to (4.13) is what we hope to use to construct solutions of the Laplace equation, are entire functions of the variables x and y. This situation is analogous to the case of cylindrical coordinates where the functions $\exp(im\phi)$ and $I_m(k\rho)$ are entire functions of ϕ and ρ, respectively, but are not entire functions of x and y. However, the products $[\exp(im\phi)\times I_m(k\rho)]$ are entire functions of x and y. In the case of the Mathieu functions, for example, there is an integral representation of the form

$$\mathrm{Ce}_{2n}(u,q)\,\mathrm{ce}_{2n}(v,q)=p_{2n}(q)\int_0^{\pi/2}d\tau\;\mathrm{ce}_{2n}(\tau,q)\cosh[kx\cos(\tau)]\cosh[ky\sin(\tau)] \qquad (17.4.78)$$

where $p_{2n}(q)$ is some q-dependent coefficient. There are similar representations for the other relevant products. The right side of (4.78) is manifestly an entire function of x and y.

17.4.7 Elliptic Cylinder Harmonic Expansion and On-Axis Gradients

The stage is now set to describe the expansion of any harmonic function ψ in terms of Mathieu functions. The general harmonic function that is analytic in x and y near the origin can be written in the form

$$\begin{aligned}\psi(x,y,z)=\psi(u,v,z) &= \sum_{n=0}^{\infty}\int_{-\infty}^{\infty} dk\; c_n(k)\exp(ikz)\mathrm{Ce}_n(u,q)\;\mathrm{ce}_n(v,q)\\ &+ \sum_{n=1}^{\infty}\int_{-\infty}^{\infty} dk\; s_n(k)\exp(ikz)\mathrm{Se}_n(u,q)\;\mathrm{se}_n(v,q)\end{aligned}\tag{17.4.79}$$

where the functions $c_n(k)$ and $s_n(k)$ are arbitrary. We will call (4.79) an *elliptic cylinder harmonic* expansion.

To exploit this expansion, suppose the magnetic field $\boldsymbol{B}(x,y,z)$ is interpolated onto the surface $u=U$ of an elliptic cylinder using values at the grid points near the surface. See Figure 4.3. Let us employ the notation $\boldsymbol{B}(x,y,z)=\boldsymbol{B}(u,v,z)$ so that the magnetic field on the surface can be written as $\boldsymbol{B}(U,v,z)$. Next, from the values on the surface, compute $B_u(U,v,z)$, the component of $\boldsymbol{B}(x,y,z)$ *normal* to the surface. Our aim will be to determine the generalized on-axis gradients from a knowledge of $B_u(U,v,z)$.

Let us begin by solving (4.11) for $(\partial\psi/\partial u)$. We find, using (4.4), the result,

$$\begin{aligned}(\partial\psi/\partial u) &= f[\cosh^2(u)-\cos^2(v)]^{1/2}B_u\\ &= f(\sinh u\cos v)B_x(u,v,z)+f(\cosh u\sin v)B_y(u,v,z).\end{aligned}\tag{17.4.80}$$

We see that the right side of (4.80) is a well-behaved function $F(u,v,z)$ whose values are known for $u=U$,

$$F(U,v,z)=f(\sinh U\cos v)B_x(U,v,z)+f(\cosh U\sin v)B_y(U,v,z).\tag{17.4.81}$$

Moreover, using the representation (4.79) in (4.80) and (4.81), we may also write

$$\begin{aligned}F(U,v,z) &= \sum_{n=0}^{\infty}\int_{-\infty}^{\infty} dk\; c_n(k)\exp(ikz)\mathrm{Ce}_n'(U,q)\;\mathrm{ce}_n(v,q)\\ &+ \sum_{n=1}^{\infty}\int_{-\infty}^{\infty} dk\; s_n(k)\exp(ikz)\mathrm{Se}_n'(U,q)\;\mathrm{se}_n(v,q).\end{aligned}\tag{17.4.82}$$

Next multiply both sides of (4.82) by $\exp(-ik'z)$ and integrate over z. So doing gives the result

$$\begin{aligned}&(1/2\pi)\int_{-\infty}^{\infty} dz\exp(-ik'z)F(U,v,z)=\\ &\sum_{n=0}^{\infty}c_n(k')\mathrm{Ce}_n'(U,q')\;\mathrm{ce}_n(v,q')+\sum_{n=1}^{\infty}s_n(k')\mathrm{Se}_n'(U,q')\;\mathrm{se}_n(v,q').\end{aligned}\tag{17.4.83}$$

Now, employ the orthogonality properties (4.38) through (4.40) to obtain the relations

$$c_r(k')\mathrm{Ce}_r'(U,q')=[1/(2\pi^2)]\int_0^{2\pi}dv\int_{-\infty}^{\infty}dz\exp(-ik'z)\mathrm{ce}_r(v,q')F(U,v,z),\tag{17.4.84}$$

$$s_r(k')\mathrm{Se}'_r(U,q') = [1/(2\pi^2)]\int_0^{2\pi} dv \int_{-\infty}^{\infty} dz \exp(-ik'z)\mathrm{se}_r(v,q')F(U,v,z). \tag{17.4.85}$$

In view of (4.84) and (4.85), define the function $\tilde{F}(v,k)$ by the rule

$$\tilde{F}(v,k) = [1/(2\pi)]\int_{-\infty}^{\infty} dz \exp(-ikz)F(U,v,z), \tag{17.4.86}$$

and define functions $\tilde{\tilde{F}}{}^c_r(k)$ and $\tilde{\tilde{F}}{}^s_r(k)$ by the rules

$$\begin{aligned}\tilde{\tilde{F}}{}^c_r(k) &= (1/\pi)\int_0^{2\pi} dv\ \mathrm{ce}_r(v,q)\tilde{F}(v,k)\\ &= [1/(2\pi^2)]\int_0^{2\pi} dv \int_{-\infty}^{\infty} dz \exp(-ikz)\mathrm{ce}_r(v,q)F(U,v,z),\end{aligned} \tag{17.4.87}$$

$$\begin{aligned}\tilde{\tilde{F}}{}^s_r(k) &= (1/\pi)\int_0^{2\pi} dv\ \mathrm{se}_r(v,q)\tilde{F}(v,k)\\ &= [1/(2\pi^2)]\int_0^{2\pi} dv \int_{-\infty}^{\infty} dz \exp(-ikz)\mathrm{se}_r(v,q)F(U,v,z).\end{aligned} \tag{17.4.88}$$

[Here we have extended the use of the ˜ notation to include angular *Mathieu* transforms, such as those in (4.87) and (4.88), where $\cos(r\phi)$ and $\sin(r\phi)$ are replaced by $\mathrm{ce}_r(v,q)$ and $\mathrm{se}_r(v,q)$.] We will call the functions $\tilde{\tilde{F}}{}^\alpha_r(k)$ *Mathieu coefficient* functions in analogy to the Fourier coefficients that arise in Fourier analysis. Note that, because F and the Mathieu functions are real, the real parts of the functions $\tilde{\tilde{F}}{}^\alpha_r(k)$ are even in k, and the imaginary parts are odd in k.

With these definitions, the relations (4.84) and (4.85) can be rewritten in the form

$$c_r(k) = \tilde{\tilde{F}}{}^c_r(k)/\mathrm{Ce}'_r(U,q), \tag{17.4.89}$$

$$s_r(k) = \tilde{\tilde{F}}{}^s_r(k)/\mathrm{Se}'_r(U,q). \tag{17.4.90}$$

Finally, employ (4.89) and (4.90) in (4.79). So doing gives the result

$$\begin{aligned}\psi(x,y,z) &= \sum_{r=0}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz)[\tilde{\tilde{F}}{}^c_r(k)/\mathrm{Ce}'_r(U,q)]\mathrm{Ce}_r(u,q)\ \mathrm{ce}_r(v,q)\\ &+ \sum_{r=1}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz)[\tilde{\tilde{F}}{}^s_r(k)/\mathrm{Se}'_r(U,q)]\mathrm{Se}_r(u,q)\ \mathrm{se}_r(v,q).\end{aligned} \tag{17.4.91}$$

We have obtained an elliptical cylinder harmonic expansion for ψ in terms of surface field data.

Of course, what we really want are the on-axis gradients. They can be found by employing two remarkable *connections* (identities) between elliptic and circular cylinder functions of the form

$$\mathrm{Ce}_r(u,q)\ \mathrm{ce}_r(v,q) = \sum_{m=0}^{\infty} \alpha_m^r(k) I_m(k\rho)\cos(m\phi), \tag{17.4.92}$$

$$\mathrm{Se}_r(u,q)\ \mathrm{se}_r(v,q) = \sum_{m=1}^{\infty} \beta_m^r(k) I_m(k\rho)\sin(m\phi). \tag{17.4.93}$$

For further reference, we will call the quantities $\alpha_m^r(k)$ and $\beta_m^r(k)$ *Mathieu-Bessel connection coefficients*. Let us employ these identities in (4.91) to find the results

$$\begin{aligned} &\sum_{r=0}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz)[\tilde{\tilde{F}}_r^c(k)/\mathrm{Ce}_r'(U,q)]\mathrm{Ce}_r(u,q)\ \mathrm{ce}_r(v,q) \\ = &\sum_{m=0}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz) I_m(k\rho)\cos(m\phi)\sum_{r=0}^{\infty}\alpha_m^r(k)[\tilde{\tilde{F}}_r^c(k)/\mathrm{Ce}_r'(U,q)], \end{aligned} \tag{17.4.94}$$

and

$$\begin{aligned} &\sum_{r=1}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz)[\tilde{\tilde{F}}_r^s(k)/\mathrm{Se}_r'(U,q)]\mathrm{Se}_r(u,q)\ \mathrm{se}_r(v,q) \\ = &\sum_{m=1}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz) I_m(k\rho)\sin(m\phi)\sum_{r=1}^{\infty}\beta_m^r(k)[\tilde{\tilde{F}}_r^s(k)/\mathrm{Se}_r'(U,q)]. \end{aligned} \tag{17.4.95}$$

Using these results, (4.91) can be rewritten in the form

$$\begin{aligned} \psi(x,y,z) \ = \ &\sum_{m=0}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz) I_m(k\rho)\cos(m\phi)\sum_{r=0}^{\infty}\alpha_m^r(k)[\tilde{\tilde{F}}_r^c(k)/\mathrm{Ce}_r'(U,q)] \\ + &\sum_{m=1}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz) I_m(k\rho)\sin(m\phi)\sum_{r=1}^{\infty}\beta_m^r(k)[\tilde{\tilde{F}}_r^s(k)/\mathrm{Se}_r'(U,q)]. \end{aligned} \tag{17.4.96}$$

Upon comparing (4.96) with (14.2.54), we conclude that there are the relations

$$G_{m,c}(k) = \sum_{r=0}^{\infty}\alpha_m^r(k)[\tilde{\tilde{F}}_r^c(k)/\mathrm{Ce}_r'(U,q)], \tag{17.4.97}$$

and

$$G_{m,s}(k) = \sum_{r=1}^{\infty}\beta_m^r(k)[\tilde{\tilde{F}}_r^s(k)/\mathrm{Se}_r'(U,q)]. \tag{17.4.98}$$

We remark that it can be shown that the real parts of the $G_{m,\alpha}$ are even in k, and the imaginary parts are odd in k. See Exercise 4.2. Finally, in view of (14.2.55) and (14.2.56), we have the desired results

$$\begin{aligned} C_{m,c}^{[n]}(z) &= i^n(1/2)^m(1/m!)\int_{-\infty}^{\infty} dk\exp(ikz)k^{n+m}\sum_{r=0}^{\infty}\alpha_m^r(k)[\tilde{\tilde{F}}_r^c(k)/\mathrm{Ce}_r'(U,q)] \\ &= i^n(1/2)^m(1/m!)\int_{-\infty}^{\infty} dk\exp(ikz)k^{n+m}G_{m,c}(k), \end{aligned} \tag{17.4.99}$$

$$\begin{aligned} C_{m,s}^{[n]}(z) &= i^n(1/2)^m(1/m!)\int_{-\infty}^{\infty} dk\exp(ikz)k^{n+m}\sum_{r=1}^{\infty}\beta_m^r(k)[\tilde{\tilde{F}}_r^s(k)/\mathrm{Se}_r'(U,q)] \\ &= i^n(1/2)^m(1/m!)\int_{-\infty}^{\infty} dk\exp(ikz)k^{n+m}G_{m,s}(k). \end{aligned} \tag{17.4.100}$$

We have found expressions for the generalized gradients in terms of field data (normal component) on the surface of an elliptic cylinder. These results hold for the cases $m \geq 1$. When $m = 0$ there are the results

$$\begin{aligned} C_{m=0,c}^{[n]}(z) &= C_0^{[n]}(z) = i^n\int_{-\infty}^{\infty} dk\exp(ikz)k^n\sum_{r=0}^{\infty}\alpha_0^r(k)[\tilde{\tilde{F}}_r^c(k)/\mathrm{Ce}_r'(U,q)] \\ &= i^n\int_{-\infty}^{\infty} dk\exp(ikz)k^nG_{0,c}(k), \end{aligned} \tag{17.4.101}$$

$$C_{m=0,s}^{[n]}(z) = 0. \tag{17.4.102}$$

Just as in the $m = 0$ case for the circular cylinder, so too here it may be better to derive and employ formulas based on the tangential component B_z rather than the normal component. See Section 19.2.

Exercises

17.4.1. Verify that (4.1) and (4.2) can be written in the form (4.7).

17.4.2. The purpose of this exercise is to study the analytic properties of elliptic coordinates. Our discussion is based on the relation (4.7). According to (4.7), the function $\zeta(w)$ is an entire function of w. What can be said about its inverse $w(\zeta)$? Verify that (4.7) has the inverse

$$w = \cosh^{-1}(\zeta/f) = \log[(\zeta/f) + \sqrt{(\zeta/f)^2 - 1}]. \tag{17.4.103}$$

Evidently $w(\zeta)$ has branch points at $\zeta = \pm f$. Verify that $w(\zeta)$ is analytic in the cut ζ plane with a cut consisting of a straight line extending from $\zeta = -f$ to $\zeta = f$ as illustrated in Figure 4.2.

17.4.3. Exercise on wave equation.

17.5 Use of Field Data on Surface of Rectangular Cylinder

17.5.1 Finding the Magnetic Scalar Potential $\psi(x, y, z)$

Consider the domain $x \in [-W/2, W/2]$, $y \in [-H/2, H/2]$, $z \in [-\infty, \infty]$. This domain is the interior and surface of a cylinder of infinite extent in the $\pm z$ direction, centered on the z axis, and having rectangular cross section with width W and height H. In this section we will describe the use of field data on the surface of this cylinder. This cylinder has 4 surfaces (sides) which we will call t and b for *top* and *bottom*, and ℓ and r for *left* and *right*.

Suppose that we are given the normal component of the magnetic field on the top, bottom, left, and right surfaces. That is, we are given the field data

$$B_y^t(x, z) = B_y(x, y, z)|_{y=H/2} \text{ with } x \in [-W/2, W/2] \text{ and } z \in [-\infty, \infty], \tag{17.5.1}$$

$$B_y^b(x, z) = B_y(x, y, z)|_{y=-H/2} \text{ with } x \in [-W/2, W/2] \text{ and } z \in [-\infty, \infty], \tag{17.5.2}$$

$$B_x^\ell(y, z) = B_x(x, y, z)|_{x=-W/2} \text{ with } y \in [-H/2, H/2] \text{ and } z \in [-\infty, \infty], \tag{17.5.3}$$

$$B_x^r(y, z) = B_x(x, y, z)|_{x=W/2} \text{ with } y \in [-H/2, H/2] \text{ and } z \in [-\infty, \infty]. \tag{17.5.4}$$

Our goal is to find the scalar magnetic potential $\psi(x, y, z)$ in terms of this field data.

For purposes of Fourier analysis, we will *extend* the normal field surface data beyond the ranges indicated above as follows:

- Extend $B_y^t(x, z)$ and $B_y^b(x, z)$ from the interval $x \in [-W/2, W/2]$ to the extended interval $x \in [-W/2, 3W/2]$ by requiring that the extension be *even* in x about the value $x = W/2$. Note that the extended interval $x \in [-W/2, 3W/2]$ can be written in the form
$$[-W/2, 3W/2] = [W/2 - W, W/2 + W]. \tag{17.5.5}$$

- Extend $B_x^\ell(y, z)$ and $B_x^b(y, z)$ from the interval $y \in [-H/2, H/2]$ to the extended interval $y \in [-H/2, 3H/2]$ by requiring that the extension be *even* in y about the value $y = H/2$. Note that the extended interval $[-H/2, 3H/2]$ can be written in the form
$$[-H/2, 3H/2] = [H/2 - H, H/2 + H]. \tag{17.5.6}$$

So doing will produce functions that are continuous over the extended intervals

$$x \in [W/2 - W, W/2 + W] \text{ and } y \in [H/2 - H, H/2 + H]. \tag{17.5.7}$$

Moreover, by construction, the extended functions will take the *same* value at both ends of each extended interval. Therefore they can be *further* extended beyond their extended intervals, both to the left and the right, in a *continuous* way by requiring that their further extensions be periodic with periods $2W$ and $2H$, respectively. (Moreover, these extensions will also be even about the values $x = -W/2$ and $y = -H/2$, respectively.) In summary, we have produced extensions that are even about $\pm W/2$ or $\pm H/2$, are periodic with periods

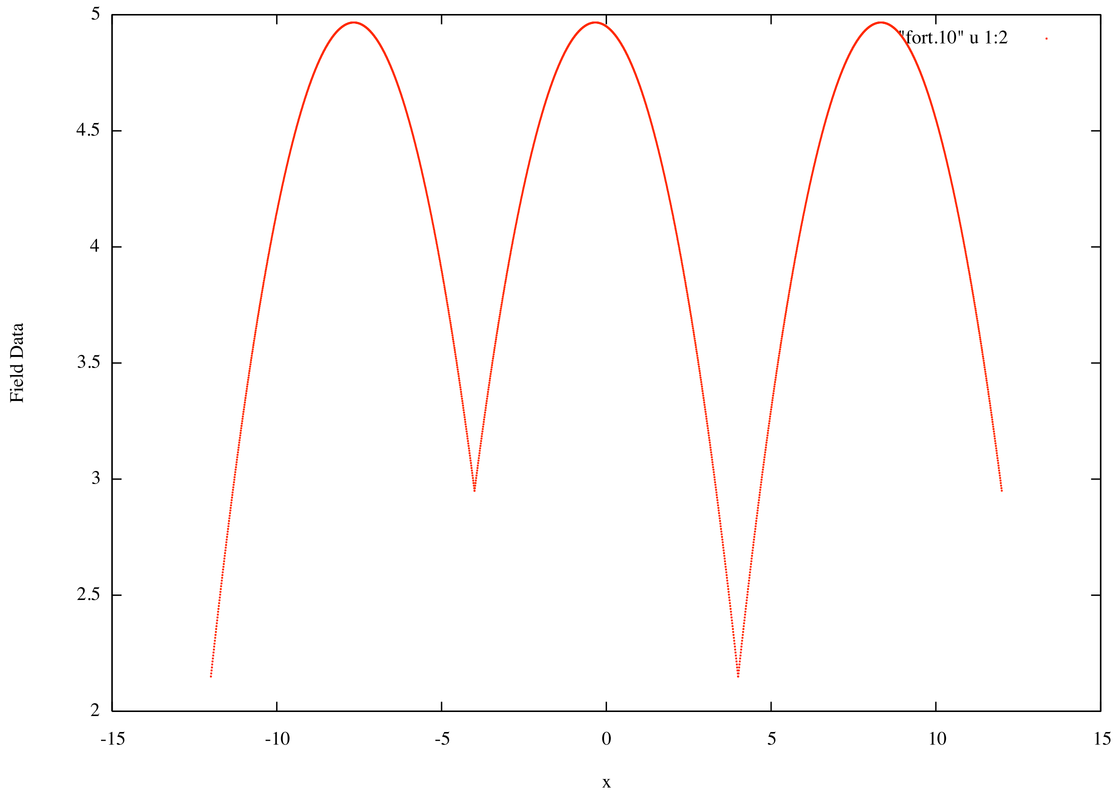

Figure 17.5.1: Hypothetical $B_y^t(x,z)$ data in the interval $x \in [-W/2, W/2]$ and its extension to the full x axis to facilitate Fourier analysis. In this example, $W = 8$ so that $[-W/2, W/2] = [-4, 4]$. The extension has period $2W = 16$, is even about the points $x = \pm W/2 = \pm 4$ and their periodic counterparts, and is continuous. Generally, the first derivative is discontinuous at the points $x = \pm W/2 = \pm 4$ and their periodic counterparts.

$2W$ or $2H$, and are continuous. See, for example, Figure 5.1. They are therefore ideally suited to Fourier analysis over the extended intervals (5.7).

Now consider the functions

$$\cos[(x + W/2)(n\pi/W)] \text{ with } n = 0, 1, 2, \cdots \tag{17.5.8}$$

and the functions

$$\sin[(x + W/2)(n\pi/W)] \text{ with } n = 1, 2, \cdots . \tag{17.5.9}$$

They have period $2W$ and form a complete orthogonal set over the interval (5.5). Therefore $B_y^t(x, z)$ and $B_y^b(x, z)$, when extended as described above, can be expanded in terms of them. Note also that the cosine functions (5.8) are even about $x = W/2$ and the sine functions (5.9) are odd. Since (by construction) the extended $B_y^t(x, z)$ and $B_y^b(x, z)$ are even about $x = W/2$, it follows that only the cosine terms will appear in the Fourier expansion. Thus, we have the Fourier representations

$$B_y^t(x, z) = \sum_{n=0}^{\infty} \tilde{B}_y^t(n, z) \cos[(x + W/2)(n\pi/W)], \tag{17.5.10}$$

$$B_y^b(x, z) = \sum_{n=0}^{\infty} \tilde{B}_y^b(n, z) \cos[(x + W/2)(n\pi/W)], \tag{17.5.11}$$

where

$$\tilde{B}_y^t(0, z) = [1/(2W)] \int_{-W/2}^{3W/2} dx\ B_y^t(x, z) = (1/W) \int_{-W/2}^{W/2} dx\ B_y^t(x, z), \tag{17.5.12}$$

$$\begin{aligned} \tilde{B}_y^t(n, z) &= (1/W) \int_{-W/2}^{3W/2} dx\ B_y^t(x, z) \cos[(x + W/2)(n\pi/W)] \\ &= (2/W) \int_{-W/2}^{W/2} dx\ B_y^t(x, z) \cos[(x + W/2)(n\pi/W)] \text{ for } n > 0, \end{aligned} \tag{17.5.13}$$

$$\tilde{B}_y^b(0, z) = [1/(2W)] \int_{-W/2}^{3W/2} dx\ B_y^b(x, z) = (1/W) \int_{-W/2}^{W/2} dx\ B_y^b(x, z), \tag{17.5.14}$$

$$\begin{aligned} \tilde{B}_y^b(n, z) &= (1/W) \int_{-W/2}^{3W/2} dx\ B_y^b(x, z) \cos[(x + W/2)(n\pi/W)] \\ &= (2/W) \int_{-W/2}^{W/2} dx\ B_y^b(x, z) \cos[(x + W/2)(n\pi/W)] \text{ for } n > 0. \end{aligned} \tag{17.5.15}$$

Here we have used the fact that $B_y^t(x, z)$ and $B_y^b(x, z)$ and the cosine functions are even about $x = W/2$.

We have already seen that the fully extended $B_y^t(x, z)$ and $B_y^b(x, z)$ are continuous and periodic with period $2W$. However, they will generally not have continuous first derivatives across the joins at $x = \pm W/2$, $x = \pm 3W/2$, etc. It follows from standard Fourier analysis theory that the coefficients $\tilde{B}^t_y(n, z)$ and $\tilde{B}^b_y(n, z)$ must, in general, fall off like $1/n^2$,

$$\tilde{B}^t_y(n, z) \sim (1/n^2) \text{ as } n \to \infty, \text{ etc.} \tag{17.5.16}$$

Therefore the series (5.10) and (5.11) are point-wise absolutely, but not wonderfully, convergent. The slow falloff (5.16) is the price to be paid for working with a bounding surface that has sharp corners. By contrast, it can be shown that the analogous coefficients in the cases of circular and elliptic cylinders fall off much more rapidly, namely as $(1/\Lambda)^{|n|}$ for some $\Lambda > 1$. See Exercises 16.2.3 and 16.2.4.

In a similar way, we have the Fourier representations

$$B^\ell_x(y, z) = \sum_{n=0}^{\infty} \tilde{B}^\ell_y(n, z) \cos[(y + H/2)(n\pi/H)], \tag{17.5.17}$$

$$B^r_x(y, z) = \sum_{n=0}^{\infty} \tilde{B}^r_y(n, z) \cos[(y + H/2)(n\pi/H)], \tag{17.5.18}$$

where

$$\tilde{B}^\ell_x(0, z) = [1/(2H)] \int_{-H/2}^{3H/2} dy\; B^\ell_x(y, z) = (1/H) \int_{-H/2}^{H/2} dx\; B^\ell_x(y, z), \tag{17.5.19}$$

$$\begin{aligned} \tilde{B}^\ell_x(n, z) &= (1/H) \int_{-H/2}^{3H/2} dy\; B^\ell_x(y, z) \cos[(y + H/2)(n\pi/H)] \\ &= (2/H) \int_{-H/2}^{H/2} dy\; B^\ell_x(y, z) \cos[(y + H/2)(n\pi/H)] \text{ for } n > 0, \end{aligned} \tag{17.5.20}$$

$$\tilde{B}^r_x(0, z) = [1/(2H)] \int_{-H/2}^{3H/2} dy\; B^r_x(y, z) = (1/H) \int_{-H/2}^{H/2} dx\; B^r_x(y, z), \tag{17.5.21}$$

$$\begin{aligned} \tilde{B}^r_x(n, z) &= (1/H) \int_{-H/2}^{3H/2} dy\; B^r_x(y, z) \cos[(y + H/2)(n\pi/H)] \\ &= (2/H) \int_{-H/2}^{H/2} dy\; B^r_x(y, z) \cos[(y + H/2)(n\pi/H)] \text{ for } n > 0. \end{aligned} \tag{17.5.22}$$

To proceed further, we perform Fourier transforms in z. Thus, we make the definitions

$$\tilde{\tilde{B}}^t_y(n, k) = [1/(2\pi)] \int_{-\infty}^{\infty} dz\; \exp(-ikz) \tilde{B}^t_y(n, z), \tag{17.5.23}$$

$$\tilde{\tilde{B}}^b_y(n, k) = [1/(2\pi)] \int_{-\infty}^{\infty} dz\; \exp(-ikz) \tilde{B}^b_y(n, z), \tag{17.5.24}$$

$$\tilde{\tilde{B}}_x^{\ell}(n,k) = [1/(2\pi)]\int_{-\infty}^{\infty} dz\ \exp(-ikz)\tilde{B}_x^{\ell}(n,z), \tag{17.5.25}$$

$$\tilde{\tilde{B}}_x^{r}(n,k) = [1/(2\pi)]\int_{-\infty}^{\infty} dz\ \exp(-ikz)\tilde{B}_x^{r}(n,z), \tag{17.5.26}$$

Note that the various $\tilde{B}$ terms on the right sides of (5.23) through (5.26) are real. It follows that the real parts of the various $\tilde{\tilde{B}}$ terms on the left sides of (5.23) through (5.26) are even in k, and the imaginary parts are odd in k.

With these definitions in hand, we are ready to determine the scalar potential $\psi(x,y,z)$ in terms of surface field values. First we note, as is easily checked, that functions of the form

$$\exp(ikz)\cos[(x+W/2)(n\pi/W)]\cosh[\sigma_n(y \pm H/2)] \tag{17.5.27}$$

and

$$\exp(ikz)\cos[(y+H/2)(n\pi/H)]\cosh[\tau_n(x \pm W/2)], \tag{17.5.28}$$

where

$$\sigma_n = [k^2 + (n\pi/W)^2]^{1/2} \tag{17.5.29}$$

and

$$\tau_n = [k^2 + (n\pi/H)^2]^{1/2}, \tag{17.5.30}$$

satisfy Laplace's equation. Next define functions $\psi^t(x,y,z)$, $\psi^b(x,y,z)$, $\psi^{\ell}(x,y,z)$, and $\psi^r(x,y,z)$ by the relations

$$\psi^t(x,y,z) = \int_{-\infty}^{\infty} dk \exp(ikz)\sum_{n=0}^{\infty}\frac{\tilde{\tilde{B}}_y^{t}(n,k)\cos[(x+W/2)(n\pi/W)]\cosh[\sigma_n(y+H/2)]}{\sigma_n\sinh(H\sigma_n)}, \tag{17.5.31}$$

$$\psi^b(x,y,z) = \int_{-\infty}^{\infty} dk \exp(ikz)\sum_{n=0}^{\infty}\frac{\tilde{\tilde{B}}_y^{b}(n,k)\cos[(x+W/2)(n\pi/W)]\cosh[\sigma_n(y-H/2)]}{\sigma_n\sinh(H\sigma_n)}, \tag{17.5.32}$$

$$\psi^{\ell}(x,y,z) = \int_{-\infty}^{\infty} dk \exp(ikz)\sum_{n=0}^{\infty}\frac{\tilde{\tilde{B}}_y^{\ell}(n,k)\cos[(y+H/2)(n\pi/H)]\cosh[\tau_n(x+W/2)]}{\tau_n\sinh(W\tau_n)}, \tag{17.5.33}$$

$$\psi^{r}(x,y,z) = \int_{-\infty}^{\infty} dk \exp(ikz)\sum_{n=0}^{\infty}\frac{\tilde{\tilde{B}}_y^{r}(n,k)\cos[(y+H/2)(n\pi/H)]\cosh[\tau_n(x-W/2)]}{\tau_n\sinh(W\tau_n)}. \tag{17.5.34}$$

Evidently by construction they all satisfy Laplace's equation.

Now watch closely: From the definition (5.31) we have the result

$$\partial\psi^t(x,y,z)/\partial x = -\int_{-\infty}^{\infty} dk \exp(ikz)\sum_{n=0}^{\infty}\frac{\tilde{\tilde{B}}_y^{t}(n,k)(n\pi/W)\sin[(x+W/2)(n\pi/W)]\cosh[\sigma_n(y+H/2)]}{\sigma_n\sinh(H\sigma_n)}. \tag{17.5.35}$$

[Note that we may interchange summation and differentiation: the series (5.31) converges absolutely and uniformly due to the $\sigma_n \sinh(H\sigma_n)$ denominator.] It follows that

$$[\partial\psi^t(x,y,z)/\partial x]|_{x=\pm W/2} = 0. \tag{17.5.36}$$

Similarly, we find that

$$[\partial\psi^b(x,y,z)/\partial x]|_{x=\pm W/2} = 0. \tag{17.5.37}$$

Also from (5.31) we find that

$$\partial\psi^t(x,y,z)/\partial y =$$
$$\int_{-\infty}^{\infty} dk\exp(ikz)\sum_{n=0}^{\infty}\frac{\tilde{\tilde{B}}{}_y^t(n,k)\cos[(x+W/2)(n\pi/W)]\sinh[\sigma_n(y+H/2)]}{\sinh(H\sigma_n)}. \tag{17.5.38}$$

It follows that

$$[\partial\psi^t(x,y,z)/\partial y]|_{y=-H/2} = 0 \tag{17.5.39}$$

and

$$\begin{aligned}
[\partial\psi^t(x,y,z)/\partial y]|_{y=H/2} &= \int_{-\infty}^{\infty} dk\exp(ikz)\sum_{n=0}^{\infty}\tilde{\tilde{B}}{}_y^t(n,k)\cos[(x+W/2)(n\pi/W)] \\
&= \sum_{n=0}^{\infty}\tilde{B}_y^t(n,z)\cos[(x+W/2)(n\pi/W)] \\
&= B_y^t(x,z).
\end{aligned} \tag{17.5.40}$$

Similarly, we find that

$$[\partial\psi^b(x,y,z)/\partial y]|_{y=H/2} = 0 \tag{17.5.41}$$

and

$$\begin{aligned}
[\partial\psi^b(x,y,z)/\partial y]|_{y=-H/2} &= \int_{-\infty}^{\infty} dk\exp(ikz)\sum_{n=0}^{\infty}\tilde{\tilde{B}}{}_y^b(n,k)\cos[(x+W/2)(n\pi/W)] \\
&= \sum_{n=0}^{\infty}\tilde{B}_y^b(n,z)\cos[(x+W/2)(n\pi/W)] \\
&= B_y^b(x,z).
\end{aligned} \tag{17.5.42}$$

Finally, analogous results hold for $\psi^\ell(x,y,z)$ and $\psi^r(x,y,z)$. They satisfy the relations

$$[\partial\psi^\ell(x,y,z)/\partial y]|_{y=\pm H/2} = 0, \tag{17.5.43}$$

$$[\partial\psi^r(x,y,z)/\partial y]|_{y=\pm H/2} = 0, \tag{17.5.44}$$

$$[\partial\psi^\ell(x,y,z)/\partial x]|_{x=W/2} = 0, \tag{17.5.45}$$

$$[\partial\psi^\ell(x,y,z)/\partial x]|_{x=-W/2} = B_x^\ell(y,z), \tag{17.5.46}$$

$$[\partial\psi^r(x,y,z)/\partial x]|_{x=-W/2} = 0, \tag{17.5.47}$$

$$[\partial\psi^r(x,y,z)/\partial x]|_{x=W/2} = B_x^r(y,z). \tag{17.5.48}$$

At last we are ready to construct $\psi(x,y,z)$. We make the definition

$$\psi(x,y,z) = \psi^t(x,y,z) + \psi^b(x,y,z) + \psi^\ell(x,y,z) + \psi^r(x,y,z). \tag{17.5.49}$$

Evidently this ψ satisfies Laplace's equation. Also we find that

$$\begin{aligned}&[\partial\psi(x,y,z)/\partial y]|_{y=H/2} = \\ &[\partial\psi^t(x,y,z)/\partial y]|_{y=H/2} + [\partial\psi^b(x,y,z)/\partial y]|_{y=H/2} \\ &+[\partial\psi^\ell(x,y,z)/\partial y]|_{y=H/2} + [\partial\psi^r(x,y,z)/\partial y]|_{y=H/2} \\ &= B_y^t(x,z).\end{aligned} \tag{17.5.50}$$

Here we have used (5.35) through (5.48). Similarly we find that

$$[\partial\psi(x,y,z)/\partial y]|_{y=-H/2} = B_y^b(x,z), \tag{17.5.51}$$

$$[\partial\psi(x,y,z)/\partial x]|_{x=-W/2} = B_x^\ell(y,z), \tag{17.5.52}$$

$$[\partial\psi(x,y,z)/\partial x]|_{x=W/2} = B_x^r(y,z). \tag{17.5.53}$$

Thus ψ satisfies the required boundary conditions on all four surfaces. Finally, observe that the quantities appearing on the right sides of (5.31) through (5.34) are *entire* functions of x, y, and z. Now suppose that x, y have values corresponding to a point *inside* the cylinder. Then, thanks to the denominators appearing on the right sides of (5.31) through (5.34), the integrals and sums are rapidly convergent. It follows that $\psi(x,y,z)$ is *analytic* in x, y, z for all points within the cylinder.

17.5.2 Finding the On-Axis Gradients

The remaining task is to determine the on-axis gradients by finding the cylindrical harmonic expansion for ψ as given by (5.31) through (5.34) and (5.49). In analogy to the case of the elliptical cylinder, this will be done with the aid of what may be called *Fourier-Bessel connection coefficients*. Namely, there are the formulas

$$\begin{aligned}&\cos[(x+W/2)(j\pi/W)]\cosh[\sigma_j(y+H/2)] = \\ &\sum_{m=0}^{\infty} d_{mj}^{tc}(k) I_m(k\rho)\cos(m\phi) + \sum_{m=1}^{\infty} d_{mj}^{ts}(k) I_m(k\rho)\sin(m\phi),\end{aligned} \tag{17.5.54}$$

$$\begin{aligned}&\cos[(x+W/2)(j\pi/W)]\cosh[\sigma_j(y-H/2)] = \\ &\sum_{m=0}^{\infty} d_{mj}^{bc}(k) I_m(k\rho)\cos(m\phi) + \sum_{m=1}^{\infty} d_{mj}^{bs}(k) I_m(k\rho)\sin(m\phi),\end{aligned} \tag{17.5.55}$$

$$\begin{aligned}&\cos[(y+H/2)(j\pi/H)]\cosh[\tau_j(x+W/2)] = \\ &\sum_{m=0}^{\infty} d_{mj}^{\ell c}(k) I_m(k\rho)\cos(m\phi) + \sum_{m=1}^{\infty} d_{mj}^{\ell s}(k) I_m(k\rho)\sin(m\phi),\end{aligned} \tag{17.5.56}$$

$$\cos[(y+H/2)(j\pi/H)]\cosh[\tau_j(x-W/2)] =$$
$$\sum_{m=0}^{\infty} d_{mj}^{rc}(k) I_m(k\rho)\cos(m\phi) + \sum_{m=1}^{\infty} d_{mj}^{rs}(k) I_m(k\rho)\sin(m\phi). \tag{17.5.57}$$

We will derive them shortly. Before doing so, we will use them to find the on-axis gradients. Suppose we employ (5.54) in (5.31). Doing so gives the result

$$\psi^t(x,y,z) = \sum_{m=0}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz) I_m(k\rho)\cos(m\phi)\sum_{j=0}^{\infty}\frac{d_{mj}^{tc}(k)\tilde{\tilde{B}}_y^t(j,k)}{\sigma_j\sinh(H\sigma_j)}$$
$$+\sum_{m=1}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz) I_m(k\rho)\sin(m\phi)\sum_{j=0}^{\infty}\frac{d_{mj}^{ts}(k)\tilde{\tilde{B}}_y^t(j,k)}{\sigma_j\sinh(H\sigma_j)}. \tag{17.5.58}$$

Similarly, we find the relations

$$\psi^b(x,y,z) = \sum_{m=0}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz) I_m(k\rho)\cos(m\phi)\sum_{j=0}^{\infty}\frac{d_{mj}^{bc}(k)\tilde{\tilde{B}}_y^b(j,k)}{\sigma_j\sinh(H\sigma_j)}$$
$$+\sum_{m=1}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz) I_m(k\rho)\sin(m\phi)\sum_{j=0}^{\infty}\frac{d_{mj}^{bs}(k)\tilde{\tilde{B}}_y^b(j,k)}{\sigma_j\sinh(H\sigma_j)}, \tag{17.5.59}$$

$$\psi^\ell(x,y,z) = \sum_{m=0}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz) I_m(k\rho)\cos(m\phi)\sum_{j=0}^{\infty}\frac{d_{mj}^{\ell c}(k)\tilde{\tilde{B}}_y^\ell(j,k)}{\tau_j\sinh(W\tau_j)}$$
$$+\sum_{m=1}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz) I_m(k\rho)\sin(m\phi)\sum_{j=0}^{\infty}\frac{d_{mj}^{\ell s}(k)\tilde{\tilde{B}}_y^\ell(j,k)}{\tau_j\sinh(W\tau_j)}, \tag{17.5.60}$$

$$\psi^r(x,y,z) = \sum_{m=0}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz) I_m(k\rho)\cos(m\phi)\sum_{j=0}^{\infty}\frac{d_{mj}^{rc}(k)\tilde{\tilde{B}}_y^r(j,k)}{\tau_j\sinh(W\tau_j)}$$
$$+\sum_{m=1}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz) I_m(k\rho)\sin(m\phi)\sum_{j=0}^{\infty}\frac{c_{mj}^{rs}(k)\tilde{\tilde{B}}_y^r(j,k)}{\tau_j\sinh(W\tau_j)}. \tag{17.5.61}$$

It follows that ψ can be written in the form

$$\psi(x,y,z) = \sum_{m=0}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz) I_m(k\rho)\cos(m\phi) G_{m,c}(k)$$
$$+\sum_{m=1}^{\infty}\int_{-\infty}^{\infty} dk\ \exp(ikz) I_m(k\rho)\sin(m\phi) G_{m,s}(k) \tag{17.5.62}$$

where

$$G_{m,c}(k) = \sum_{j=0}^{\infty}[\frac{d^{tc}_{mj}(k)\tilde{\tilde{B}}^{t}_y(j,k) + d^{bc}_{mj}(k)\tilde{\tilde{B}}^{b}_y(j,k)}{\sigma_j \sinh(H\sigma_j)} + \frac{d^{\ell c}_{mj}(k)\tilde{\tilde{B}}^{\ell}_y(j,k) + d^{rc}_{mj}(k)\tilde{\tilde{B}}^{r}_y(j,k)}{\tau_j \sinh(W\tau_j)}], \tag{17.5.63}$$

$$G_{m,s}(k) = \sum_{j=0}^{\infty}[\frac{d^{ts}_{mj}(k)\tilde{\tilde{B}}^{t}_y(j,k) + d^{bs}_{mj}(k)\tilde{\tilde{B}}^{b}_y(j,k)}{\sigma_j \sinh(H\sigma_j)} + \frac{d^{\ell s}_{mj}(k)\tilde{\tilde{B}}^{\ell}_y(j,k) + d^{rs}_{mj}(k)\tilde{\tilde{B}}^{r}_y(j,k)}{\tau_j \sinh(W\tau_j)}]. \tag{17.5.64}$$

We remark that it can be shown that the real parts of the $G_{m,\alpha}$ are even in k, and the imaginary parts are odd in k. See Exercise 5.2. Finally, in view of (14.2.55) and (14.2.56), we have the desired results

$$C^{[n]}_{m,c}(z) = i^n(1/2)^m(1/m!)\int_{-\infty}^{\infty} dk \exp(ikz)k^{n+m}G_{m,c}(k), \tag{17.5.65}$$

$$C^{[n]}_{m,s}(z) = i^n(1/2)^m(1/m!)\int_{-\infty}^{\infty} dk \exp(ikz)k^{n+m}G_{m,s}(k). \tag{17.5.66}$$

We have found expressions for the generalized gradients in terms of field data (normal component) on the surface of a rectangular cylinder. These results hold for the cases $m \geq 1$. When $m = 0$ there are the results

$$C^{[n]}_{m=0,c}(z) \quad = \quad C^{[n]}_0(z) = i^n \int_{-\infty}^{\infty} dk \exp(ikz)k^n G_{0,c}(k), \tag{17.5.67}$$

$$C^{[n]}_{m=0,s}(z) = 0. \tag{17.5.68}$$

Just as in the $m = 0$ case for the circular and elliptical cylinder, in the rectangular case it may also be better to derive and employ formulas based on the tangential component B_z rather than the normal component. See Section 18.2.

17.5.3 Fourier-Bessel Connection Coefficients

The purpose of this subsection is to derive the Fourier-Bessel connection coefficients postulated in (5.54) through (5.57). We will do so in pieces. First, recall the Bessel generating-function relation

$$\begin{aligned}\exp[z\cos(\theta)] \quad &= \quad I_0(z) + 2\sum_{m=1}^{\infty}\cos(m\theta)I_m(z) \\ &= \quad \sum_{m=-\infty}^{\infty}\exp(im\theta)I_m(z).\end{aligned} \tag{17.5.69}$$

Here we have again employed (14.2.12). Second, we have been taught from the cradle that circular and hyperbolic functions, which appear on the left sides of (5.54) through (5.57), are made of exponential functions. We will see that the combinations of these exponential functions that occur in (5.54) through (5.57) can in turn be written in a form that enables the use of (5.69).

Begin with (5.54), whose left side can be written in the expanded form

$$\begin{aligned}&\cos[(x+W/2)(j\pi/W)]\cosh[\sigma_j(y+H/2)] = (1/4)\times\\ &\{\exp[i(x+W/2)(j\pi/W)]+\exp[-i(x+W/2)(j\pi/W)]\}\times\\ &\{\exp[\sigma_j(y+H/2)]+\exp[-\sigma_j(y+H/2)]\}.\end{aligned} \tag{17.5.70}$$

Multiplying out the factors that occur on the right side of (5.70) produces a sum of four terms:

$$\begin{aligned}&\cos[(x+W/2)(j\pi/W)]\cosh[\sigma_j(y+H/2)] = (1/4)\times\\ &[(i)^j\exp(\sigma_jH/2)\exp(ij\pi x/W)\exp(\sigma_jy)+\\ &(i)^j\exp(-\sigma_jH/2)\exp(ij\pi x/W)\exp(-\sigma_jy)+\\ &(-i)^j\exp(\sigma_jH/2)\exp(-ij\pi x/W)\exp(\sigma_jy)+\\ &(-i)^j\exp(-\sigma_jH/2)\exp(-ij\pi x/W)\exp(-\sigma_jy)].\end{aligned} \tag{17.5.71}$$

Here we have used the the result

$$\exp[(\pm iW/2)(j\pi/W)] = \exp(\pm ij\pi/2) = (\pm i)^j. \tag{17.5.72}$$

We see that we have to deal with products of the form $\exp(\pm ij\pi x/W)\exp(\pm\sigma_jy)$ where the signs are to be taken independently. We will treat each of these four possibilities separately.

For the ++ possibility we write

$$\exp(ij\pi x/W)\exp(\sigma_jy) = \exp(ij\pi x/W+\sigma_jy) = \exp[(ij\pi\rho/W)\cos\phi+(\rho\sigma_j)\sin\phi]. \tag{17.5.73}$$

Here we have made the substitutions (14.2.3) and (14.2.4). Next recall the identity

$$\cos(\phi+\psi) = \cos\psi\cos\phi - \sin\psi\sin\phi. \tag{17.5.74}$$

Let us write the argument appearing on the right side of (5.73) in the form

$$(ij\pi\rho/W)\cos\phi + (\rho\sigma_j)\sin\phi = \lambda\cos(\phi+\psi) = \lambda\cos\psi\cos\phi - \lambda\sin\psi\sin\phi \tag{17.5.75}$$

where λ, $\sin\psi$, and $\cos\psi$ are yet to be determined. Equating like terms in ϕ yields the relations

$$\lambda\cos\psi = ij\pi\rho/W, \tag{17.5.76}$$

$$\lambda\sin\psi = -\rho\sigma_j. \tag{17.5.77}$$

Now square both sides of (5.76) and (5.77) and add the results to obtain the relation

$$\lambda^2 = \rho^2[-(j\pi/W)^2+\sigma_j^2] = (k\rho)^2. \tag{17.5.78}$$

Here we have used (5.29). It follows that

$$\lambda = k\rho, \tag{17.5.79}$$

and we may also write

$$\cos\psi = ij\pi/(kW), \tag{17.5.80}$$

$$\sin\psi = -\sigma_j/k. \tag{17.5.81}$$

For future use, we invoke Euler to write

$$\exp(i\psi) = \cos\psi + i\sin\psi = ij\pi/(kW) - i\sigma_j/k = (i/k)(j\pi/W - \sigma_j), \tag{17.5.82}$$

$$\exp(-i\psi) = \cos\psi - i\sin\psi = ij\pi/(kW) + i\sigma_j/k = (i/k)(j\pi/W + \sigma_j). \tag{17.5.83}$$

Finally employing (5.79), first in (5.75) and then in (5.73), yields the results

$$(ij\pi\rho/W)\cos\phi + (\rho\sigma_j)\sin\phi = k\rho\cos(\phi + \psi) \tag{17.5.84}$$

and

$$\exp(ij\pi x/W)\exp(\sigma_j y) = \exp[k\rho\cos(\phi + \psi)]. \tag{17.5.85}$$

We next deal with the other sign possibilities. Consider the substitutions $\phi \rightarrow -\phi$, $\phi \rightarrow \phi + \pi$, and $\phi \rightarrow \pi - \phi$. It is readily verified from (14.2.3) and (14.2.4) that these substitutions correspond to the following substitutions in x and y:

$$\phi \rightarrow -\phi \Longleftrightarrow x \rightarrow x, y \rightarrow -y; \tag{17.5.86}$$

$$\phi \rightarrow \phi + \pi \Longleftrightarrow x \rightarrow -x, y \rightarrow -y; \tag{17.5.87}$$

$$\phi \rightarrow \pi - \phi \Longleftrightarrow x \rightarrow -x, y \rightarrow y. \tag{17.5.88}$$

Therefore, from (5.85), we find the results

$$\exp(ij\pi x/W)\exp(-\sigma_j y) = \exp[k\rho\cos(-\phi + \psi)] = \exp[k\rho\cos(\phi - \psi)], \tag{17.5.89}$$

$$\exp(-ij\pi x/W)\exp(\sigma_j y) = \exp[k\rho\cos(\pi - \phi + \psi)] = \exp[k\rho\cos(\phi - \psi - \pi)], \tag{17.5.90}$$

$$\exp(-ij\pi x/W)\exp(-\sigma_j y) = \exp[k\rho\cos(\phi + \psi + \pi)]. \tag{17.5.91}$$

Let us now see how the results for the products $\exp(\pm ij\pi x/W)\exp(\pm\sigma_j y)$, as given by (5.85) and (5.89) through (5.91), can be used in conjunction with (5.69). For the ++ case use of (5.69) and (5.85) gives the result

$$\begin{aligned} &\exp(ij\pi x/W)\exp(\sigma_j y) = \exp[k\rho\cos(\phi + \psi)] = \\ &\sum_{m=-\infty}^{\infty} \exp[im(\phi + \psi)] I_m(k\rho) = \\ &\sum_{m=-\infty}^{\infty} \exp(im\psi)\exp(im\phi) I_m(k\rho) = \\ &\sum_{m=-\infty}^{\infty} (i/k)^m (j\pi/W - \sigma_j)^m \exp(im\phi) I_m(k\rho). \end{aligned} \tag{17.5.92}$$

Here we have also used (5.82). Similarly, for the remaining cases, we find the results

$$\begin{aligned}&\exp(ij\pi x/W)\exp(-\sigma_j y) = \exp[k\rho\cos(\phi-\psi)] = \\ ,\quad &\sum_{m=-\infty}^{\infty}\exp(-im\psi)\exp(im\phi)I_m(k\rho) = \\ &\sum_{m=-\infty}^{\infty}(i/k)^m(j\pi/W+\sigma_j)^m\exp(im\phi)I_m(k\rho),\end{aligned} \tag{17.5.93}$$

$$\begin{aligned}&\exp(-ij\pi x/W)\exp(\sigma_j y) = \exp[k\rho\cos(\phi-\psi-\pi)] = \\ &\sum_{m=-\infty}^{\infty}\exp(-im\pi)\exp(-im\psi)\exp(im\phi)I_m(k\rho) = \\ &\sum_{m=-\infty}^{\infty}(-1)^m(i/k)^m(j\pi/W+\sigma_j)^m\exp(im\phi)I_m(k\rho),\end{aligned} \tag{17.5.94}$$

$$\begin{aligned}&\exp(-ij\pi x/W)\exp(-\sigma_j y) = \exp[k\rho\cos(\phi+\psi+\pi)] = \\ &\sum_{m=-\infty}^{\infty}\exp(im\pi)\exp(im\psi)\exp(im\phi)I_m(k\rho) = \\ &\sum_{m=-\infty}^{\infty}(-1)^m(i/k)^m(j\pi/W-\sigma_j)^m\exp(im\phi)I_m(k\rho).\end{aligned} \tag{17.5.95}$$

Bessel expansions have now been obtained for all the various pieces that result from expanding in exponentials the terms on the left side of (5.54). We now combine them to find a Bessel expansion for the left side of (5.54). From (5.71) and (5.92) through (5.95), we find the result

$$\begin{aligned}&\cos[(x+W/2)(j\pi/W)]\cosh[\sigma_j(y+H/2)] = \\ &\sum_{m=-\infty}^{\infty}d^t_{mj}(k)I_m(k\rho)\exp(im\phi)\end{aligned} \tag{17.5.96}$$

where

$$\begin{aligned}d^t_{mj}(k) &= (1/4)(i)^{j+m}\{[(j\pi/W-\sigma_j)/k]^m + (-1)^{j+m}[(j\pi/W+\sigma_j)/k]^m\}\exp(\sigma_j H/2) \\ &+ (1/4)(i)^{j+m}\{[(j\pi/W+\sigma_j)/k]^m + (-1)^{j+m}[(j\pi/W-\sigma_j)/k]^m\}\exp(-\sigma_j H/2).\end{aligned} \tag{17.5.97}$$

Upon comparing (5.54) and (5.96) we see that for $m \geq 1$ there are the relations

$$d^{tc}_{mj} = d^t_{mj} + d^t_{-mj}, \tag{17.5.98}$$

$$d^{ts}_{mj} = id^t_{mj} - id^t_{-mj}. \tag{17.5.99}$$

And for $m = 0$ there is the result

$$d^{tc}_{0j} = d^{t}_{0j}, \tag{17.5.100}$$

$$d^{ts}_{0j} = 0. \tag{17.5.101}$$

Let us first deal with the simplest case, that for $m = 0$. Use of (5.97) then gives the result

$$\begin{aligned} d^{t}_{0j}(k) &= (1/4)(i)^{j}\{[1 + (-1)^{j}\}\exp(\sigma_j H/2) \\ &+ (1/4)(i)^{j}\{[1 + (-1)^{j}\}\exp(-\sigma_j H/2). \end{aligned} \tag{17.5.102}$$

Therefore, for $m = 0$, we conclude that

$$d^{tc}_{0j} = 0 \text{ for } j \text{ odd}, \tag{17.5.103}$$

$$d^{tc}_{0j} = (-1)^{j/2}\cosh(\sigma_j H/2) \text{ for } j \text{ even}. \tag{17.5.104}$$

Now tackle the more complicated case $m \geq 1$. Note that there is the relation

$$[(j\pi/W - \sigma_j)/k][(j\pi/W + \sigma_j)/k] = [(j\pi/W)^2 - (\sigma_j^2)]/k^2 = -k^2/k^2 = -1. \tag{17.5.105}$$

Here we have again used (5.29). Consequently, we find that

$$\begin{aligned} d^{t}_{-mj}(k) &= (1/4)(i)^{j-m}\{[(j\pi/W - \sigma_j)/k]^{-m} + (-1)^{j-m}[(j\pi/W + \sigma_j)/k]^{-m}\}\exp(\sigma_j H/2) \\ &+ (1/4)(i)^{j-m}\{[(j\pi/W + \sigma_j)/k]^{-m} + (-1)^{j-m}[(j\pi/W - \sigma_j)/k]^{-m}\}\exp(-\sigma_j H/2) \\ &= (1/4)(i)^{j-m}(-1)^{m}\{[(j\pi/W + \sigma_j)/k]^{m} + (-1)^{j-m}[(j\pi/W - \sigma_j)/k]^{m}\}\exp(\sigma_j H/2) \\ &+ (1/4)(i)^{j-m}(-1)^{m}\{[(j\pi/W - \sigma_j)/k]^{m} + (-1)^{j-m}[(j\pi/W + \sigma_j)/k]^{m}\}\exp(-\sigma_j H/2). \end{aligned} \tag{17.5.106}$$

We also note that

$$(i)^{j-m}(-1)^{m} = (i)^{j-m}(i)^{2m} = (i)^{j+m} \tag{17.5.107}$$

and

$$(-1)^{j-m} = (-1)^{2m}(-1)^{j-m} = (-1)^{j+m}. \tag{17.5.108}$$

Therefore, we may also write

$$\begin{aligned} d^{t}_{-mj}(k) &= (1/4)(i)^{j+m}\{[(j\pi/W + \sigma_j)/k]^{m} + (-1)^{j+m}[(j\pi/W - \sigma_j)/k]^{m}\}\exp(\sigma_j H/2) \\ &+ (1/4)(i)^{j+m}\{[(j\pi/W - \sigma_j)/k]^{m} + (-1)^{j+m}[(j\pi/W + \sigma_j)/k]^{m}\}\exp(-\sigma_j H/2). \end{aligned} \tag{17.5.109}$$

Let us now compute $d^{tc}_{mj}(k)$. It follows from (5.97), (5.98), and (5.109) that for $m \geq 1$ there is the result

$$\begin{aligned} d^{tc}_{mj}(k) &= (1/4)(i)^{j+m}[1 + (-1)^{j+m}] \times \\ &\quad \{[(j\pi/W - \sigma_j)/k]^{m} + [(j\pi/W + \sigma_j)/k]^{m}\}\exp(\sigma_j H/2) \\ &+ (1/4)(i)^{j+m}[1 + (-1)^{j+m}] \times \\ &\quad \{[(j\pi/W + \sigma_j)/k]^{m} + [(j\pi/W - \sigma_j)/k]^{m}\}\exp(-\sigma_j H/2) \\ &= (1/2)(i)^{j+m}[1 + (-1)^{j+m}] \times \\ &\quad \{[(j\pi/W - \sigma_j)/k]^{m} + [(j\pi/W + \sigma_j)/k]^{m}\}\cosh(\sigma_j H/2). \end{aligned} \tag{17.5.110}$$

Therefore, when $(j+m)$ is odd,

$$d^{tc}_{mj} = 0. \tag{17.5.111}$$

And, when $(j+m)$ is even,

$$d^{tc}_{mj} = (-1)^{(j+m)/2}\{[(j\pi/W - \sigma_j)/k]^m + [(j\pi/W + \sigma_j)/k]^m\}\cosh(\sigma_j H/2). \tag{17.5.112}$$

Finally, let us compute d^{ts}_{mj}. It follows from (5.97), (5.99), and (5.109) that for $m \geq 1$ there is the result

$$\begin{aligned} d^{ts}_{mj}(k) &= (1/4)i(i)^{j+m}[1-(-1)^{j+m}] \times \\ &\quad \{[(j\pi/W - \sigma_j)/k]^m - [(j\pi/W + \sigma_j)/k]^m\}\exp(\sigma_j H/2) \\ &+ (1/4)i(i)^{j+m}[1-(-1)^{j+m}] \times \\ &\quad \{[(j\pi/W + \sigma_j)/k]^m - [(j\pi/W - \sigma_j)/k]^m\}\exp(-\sigma_j H/2) \\ &= (1/2)i(i)^{j+m}[1-(-1)^{j+m}] \times \\ &\quad \{[(j\pi/W - \sigma_j)/k]^m - [(j\pi/W + \sigma_j)/k]^m\}\sinh(\sigma_j H/2). \end{aligned} \tag{17.5.113}$$

Therefore, when $(j+m)$ is even,

$$d^{ts}_{mj} = 0. \tag{17.5.114}$$

And, when $(j+m)$ is odd,

$$d^{ts}_{mj} = (-1)^{(j+m+1)/2}\{[(j\pi/W - \sigma_j)/k]^m - [(j\pi/W + \sigma_j)/k]^m\}\sinh(\sigma_j H/2). \tag{17.5.115}$$

We have found the Fourier-Bessel coefficients $d^{t\alpha}_{mj}(k)$. Next observe that the left sides of (5.54) and (5.55) are interchanged under the substitution $H \leftrightarrow -H$. Therefore, for $m \geq 1$, there are also the relations

$$d^{bc}_{mj} = d^{tc}_{mj}, \tag{17.5.116}$$

$$d^{bs}_{mj} = -d^{ts}_{mj}. \tag{17.5.117}$$

And for $m = 0$ there are the results

$$d^{bc}_{0j} = d^{tc}_{0j}, \tag{17.5.118}$$

$$d^{bs}_{0j} = 0. \tag{17.5.119}$$

Analogous calculations can be made to find Bessel expansions for the right sides of (5.56) and (5.57). Instead, for variety, we will take a different approach that utilizes results already obtained. Consider the relation (5.54). Using (14.2.3) and (14.2.4) we may rewrite it in the form

$$\begin{gathered} \cos\{[\rho\cos(\phi) + W/2][j\pi/W]\}\cosh\{\sigma_j[\rho\sin(\phi) + H/2]\} = \\ \sum_{m=0}^{\infty} d^{tc}_{mj}(k) I_m(k\rho)\cos(m\phi) + \sum_{m=1}^{\infty} d^{ts}_{mj}(k) I_m(k\rho)\sin(m\phi). \end{gathered} \tag{17.5.120}$$

Now make the substitution $\phi \to \phi + \pi/2$. So doing gives the result

$$\begin{gathered} \cos\{[\rho\cos(\phi+\pi/2) + W/2][j\pi/W]\}\cosh\{\sigma_j[\rho\sin(\phi+\pi/2) + H/2]\} = \\ \sum_{m=0}^{\infty} d^{tc}_{mj}(k) I_m(k\rho)\cos[m(\phi+\pi/2)] + \sum_{m=1}^{\infty} d^{ts}_{mj}(k) I_m(k\rho)\sin[m(\phi+\pi/2)]. \end{gathered} \tag{17.5.121}$$

Next employ the identities

$$\rho\cos(\phi+\pi/2) = -\rho\sin(\phi) = -y, \tag{17.5.122}$$

$$\rho\sin(\phi+\pi/2) = \rho\cos(\phi) = x, \tag{17.5.123}$$

$$\cos[m(\phi+\pi/2)] = \cos(m\phi)\cos(m\pi/2) - \sin(m\phi)\sin(m\pi/2), \tag{17.5.124}$$

$$\sin[m(\phi+\pi/2)] = \sin(m\phi)\cos(m\pi/2) + \cos(m\phi)\sin(m\pi/2). \tag{17.5.125}$$

We see that (5.120) can be rewritten in the form

$$\begin{aligned}&\cos\{[-y+W/2][j\pi/W]\}\cosh\{\sigma_j[x+H/2]\} = \\ &\sum_{m=0}^{\infty} D^c_{mj}(k)I_m(k\rho)\cos(m\phi) + \sum_{m=1}^{\infty} D^s_{mj}(k)I_m(k\rho)\sin(m\phi)\end{aligned} \tag{17.5.126}$$

where

$$D^c_{mj}(k) = d^{tc}_{mj}(k)\cos(m\pi/2) + d^{ts}_{mj}(k)\sin(m\pi/2), \tag{17.5.127}$$

$$D^s_{mj}(k) = -d^{tc}_{mj}(k)\sin(m\pi/2) + d^{ts}_{mj}(k)\cos(m\pi/2). \tag{17.5.128}$$

Now employ the already known results (5.101), (5.103), (5.104), (5.111), (5.112), (5.114), and (5.115). First, for $m=0$, we find the relations

$$D^c_{0j}(k) = d^{tc}_{0j} = (-1)^{j/2}\cosh(\sigma_j H/2) \text{ for } j \text{ even}, \tag{17.5.129}$$

$$D^c_{0j}(k) = d^{tc}_{0j} = 0 \text{ for } j \text{ odd}, \tag{17.5.130}$$

$$D^s_{0j}(k) = d^{ts}_{0j} = 0. \tag{17.5.131}$$

For the remaining $D^\alpha_{mj}(k)$ we must distinguish the cases $(j+m)$ odd and even. When $(j+m)$ is odd we find the results

$$\begin{aligned}&D^c_{mj}(k) = d^{ts}_{mj}(k)\sin(m\pi/2) \\ &= (-1)^{(j+m+1)/2}\sin(m\pi/2)\{[(j\pi/W-\sigma_j)/k]^m - [(j\pi/W+\sigma_j)/k]^m\}\sinh(\sigma_j H/2),\end{aligned} \tag{17.5.132}$$

$$\begin{aligned}&D^s_{mj}(k) = d^{ts}_{mj}(k)\cos(m\pi/2) \\ &= (-1)^{(j+m+1)/2}\cos(m\pi/2)\{[(j\pi/W-\sigma_j)/k]^m - [(j\pi/W+\sigma_j)/k]^m\}\sinh(\sigma_j H/2).\end{aligned} \tag{17.5.133}$$

And, when $(j+m)$ is even, we find the results

$$\begin{aligned}&D^c_{mj}(k) = d^{tc}_{mj}(k)\cos(m\pi/2) \\ &= (-1)^{(j+m)/2}\cos(m\pi/2)\{[(j\pi/W-\sigma_j)/k]^m + [(j\pi/W+\sigma_j)/k]^m\}\cosh(\sigma_j H/2),\end{aligned} \tag{17.5.134}$$

$$\begin{aligned} D^{s}_{mj}(k) &= -d^{tc}_{mj}(k)\sin(m\pi/2) \\ &= (-1)^{(j+m)/2}\sin(m\pi/2)\{[(j\pi/W-\sigma_j)/k]^m+[(j\pi/W+\sigma_j)/k]^m\}\cosh(\sigma_j H/2). \end{aligned} \tag{17.5.135}$$

For the penultimate step, compare the left side of (5.126) with the left side of (5.56). We see that the first is transformed into the second under the substitutions $W \to -H$, $\sigma_j \to \tau_j$, and $H \to W$. It follows that there are the relations

$$d^{\ell c}_{0j} = (-1)^{j/2}\cosh(\tau_j W/2) \text{ for } j \text{ even}, \tag{17.5.136}$$

$$d^{\ell c}_{0j} = 0 \text{ for } j \text{ odd}, \tag{17.5.137}$$

$$d^{\ell s}_{0j} = 0. \tag{17.5.138}$$

For the remaining $d^{\ell\alpha}_{mj}$ we must again distinguish the cases $(j+m)$ odd and even. When $(j+m)$ is odd we find the results

$$d^{\ell c}_{mj}(k) = (-1)^{(j+m+1)/2}(-1)^m\sin(m\pi/2)\{[(j\pi/H+\tau_j)/k]^m-[(j\pi/H-\tau_j)/k]^m\}\sinh(\tau_j W/2), \tag{17.5.139}$$

$$d^{\ell s}_{mj}(k) = (-1)^{(j+m+1)/2}(-1)^m\cos(m\pi/2)\{[(j\pi/H+\tau_j)/k]^m-[(j\pi/H-\tau_j)/k]^m\}\sinh(\tau_j W/2). \tag{17.5.140}$$

And, when $(j+m)$ is even, we find the results

$$d^{\ell c}_{mj}(k) = (-1)^{(j+m)/2}(-1)^m\cos(m\pi/2)\{[(j\pi/H+\tau_j)/k]^m+[(j\pi/H-\tau_j)/k]^m\}\cosh(\tau_j W/2), \tag{17.5.141}$$

$$d^{\ell s}_{mj}(k) = -(-1)^{(j+m)/2}(-1)^m\sin(m\pi/2)\{[(j\pi/H+\tau_j)/k]^m+[(j\pi/H-\tau_j)/k]^m\}\cosh(\tau_j W/2). \tag{17.5.142}$$

Finally, observe that the left sides of (5.56) and (5.57) are interchanged under the substitution $W \leftrightarrow -W$. It follows that for $m=0$ there are the relations

$$d^{rc}_{0j} = d^{\ell c}_{0j}, \tag{17.5.143}$$

$$d^{rs}_{0j} = 0. \tag{17.5.144}$$

For the remaining $d^{r\alpha}_{mj}$, when $(j+m)$ is odd, we find the results

$$d^{rc}_{mj}(k) = -d^{\ell c}_{mj}(k), \tag{17.5.145}$$

$$d^{rs}_{mj}(k) = -d^{\ell s}_{mj}(k). \tag{17.5.146}$$

And, when $(j+m)$ is even, we find the results

$$d^{rc}_{mj}(k) = d^{\ell c}_{mj}(k), \tag{17.5.147}$$

$$d^{rs}_{mj}(k) = d^{\ell s}_{mj}(k). \tag{17.5.148}$$

Exercises

17.5.1. How could one have known that Fourier-Bessel expansions of the form (5.54) through (5.57) must exist? Consider, for example, (5.54). Multiply both sides by $\exp(ikz)$. Show that both sides then become harmonic functions. Moreover, the left side is analytic in the vicinity of the z axis. But we know from Section 14.2.1 that such functions must have an expansion of the form (14.2.11).

17.5.2. Verify the relations (5.116) through (5.119).

17.5.3. Check the consistency of the relations (5.92) through (5.95) by verifying that they are transformed among themselves by the substitutions $W \leftrightarrow -W$ and $\sigma_j \leftrightarrow -\sigma_j$.

17.5.4. Verify that the functions $\sigma_j \sinh(H\sigma_j)$ and $\tau_j \sinh(W\tau_j)$ and the Fourier-Bessel coefficients $d_{mj}^{\beta\alpha}$ are even functions of k. Use these facts to show that the real parts of the $G_{m,\alpha}$ are even in k, and the imaginary parts are odd in k.

17.5.5. Consider the functions $\psi_j(x, y, z)$ for $j = 1, 2, 3$ defined by the relations

$$\psi_1(x, y, z) = a\cos(k_x x)\sinh(k_y y)\cos(kz + \chi) \tag{17.5.149}$$

with

$$-k_x^2 + k_y^2 = k^2; \tag{17.5.150}$$

$$\psi_2(x, y, z) = a\cosh(k_x x)\sinh(k_y y)\cos(kz + \chi) \tag{17.5.151}$$

with

$$k_x^2 + k_y^2 = k^2; \tag{17.5.152}$$

$$\psi_3(x, y, z) = a\cosh(k_x x)\sin(k_y y)\cos(kz + \chi) \tag{17.5.153}$$

with

$$k_x^2 - k_y^2 = k^2. \tag{17.5.154}$$

Verify that each ψ_j satisfies Laplace's equation, is analytic everywhere, and in particular is analytic in x, y near the z axis. Verify that each ψ_j can be written in the form (14.2.11). Verify that each ψ_j produces a vertical ($\pm y$ direction) field in the midplane $y = 0$ that oscillates in z, and therefore is some approximation (at least near the z axis) to the field of an infinitely long wiggler.

17.5.6. Consider a ψ of the form

$$\psi(x, y, z) = (a + by)\exp(kx)\exp(ikz). \tag{17.5.155}$$

Verify that this ψ satisfies Laplace's equation, is analytic everywhere, and in particular is analytic in x, y near the z axis. Verify that this ψ can be written in the form (14.2.11). In particular, verify that this ψ can be written in the form

$$\begin{aligned}\psi &= a[\mathrm{I}_0(k\rho) + 2\sum_{m=1}^{\infty}\cos(m\phi)\mathrm{I}_m(k\rho)]\exp(ikz) \\ &+ [(2b/k)\sum_{m=1}^{\infty} m\sin(m\phi)\mathrm{I}_m(k\rho)]\exp(ikz).\end{aligned} \tag{17.5.156}$$

17.6 Attempted Use of Nearly On-Axis and Midplane Field Data

As promised at the end of Section 14, here we examine other attempted approaches. All will be seen to involve what, in essence, is high-order numerical differentiation. Therefore, they are unlikely to yield reliable results beyond modest order, at best.

17.6.1 Use of Nearly On-Axis Data

Let us begin with the cylindrical multipole expansion

$$\begin{aligned}\psi(\rho,\phi,z) &= \psi(x,y,z)=\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!\ell!}C_0^{[2\ell]}(z)\rho^{2\ell}\\ &+ \sum_{m=1}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,c}^{[2\ell]}(z)\rho^{2\ell+m}\\ &+ \sum_{m=1}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,s}^{[2\ell]}(z)\rho^{2\ell+m}.\end{aligned}\tag{17.6.1}$$

Suppose (6.1) is multiplied by factors of $\cos(m\phi)$ or $\sin(m\phi)$ and the integrated over ϕ. Doing so gives the results

$$\tilde{\psi}(\rho,0,z)=\int_0^{2\pi}d\phi\;\psi(\rho,\phi,z)=\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{2\pi}{2^{2\ell}\ell!\ell!}C_0^{[2\ell]}(z)\rho^{2\ell},\tag{17.6.2}$$

$$\tilde{\psi}_c(\rho,m,z)=\int_0^{2\pi}d\phi\;\cos(m\phi)\psi(\rho,\phi,z)=\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{\pi\;m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,c}^{[2\ell]}(z)\rho^{2\ell+m},\tag{17.6.3}$$

$$\tilde{\psi}_s(\rho,m,z)=\int_0^{2\pi}d\phi\;\sin(m\phi)\psi(\rho,\phi,z)=\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{\pi\;m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,s}^{[2\ell]}(z)\rho^{2\ell+m}.\tag{17.6.4}$$

If $\psi(\rho,\phi,z)$ is known, and it is in fact provided at grid points by some three-dimensional codes, then the integrals in (6.2) through (6.4) can be computed. Moreover, we have the relations

$$C_0^{[0]}(z)=[1/(2\pi)]\lim_{\rho\to 0}\tilde{\psi}(\rho,0,z),\tag{17.6.5}$$

$$C_{m.c}^{[0]}(z)=(1/\pi)\lim_{\rho\to 0}(1/\rho^m)\tilde{\psi}_c(\rho,m,z),\tag{17.6.6}$$

$$C_{m,s}^{[0]}(z)=(1/\pi)\lim_{\rho\to 0}(1/\rho^m)\tilde{\psi}_s(\rho,m,z).\tag{17.6.7}$$

It is also in principle possible to compute the on-axis gradients from field data. Let $B_\rho(\rho,\phi,z)$ be the ρ component of $\boldsymbol{B}$. It is defined by the relation

$$B_\rho(\rho,\phi,z)=B_\rho(x,y,z)=\boldsymbol{e}_\rho\cdot\boldsymbol{B}=(x/\rho)B_x+(y/\rho)B_y=\cos(\phi)B_x+\sin(\phi)B_y.\tag{17.6.8}$$

In terms of $B_\rho(\rho,\phi,z)$, define the quantities

$$\tilde{B}_\rho(\rho,0,z) = \int_0^{2\pi} d\phi \; B_\rho(\rho,\phi,z), \tag{17.6.9}$$

$$\tilde{B}_{\rho c}(\rho,m,z) = \int_0^{2\pi} d\phi \; \cos(m\phi) B_\rho(\rho,\phi,z), \tag{17.6.10}$$

$$\tilde{B}_{\rho s}(\rho,m,z) = \int_0^{2\pi} d\phi \; \sin(m\phi) B_\rho(\rho,\phi,z). \tag{17.6.11}$$

We also know that

$$B_\rho(\rho,\phi,z) = (\partial/\partial\rho)\psi(\rho,\phi,z). \tag{17.6.12}$$

It follows that there are the relations

$$\tilde{B}_\rho(\rho,0,z) = \sum_{\ell=0}^{\infty}(-1)^\ell \frac{4\pi\ell}{2^{2\ell}\ell!\ell!} C_0^{[2\ell]}(z)\rho^{2\ell-1}, \tag{17.6.13}$$

$$\tilde{B}_{\rho c}(\rho,m,z) = \sum_{\ell=0}^{\infty}(-1)^\ell \frac{\pi \; (2\ell+m)m!}{2^{2\ell}\ell!(\ell+m)!} C_{m,c}^{[2\ell]}(z)\rho^{2\ell+m-1}, \tag{17.6.14}$$

$$\tilde{B}_{\rho s}(\rho,m,z) = \sum_{\ell=0}^{\infty}(-1)^\ell \frac{\pi \; (2\ell+m)m!}{2^{2\ell}\ell!(\ell+m)!} C_{m,s}^{[2\ell]}(z)\rho^{2\ell+m-1}. \tag{17.6.15}$$

Consequently, there are the relations

$$C_0^{[2]}(z) = (1/\pi)\lim_{\rho\to 0}(1/\rho^m)\tilde{B}_\rho(\rho,0,z), \tag{17.6.16}$$

$$C_{m,c}^{[0]}(z) = (1/\pi)\lim_{\rho\to 0}(1/\rho^?)\tilde{B}_{\rho c}(\rho,m,z), \tag{17.6.17}$$

$$C_{m,s}^{[0]}(z) = (1/\pi)\lim_{\rho\to 0}(1/\rho^m)\tilde{B}_{\rho s}(\rho,m,z). \tag{17.6.18}$$

Also, from *, we have the relation.

$$C_0^{[1]}(z) = \lim_{x,y\to 0} B_z(x,y,z) = B_z(0,0,z). \tag{17.6.19}$$

Let us now examine the feasibility of carrying out the indicated calculations based on numerical data provided on a 3-d grid. We see that, apart from (6.5) and (6.19), which can be reliably estimated, particularly if the grid is chosen so that there are grid points on the z axis, it is necessary to perform a limiting process in which both a numerator and denominator approach zero. Such a limiting process is akin to numerical differentiation. Also, to compute the $C_{m,\alpha}^{[n]}(z)$ for larger values of n, it is necessary to repeatedly differentiate the above relations with respect to z. When based on grid data, this again involves multiple numerical differentiation.

17.6.2 Use of Midplane Field Data

In place of nearly on-axis data, one might consider the use of Midplane Field Data. Use of the relations (H.1.17) through (H.1.19) gives for the nearly midplane field the expansions

$$\begin{aligned}&B_x(x,y,z)=\partial_x\psi=C_{1,c}^{[0]}(z)+x[2C_{2,c}^{[0]}(z)-(1/2)C_0^{[2]}(z)]+2yC_{2,s}^{[0]}(z)\\&+3x^2[C_{3,c}^{[0]}(z)-(1/8)C_{1,c}^{[2]}(z)]-y^2[3C_{3,c}^{[0]}(z)+(1/8)C_{1,c}^{[2]}(z)]\\&+2xy[3C_{3,s}^{[0]}(z)-(1/8)C_{1,s}^{[2]}(z)]\cdots,\end{aligned}\tag{17.6.20}$$

$$\begin{aligned}&B_y(x,y,z)=\partial_y\psi=+C_{1,s}^{[0]}(z)-y[2C_{2,c}^{[0]}(z)+(1/2)C_0^{[2]}(z)]+2xC_{2,s}^{[0]}(z)\\&-3y^2[C_{3,s}^{[0]}(z)+(1/8)C_{1,s}^{[2]}(z)]+x^2[3C_{3,s}^{[0]}(z)-(1/8)C_{1,s}^{[2]}(z)]\\&-2xy[3C_{3,c}^{[0]}(z)+(1/8)C_{1,c}^{[2](z)}]+\cdots,\end{aligned}\tag{17.6.21}$$

$$\begin{aligned}&B_z(x,y,z)=\partial_z\psi=C_0^{[1]}(z)+xC_{1,c}^{[1]}(z)+yC_{1,s}^{[1]}(z)\\&+(x^2-y^2)C_{2,c}^{[1]}(z)+2xyC_{2,s}^{[1]}(z)-(1/4)(x^2+y^2)C_0^{[3]}(z)+\cdots.\end{aligned}\tag{17.6.22}$$

Evaluating these expansions in the midplane gives the results

$$\begin{aligned}&B_x(x,y=0,z)=C_{1,c}^{[0]}(z)+x[2C_{2,c}^{[0]}(z)-(1/2)C_0^{[2]}(z)]\\&+3x^2[C_{3,c}^{[0]}(z)-(1/8)C_{1,c}^{[2]}(z)]\cdots,\end{aligned}\tag{17.6.23}$$

$$\begin{aligned}&B_y(x,y=0,z)=C_{1,s}^{[0]}(z)+2xC_{2,s}^{[0]}(z)\\&+x^2[3C_{3,s}^{[0]}(z)-(1/8)C_{1,s}^{[2]}(z)]+\cdots,\end{aligned}\tag{17.6.24}$$

$$\begin{aligned}&B_z(x,y=0,z)=C_0^{[1]}(z)+xC_{1,c}^{[1]}(z)\\&+x^2[C_{2,c}^{[1]}(z)-(1/4)C_0^{[3]}(z)]+\cdots.\end{aligned}\tag{17.6.25}$$

The relations (6.4) through (6.6) express the midplane fields in terms of on-axis gradients. These relations can be inverted to determine the on-axis gradients in terms of the midplane fields. By repeatedly differentiating them with respect to x and z and then setting $x=0$, one finds the results

$$C_0^{[1]}(z)=B_z(x=0,y=0,z),\tag{17.6.26}$$

$$C_{1,c}^{[0]}(z)=B_x(x=0,y=0,z),\tag{17.6.27}$$

$$C_{1,s}^{[0]}(z)=B_y(x=0,y=0,z),\tag{17.6.28}$$

$$C_{2,c}^{[0]}(z)=(1/2)(\partial B_x/\partial x)\Big|_{(0,0,z)}+(1/4)(\partial B_z/\partial z)\Big|_{(0,0,z)},\tag{17.6.29}$$

$$C_{2,s}^{[0]}(z) = (1/2)(\partial B_y/\partial x)\Big|_{(0,0,z)}, \tag{17.6.30}$$

$$C_{3,c}^{[0]}(z) = (1/6)(\partial^2 B_x/\partial x^2)\Big|_{(0,0,z)} + (1/8)(\partial^2 B_x/\partial z^2)\Big|_{(0,0,z)}, \tag{17.6.31}$$

$$C_{3,s}^{[0]}(z) = (1/6)(\partial^2 B_y/\partial x^2)\Big|_{(0,0,z)} + (1/24)(\partial^2 B_y/\partial z^2)\Big|_{(0,0,z)}, \text{etc.} \tag{17.6.32}$$

See Exercise 6.1. Finally, by repeatedly differentiating these relations with respect to z, one can obtain the $C_{m,\alpha}^{[n]}(z)$ for $n > 0$. In general, the computation of the $C_{m,\alpha}^{[n]}(z)$ requires $m+n-1$ differentiations. Again, when based on grid data, this involves multiple numerical differentiation, and therefore is expected to be unreliable.

Exercises

17.6.1. The aim of this exercise is to verify the relations (6.26) through (6.32). Begin by setting $x = 0$ in the relations (6.4) through (6.6). Show that so doing yields the results

$$B_x(x=0, y=0, z) = C_{1,c}^{[0]}(z), \tag{17.6.33}$$

$$B_y(x=0, y=0, z) = C_{1,s}^{[0]}(z), \tag{17.6.34}$$

$$B_z(x=0, y=0, z) = C_0^{[1]}(z). \tag{17.6.35}$$

Next, differentiate (6.4) through (6.6) with respect to x and then set $x = 0$. Show that so doing gives the results

$$(\partial B_x/\partial x)|_{0,0,z} = -(1/2)C_0^{[2]}(z) + 2C_{2,c}^{[0]}(z), \tag{17.6.36}$$

$$(\partial B_y/\partial x)|_{0,0,z} = 2C_{2,s}^{[0]}(z), \tag{17.6.37}$$

$$(\partial B_z/\partial x)|_{0,0,z} = C_{1,c}^{[1]}(z). \tag{17.6.38}$$

Show that solving (6.7) through (6.12) for the on-axis gradients gives, so far, the results

$$C_{1,c}^{[0]}(z) = B_x(x=0, y=0, z), \tag{17.6.39}$$

$$C_{1,s}^{[0]}(z) = B_y(x=0, y=0, z), \tag{17.6.40}$$

$$C_0^{[1]}(z) = B_z(x=0, y=0, z), \tag{17.6.41}$$

$$C_{2,c}^{[0]}(z) = (1/2)(\partial B_x/\partial x)|_{0,0,z} + (1/4)(\partial B_z/\partial z)|_{0,0,z}, \tag{17.6.42}$$

$$C_{2,s}^{[0]}(z) = (1/2)(\partial B_y/\partial x)|_{0,0,z}, \tag{17.6.43}$$

$$C_{1,c}^{[1]}(z) = (\partial B_z/\partial x)|_{0,0,z}. \tag{17.6.44}$$

Verify that (6.18) is redundant because from (6.13) we also have the relation

$$C_{1,c}^{[1]}(z) = (\partial B_x/\partial z)|_{0,0,z}. \tag{17.6.45}$$

Alternatively, (6.19) serves as a consistency check on (6.18).[12] Next differentiate the mid-plane fields twice with respect to x and then set $x = 0$. Show that so doing yields the relations

$$(\partial^2 B_x/\partial x^2)|_{0,0,z} = 6[C_{3,c}^{[0]}(z) - (1/8)C_{1,c}^{[2]}(z)], \tag{17.6.46}$$

$$(\partial^2 B_y/\partial x^2)|_{0,0,z} = 2[3C_{3,s}^{[0]}(z) - (1/8)C_{1,s}^{[2]}(z)], \tag{17.6.47}$$

$$(\partial^2 B_z/\partial x^2)|_{0,0,z} = 2[C_{2,c}^{[1]}(z) - (1/4)C_{0}^{[3]}(z)]. \tag{17.6.48}$$

Show that these relations, with the aid of the previous relations, can be solved for the next set of on-axis gradients to give the results

$$(\partial^2 B_x/\partial x^2)|_{0,0,z} = 6[C_{3,c}^{[0]}(z) - (1/8)C_{1,c}^{[2]}(z)], \tag{17.6.49}$$

$$(\partial^2 B_y/\partial x^2)|_{0,0,z} = 2[3C_{3,s}^{[0]}(z) - (1/8)C_{1,s}^{[2]}(z)], \tag{17.6.50}$$

$$(\partial^2 B_z/\partial x^2)|_{0,0,z} = 2[C_{2,c}^{[1]}(z) - (1/4)C_{0}^{[3]}(z)], \tag{17.6.51}$$

$$[C_{3,c}^{[0]}(z) - (1/8)C_{1,c}^{[2]}(z)] = (1/6)(\partial^2 B_x/\partial x^2)|_{0,0,z}, \tag{17.6.52}$$

$$C_{3,c}^{[0]}(z) = (1/6)(\partial^2 B_x/\partial x^2)|_{0,0,z} + (1/8)C_{1,c}^{[2]}(z), \tag{17.6.53}$$

$$C_{3,c}^{[0]}(z) = (1/6)(\partial^2 B_x/\partial x^2)|_{0,0,z} + (1/8)(\partial^2 B_x/\partial z^2)\Big|_{(0,0,z)}, \tag{17.6.54}$$

$$(\partial^2 B_y/\partial x^2)|_{0,0,z} = 2[3C_{3,s}^{[0]}(z) - (1/8)C_{1,s}^{[2]}(z)]. \tag{17.6.55}$$

17.7 Terminating End Fields

In principle, the fringe field of an individual beam-line element at either end of the element has infinite extent. But in practice in many instances we may wish to regard a beam line as a collection of separated/isolated elements. To do this it is necessary to make an approximation in which leading and trailing end fields are "terminated" in some way. The crucial problem is how to relate canonical coordinates in the absence of a magnetic field with canonical coordinates in the presence of a magnetic field.

17.7.1 Preliminary Observations

We begin with some preliminary observations. In Cartesian coordinates the Hamiltonian describing charged-particle motion with z as the independent variable is given by the relation

$$K = -[(p_t^{\rm can})^2/c^2 - m^2c^2 - (p_x^{\rm can} - qA_x)^2 - (p_y^{\rm can} - qA_y)^2]^{1/2} - qA_z. \tag{17.7.1}$$

Here we have assumed that the electric scalar potential ψ vanishes and $\boldsymbol{A}$ is static so that there is no electric field. Also, we have used the notation $p_x^{\rm can}$, $p_y^{\rm can}$, and $p_t^{\rm can}$ to indicate that it is the components of the *canonical* momenta that are involved in a Hamiltonian description of motion. See (1.6.16).

[12] This check arises from the requirement $\nabla \times B = 0$.

According to Hamilton's equations of motion, the change of a coordinate, say $x(z)$, with z is given by

$$\begin{aligned} dx/dz &= \partial K/\partial p_x^{\rm can} \\ &= (p_x^{\rm can} - qA_x)/[(p_t^{\rm can})^2/c^2 - m^2c^2 - (p_x^{\rm can} - qA_x)^2 - (p_y^{\rm can} - qA_y)^2]^{1/2} \\ &= (p_x^{\rm can} - qA_x)/[-(K + qA_z)]. \end{aligned} \tag{17.7.2}$$

Let us verify that this result agrees with what we already know. Recall that

$$K = -p_z^{\rm can}. \tag{17.7.3}$$

See (1.6.6). It follows that (7.2) can be rewritten in the form

$$dx/dz = (p_x^{\rm can} - qA_x)/(p_z^{\rm can} - qA_z). \tag{17.7.4}$$

According to (1.5.27) through (1.5.30) there is the relation

$$\boldsymbol{p}^{\rm can} - q\boldsymbol{A} = \boldsymbol{p}^{\rm mech} \tag{17.7.5}$$

where $\boldsymbol{p}^{\rm mech}$ is the *mechanical* momentum given by

$$\boldsymbol{p}^{\rm mech} = \gamma m\boldsymbol{v}. \tag{17.7.6}$$

Consequently, (7.4) can be rewritten in the form

$$dx/dz = p_x^{\rm mech}/p_z^{\rm mech} = \gamma m v_x/(\gamma m v_z) = v_x/v_z = \frac{dx/dt}{dz/dt}. \tag{17.7.7}$$

Evidently, the far left and far right sides of (7.7) agree. It is also easy to see that results analogous to those just found also hold for $y(z)$.

To complete the story we need to examine also the equation of motion for $t(z)$. In this case application of the standard Hamiltonian rules gives the result

$$\begin{aligned} dt/dz &= \partial K/\partial p_t^{\rm can} \\ &= (-p_t^{\rm can}/c^2)/[(p_t^{\rm can})^2/c^2 - m^2c^2 - (p_x^{\rm can} - qA_x)^2 - (p_y^{\rm can} - qA_y)^2]^{1/2} \\ &= (-p_t^{\rm can}/c^2)/[-(K + qA_z)]. \end{aligned} \tag{17.7.8}$$

Now use of (7.3), (7.5), and (1.6.17) yields the relation

$$dt/dz = (-p_t^{\rm can}/c^2)/p_z^{\rm mech} = \gamma m/(\gamma m v_z) = \frac{1}{dz/dt} \tag{17.7.9}$$

so that the far left and far right sides of (7.9) also agree.

17.7.2 Changing Gauge

It may be useful to change gauges at various points during the course of integrating a trajectory and computing an associated transfer map. Suppose the gauge is to be *changed* at the point $z = z^c$. Let x^b, y^b, and t^b denote coordinate functions *before* the change, and let x^a, y^a, and t^a denote coordinate functions *after* the change. Also, let $\boldsymbol{A}^b(x^b, y^b; z)$ and $\boldsymbol{A}^a(x^a, y^a; z)$ be the vector potentials before $(z < z^c)$ and after $(z > z^c)$ the change point z^c. Finally, let $p_x^{\rm canb}$, $p_y^{\rm canb}$, $p_t^{\rm canb}$ be the canonical momentum functions before the change, and let $p_x^{\rm cana}$, $p_y^{\rm cana}$, $p_t^{\rm cana}$ be the canonical momentum functions after the change. In terms of these quantities, the before and after Hamiltonians K^b and K^a are given by the relations

$$K^b = -[(p_t^{\rm canb})^2/c^2 - m^2c^2 - (p_x^{\rm canb} - qA_x^b)^2 - (p_y^{\rm canb} - qA_y^b)^2]^{1/2} - qA_z^b \text{ for } z < z^c, \quad (17.7.10)$$

$$K^a = -[(p_t^{\rm cana})^2/c^2 - m^2c^2 - (p_x^{\rm cana} - qA_x^a)^2 - (p_y^{\rm cana} - qA_y^a)^2]^{1/2} - qA_z^a \text{ for } z > z^c. \quad (17.7.11)$$

What should be the matching relations between the phase-space quantities before and after? Since the choice of gauge should have no physical effect, there is the immediate requirement that the coordinate functions be continuous:

$$\begin{aligned} x^a(z) &= x^b(z) \text{ when } z = z^c, \\ y^a(z) &= y^b(z) \text{ when } z = z^c, \\ t^a(z) &= t^b(z) \text{ when } z = z^c. \end{aligned} \quad (17.7.12)$$

For the same reason, we require that the velocities, and hence the mechanical momenta, be continuous. From (7.5) and (7.6) we see that this requirement is equivalent to the relations

$$\boldsymbol{p}^{\rm cana} - q\boldsymbol{A^a} = \boldsymbol{p}^{\rm canb} - q\boldsymbol{A^b} \text{ when } z = z^c. \quad (17.7.13)$$

In terms of components, (7.13) yields the matching relations

$$\begin{aligned} p_x^{\rm cana} &= p_x^{\rm canb} + q(A_x^a - A_x^b) \text{ when } z = z^c, \\ p_y^{\rm cana} &= p_y^{\rm canb} + q(A_y^a - A_y^b) \text{ when } z = z^c. \end{aligned} \quad (17.7.14)$$

Finally, the total energy cannot change under a gauge transformation and therefore, since we have assumed that the scalar potential ψ vanishes, there is the matching relation

$$p_t^{\rm cana} = p_t^{\rm canb} \text{ when } z = z^c. \quad (17.7.15)$$

We note that this relation also follows from (1.6.17), (7.5), (7.6), and (7.13).

We assume there is some common overlap region where both $\boldsymbol{A}^b$ and $\boldsymbol{A}^a$ are defined. Since they both give rise to the same magnetic field, there is the relation

$$\nabla \times (\boldsymbol{A}^a - \boldsymbol{A}^b) = 0. \quad (17.7.16)$$

It follows that there is a function χ such that

$$\boldsymbol{A}^a - \boldsymbol{A}^b = \nabla\chi. \quad (17.7.17)$$

Consequently, the relations (7.14) can be rewritten in the form

$$\begin{aligned} p_x^{\rm cana} &= p_x^{\rm canb} + q(\partial/\partial x)\chi \text{ when } z = z^c, \\ p_y^{\rm cana} &= p_y^{\rm canb} + q(\partial/\partial y)\chi \text{ when } z = z^c. \end{aligned} \tag{17.7.18}$$

There is one last step. Let $\mathcal{T}^c$ be the symplectic *transformation* map defined by the relation

$$\mathcal{T}^c = \exp(q : \chi :). \tag{17.7.19}$$

With aid of this map it is easily verified that the relations (7.12), (7.14), and (7.15) can be rewritten in the form

$$\begin{aligned} x^a(z) &= \exp(q : \chi :)x^b(z) \text{ with } z = z^c, \\ y^a(z) &= \exp(q : \chi :)y^b(z) \text{ with } z = z^c, \\ t^a(z) &= \exp(q : \chi :)t^b(z) \text{ with } z = z^c; \end{aligned} \tag{17.7.20}$$

$$\begin{aligned} p_x^{\rm cana}(z) &= \exp(q : \chi :)p_x^{\rm canb}(z) \text{ with } z = z^c, \\ p_y^{\rm cana}(z) &= \exp(q : \chi :)p_y^{\rm canb}(z) \text{ with } z = z^c, \\ p_t^{\rm cana}(z) &= \exp(q : \chi :)p_t^{\rm canb}(z) \text{ with } z = z^c. \end{aligned} \tag{17.7.21}$$

We have determined that a change in gauge amounts to making a symplectic transformation. Review Exercises 6.2.8 and 6.5.3.

17.7.3 Finding the Minimal Vector Potential

The goal of this subsection is, given $\boldsymbol{B}(\boldsymbol{r})$ in some region, to find an associated vector potential $\boldsymbol{A}^s$ that is as *small*/minimal as possible in the sense that $\boldsymbol{A}^s$ is small if $\boldsymbol{B}(\boldsymbol{r})$ is small. The reason for this goal will become apparent in following subsections.

Our plan is as follows: Make Taylor expansions, with initially unknown coefficients, for the Cartesian components of $\boldsymbol{A}^s$, organize these expansions into homogeneous polynomials, and then further organize them as spherical polynomial vector fields. Then use this representation to compute and organize $\nabla \times \boldsymbol{A}^s$ in terms of spherical polynomial vector fields. At the same time parameterize $\boldsymbol{B}(\boldsymbol{r})$ in terms of a scalar potential ψ expanded in harmonic polynomials. Finally, compare the two expansions for $\boldsymbol{B}(\boldsymbol{r})$ given by $\boldsymbol{B} = \nabla\psi$ and $\boldsymbol{B} = \nabla \times \boldsymbol{A}^s$, equate coefficients of like terms, and thereby determine the coefficients in the Taylor expansion for the components of $\boldsymbol{A}^s$ in terms of the coefficients in the expansion for ψ. For the notation and machinery required for the execution of this plan, see Appendix U.

We begin with an expansion for $\boldsymbol{B}(\boldsymbol{r})$ based on the use of a scalar potential. Without loss of generality, we may take the region of interest to be centered at the origin. We also assume that $\boldsymbol{B}(\boldsymbol{r})$ has a Taylor expansion in the components of $\boldsymbol{r}$ and is divergence and curl free. In this case there is a harmonic magnetic scalar potential $\psi(\boldsymbol{r})$ such that

$$\boldsymbol{B} = \nabla\psi. \tag{17.7.22}$$

Recall the beginning of Section 15.2. Employing the notation of Appendix U, we may assume without loss of generality that ψ has a spherical polynomial expansion of the form

$$\psi(\boldsymbol{r}) = \sum_{n=1}^{n_{\max}} \sum_{m} d_{nm} S_{nn}^{m}(\boldsymbol{r}) \tag{17.7.23}$$

where the quantities d_{nm} are arbitrary coefficients. Here we assume an expansion through terms of degree $n_{\max}$ and omit $n = 0$ terms since constant terms make no contribution to $\boldsymbol{B}$ as given by (7.22).

For the associated vector potential $\boldsymbol{A}^s$ we make the spherical polynomial vector field expansion

$$\boldsymbol{A}^s(\boldsymbol{r}) = \sum_{n=1}^{n_{\max}} \sum_{\ell} \sum_{J} \sum_{M} c_{n\ell JM} \boldsymbol{S}_{n\ell J}^{M}(\boldsymbol{r}). \tag{17.7.24}$$

Again see Appendix U. Given the coefficients d_{nm}, our task is to use the equality

$$\nabla \times \boldsymbol{A}^s(\boldsymbol{r}) = \nabla \times \sum_{n=1}^{n_{\max}} \sum_{\ell} \sum_{J} \sum_{M} c_{n\ell JM} \boldsymbol{S}_{n\ell J}^{M}(\boldsymbol{r}) = \nabla \sum_{n=1}^{n_{\max}} \sum_{m} d_{nm} S_{nn}^{m}(\boldsymbol{r}) = \nabla\psi(\boldsymbol{r}) \tag{17.7.25}$$

to find the coefficients $c_{n\ell JM}$.

Let us begin by evaluating the right side of (7.25). We find the results

$$\boldsymbol{B}(r) = \nabla\psi(\boldsymbol{r}) = \nabla \sum_{n=1}^{n_{\max}} \sum_{m} d_{nm} S_{nn}^{m}(\boldsymbol{r}) = \sum_{n=1}^{n_{\max}} \sum_{m} d_{nm} \sqrt{n(2n+1)} \boldsymbol{S}_{n-1,n-1,n}^{m}(\boldsymbol{r}). \tag{17.7.26}$$

Here we have used (U.5.3).

Next work on evaluating the left side of (7.25). This is a more complicated task. In accord with the range rules (U.3.7) and (U.3.8) we decompose the expansion into the sum of four pieces with each containing a particular kind of term:

a) All terms for which $\ell = 0$ and hence $J = 1$. Also, therefore, $n = 2k$ with $k > 0$. The associated spherical polynomial vectors are of the form $\boldsymbol{S}_{2k,0,1}^{M}(\boldsymbol{r})$.

b) All terms for which $\ell > 0$ and $J = \ell + 1$. The associated spherical polynomial vectors are of the form $\boldsymbol{S}_{n,\ell,\ell+1}^{M}(\boldsymbol{r})$.

c) All terms for which $\ell > 0$ and $J = \ell$. The associated spherical polynomial vectors are of the form $\boldsymbol{S}_{n,\ell,\ell}^{M}(\boldsymbol{r})$.

d) All terms for which $\ell > 0$ and $J = \ell - 1$. The associated spherical polynomial vectors are of the form $\boldsymbol{S}_{n,\ell,\ell-1}^{M}(\boldsymbol{r})$.

Thus, we write

$$\boldsymbol{A}^s = \boldsymbol{A}^{sa} + \boldsymbol{A}^{sb} + \boldsymbol{A}^{sc} + \boldsymbol{A}^{sd} \tag{17.7.27}$$

where

$$\boldsymbol{A}^{sa}(\boldsymbol{r}) = \sum_{k=1}^{k_{\max}} \sum_{M} c_{2k,0,1,M} \boldsymbol{S}_{2k,0,1}^{M}(\boldsymbol{r}), \tag{17.7.28}$$

$$\boldsymbol{A}^{sb}(\boldsymbol{r}) = \sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} c_{n,\ell,\ell+1,M} \boldsymbol{S}^M_{n,\ell,\ell+1}(\boldsymbol{r}), \tag{17.7.29}$$

$$\boldsymbol{A}^{sc}(\boldsymbol{r}) = \sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} c_{n,\ell,\ell,M} \boldsymbol{S}^M_{n,\ell,\ell}(\boldsymbol{r}), \tag{17.7.30}$$

$$\boldsymbol{A}^{sd}(\boldsymbol{r}) = \sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} c_{n,\ell,\ell-1,M} \boldsymbol{S}^M_{n,\ell,\ell-1}(\boldsymbol{r}). \tag{17.7.31}$$

We are now ready to proceed. For the $\boldsymbol{A}^{sa}$ term we find, using (U.5.20), the result

$$\nabla \times \boldsymbol{A}^{sa}(\boldsymbol{r}) = \nabla \times \sum_{k=1}^{k_{\max}} \sum_{M} c_{2k,0,1,M} \boldsymbol{S}^M_{2k,0,1}(\boldsymbol{r}) = \sum_{k=1}^{k_{\max}} \sum_{M} c_{2k,0,1,M} [i(\sqrt{2/3})(2k)] \boldsymbol{S}^M_{2k-1,1,1}(\boldsymbol{r}). \tag{17.7.32}$$

For the $\boldsymbol{A}^{sb}$ term we find, using (U.5.17), the result

$$\nabla \times \boldsymbol{A}^{sb}(\boldsymbol{r}) = \nabla \times \sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} c_{n,\ell,\ell+1,M} \boldsymbol{S}^M_{n,\ell,\ell+1}(\boldsymbol{r}) =$$
$$\sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} c_{n,\ell,\ell+1,M} [i\sqrt{(\ell+2)/(2\ell+3)}(n-\ell)] \boldsymbol{S}^M_{n-1,\ell+1,\ell+1}(\boldsymbol{r}). \tag{17.7.33}$$

For the $\boldsymbol{A}^{sc}$ term we find, using (U.5.18), the result

$$\nabla \times \boldsymbol{A}^{sc}(\boldsymbol{r}) = \nabla \times \sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} c_{n,\ell,\ell,M} \boldsymbol{S}^M_{n,\ell,\ell}(\boldsymbol{r}) =$$
$$\sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} c_{n,\ell,\ell,M} [i\sqrt{(\ell+1)/(2\ell+1)}(n+\ell+1)] \boldsymbol{S}^M_{n-1,\ell-1,\ell}(\boldsymbol{r})$$
$$+ \sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} c_{n,\ell,\ell,M} [i\sqrt{\ell/(2\ell+1)}(n-\ell)] \boldsymbol{S}^M_{n-1,\ell+1,\ell}(\boldsymbol{r}). \tag{17.7.34}$$

Finally, for the $\boldsymbol{A}^{sd}$ term we find, using (U.5.19), the result

$$\nabla \times \boldsymbol{A}^{sd}(\boldsymbol{r}) = \nabla \times \sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} c_{n,\ell,\ell-1,M} \boldsymbol{S}^M_{n,\ell,\ell-1}(\boldsymbol{r}) =$$
$$\sum_{n=1}^{n_{\max}} \sum_{\ell>0} \sum_{M} c_{n,\ell,\ell-1,M} [i\sqrt{(\ell-1/(2\ell-1)}(n+\ell+1)] \boldsymbol{S}^M_{n-1,\ell-1,\ell-1}(\boldsymbol{r}). \tag{17.7.35}$$

We are now prepared to equate coefficients of like terms. Let us begin with the first few corresponding to small values of n. The first of these, corresponding to $n = 0$, is $\boldsymbol{S}^M_{0,0,1}$. From (7.26) we see that

$$\text{coefficient of } \boldsymbol{S}^M_{0,0,1} \text{ in } \nabla\psi = \sqrt{3}\, d_{1M}. \tag{17.7.36}$$

We next examine the terms in $\nabla \times \boldsymbol{A}^s$: From (7.32) we see that there are no terms of the desired kind, namely terms involving $\boldsymbol{S}^M_{0,0,1}$, in $\nabla \times \boldsymbol{A}^{sa}$. From (7.33) we see that there are no terms of the desired kind in $\nabla \times \boldsymbol{A}^{sb}$. From (7.34) we see that there are terms of the desired kind in $\nabla \times \boldsymbol{A}^{sc}$, and find the relation

$$\text{coefficient of } \boldsymbol{S}^M_{0,0,1} \text{ in } \nabla \times \boldsymbol{A}^{sc} = i\sqrt{6}\, c_{1,1,1,M}. \tag{17.7.37}$$

Finally, from (7.35) we see that there are no terms of the desired kind in $\nabla \times \boldsymbol{A}^{sd}$.

Upon comparing (7.36) and (7.37) we conclude that there must be the relation

$$i\sqrt{6}\, c_{1,1,1,M} = \sqrt{3}\, d_{1M}, \tag{17.7.38}$$

and therefore

$$c_{1,1,1,M} = -i\sqrt{1/2}\, d_{1M}. \tag{17.7.39}$$

Note that this relation is consistent with (U.6.39). Moreover, we conclude that the six remaining $n = 1$ coefficients in $\boldsymbol{A}^s$, namely $c_{1,1,0,0}$ and the $c_{1,1,2,M}$, can be anything since there are the relations (U.6.38) and (U.6.40). For simplicity, we set these coefficients to zero. Then, so far, we have the result

$$\boldsymbol{A}^s(\boldsymbol{r}) = \sum_M (-i)\sqrt{1/2}\, d_{1M}\, \boldsymbol{S}^M_{111}(\boldsymbol{r}) + \text{ terms of degree } > 1. \tag{17.7.40}$$

In terms of Cartesian components, (7.40) yields the relation

$$\boldsymbol{A}^s(\boldsymbol{r}) = -(1/2)\boldsymbol{r} \times \boldsymbol{B}(0) + \text{ terms of degree } > 1. \tag{17.7.41}$$

Here we have used (7.22), (7.23), and (U.6.25) evaluated for $n = 1$. We observe that this choice for the leading term in $\boldsymbol{A}^s$ is in the symmetric/Poincaré/Coulomb gauge. See Exercise 28.2.7.

Let us push on to the case $n = 1$; in which case there are the spherical polynomial vector fields $\boldsymbol{S}^0_{110}$, $\boldsymbol{S}^M_{111}$ with $-1 \le M \le 1$, and $\boldsymbol{S}^M_{112}$ with $-2 \le M \le 2$. First see where/how they occur in $\nabla\psi$. Examination of (7.26) shows that the only such term in $\nabla\psi$ is $\boldsymbol{S}^M_{112}$, and we have the relation

$$\text{coefficient of } \boldsymbol{S}^M_{1,1,2} \text{ in } \nabla\psi = \sqrt{10}\, d_{2M}. \tag{17.7.42}$$

We next examine the terms in $\nabla \times \boldsymbol{A}^s$: From (7.32) we see that there are no terms of the desired kind, namely terms involving $\boldsymbol{S}^M_{1,1,2}$, in $\nabla \times \boldsymbol{A}^{sa}$. From (7.33) we see that there are no terms of the desired kind in $\nabla \times \boldsymbol{A}^{sb}$. From (7.34) we see that there are terms of the desired kind in $\nabla \times \boldsymbol{A}^{sc}$, and find the relation

$$\text{coefficient of } \boldsymbol{S}^M_{1,1,2} \text{ in } \nabla \times \boldsymbol{A}^{sc} = i\sqrt{15}\, c_{2,2,2,M}. \tag{17.7.43}$$

Finally, from (7.35) we see that there are no terms of the desired kind in $\nabla \times \boldsymbol{A}^{sd}$.

Upon comparing (7.42) and (7.43) we conclude that there must be the relation

$$i\sqrt{15}\, c_{2,2,2,M} = \sqrt{10}\, d_{2M}, \tag{17.7.44}$$

and therefore

$$c_{2,2,2,M} = -i\sqrt{2/3}\, d_{2M}. \tag{17.7.45}$$

What can be said about the thirteen remaining $n = 2$ coefficients in $\boldsymbol{A}^s$, namely the c_{201M}, $c_{2,2,3,M}$, and $c_{2,2,1,M}$? It can be shown that $\nabla \times \boldsymbol{S}_{223}^M(\boldsymbol{r}) = 0$, and therefore the terms with coefficients $c_{2,2,3,M}$ make no contribution to $\boldsymbol{B}(\boldsymbol{r})$. See Exercise (U.6.21). For simplicity, we set these coefficients to zero. It can be shown that terms with the coefficients c_{201M} and $c_{2,2,1,M}$ produce terms in $\boldsymbol{B}(\boldsymbol{r})$ having nonzero curl. Again see Exercise (U.6.21). We also set these coefficients to zero to ensure that $\boldsymbol{B}(\boldsymbol{r})$ is curl free. Then, so far, we have the result

$$\boldsymbol{A}^s(\boldsymbol{r}) = \sum_M (-i)\sqrt{1/2}\; d_{1M}\; \boldsymbol{S}_{111}^M(\boldsymbol{r}) + \sum_M (-i)\sqrt{2/3}\; d_{2M}\; \boldsymbol{S}_{222}^M(\boldsymbol{r}) + \text{ terms of degree } > 2. \tag{17.7.46}$$

The pattern should now be clear. There are the general relations

$$\nabla S_{nn}^M(\boldsymbol{r}) = \sqrt{n(2n+1)}\boldsymbol{S}_{n-1,n-1,n}^M(\boldsymbol{r}) \tag{17.7.47}$$

and

$$\nabla \times \boldsymbol{S}_{n,n,n}^M(\boldsymbol{r}) = i\sqrt{(n+1)(2n+1)}\boldsymbol{S}_{n-1,n-1,n}^M(\boldsymbol{r}). \tag{17.7.48}$$

Therefore there is the general relation

$$\boldsymbol{A}^s(\boldsymbol{r}) = \sum_{n=1}^{n_{\max}} \sum_{M=-n}^{n} (-i)\sqrt{n/(n+1)}\; d_{nM}\boldsymbol{S}_{nnn}^M(\boldsymbol{r}). \tag{17.7.49}$$

It can be verified that this particular choice of $\boldsymbol{A}^s(\boldsymbol{r})$ has the two properties

$$\nabla \cdot \boldsymbol{A}^s(\boldsymbol{r}) = 0 \tag{17.7.50}$$

and

$$\boldsymbol{r} \cdot \boldsymbol{A}^s(\boldsymbol{r}) = 0. \tag{17.7.51}$$

See (U.5.11) and (U.6.9). Thus this vector potential is in both a Coulomb and Poincaré gauge.

The relation (7.49) can be further manipulated using (U.6.25). Doing so gives the result

$$\boldsymbol{A}^s(\boldsymbol{r}) = -\sum_{n=1}^{n_{\max}} \sum_{M=-n}^{n} [1/(n+1)] d_{nM} [\boldsymbol{r} \times \nabla S_{nn}^M(\boldsymbol{r})]. \tag{17.7.52}$$

We observe that this result agrees with that found by Ansatz in Exercises (15.5.8) and (15.5.9). See (15.5.81) and (15.5.82).

Have we achieved our goal of finding a "minimal vector potential"? We have, in the following sense: Inspection of (7.26) shows that it provides an expansion of $\boldsymbol{B}(r)$ in terms of spherical polynomial vector fields $\boldsymbol{S}_{n-1,n-1,n}^m(\boldsymbol{r})$ with expansion coefficients proportional to the d_{nm}. Inspection of (7.49) shows that it provides an expansion of $\boldsymbol{A}^s(r)$ in terms of spherical polynomial vector fields $\boldsymbol{S}_{nnn}^M(\boldsymbol{r})$ with expansion coefficients again proportional to the d_{nM}. The vector potential $\boldsymbol{A}^s(\boldsymbol{r})$ has no constant part, and its non-constant parts are directly proportional to the coefficients d_{nm} that describe the constant and non-constant parts of $\boldsymbol{B}(r)$. Moreover, there is an order-by-order relation. Terms of order n in $\boldsymbol{A}^s(\boldsymbol{r})$ are proportional to terms of order $n - 1$ in $\boldsymbol{B}(r)$. Thus, $\boldsymbol{A}^s(\boldsymbol{r})$ is small if $\boldsymbol{B}(r)$ is small. In particular, if high-order terms in $\boldsymbol{B}(r)$ are negligible, they will also be negligible in $\boldsymbol{A}^s(\boldsymbol{r})$.

There is yet another sense in which the vector potential we have found is minimal. Suppose, for example, that we confine our attention to the case of a vector potential that is homogeneous of degree 1, which is the case we need to produce a constant magnetic field. When $n = 1$ we see from Table U.3.1 that $\ell = 1$ and $J = 0, 1, 2$. Therefore, such a vector potential, call it $\boldsymbol{A}^{[1]}$, can be written in the form

$$\boldsymbol{A}^{[1]}(\boldsymbol{r}) = \sum_J \sum_M c_{11JM} \boldsymbol{S}_{11J}^M(\boldsymbol{r}). \tag{17.7.53}$$

Recall (7.24). Let us compute the *norm* of $\boldsymbol{A}^{[1]}$ as defined by the relation

$$||\boldsymbol{A}^{[1]}(\boldsymbol{r})||^2 = \int d\Omega\, [\boldsymbol{A}^{[1]}(\boldsymbol{r})]^* \cdot \boldsymbol{A}^{[1]}(\boldsymbol{r}). \tag{17.7.54}$$

Since the $\boldsymbol{S}_{11J}^M(\boldsymbol{r})$ are mutually orthogonal under angular integration, we find from (7.53), (U.3.18), and (U.4.3) the result

$$||\boldsymbol{A}^{[1]}(\boldsymbol{r})||^2 = r^2 \sum_J \sum_M |c_{11JM}|^2. \tag{17.7.55}$$

We know the value of c_{111M} is fixed by(7.39), and we have chosen to set the remaining c_{11JM} to zero. We now see, since (7.55) is a sum of squares, that doing so *minimizes* $||\boldsymbol{A}^{[1]}(\boldsymbol{r})||$. Similar computations may be made for other values of n. The result is that the choice we have made for $\boldsymbol{A}^s$ minimizes $||\boldsymbol{A}^{s[n]}(\boldsymbol{r})||$ for each value of n.

17.7.4 The $m = 0$ Case: Solenoid Example

In this subsection we will explore the fringe fields for a solenoid. Our aim will be to compare the vector potential in the symmetric Coulomb gauge as given in Section 15.4 and the vector potential in the minimum gauge.[13] Reference to Section 20.1.2 shows that, for a simple air-core solenoid, $C_0^{[1]}(z)$ falls off as $1/|z|^3$ for large $|z|$. See (20.1.28) and Figures 20.1.3 and 20.1.4. Correspondingly, in this case, the $C_0^{[n+1]}(z)$ will fall off as $1/|z|^{n+3}$ for large $|z|$. We expect the simple air-core to be representative of the worst scenario in the sense that the fringe fields for other kinds of solenoids will fall of at this same rate or *faster*.

According to Subsection 15.2.3, the scalar potential for the $m = 0$ case is given by the relation

$$\psi_0(x, y, z) = C_0^{[0]}(z) - (1/4)(x^2 + y^2)C_0^{[2]}(z) + \cdots . \tag{17.7.56}$$

Let us expand ψ about the point $(0, 0, z_0)$. To do so, introduce local deviation variables ξ, η, and ζ by making the definitions

$$x = 0 + \xi, \tag{17.7.57}$$

$$y = 0 + \eta, \tag{17.7.58}$$

$$z = z_0 + \zeta. \tag{17.7.59}$$

[13] Note that according to Section 15.5 there are a variety of Coulomb gauges including vertical-free and horizontal-free Coulomb gauges. Here we treat the case where there is the greatest symmetry between the vertical and horizontal components of $\boldsymbol{A}$.

Also define a *deviation* vector $\boldsymbol{r}^d$ by writing

$$\boldsymbol{r}^d = \xi \boldsymbol{e}_x + \eta \boldsymbol{e}_y + \zeta \boldsymbol{e}_z. \tag{17.7.60}$$

We can then define a scalar potential ψ^e suitable for *expansion* by writing the relation

$$\psi^e(\boldsymbol{r}^d; z_0) = \psi(\xi, \eta, z_0 + \zeta). \tag{17.7.61}$$

Indeed, making use of (7.56) yields for ψ^e the expansion

$$\begin{aligned} \psi^e(\boldsymbol{r}^d; z_0) &= C_0^{[0]}(z_0+\zeta) - (1/4)(\xi^2+\eta^2)C_0^{[2]}(z_0+\zeta) + \text{ terms of order 3 and higher} \\ &= C_0^{[0]}(z_0) + C_0^{[1]}(z_0)\zeta \\ &\quad + C_0^{[2]}(z_0)(\zeta^2/2) - (1/4)(\xi^2+\eta^2)C_0^{[2]}(z_0) \\ &\quad + \text{ terms of order 3 and higher} \\ &= \psi^{e[0]} + \psi^{e[1]} + \psi^{e[2]} + \text{ terms of order 3 and higher.} \end{aligned} \tag{17.7.62}$$

Here the upper index in square brackets on a quantity denotes its degree.[14] And, from (7.22), the magnetic field associated with this expansion is given by the expansion

$$\boldsymbol{B} = \boldsymbol{B}^{[0]} + \boldsymbol{B}^{[1]} + \text{ terms of order 2 and higher} \tag{17.7.63}$$

where

$$\boldsymbol{B}^{[0]} = C_0^{[1]}(z_0)\boldsymbol{e}_z \tag{17.7.64}$$

and

$$\begin{aligned} \boldsymbol{B}^{[1]} &= -(1/2)C_0^{[2]}(z_0)(\xi\boldsymbol{e}_x + \eta\boldsymbol{e}_y) + C_0^{[2]}(z_0)\zeta\boldsymbol{e}_z \\ &= -(1/2)C_0^{[2]}(z_0)(\xi\boldsymbol{e}_x + \eta\boldsymbol{e}_y - 2\zeta\boldsymbol{e}_z) \\ &= -(1/2)C_0^{[2]}(z_0)(\xi\boldsymbol{e}_x + \eta\boldsymbol{e}_y + \zeta\boldsymbol{e}_z - 3\zeta\boldsymbol{e}_z) \\ &= -(1/2)C_0^{[2]}(z_0)(\boldsymbol{r}^d - 3\zeta\boldsymbol{e}_z). \end{aligned} \tag{17.7.65}$$

Let us find the associated minimum vector potential. According to (7.52), we expect that $\boldsymbol{A}^s$ will be of the form

$$\boldsymbol{A}^s(\boldsymbol{r}^d) = \boldsymbol{A}^{s[1]}(\boldsymbol{r}^d) + \boldsymbol{A}^{s[2]}(\boldsymbol{r}^d) \tag{17.7.66}$$

with

$$\boldsymbol{A}^{s[1]}(\boldsymbol{r}^d) = -(1/2)\boldsymbol{r}^d \times \boldsymbol{B}^{[0]}(\boldsymbol{r}^d) \tag{17.7.67}$$

and

$$\boldsymbol{A}^{s[2]}(\boldsymbol{r}) = -(1/3)\boldsymbol{r}^d \times \boldsymbol{B}^{[1]}(\boldsymbol{r}^d). \tag{17.7.68}$$

Working out the indicated cross products in (7.67) and (7.68) gives the results

$$\boldsymbol{A}^{s[1]}(\boldsymbol{r}^d) = -(1/2)C_0^{[1]}(z_0)(\eta\boldsymbol{e}_x - \xi\boldsymbol{e}_y), \tag{17.7.69}$$

[14] Note that according to Section U.7 the $\psi^{e[n]}$ will be homogenous harmonic polynomials of degree n.

$$\boldsymbol{A}^{s[2]}(\boldsymbol{r}^d) = -(1/2)C_0^{[2]}(z_0)(\zeta\eta\boldsymbol{e}_x - \zeta\xi\boldsymbol{e}_y). \tag{17.7.70}$$

Simple calculation verifies that there are indeed the relations

$$\nabla \times \boldsymbol{A}^{s[1]}(\boldsymbol{r}^d) = \boldsymbol{B}^{[0]}(\boldsymbol{r}^d), \tag{17.7.71}$$

$$\nabla \times \boldsymbol{A}^{s[2]}(\boldsymbol{r}^d) = \boldsymbol{B}^{[1]}(\boldsymbol{r}^d), \tag{17.7.72}$$

as desired.

How do the results given by (7.69) and (7.70) compare with those provided by the symmetric Coulomb gauge? According to Section 15.4, the vector potential in the symmetric Coulomb gauge for the $m = 0$ case is given by the expressions

$$\begin{aligned}\hat{A}_x^0(\boldsymbol{r}) &= -(y/2)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{1}{2^{2\ell}\ell!(\ell+1)!}C_0^{[2\ell+1]}(z)(x^2+y^2)^\ell \\ &= -(y/2)[C_0^{[1]}(z) - (1/8)C_0^{[3]}(z)(x^2+y^2) + \cdots],\end{aligned} \tag{17.7.73}$$

$$\begin{aligned}\hat{A}_y^0(\boldsymbol{r}) &= (x/2)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{1}{2^{2\ell}\ell!(\ell+1)!}C_0^{[2\ell+1]}(z)(x^2+y^2)^\ell \\ &= (x/2)[C_0^{[1]}(z) - (1/8)C_0^{[3]}(z)(x^2+y^2) + \cdots],\end{aligned} \tag{17.7.74}$$

$$\hat{A}_z^0(\boldsymbol{r}) = 0. \tag{17.7.75}$$

In terms of the expansion variables (7.57) through (7.59) these expressions become

$$\begin{aligned}\hat{A}_x^0(\xi,\eta,z_0+\zeta) &= -(\eta/2)[C_0^{[1]}(z_0+\zeta) - (1/8)C_0^{[3]}(z_0+\zeta)(\xi^2+\eta^2) + \cdots] \\ &= -(\eta/2)[C_0^{[1]}(z_0) + C_0^{[2]}(z_0)\zeta] + \cdots \\ &= -(1/2)C_0^{[1]}(z_0)\eta - (1/2)C_0^{[2]}(z_0)\zeta\eta + \text{terms of order 3 and higher},\end{aligned} \tag{17.7.76}$$

$$\begin{aligned}\hat{A}_y^0(\xi,\eta,z_0+\zeta) &= (\xi/2)[C_0^{[1]}(z_0+\zeta) - (1/8)C_0^{[3]}(z_0+\zeta)(\xi^2+\eta^2) + \cdots] \\ &= (\xi/2)[C_0^{[1]}(z_0) + C_0^{[2]}(z_0)\zeta] + \cdots \\ &= (1/2)C_0^{[1]}(z_0)\xi + (1/2)C_0^{[2]}(z_0)\zeta\xi + \text{terms of order 3 and higher},\end{aligned} \tag{17.7.77}$$

$$\hat{A}_z^0(\xi,\eta,z_0+\zeta) = 0. \tag{17.7.78}$$

Comparison of (7.69) and (7.70) with (7.76) through (7.78) shows that for the $m = 0$ case, at least for the orders computed, the minimum vector potential constructed from field expansions about on-axis points *agrees* with the symmetric Coulomb gauge vector potential constructed from on-axis field data. In retrospect, this result should not be surprising. We should expect agreement through *all* orders because, according to Subsection 15.6.2, the $m = 0$ symmetric Coulomb gauge vector potential constructed from on-axis field data is, in fact, in the Poincaré-Coulomb gauge.

17.7.5 The $m = 1$ Case: Magnetic Monopole Doublet and Wiggler Examples

In this subsection we will first study the behavior of the leading and trailing fringe fields for a magnetic monopole doublet. Subsequently we will examine the case of a wiggler.

Magnetic Monopole Doublet Example

The doublet will be located at the origin $(0, 0, 0)$ as in Subsection 15.8.1 and we will expand the scalar potential $\psi(x, y, z)$ given by (15.8.3) about the mid-plane point $(x_0, 0, z_0)$. Consequently, if $z_0 \ll 0$, we will obtain an expansion in the leading region, and if $z_0 \gg 0$, we will obtain an expansion in the trailing region. Moreover, if $x_0 = 0$, the expansion will be on axis; and setting $x_0 \neq 0$ allows for expansion about a point on the design orbit. See Subsection 21.5.1 and Figures 21.5.1 and 21.5.6.

As before, introduce local deviation variables ξ, η, and ζ and a deviation vector $\boldsymbol{r}^d$ by making the definitions

$$x = x_0 + \xi, \tag{17.7.79}$$

$$y = \eta, \tag{17.7.80}$$

$$z = z_0 + \zeta, \tag{17.7.81}$$

and (7.60). We can then define a scalar potential ψ^e by writing the relation

$$\psi^e(\boldsymbol{r}^d; x_0, z_0) = \psi(x_0 + \xi, \eta, z_0 + \zeta). \tag{17.7.82}$$

Indeed, making use of (15.8.3) and (7.82) yields the expansion

$$\begin{aligned}\psi^e(\boldsymbol{r}^d; x_0, z_0) \;\; = \;\; & [-2ga/(x_0^2 + z_0^2 + a^2)^{3/2}]\eta \\ & +[6ga/(x_0^2 + z_0^2 + a^2)^{5/2}][\eta(x_0\xi + z_0\zeta)] \\ & + \text{ terms of order 3 and higher.}\end{aligned} \tag{17.7.83}$$

Note that $\psi(x_0, 0, z_0)$ vanishes so that there is no constant term in the expansion (7.83). We observe that the first term in (7.83) falls off as $(1/x_0)^3$ or $(1/z_0)^3$ for large x_0 or z_0, and the second falls off as $(1/x_0)^4$ or $(1/z_0)^4$. In general, successive terms fall off with ever increasing powers of $(1/x_0)$ or $(1/z_0)$.

Let us compute the magnetic field $\boldsymbol{B}$ associated with the first two terms in (7.83). We find the result

$$\begin{aligned}\boldsymbol{B}(\boldsymbol{r}^d; x_0, z_0) \;\; = \;\; & -[2ga/(x_0^2 + z_0^2 + a^2)^{3/2}]\boldsymbol{e}_y \\ & +[6ga/(x_0^2 + z_0^2 + a^2)^{5/2}](x_0\xi + z_0\zeta)\boldsymbol{e}_y \\ & +[6ga/(x_0^2 + z_0^2 + a^2)^{5/2}][\eta(x_0\boldsymbol{e}_x + z_0\boldsymbol{e}_z)].\end{aligned} \tag{17.7.84}$$

Next let us find the minimum vector potential $\boldsymbol{A}^s$ associated with the first two terms in (7.83). Begin by decomposing $\boldsymbol{B}$ into homogeneous polynomials by rewriting (7.84) in the form (7.63) with

$$\boldsymbol{B}^{[0]}(\boldsymbol{r}^d) \;\; = \;\; -[2ga/(x_0^2 + z_0^2 + a^2)^{3/2}]\boldsymbol{e}_y \tag{17.7.85}$$

and

$$\boldsymbol{B}^{[1]}(\boldsymbol{r}^d) = [6ga/(x_0^2 + z_0^2 + a^2)^{5/2}][(x_0\xi + z_0\zeta)\boldsymbol{e}_y + \eta(x_0\boldsymbol{e}_x + z_0\boldsymbol{e}_z)]. \tag{17.7.86}$$

The minimum vector potential associated with this magnetic field will again be given by the relations (7.66) through (7.68). Working out the indicated cross products yields the results

$$\boldsymbol{A}^{s[1]}(\boldsymbol{r}^d) = [ga/(x_0^2 + z_0^2 + a^2)^{3/2}](-\zeta\boldsymbol{e}_x + \xi\boldsymbol{e}_z), \tag{17.7.87}$$

$$\begin{gathered}\boldsymbol{A}^{s[2]}(\boldsymbol{r}^d) = [-2ga/(x_0^2 + z_0^2 + a^2)^{5/2}] \times \\ [(z_0\eta^2 - z_0\zeta^2 - x_0\xi\zeta)\boldsymbol{e}_x + (x_0\eta\zeta - z_0\xi\eta)\boldsymbol{e}_y + (x_0\xi^2 + z_0\xi\zeta - x_0\eta^2)\boldsymbol{e}_z].\end{gathered} \tag{17.7.88}$$

Simple calculation verifies that there are indeed the relations (7.71) and (7.72) as desired.

At this point it is instructive to compare the minimum vector potential with other possible vector potentials. We note that the design orbit for a dipole field is *curved*, and therefore for the most part does not lie on axis. Consequently we must generally compare the minimum vector potential with other possible vector potentials at off-axis points. By construction, the minimum vector potential *vanishes* at every expansion point. In contrast, other vector potentials (for example those based on employing on-axis expansions of a scalar potential or the use of Dirac strings) generally not have this property. We conclude that problems involving curved design orbits are more complicated than those for straight beam-line elements, and their treatment requires special care. This treatment is deferred to Chapter 21.

On-axis Entry and Exit Wiggler Example

There is an application for which expansions of $m = 1$ cylindrical harmonics may be useful, namely the case of wigglers when the excursion of the design orbit from the axis may be treated as small. That is, it is assumed that the design orbit enters and exits the wiggler on axis and nearly along the axis, and the excursions of the design orbit from the axis while within the wiggler may be treated as small.

According to (15.2.61) the the scalar potential for a (normal) dipole is given by the relation

$$\psi_{1,s}(x, y, z) = y[C_{1,s}^{[0]}(z) - (1/8)(x^2 + y^2)C_{1,s}^{[2]}(z) + \cdots]. \tag{17.7.89}$$

Upon invoking the definitions (7.57) through (7.60), the expansion (7.89) yields the expansion

$$\begin{aligned}\psi^e(\boldsymbol{r}^d; z_0) &= \eta[C_{1,s}^{[0]}(z_0 + \zeta) - (1/8)(\xi^2 + \eta^2)C_{1,s}^{[2]}(z_0 + \zeta) + \cdots] \\ &= \eta C_{1,s}^{[0]}(z_0) + \eta\zeta C_{1,s}^{[1]}(z_0) + \text{terms of order 3 and higher}.\end{aligned} \tag{17.7.90}$$

The magnetic field associated with the scalar potential (7.90) has an expansion of the form (7.63) with

$$\boldsymbol{B}^{[0]} = C_{1,s}^{[0]}(z_0)\boldsymbol{e}_y \tag{17.7.91}$$

and

$$\boldsymbol{B}^{[1]} = \zeta C^{[1]}_{1,s}(z_0)\boldsymbol{e}_y + \eta C^{[1]}_{1,s}(z_0)\boldsymbol{e}_z. \tag{17.7.92}$$

The first two terms in minimum vector potential expansion associated with this magnetic field will again be given by the relations (7.66) through (7.68). Working out the indicated cross products now yields the results

$$\boldsymbol{A}^{s[1]}(\boldsymbol{r}^d) = (1/2)C^{[0]}_{1,s}(z_0)(\zeta\boldsymbol{e}_x - \xi\boldsymbol{e}_z), \tag{17.7.93}$$

$$\boldsymbol{A}^{s[2]}(\boldsymbol{r}^d) = (1/3)C^{[1]}_{1,s}(z_0)[(\zeta^2 - \eta^2)\boldsymbol{e}_x + \xi\eta\boldsymbol{e}_y - \xi\zeta\boldsymbol{e}_z]. \tag{17.7.94}$$

And again simple calculation verifies that there are indeed the relations (7.71) and (7.72) as desired.

How does the the vector potential for a normal dipole in the Coulomb gauge compare with the minimum vector potential just found? From (15.4.95) through (15.4.97) we find, in the Coulomb gauge, that $\hat{\boldsymbol{A}}^{1,s}$ has the expansion

$$\begin{aligned}\hat{A}^{1,s}_x(\xi,\eta,z_0+\zeta) &= (1/4)(\xi^2-\eta^2)C^{[1]}_{1,s}(z_0+\zeta)+\cdots\\ &= (1/4)(\xi^2-\eta^2)C^{[1]}_{1,s}(z_0) + \text{terms of order 3 and higher,}\end{aligned} \tag{17.7.95}$$

$$\begin{aligned}\hat{A}^{1,s}_y(\xi,\eta,z_0+\zeta) &= (1/2)\xi\eta C^{[1]}_{1,s}(z_0+\zeta)+\cdots\\ &= (1/2)\xi\eta C^{[1]}_{1,s}(z_0) + \text{terms of order 3 and higher,}\end{aligned} \tag{17.7.96}$$

$$\begin{aligned}\hat{A}^{1,s}_z(\xi,\eta,z_0+\zeta) &= -\xi C^{[0]}_{1,s}(z_0+\zeta)+\cdots\\ &= -\xi C^{[0]}_{1,s}(z_0) - \xi\zeta C^{[1]}_{1,s}(z_0) + \text{terms of order 3 and higher.}\end{aligned} \tag{17.7.97}$$

Comparison of (7.93) and (7.94) with (7.95) through (7.97) shows that for the $m=1$ case the minimum vector potential constructed from field expansions about on-axis points *differs* from the Coulomb gauge vector potential constructed from on-axis field data.

What can be said about the $m=1$ azimuthal-free gauge vector potential? From (15.3.31) through (15.3.33), we see that $\boldsymbol{A}^{1,s}$ has the expansion

$$A^{1,s}_x(\xi,\eta,z_0+\zeta) = \xi^2 C^{[1]}_{1,s}(z_0)+\cdots\ , \tag{17.7.98}$$

$$A^{1,s}_y(\xi,\eta,z_0+\zeta) = \xi\eta C^{[1]}_{1,s}(z_0)+\cdots\ , \tag{17.7.99}$$

$$\begin{aligned}A^{1,s}_z(\xi,\eta,z_0+\zeta) &= -\xi C^{[0]}_{1,s}(z_0+\zeta)+\cdots\\ &= -\xi C^{[0]}_{1,s}(z_0) - \xi\zeta C^{[1]}_{1,s}(z_0) + \text{terms of order 3 and higher.}\end{aligned} \tag{17.7.100}$$

Comparison of (7.93) and (7.94) with (7.98) through (7.100) shows that for the $m = 1$ case the minimum vector potential constructed from field expansions about on-axis points also *differs* the azimuthal-free gauge vector potential constructed from on-axis field data. In retrospect, this difference should be less surprising because the minimum vector potential satisfies the Coulomb gauge condition, and the azimuthal-free gauge vector potential does not.

17.7.6 The $m = 2$ Case

Text to be worked on:

As a second example of a vector potential in the azimuthal-free gauge, suppose all terms in (2.37) vanish save for the 'pure' quadrupole terms $C^{[n]}_{2,s}(z)$. Then, again using (3.28) through (3.30), we find through terms of degree four that $\boldsymbol{A}^{2,s}$ has the expansion

$$A^{2,s}_x = (1/2)(x^3 - xy^2)C^{[1]}_{2,s}(z) + \cdots , \tag{17.7.101}$$

$$A^{2,s}_y = -(1/2)(y^3 - yx^2)C^{[1]}_{2,s}(z) + \cdots , \tag{17.7.102}$$

$$A^{2,s}_z = -(x^2 - y^2)C^{[0]}_{2,s}(z) + (1/6)(x^4 - y^4)C^{[2]}_{2,s}(z) + \cdots . \tag{17.7.103}$$

Note that the results (3.34) through (3.36) agree with (1.5.59) if we make the identification $Q/2 = C^{[0]}_{2,s}$. However, we know that $C^{[0]}_{2,s}(z)$ must depend on z because the on-axis gradients must vanish far outside any magnet. Therefore the functions $C^{[1]}_{2,s}(z)$, $C^{[2]}_{2,s}(z)$, etc. must be nonzero, at least near the end and fringe-field regions of any quadrupole magnet. We conclude again that, as a consequence of Maxwell's equations, the vector potential must contain terms beyond degree two in the variables x, y. Correspondingly, the transfer map for any real quadrupole must contain nonlinear terms.

As a second example of the use of these relations, let us compute $\hat{\boldsymbol{A}}^{2,s}$ for the quadrupole case $m = 2$. As before, suppose all terms in (2.37) vanish save for the quadrupole terms $C^{[n]}_{2,s}(z)$. Then, again using (4.92) through (4.94), we find, through terms of degree four, that $\hat{\boldsymbol{A}}^{2,s}$ has the expansion

$$\hat{A}^{2,s}_x = (1/6)(x^3 - 3xy^2)C^{[1]}_{2,s}(z) + \cdots , \tag{17.7.104}$$

$$\hat{A}^{2,s}_y = -(1/6)(y^3 - 3x^2y)C^{[1]}_{2,s}(z) + \cdots , \tag{17.7.105}$$

$$\hat{A}^{2,s}_z = -(x^2 - y^2)C^{[0]}_{2,s}(z) + (1/12)(x^4 - y^4)C^{[2]}_{2,s}(z) + \cdots . \tag{17.7.106}$$

This expansion should be compared with the azimuthal-free gauge expansion given by (3.34) through (3.36). Direct calculation again verifies that (4.1) and (4.4) are satisfied by $\hat{\boldsymbol{A}}^{2,s}$ through the order of the terms that have been retained in the expansion

17.7.7 The $m = 3$ Case

Exercises

17.7.1. Verify the relations (7.32) through (7.39).

17.7.2. Evidently the second-order portion of $\psi^e(\boldsymbol{r}^d; x_0, z_0)$ as given in (7.61) is composed of the monomials $\xi\eta$ and $\eta\zeta$. Show that these are the only monomials alowed at this order based on symmetry considerations. Verify that each monomial is an harmonic polynomial. Indeed, making the usual correspondence between ξ, η, ζ and x, y, z show, following the harmonic polynomial labeling scheme (U.2.9), that there are the relations

$$\xi\eta = [1/(4i)][\sqrt{32\pi/15}][H_2^2(\boldsymbol{r}) - H_2^{-2}(\boldsymbol{r})], \tag{17.7.107}$$

$$\eta\zeta = [-1/(2i)][\sqrt{8\pi/15}][H_2^1(\boldsymbol{r}) + H_2^{-1}(\boldsymbol{r})]. \tag{17.7.108}$$

Would these relations have been simpler had the polar axis, used to set up spherical polar coordinates, been taken to be the y axis instead of the z axis?

17.7.8 More Text

To proceed further it is useful to introduce some notation. Let z^{en} denote the z value where a transition is to be made from a region where the magnetic field is *taken* to vanish to the beginning of the leading fringe-field region. That is, the charged particle in question *enters* the leading fringe-field region when $z = z^{\text{en}}$. We will also use the notation z^{ben} and z^{aen} to denote z values just *before* and just *after* entry. Similarly, let z^{ex} denote the z value where a transition is to be made from the end of a trailing fringe-field region to a region where the magnetic field is again taken to vanish. That is, the charged particle in question *exits* the trailing fringe-field region when $z = z^{\text{ex}}$.

Entering a Leading Fringe-Field Region

Suppose we begin with a consideration of the transition between a field-free region and a leading-fringe field region. Let K^{ben} be the Hamiltonian before entry into the fringe-field region, and let K^{aen} be the Hamiltonian after entry into the fringe-field region. Then, since the magnetic field and its associated vector potential are assumed to vanish before entry, we have the relation

$$K^{\text{ben}} = -[(p_t^{\text{canben}})^2/c^2 - m^2c^2 - (p_x^{\text{canben}})^2 - (p_y^{\text{canben}})^2]^{1/2}. \tag{17.7.109}$$

And, since the magnetic field (and therefore also the vector potential) is nonzero after entry, we have the relation

$$K^{\text{aen}} = -[(p_t^{\text{canaen}})^2/c^2 - m^2c^2 - (p_x^{\text{canaen}} - qA_x)^2 - (p_y^{\text{canean}} - qA_y)^2]^{1/2} - qA_z. \tag{17.7.110}$$

Here we have added the suffixes *ben* and *aen* to the phase-space coordinates to denote their values before and after entry. Our task is to relate these phase-space coordinates.

As a first step, we naturally require that the coordinates be continous at $z^{\rm en}$,

$$x^{\rm ben} = x^{\rm aen}, \tag{17.7.111}$$

$$y^{\rm ben} = y^{\rm aen}, \tag{17.7.112}$$

$$t^{\rm ben} = t^{\rm aen}, \tag{17.7.113}$$

when $z = z^{\rm en}$. The next step is specify what is to be done with the momenta.

One possibility is to require that the slopes/"velocities" dx/dz, dy/dz, and dt/dz be continuous at $z^{\rm en}$. Let us work out the consequences of such a requirement. Before entry we have the result

$$\begin{aligned} &dx/dz = \partial K^{\rm ben}/\partial p_x^{\rm canben} = \\ &(p_x^{\rm canben}/[(p_t^{\rm canben})^2/c^2 - m^2c^2 - (p_x^{\rm canben})^2 - (p_y^{\rm canben})^2]^{1/2}, \end{aligned} \tag{17.7.114}$$

and after entry there is the result

$$\begin{aligned} &dx/dz = \partial K^{\rm aen}/\partial p_x^{\rm canaen} = \\ &(p_x^{\rm canaen} - qA_x)/[(p_t^{\rm canaen})^2/c^2 - m^2c^2 - (p_x^{\rm canaen} - qA_x)^2 - (p_y^{\rm canaen} - qA_y)^2]^{1/2}. \end{aligned} \tag{17.7.115}$$

An analogous result holds for dy/dz. Finally, for dt/dz there is the before entry result

$$\begin{aligned} &dt/dz = \partial K^{\rm ben}/\partial p_t^{\rm canben} = \\ &(-p_t^{\rm canben}/c^2)/[(p_t^{\rm canben})^2/c^2 - m^2c^2 - (p_x^{\rm canben})^2 - (p_y^{\rm canben})^2]^{1/2}, \end{aligned} \tag{17.7.116}$$

and the after entry result

$$\begin{aligned} &dt/dz = \partial K^{\rm aen}/\partial p_t^{\rm canaen} = \\ &(-p_t^{\rm canaen}/c^2)/[(p_t^{\rm canaen})^2/c^2 - m^2c^2 - (p_x^{\rm canaen} - qA_x)^2 - (p_y^{\rm canaen} - qA_y)^2]^{1/2}. \end{aligned} \tag{17.7.117}$$

Now equate the far right sides of (7.16) and (7.17), the far right sides of there dy/dz counterparts, and the far right sides of (7.18) and (7.19). So doing yields the transition matching relations

$$p_x^{\rm canben} = p_x^{\rm canaen} - qA_x, \tag{17.7.118}$$

$$p_y^{\rm canben} = p_y^{\rm canaen} - qA_y, \tag{17.7.119}$$

$$p_t^{\rm canben} = p_t^{\rm canaen}. \tag{17.7.120}$$

In view of (7.3) and (7.5) these relations can also be written in the form

$$p_x^{\rm mechben} = p_x^{\rm mechaen}, \tag{17.7.121}$$

$$p_y^{\rm mechben} = p_y^{\rm mechaen}, \tag{17.7.122}$$

$$p_z^{\rm mechben} = p_z^{\rm mechaen}, \tag{17.7.123}$$

The relation (7.22) is satisfactory because magnetic forces do not change the energy. Recall (1.6.17). However, we also desire that the phase-space transformation given by (7.12) through (7.14) and (7.20) through (7.22) be symplectic. Calculation shows that it is not. Compute the Poisson bracket of the right sides of (7.20) and (7.21) to find the result

$$\begin{aligned}[p_x^{\rm canaen} - qA_x, p_y^{\rm canaen} - qA_y] &= [p_x^{\rm canaen}, -qA_y] + [-qA_x, p_y^{\rm canaen}] \\ &= q\{\partial A_y/\partial x^{\rm aen} - \partial A_x/\partial y^{\rm aen}\} = qB_z. \quad (17.7.124)\end{aligned}$$

While hopefully small, generally $B_z(x, y, z^{\rm en})$ differs from zero at the beginning of the leading fringe-field region. On the other hand, the Poisson bracket of the left sides of (7.20) and (7.21) must vanish since $p_x^{\rm canben}$ and $p_y^{\rm canben}$ are supposed to be canonical momenta. Therefore the the phase-space transformation given by (7.12) through (7.14) and (7.20) through (7.22) is generally not symplectic.

We expect that neglect of the magnetic field in the region $z < z^{\rm en}$ will lead to some error in trajectories. However, we do not want this error to violate the symplectic condition. The simplest way to maintain the symplectic condition is to retain the relations (7.12) through (7.14) and replace the relations (7.20) through (7.22) by the relations

$$p_x^{\rm canben} = p_x^{\rm canaen}, \quad (17.7.125)$$

$$p_y^{\rm canben} = p_y^{\rm canaen}, \quad (17.7.126)$$

$$p_t^{\rm canben} = p_t^{\rm canaen}. \quad (17.7.127)$$

In this case the transition matching relations (7.12) through (7.14) and (7.20) through (7.22) amount to the identity map $\mathcal{I}$, and the symplectic condition is trivially satisfied. Now, however, the error in trajectories manifests itself in that the slopes/"velocities" dx/dz, dy/dz, and dt/dz may be expected to be discontinuous at at $z^{\rm en}$. Inspection of (7.16) and (7.17), their dy/dz counterparts, and (7.18) and (7.19) shows that, in lowest approximation, these discontinuities are proportional to $A_x(x, y, z^{\rm en})$ and $A_y(x, y, z^{\rm en})$. Indeed, again in view of (7.3) and (7.5), the transition relations (7.26) through (7.28) can be written in the form

$$\Delta \boldsymbol{p}^{\rm mech} = \boldsymbol{p}^{\rm mechaen} - \boldsymbol{p}^{\rm mechben} = q\boldsymbol{A}(x, y, z^{\rm en}). \quad (17.7.128)$$

It is therefore desirable, where feasible, to work in a gauge where $\boldsymbol{A}(x, y, z^{\rm en})$ is as small as possible.

One way to view the symplectic matching relations (7.12) and (7.14) and (7.24) through (7.26) is to replace the Hamiltonian (7.1) by a modified Hamiltonian $K^{\rm mod}$ given by

$$K^{\rm mod} = -[(p_t^{\rm can})^2/c^2 - m^2c^2 - (p_x^{\rm can} - qA_x^{\rm mod})^2 - (p_y^{\rm can} - qA_y^{\rm mod})^2]^{1/2} - qA_z^{\rm mod} \quad (17.7.129)$$

where

$$\boldsymbol{A}^{\rm mod}(x, y, z) = \theta(z - z^{\rm en})\boldsymbol{A}(x, y, z). \quad (17.7.130)$$

That is, the vector potential is taken to vanish for $z < z^{\rm en}$ and turns on at $z = z^{\rm en}$. A little thought shows that integrating the equations of motion associated with this modified Hamiltonian automatically produces the matching relations (7.12) and (7.14) and (7.24) through (7.26).

What is the modified magnetic field $\boldsymbol{B}^{\rm mod}$ associated with this modified vector potential? Evaluation of $\nabla \times \boldsymbol{A}^{\rm mod}$ gives the relations

$$B_x^{\rm mod}(x,y,z) = \theta(z - z^{\rm en})B_x(x,y,z) - \delta(z - z^{\rm en})A_y(x,y,z), \tag{17.7.131}$$

$$B_y^{\rm mod}(x,y,z) = \theta(z - z^{\rm en})B_y(x,y,z) + \delta(z - z^{\rm en})A_x(x,y,z), \tag{17.7.132}$$

$$B_z^{\rm mod}(x,y,z) = \theta(z - z^{\rm en})B_z(x,y,z). \tag{17.7.133}$$

Calculation shows that $\boldsymbol{B}^{\rm mod}$ has divergence

$$\nabla \cdot \boldsymbol{B}^{\rm mod} = 0, \tag{17.7.134}$$

as desired. What current produces this modified magnetic field? The modified magnetic field satisfies the curl relation

$$\nabla \times \boldsymbol{B}^{\rm mod} = \boldsymbol{j}^{\rm mod} \tag{17.7.135}$$

where

$$\begin{aligned} j_x^{\rm mod} &= (\partial/\partial y)B_z^{\rm mod} - (\partial/\partial z)B_y^{\rm mod} \\ &= -\delta(z - z^{\rm en})[B_y(x,y,z) + (\partial/\partial z)A_x(x,y,z)] - \delta'(z - z^{\rm en})A_x(x,y,z) \\ &= -\delta(z - z^{\rm en})[2(\partial/\partial z)A_x(x,y,z) - (\partial/\partial x)A_z(x,y,z)] - \delta'(z - z^{\rm en})A_x(x,y,z), \end{aligned} \tag{17.7.136}$$

$$\begin{aligned} j_y^{\rm mod} &= (\partial/\partial z)B_x^{\rm mod} - (\partial/\partial x)B_z^{\rm mod} \\ &= -\delta(z - z^{\rm en})[-B_x(x,y,z) + (\partial/\partial z)A_y(x,y,z)] - \delta'(z - z^{\rm en})A_y(x,y,z) \\ &= -\delta(z - z^{\rm en})[2(\partial/\partial z)A_y(x,y,z) - (\partial/\partial y)A_z(x,y,z)] - \delta'(z - z^{\rm en})A_y(x,y,z), \end{aligned} \tag{17.7.137}$$

$$\begin{aligned} j_z^{\rm mod} &= (\partial/\partial x)B_y^{\rm mod} - (\partial/\partial y)B_x^{\rm mod} \\ &= \delta(z - z^{\rm en})[(\partial/\partial x)A_x(x,y,z) + (\partial/\partial y)A_y(x,y,z)]. \end{aligned} \tag{17.7.138}$$

Evidently terminating the vector potential at $z = z^{\rm en}$ is equivalent to introducing sheet (corresponding to the δ function) and double-sheet (corresponding to the δ' function) currents at $z = z^{\rm en}$. And the strengths of these currents are proportional to the values of $\boldsymbol{A}$ and its first derivatives at $z = z^{\rm en}$.

Chapter 18

Tools for Numerical Implementation

This chapter develops the tools that are necessary for the numerical implementation of the methods of Chapter 14. These tools include splines, bicubic interpolation, spline-based Fourier transforms, and routines for the calculation of Bessel and Mathieu functions.

18.1 Third-Order Splines

For our purposes splines are piecewise polynomial fits where various continuity conditions are imposed at the points the pieces join. There are two common possibilities: Either a fit is desired over some interval that may be viewed a portion of the real line; or a fit is desired over a full angular interval, in which case periodicity is to be imposed.

18.1.1 Fitting Over an Interval

Let $y = f(x)$ be a function of a single variable. Suppose its values y_j are specified at $N + 1$ equally spaced points x_0, x_1, $\cdots$, x_N over the interval $[x_0, x_N]$. (See Figure 2.1.1 for a similar setup employing the variable t.) Also suppose that on each subinterval $[x_j, x_{j+1}]$ we want to approximate f by a cubic polynomial with cubic polynomials on adjacent subintervals matched is such a way that f has continuous first and second derivatives at each *interior* point x_j. Such an approximation will be called a *cubic* or *third-order spline*. We will use these splines both for interpolation and for the calculation of direct and inverse Fourier transforms. See Sections 15.2 and 15.3.5.

Let us see what information is required to construct such a sequence of third-order polynomials (one for each interval). On the first subinterval, $[x_0, x_1]$, write

$$y = f_0(x) = a_0 + b_0(x - x_0) + c_0(x - x_0)^2 + d_0(x - x_0)^3 \tag{18.1.1}$$

where the coefficients a_0 through d_0 are to be determined. Then the condition

$$f_0(x_0) = y_0 \tag{18.1.2}$$

yields the relation

$$a_0 = y_0. \tag{18.1.3}$$

Next, for the moment, suppose we further require that

$$f_0'(x_0) = \beta_0 \tag{18.1.4}$$

and

$$f_0''(x_0) = \gamma_0. \tag{18.1.5}$$

These requirements yield the further relations

$$b_0 = \beta_0, \tag{18.1.6}$$

$$c_0 = \gamma_0/2. \tag{18.1.7}$$

Finally, the condition

$$f_0(x_1) = y_1 \tag{18.1.8}$$

yields the relation

$$y_1 = y_0 + \beta_0(x_1 - x_0) + (\gamma_0/2)(x_1 - x_0)^2 + d_0(x_1 - x_0)^3, \tag{18.1.9}$$

which can be solved to yield the value of d_0. The conditions (1.2) and (1.8), plus the requirements (1.4) and (1.5), have completely specified the first cubic polynomial (1.1).

Let us now move on to the second subinterval $[x_1, x_2]$. On this subinterval we assume that there is the cubic polynomial representation

$$y = f_1(x) = a_1 + b_1(x - x_1) + c_1(x - x_1)^2 + d_1(x - x_1)^3, \tag{18.1.10}$$

and we find from the condition

$$f_1(x_1) = y_1 \tag{18.1.11}$$

the relation

$$a_1 = y_1. \tag{18.1.12}$$

Also, since $f_0(x)$ has already been determined, the values $f_0'(x_1)$ and $f_0''(x_1)$ are already known. The relations (1.8) and (1.11) already guarantee continuity of f_0 and f_1 across the join at x_1. Next, as set forth in our initial statement of intent, let us require that

$$f_1'(x_1) = \beta_1 = f_0'(x_1) \tag{18.1.13}$$

and

$$f_1''(x_1) = \gamma_1 = f_0''(x_1). \tag{18.1.14}$$

That is, we also require continuity in the first and second derivatives. From (1.13) and (1.14) we conclude that

$$b_1 = \beta_1 = f_0'(x_1) \tag{18.1.15}$$

and

$$c_1 = \gamma_1/2 = f_0''(x_1)/2. \tag{18.1.16}$$

Finally, the condition

$$f_1(x_2) = y_2 \tag{18.1.17}$$

yields the relation

$$y_2 = y_1 + \beta_1(x_2 - x_1) + (\gamma_1/2)(x_2 - x_1)^2 + d_1(x_2 - x_1)^3, \tag{18.1.18}$$

which can be solved to yield the value of d_1. We see that the condition (1.17) plus the continuity requirements have completely specified the second cubic polynomial (1.10).

It is clear that this process can be continued for the subsequent subintervals $[x_2, x_3]$ $\cdots$ $[x_{N-1}, x_N]$ so that all the cubic polynomials are completely specified in terms of the y_0 $\cdots$ y_N and the two numbers β_0 and γ_0. Now we come to a subtle point. Since the cubic polynomials are all completely specified, the value $f'_{N-1}(x_N)$ is also specified in terms of the y_1 $\cdots$ y_N and the two numbers β_0 and γ_0. In fact, there will be a relation of the form

$$f'_{N-1}(x_N) = \delta + \epsilon\gamma_0 \tag{18.1.19}$$

where $\delta(\beta_0, y_0, \cdots, y_N)$ is some (linear) function of $\beta_0, y_0, \cdots, y_N$, and ϵ is some *nonzero* coefficient. Therefore, we may adjust γ_0 in such a way as to give $f'_{N-1}(x_N)$ any desired value. Put another way, we may replace a knowledge of γ_0 with a specification of $f'_{N-1}(x_N)$. Let us write

$$f'(x_0) = f'_0(x_0) = \beta_0 \tag{18.1.20}$$

and

$$f'(x_N) = f'_{N-1}(x_N). \tag{18.1.21}$$

With this notation in mind, we may view a cubic spline as being completely specified by the values y_0 $\cdots$ y_N and the two end-point derivatives $f'(x_0)$ and $f'(x_N)$.[1]

Of course, in general the end-point derivatives are unknown. Many users of cubic splines simply set end-point derivatives (either first or second) to zero on the grounds of convenience and the fact (to be demonstrated shortly) that their values actually have little effect on the spline approximation once one is a few grid points away from the ends.[2] For our purposes, we prefer to use the first few data points near the end points to estimate the end-point first derivatives. For example, upon deciding to use the first three points to estimate $f'(x_0)$ and the last three to estimate $f'(x_N)$, we use the approximations

$$\begin{aligned} f'(x_0) &= (1/h)[-(3/2)y_0 + 2y_1 - (1/2)y_2] + O(h^2), \\ f'(x_N) &= (1/h)[(3/2)y_N - 2y_{N-1} + (1/2)y_{N-2}] + O(h^2) \end{aligned} \tag{18.1.22}$$

where h is the spacing between successive grid points,

$$h = x_1 - x_0. \tag{18.1.23}$$

If we choose to employ the first and last four points, we use the approximations

$$\begin{aligned} f'(x_0) &= (1/h)[-(11/6)y_0 + 3y_1 - (3/2)y_2 + (1/3)y_3] + O(h^3), \\ f'(x_N) &= (1/h)[(11/6)y_N - 3y_{N-1} + (3/2)y_{N-2} - (1/3)y_{N-3}] + O(h^3). \end{aligned} \tag{18.1.24}$$

[1] Evidently, an alternate procedure is to specify the values y_0 $\cdots$ y_N and the two second-order end-point derivatives $f''(x_0)$ and $f''(x_N)$.

[2] If the second derivatives at each end point are set to zero, such a cubic spline is said to be *natural*.

See Exercise 1.1.

At this juncture we must remark that the algorithm we have been describing for computing cubic splines, while pedagogically instructive, is not numerically stable against roundoff errors. A stable spline routine is given in Appendix L.

As already alluded to, one of the advantages of spline fits is *localization* in that the fits over any subinterval in x depend primarily on the y_j values whose corresponding x_j lie within that subinterval. For example, consider the function $y = f(x)$ defined on the interval $x \in [0, 3]$ such that $f(1.5) = 1$ and $f = 0$ elsewhere. Figure 1.1 shows the function that is produced by a cubic spline fit when $h = .1$. In this case 31 points are used to make the fit with $x_0 = 0$, $x_{30} = 3$, and all y_j set to zero save for setting y_{15}=1. Also, $f'(0)$ and $f'(3)$ are set to zero. Evidently the spline fit falls rapidly to zero on either side of $x = 1.5$. In fact, it can be shown that the successive maxima *decay exponentially* as

$$y(x) \sim \exp[-\alpha(1/h)|x - 1.5|] \tag{18.1.25}$$

where

$$\alpha = \log(2 + \sqrt{3}) \simeq 1.317. \tag{18.1.26}$$

Similarly, Figure 1.2 shows the fit that is produced for the same setup when all y_j are set to zero, $f'(0)$ is set to 1, and $f'(3)$ is set to zero. Again the fit decays to zero exponentially with exponent $-\alpha$.

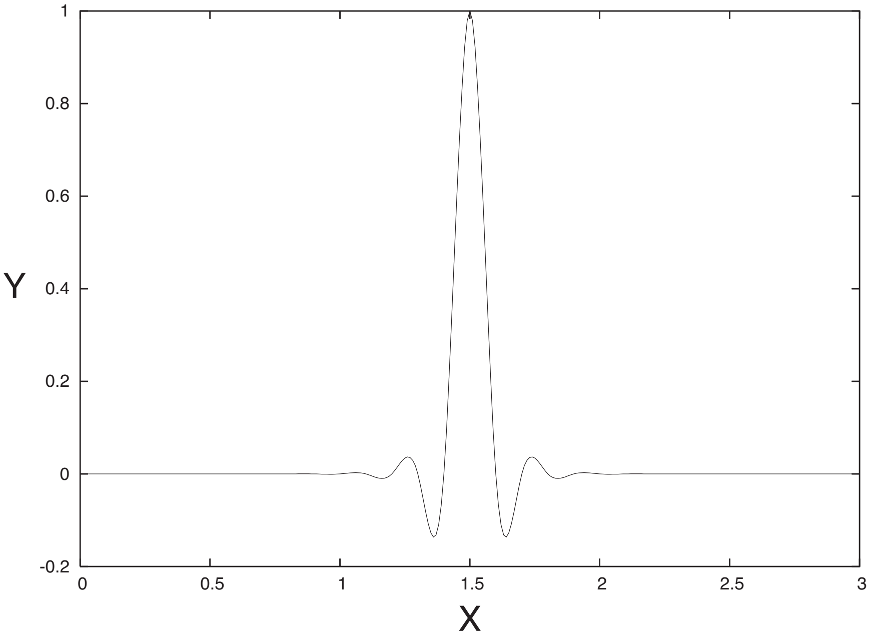

Figure 18.1.1: The 31-point spline fit associated with $y_{15} = 1$ and all other $y_j = 0$. Also, $f'(0)$ and $f'(3)$ are set to zero. Note that the fit falls rapidly to zero on either side of $x = 1.5$.

18.1.2 Periodic Splines

The splines defined so far are useful for fitting a general function over an interval. Suppose we instead want to fit a function which is known to be periodic. Such functions will typically

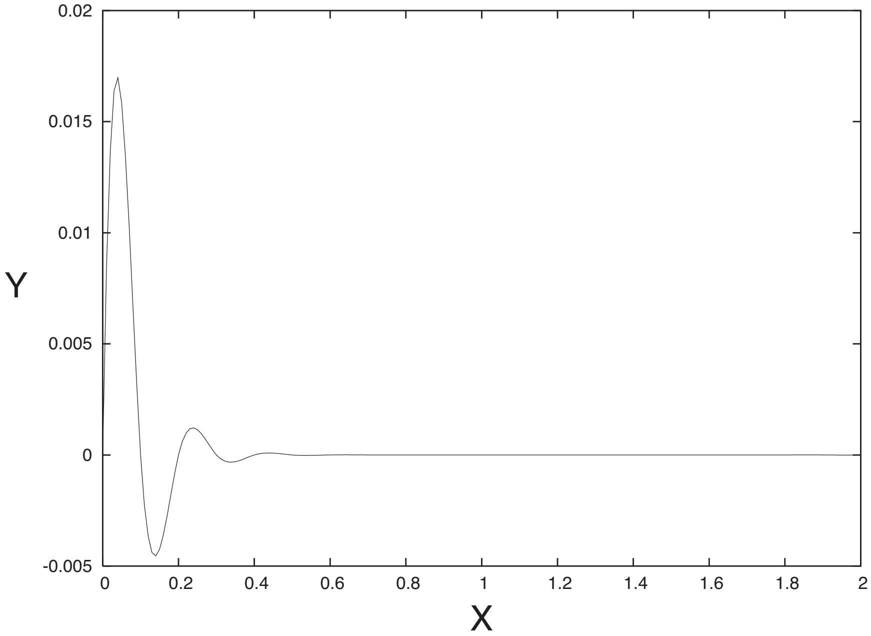

Figure 18.1.2: The spline fit associated with $f'(x_0) = 1$, all $y_j = 0$, and $f'(x_{30}) = 0$. Note that the fit falls rapidly to zero for x beyond $x_0 = 0$. Only the results over the interval $x \in [0, 2]$ are displayed.

depend on angular variables.

As before, we imagine that there are known function values y_j at the points x_0 to x_N, but that now $y_0 = y_N$. Begin the construction as before to find a unique set of cubic polynomials in terms of the y_j and β_0 and γ_0. With this construction, the quantities $f'_{N-1}(x_N)$ and $f''_{N-1}(x_N)$ are specified. Indeed, there will be relations of the form

$$f'_{N-1}(x_N) = r(y_0, \cdots, y_N) + s\beta_0 + t\gamma_0, \tag{18.1.27}$$

$$f''_{N-1}(x_N) = \rho(y_0, \cdots, y_N) + \sigma\beta_0 + \tau\gamma_0 \tag{18.1.28}$$

where r and ρ are linear functions of the y_j; and s, t, σ, and τ are proportionality constants. Now adjust both β_0 and γ_0 such that there are the relations

$$f'_{N-1}(x_N) = f'_0(x_0) \tag{18.1.29}$$

and

$$f''_{N-1}(x_N) = f''_0(x_0). \tag{18.1.30}$$

So doing will make the spline fit periodic in that not only will $y_0 = y_N$, also the first and second derivatives will match at the endpoints. In view of (1.4), (1.5), (1.27), and (1.28), these matching relations are equivalent to the conditions

$$\beta_0 = r(y_0, \cdots, y_N) + s\beta_0 + t\gamma_0, \tag{18.1.31}$$

$$\gamma_0 = \rho(y_0, \cdots, y_N) + \sigma\beta_0 + \tau\gamma_0. \tag{18.1.32}$$

These equations have a (unique) solution provided the matrix M defined by

$$M = \begin{pmatrix} s-1 & t \\ \sigma & \tau - 1 \end{pmatrix}. \tag{18.1.33}$$

has a nonzero determinant, which can be shown to be always the case. We conclude that a periodic cubic spline is uniquely specified by the values $y_0, \cdots, y_N$ with $y_0 = y_N$.

Here again we must remark that the pedagogically instructive algorithm we have been describing for computing periodic cubic splines is not numerically stable against roundoff errors. A stable periodic spline routine is also given in Appendix L.

18.1.3 Error Estimate for Spline Approximation

There remains the question of accuracy for a cubic spline approximation. Suppose the function f that is being approximated is known to have a continuous fourth-order derivative. Then it can be shown that the error involved in using its spline approximation f_{sa} has the estimate

$$\text{error}(x) = f(x) - f_{\text{sa}}(x) = (h^4/24)\theta^2(1-\theta)^2 f^{\text{iv}}(x) + O(h^5) \tag{18.1.34}$$

for x in the subinterval $[x_j, x_{j+1}]$ and

$$\theta = (x - x_j)/h. \tag{18.1.35}$$

Note that, according to (1.35), θ lies in the interval $\theta \in [0, 1]$. It is easy to check that in this interval the quantity $\theta^2(1-\theta)^2$ does not exceed 1/16.

As an example, suppose

$$f(x) = 1 - x^4 \tag{18.1.36}$$

and we wish to approximate f over the interval $[-1, 1]$. That is, we set $x_0 = -1$ and $x_N = 1$. Figure 1.3 shows f and its spline fit f_{sa} for $h = .1$ (which corresponds to $N = 20$). They are indistinguishable on the scale shown. Figure 1.4 shows the error that occurs when $h = .1$. By construction the error vanishes at the grid points x_j, and the global error is consistent with the estimate (1.34).

In making the spline fits for Figures 1.3 and 1.4, we have used as input for the end-point derivatives the exact results $f'(-1) = 4$ and $f'(+1) = -4$ based on (1.36). Suppose we instead use (1.24) to estimate the end-point derivatives. Figure 1.5 shows the error that then occurs. We see that there is some error at the endpoints and that, as expected from localization, this error soon damps away so that only the error already seen in Figure 1.4 remains. We remark that the use of (1.24) gives the results $f'(-1) = 3.994$ and $f'(+1) = -3.994$. It is pleasantly surprising that, at its worst, the error in the spline fit is considerably less than might have naively been expected based on the error in the estimated end-point derivatives. Finally we remark that, for our applications, the end points occur in fringe-field regions where both the function being approximated and its derivatives are very small. Thus, we expect that the error made in using (1.22) or (1.24) in this case will be negligible.

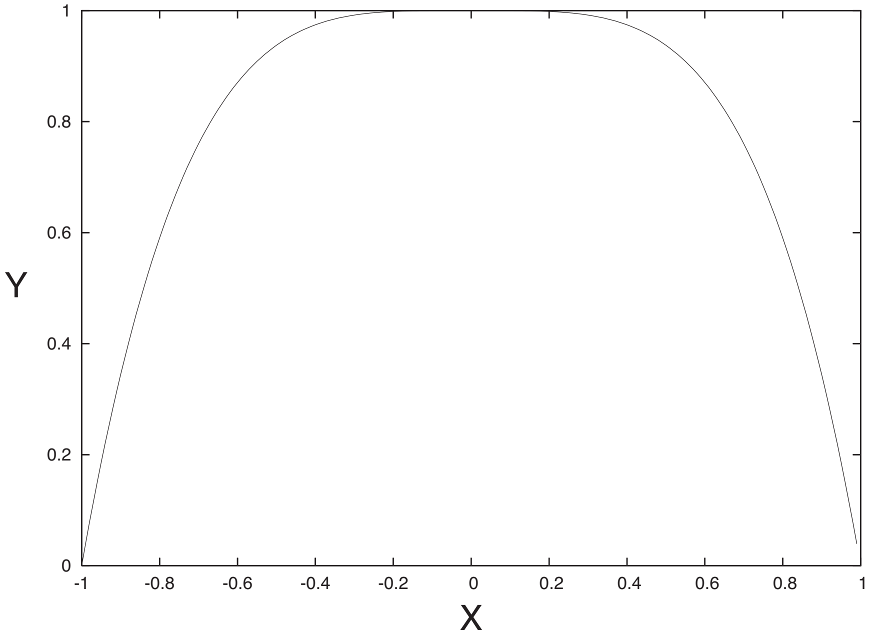

Figure 18.1.3: The function f and its spline fit $f_{\rm sa}$ for $h = .1$. They appear identical.

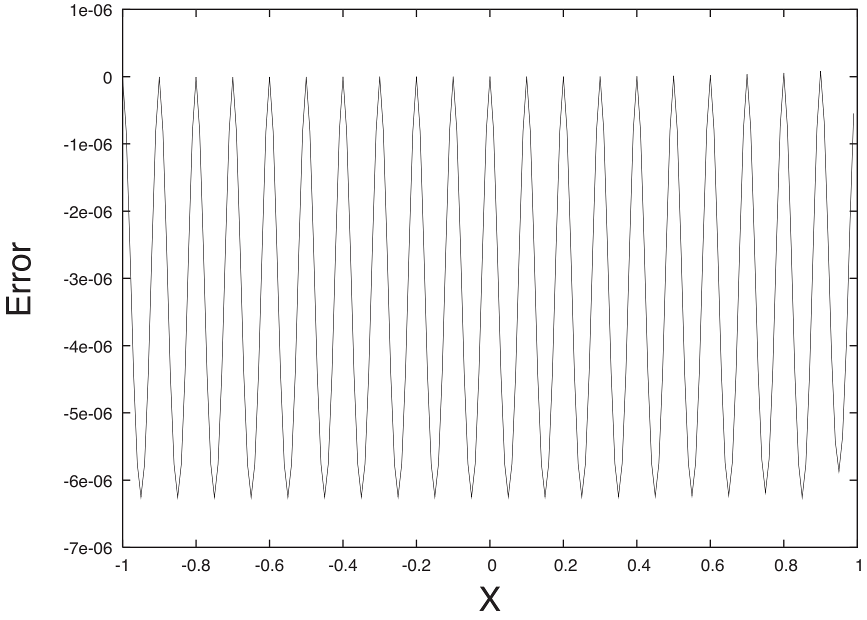

Figure 18.1.4: The difference between the function f and its spline fit $f_{\rm sa}$ for $h = .1$. Here error $= f(x) - f_{\rm sa}(x)$. The spline $f_{\rm sa}$ is constructed using the exact values for the end-point derivatives.

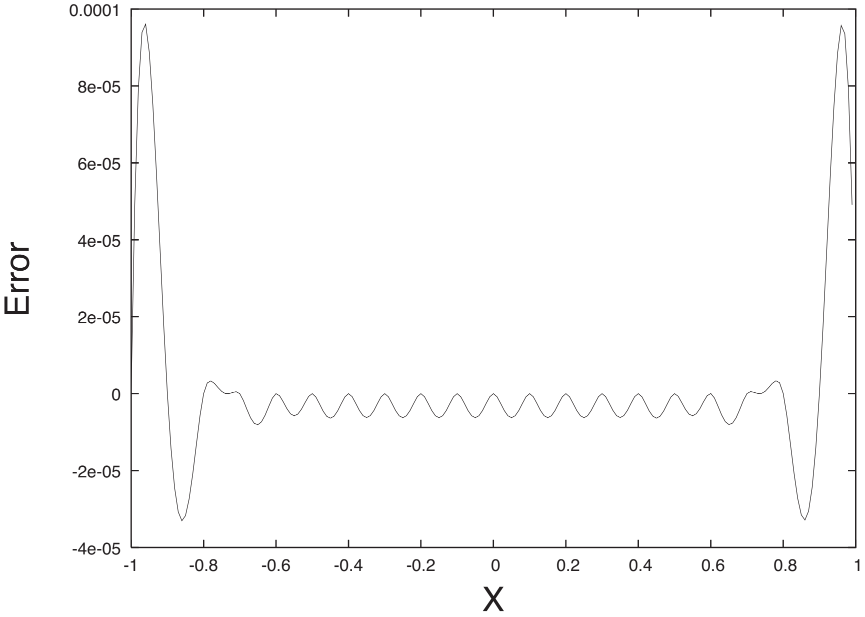

Figure 18.1.5: The difference between the function f and its spline fit $f_{\rm sa}$ for $h = .1$. Here error $= f(x) - f_{\rm sa}(x)$. The spline $f_{\rm sa}$ is constructed using (1.24) to estimate the end-point derivatives.

Exercises

18.1.1. Verify (1.22) through (1.24) using the finite difference calculus of Section 2.4.

18.2 Interpolation

The calculations of Chapter 14 begin with data provided on some regular Cartesian grid. With regard to locations in the z coordinate, we will use those provided, and call them Z_L. However, for the coordinates x and y, interpolation may be required.

In the case where a circular cylinder is employed, we need to interpolate to equi-angular locations given by the relations

$$\bar{x}_i = R\cos(\phi_i), \tag{18.2.1}$$

$$\bar{y}_i = R\sin(\phi_i) \tag{18.2.2}$$

where

$$\phi_0 = 0 \tag{18.2.3}$$

and

$$\phi_N = 2\pi. \tag{18.2.4}$$

See the second frame of Figure 14.1.1. Typically, in the circular cylinder case we take N to have the value $N \approx 50$.

In the case of an elliptical cylinder we write

$$\bar{x}_i = f\cosh(U)\cos(v_i), \tag{18.2.5}$$

$$\bar{y}_i = f \sinh(U) \sin(v_i) \tag{18.2.6}$$

where the v_i are equally spaced with

$$v_0 = 0 \tag{18.2.7}$$

and

$$v_N = 2\pi. \tag{18.2.8}$$

See Figure 14.4.3. Typically, in the elliptic cylinder case, we take N to have the value $N \approx 120$.

18.2.1 Bicubic Interpolation

For each $\bar{x}_i$, $\bar{y}_i$ pair, find the closest 16 points in the regular grid in the x, y plane. See Figure 2.1. Note that the regular grid may be rectangular rather than square. Let X_J and Y_K be the coordinates of the grid point in the lower left corner. That is, we have the following inequalities:

$$X_{J+1} \le \bar{x}_i \le X_{J+2}, \tag{18.2.9}$$

$$Y_{K+1} \le \bar{y}_i \le Y_{K+2}. \tag{18.2.10}$$

Introduce local expansion variables ξ and η by the relations

$$x = X_J + \xi, \tag{18.2.11}$$

$$y = Y_K + \eta; \tag{18.2.12}$$

and also write

$$\bar{x}_i = X_J + \bar{\xi}_i, \tag{18.2.13}$$

$$\bar{y}_i = Y_K + \bar{\eta}_i. \tag{18.2.14}$$

We then interpolate the quantity of interest, be it a potential value or some transverse field component, from the regular grid to the point $\bar{\xi}_i$, $\bar{\eta}_i$ with the aid of a *bicubic* polynomial P in the variables ξ and η.[3] This is a polynomial of the form

$$P(\xi,\eta) = \sum_{m,n=1}^{4} c_{mn}\xi^{m-1}\eta^{n-1} = \sum_{m=1}^{4}(\sum_{n=1}^{4} c_{mn}\eta^{n-1})\xi^{m-1} = \sum_{n=1}^{4}(\sum_{m=1}^{4} c_{mn}\xi^{m-1})\eta^{n-1} \tag{18.2.15}$$

where the coefficients c_{mn} are to be determined. Note that P is cubic in each of the variables ξ and η separately. Hence the name bicubic. Also, note that P is *not* a homogeneous polynomial. For example, it contains the term $\xi^3\eta^3$, but it does not contain the terms ξ^6 or η^6. Finally note that, because c is 4×4, it requires 16 numbers to specify the c_{mn}. This is encouraging, because we have assumed that we have data on the 16 nearest-neighbor grid points.[4]

[3] If the point $\bar{\xi}_i$, $\bar{\eta}_i$ happens to fall on a grid line, then only one-dimensional cubic interpolation is required. If it falls on a grid point, no interpolation is required at all.

[4] This count would not work out so neatly had we attempted what might appear to be more desirable, namely an expansion in homogenous polynomials.

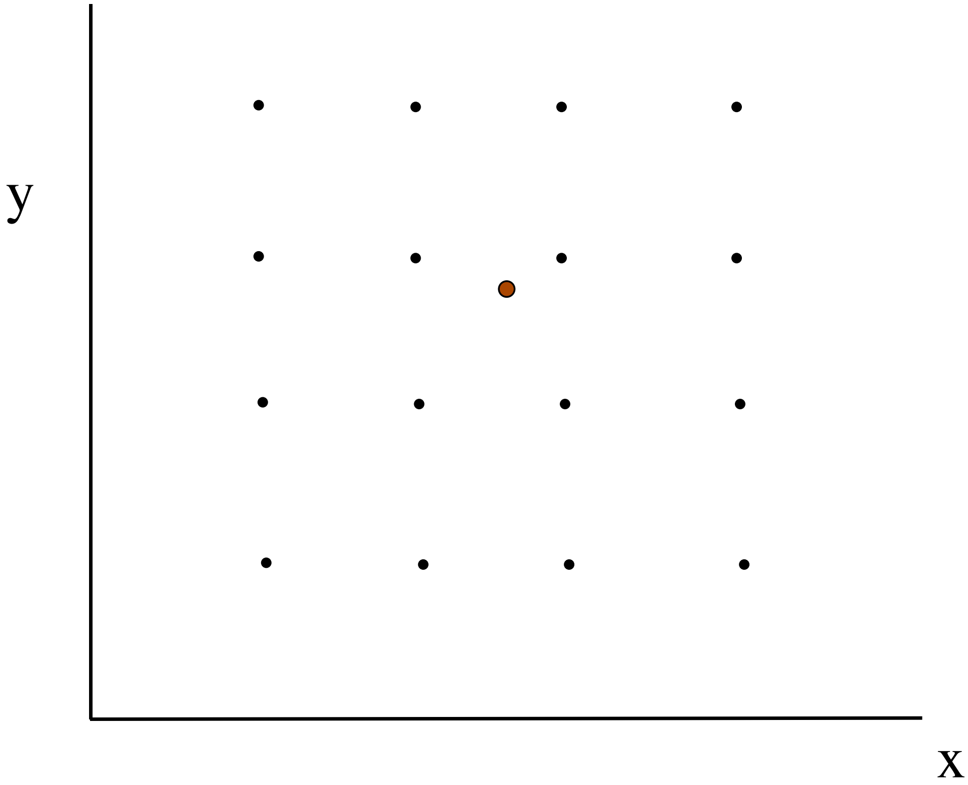

Figure 18.2.1: The point $\bar{x}_i$, $\bar{y}_i$ and its 16 nearest-neighbor grid points. The coordinates of the grid point at the lower left corner are X_J and Y_K.

Let us first verify that P is uniquely defined in terms of values at the the 16 nearest-neighbor grid points. For example, suppose we wish to interpolate a potential function ψ. Let h_x and h_y be the grid spacings in the x and y directions, respectively. Then we know the values Ψ_{jk} given by the relations

$$\Psi_{jk} = \psi[X_J + (j-1)h_x, Y_K + (k-1)h_y, Z_L] \text{ for } j,k \in [1,4]. \tag{18.2.16}$$

In the spirit of (2.11) and (2.12), write

$$\xi_j = (j-1)h_x \tag{18.2.17}$$

and

$$\eta_k = (k-1)h_y. \tag{18.2.18}$$

Then we wish to have the relations

$$\Psi_{jk} = P(\xi_j, \eta_k) = \sum_{m,n=1}^{4} c_{mn} \xi_j^{m-1} \eta_k^{n-1} \ \text{ for } \ j,k \in [1,4], \tag{18.2.19}$$

and hope that these 16 desiderata will determine the 16 c_{mn}.

To explore these relations, define vectors $\hat{\xi}_j$ and $\hat{\eta}_k$ by the rules

$$\hat{\xi}_j = (\xi_j^0, \xi_j^1, \xi_j^2, \xi_j^3)^T = (1, \xi_j, \xi_j^2, \xi_j^3)^T, \tag{18.2.20}$$

and

$$\hat{\eta}_k = (\eta_k^0, \eta_k^1, \eta_k^2, \eta_k^3)^T = (1, \eta_k, \eta_k^2, \eta_k^3)^T. \tag{18.2.21}$$

We will call $\hat{\xi}_j$ and $\hat{\eta}_k$ the *cubic vectors* associated with ξ_j and η_k since they are formed out of the cubic and lower powers of ξ_j and η_k, respectively. With this notation, (2.19) is equivalent to the inner product relations

$$\Psi_{jk} = (\hat{\xi}_j, c\, \hat{\eta}_k) \ \text{ for } \ j,k \in [1,4], \tag{18.2.22}$$

where c is the matrix with entries c_{mn}.

Let $\mathcal{X}$ be the matrix whose columns are the vectors $\hat{\xi}_j$,

$$\mathcal{X} = \begin{pmatrix} 1 & 1 & 1 & 1 \\ \xi_1 & \xi_2 & \xi_3 & \xi_4 \\ \xi_1^2 & \xi_2^2 & \xi_3^2 & \xi_4^2 \\ \xi_1^3 & \xi_2^3 & \xi_3^3 & \xi_4^3 \end{pmatrix}. \tag{18.2.23}$$

Then, by construction, we have the relations

$$\mathcal{X} e^j = \hat{\xi}_j \tag{18.2.24}$$

where the e^j are the standard orthonormal vectors (3.6.4). Similarly, if $\mathcal{Y}$ is the matrix whose columns are the vectors $\hat{\eta}_k$, we have the relations

$$\mathcal{Y} e^k = \hat{\eta}_k. \tag{18.2.25}$$

Insert these relations into (2.22). So doing gives the result

$$\Psi_{jk} = (\mathcal{X}e^j, c\,\mathcal{Y}e^k) = (e^j, \mathcal{X}^T c\,\mathcal{Y}e^k), \tag{18.2.26}$$

which is equivalent to the matrix relation

$$\Psi = \mathcal{X}^T c\,\mathcal{Y}. \tag{18.2.27}$$

We will see shortly that the matrices $\mathcal{X}$ and $\mathcal{Y}$ are invertible. Assuming this to be the case, we may solve (2.27) for c to find the result

$$c = (\mathcal{X}^T)^{-1}\Psi\,\mathcal{Y}^{-1}. \tag{18.2.28}$$

We have found the c_{mn} in terms of the Ψ_{jk}, and therefore P is uniquely specified by the values Ψ_{jk}.

To see that $\mathcal{X}$ is invertible, we examine $\det\mathcal{X}$, which (happily) is a *Vandermonde* determinant. It has the known value

$$\det\mathcal{X} = \prod_{j>k}(\xi_j - \xi_k). \tag{18.2.29}$$

Since the ξ_j are assumed to be *distinct* by construction, $\det\mathcal{X}$ can never vanish. Thus $\mathcal{X}$, and similarly $\mathcal{Y}$, are invertible.

Now that P has been constructed, we find the desired interpolated result $\psi(\bar{x}_i, \bar{y}_i, Z_L)$ by writing

$$\psi(\bar{x}_i, \bar{y}_i, Z_L) \approx P(\bar{\xi}_i, \bar{\eta}_i). \tag{18.2.30}$$

Note that the right side of (2.30) can be written an inner product form involving the two cubic vectors $\hat{\bar{\xi}}_i$ and $\hat{\bar{\eta}}_i$,

$$P(\bar{\xi}_i, \bar{\eta}_i) = (\hat{\bar{\xi}}_i, c\,\hat{\bar{\eta}}_i). \tag{18.2.31}$$

Hence the term *bicubic* interpolation again seems particularly appropriate.

In actual practice, since typically for our purposes any given P would be used only once, it is convenient to proceed somewhat differently. We will interpolate the quantity of interest, be it a potential value or some transverse field component, from the regular grid to the point $\bar{x}_i$, $\bar{y}_i$ with the aid of four plus one cubic polynomials. This approach gives the same result as that obtained by first constructing P and then using (2.30), but employs somewhat more standard tools.

Suppose again that we wish to interpolate a potential function ψ. Using the four values $\psi(X_J, Y_K, Z_L)$, $\psi(X_J, Y_{K+1}, Z_L)$, $\psi(X_J, Y_{K+2}, Z_L)$, $\psi(X_J, Y_{K+3}, Z_L)$, construct the cubic polynomial $g_1(\sigma)$ given by

$$g_1(\sigma) = a_1 + b_1\sigma + c_1\sigma^2 + d_1\sigma^3 \tag{18.2.32}$$

such that

$$g_1[(m-1)h_y] = \psi(X_J, Y_{K+m-1}, Z_L) \text{ for } m = 1, 2, 3, 4. \tag{18.2.33}$$

(This is a standard construction in uniform-spacing *Lagrangian* interpolation.) Also form three more cubic polynomials g_2 through g_4 such that

$$g_k[(m-1)h_y) = \psi(X_{J+k-1}, Y_{K+m-1}, Z_L) \text{ for } m = 1, 2, 3, 4. \tag{18.2.34}$$

Together the four polynomials g_1 through g_4 allow us to interpolate in y for each of the four different x values X_K, X_{K+1}, X_{K+2}, X_{K+3}. (Pictorially, we are interpolating along the four different columns in Figure 2.1.) In particular,using (2.14), we have the four interpolated values

$$\psi_y(X_J, \bar{y}_i, Z_L) = g_1(\bar{\eta}_i), \tag{18.2.35}$$

$$\psi_y(X_{J+1}, \bar{y}_i, Z_L) = g_2(\bar{\eta}_i), \tag{18.2.36}$$

$$\psi_y(X_{J+2}, \bar{y}_i, Z_L) = g_3(\bar{\eta}_i), \tag{18.2.37}$$

$$\psi_y(X_{J+3}, \bar{y}_i, Z_L) = g_4(\bar{\eta}_i). \tag{18.2.38}$$

Next, using the four interpolated potential values $\psi_y(X_{J+k-1}, \bar{y}_i, Z_L)$ with $k \in [1, 4]$, we will interpolate in x. Construct a fifth cubic polynomial $f(\tau)$ of the form

$$f(\tau) = \alpha + \beta\tau + \gamma\tau^2 + \delta\tau^3 \tag{18.2.39}$$

such that

$$f[(k-1)h_x) = \psi_y(X_{J+k-1}, \bar{y}_i, Z_L) \text{ for } k = 1, 2, 3, 4. \tag{18.2.40}$$

Then, interpolating in x using f and (2.13) gives the final desired result

$$\psi(\bar{x}_i, \bar{y}_i, Z_L) \approx \psi_{xy}(\bar{x}_i, \bar{y}_i, Z_L) = f(\bar{\xi}_i). \tag{18.2.41}$$

At this point the observant reader has no doubt noticed that it also possible to interpolate in x first, and then in y, to get a result that we will call $\psi_{yx}(\bar{x}_i, \bar{y}_i, Z_L)$. How are $\psi_{xy}(\bar{x}_i, \bar{y}_i, Z_L)$ and $\psi_{yx}(\bar{x}_i, \bar{y}_i, Z_L)$ related? They are equal. In fact, there are the relations.

$$\psi_{xy}(\bar{x}_i, \bar{y}_i, Z_L) = \psi_{yx}(\bar{x}_i, \bar{y}_i, Z_L) = P(\bar{\xi}_i, \bar{\eta}_i). \tag{18.2.42}$$

That is, all three interpolation results agree. See Exercise 2.1

18.2.2 Bicubic Spline Interpolation

In the discussion so far, we have used cubic polynomials to interpolate in both x and y. An alternate approach is to use the cubic splines of Subsection 15.1.1 to perform interpolations. As before, one could interpolate first in y and then in x, or vice versa. It can be shown that these two results will again be the same. Look again at Figure 2.1, and consider the *central* square/rectangle that contains the point $\bar{x}_i$, $\bar{y}_i$. The coordinates of the grid point at the lower left corner of the central square/rectangle are X_{J+1} and Y_{K+1}. Now introduce *central* expansion variables, again call them ξ and η, by writing

$$\begin{aligned} x &= X_{J+1} + \xi, \\ y &= Y_{K+1} + \eta. \end{aligned} \tag{18.2.43}$$

Then it can be shown that this interpolation procedure is equivalent to using a bicubic polynomial again of the form (2.15), but now in the central expansion variables with the coefficients c_{mn} now determined from the Ψ_{jk} with the aid of cubic splines.

Exercises

18.2.1. Verify that ....

18.3 Fourier Transforms

The work of Sections 14.2 through 14.5 required the computation of Fourier transforms. In this section we will describe numerical methods for this task. We will first define the Fourier transform and find its large $|k|$ behavior. We will then define *discrete* Fourier transforms, and explore their large $|k|$ behavior. Finally, we will define *spline-based* Fourier transforms that have, for our purposes, superior properties.

18.3.1 Exact Fourier Transform and Its Large $|k|$ Behavior

Suppose $f(z)$ is a function that is nonzero (has *support*) only within the interval $[a, b]$, and that we wish to find its linear Fourier transform

$$\tilde{f}(k) = [1/(2\pi)]\int_{-\infty}^{\infty} dz \exp(-ikz)f(z) = [1/(2\pi)]\int_{a}^{b} dz \exp(-ikz)f(z). \tag{18.3.1}$$

Let us examine the behavior of $\tilde{f}$ under the further supposition that f is differentiable and perhaps also has specific properties at the endpoints a and b. Then (3.1) may be integrated by parts to give the relation

$$\tilde{f}(k) = -[1/(2\pi)][1/(ik)]\exp(-ikz)f(z)|_a^b + [1/(2\pi)][1/(ik)]\int_a^b dz \exp(-ikz)f'(z). \tag{18.3.2}$$

The second term on the right in (3.2) may again be integrated by parts to give the result

$$\begin{aligned}&[1/(2\pi)][1/(ik)]\int_a^b dz \exp(-ikz)f'(z)\\ &= -[1/(2\pi)][1/(ik)^2]\exp(-ikz)f'(z)|_a^b + [1/(2\pi)][1/(ik)^2]\int_a^b dz \exp(-ikz)f''(z).\end{aligned} \tag{18.3.3}$$

Evidently, this process of integration by parts may be repeated at will as long as the required higher derivatives of f exist, and each such repetition produces one more power of $1/k$. For future use, we will repeat the process two more times to arrive at the result

$$\begin{aligned}\tilde{f}(k) &= -[1/(2\pi)][1/(ik)]\exp(-ikz)f(z)|_a^b - [1/(2\pi)][1/(ik)^2]\exp(-ikz)f'(z)|_a^b\\ &- [1/(2\pi)][1/(ik)^3]\exp(-ikz)f''(z)|_a^b - [1/(2\pi)][1/(ik)^4]\exp(-ikz)f'''(z)|_a^b\\ &+ [1/(2\pi)][1/(ik)^4]\int_a^b dz \exp(-ikz)f^{\rm iv}(z).\end{aligned} \tag{18.3.4}$$

We see that in general

$$|\tilde{f}(k)| \sim 1/|k| \text{ as } k \to \infty, \tag{18.3.5}$$

and that if f vanishes at the endpoints, $f(a) = f(b) = 0$, as will often be the case, then the first term on the right side of (3.4) will vanish so that

$$|\tilde{f}(k)| \sim 1/|k|^2 \text{ as } k \to \infty, \text{ etc.} \tag{18.3.6}$$

Thus, $\tilde{f}(k)$ must vanish at least as fast as $1/|k|$ for large $|k|$, and often vanishes as $1/|k|^2$.

18.3.2 Inverse Fourier Transform

One of the key features of the linear Fourier transform is the inverse Fourier transform relation

$$f(z) = \int_{-\infty}^{\infty} dk \exp(ikz)\tilde{f}(k). \tag{18.3.7}$$

That is, a function can be *reconstructed* from its linear Fourier transform by using an inverse Fourier transform. Let us further assume that the integral (3.7) can be *cut off* for $|k| > K_c$ where K_c is some suitably large value, say a value where and beyond which the asymptotic behavior (3.5) or (3.6) has effectively driven $\tilde{f}$ to zero. Thus, we write

$$f(z) \approx \int_{-K_c}^{K_c} dk \exp(ikz)\tilde{f}(k). \tag{18.3.8}$$

Eventually we will need to evaluate integrals of the form (3.8) numerically. Therefore, we would like to know something about the properties of $\tilde{f}(k)$ in the interval $[-K_c, K_c]$. In particular, we would like to know how much $\tilde{f}(k)$ oscillates. Suppose that $f(z)$ has support only in the interval $[a, b]$. Then $\tilde{f}(k)$ must encode two pieces of information: it must encode that $f(z)$ is zero outside $[a, b]$ and it must encode the behavior of $f(z)$ within the interval $[a, b]$. We see from (3.1) that $\tilde{f}(k)$ is a generalized sum (integral) of terms of the form $\exp(-i\omega k)$ where $\omega \in [a, b]$. That is, $\tilde{f}(k)$ contains all frequencies $\omega \in [a, b]$ with weights $f(\omega)$. This is a potential disaster, because $|a|$ and/or $|b|$ could be quite large.

For example consider the functions $f_{-1,1}(z)$ and $f_{0,2}(z)$ defined by the relations

$$\begin{aligned} f_{-1,1}(z) &= 1 - z^4 \text{ for } z \in [-1, 1], \\ &= 0 \text{ for } z \text{ outside } [-1, 1]; \end{aligned} \tag{18.3.9}$$

$$\begin{aligned} f_{0,2}(z) &= 1 - (z-1)^4 \text{ for } z \in [0, 2], \\ &= 0 \text{ for } z \text{ outside } [0, 2]. \end{aligned} \tag{18.3.10}$$

Figures 3.1 and 3.2 show their graphs which, evidently and by construction, are simply translations of each other. [See also (1.36) and Figure 1.3.] Calculation shows that their Fourier transforms are given by

$$\Re\tilde{f}_{-1,1}(k) = -[4/(\pi k^5)][k(k^2 - 6)\cos k - 3(k^2 - 2)\sin k], \tag{18.3.11}$$

$$\Im\tilde{f}_{-1,1}(k) = 0; \tag{18.3.12}$$

$$\Re\tilde{f}_{0,2}(k) = [1/(\pi k^5)][-4k(k^2-6)\cos^2 k + 6(k^2-2)\sin 2k], \tag{18.3.13}$$

$$\Im\tilde{f}_{0,2}(k) = [1/(\pi k^5)][12(k^2-2)\sin^2 k - 2k(k^2-6)\sin 2k]. \tag{18.3.14}$$

As expected, $\tilde{f}_{-1,1}(k)$ contains frequency $|\omega| = 1$ from the $\sin k$ and $\cos k$ terms. By contrast, $\tilde{f}_{0,2}(k)$ contains frequency $|\omega| = 2$ from the $\sin 2k$, $\cos^2 k$, and $\sin^2 k$ terms. These different behaviors are also evident in the graphs of these Fourier transforms as shown in Figures 3.3 through 3.5. Clearly the integral (3.8) is more difficult to evaluate for $\tilde{f}_{0,2}(k)$ than for $\tilde{f}_{-1,1}(k)$ because $\tilde{f}_{0,2}(k)$ oscillates twice as often as $\tilde{f}_{-1,1}(k)$. There is an oscillation penalty to be paid for encoding the fact that some f has support in the interval $[0, 2]$ rather than the interval $[-1, 1]$.

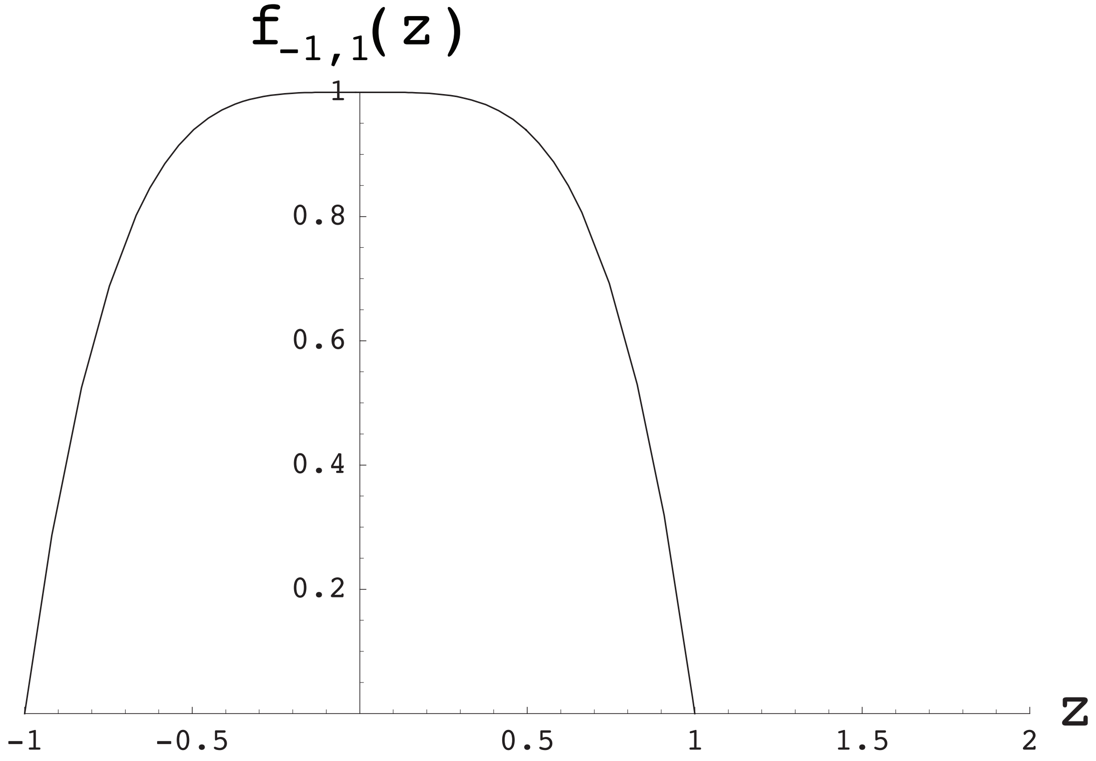

Figure 18.3.1: The function $f_{-1,1}(z)$.

What to do? By simple translation it is always possible to send the interval $[a, b]$ to the interval $[-Z_c, Z_c]$. Therefore. without loss of generality, we may restrict our attention to integrals of the form

$$\tilde{f}(k) = [1/(2\pi)] \int_{-Z_c}^{Z_c} dz \exp(-ikz) f(z). \tag{18.3.15}$$

Then, after all operations have been carried out, we may undo, if we wish, the translation to obtain results in terms of the original coordinates. In this way, we only have to deal with $\tilde{f}(k)$ that contain frequencies satisfying $|\omega| \leq Z_c$.

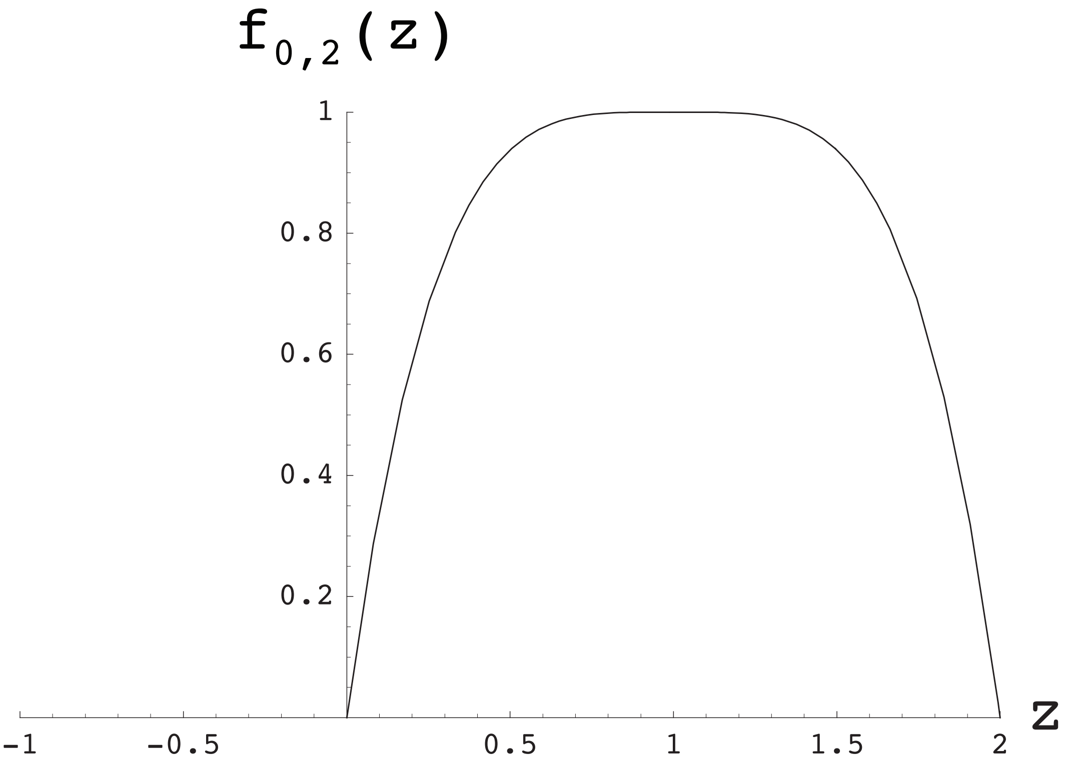

Figure 18.3.2: The function $f_{0,2}(z)$.

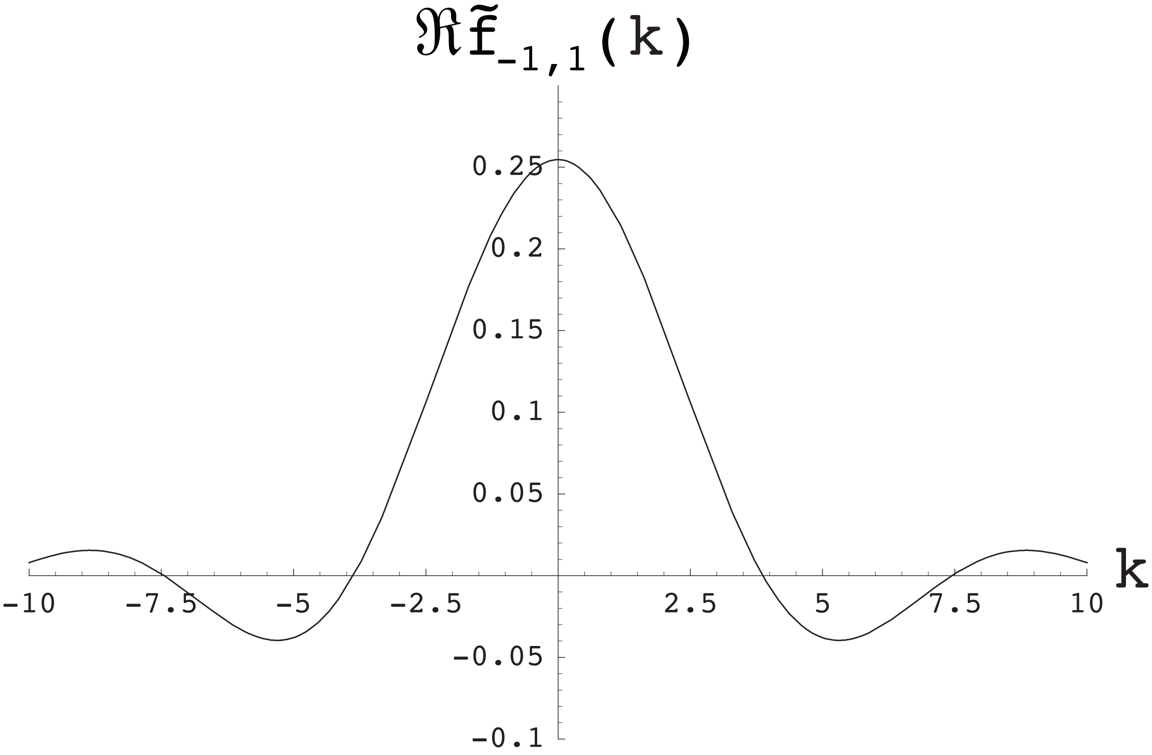

Figure 18.3.3: The function $\Re\tilde{f}_{-1,1}(k)$.

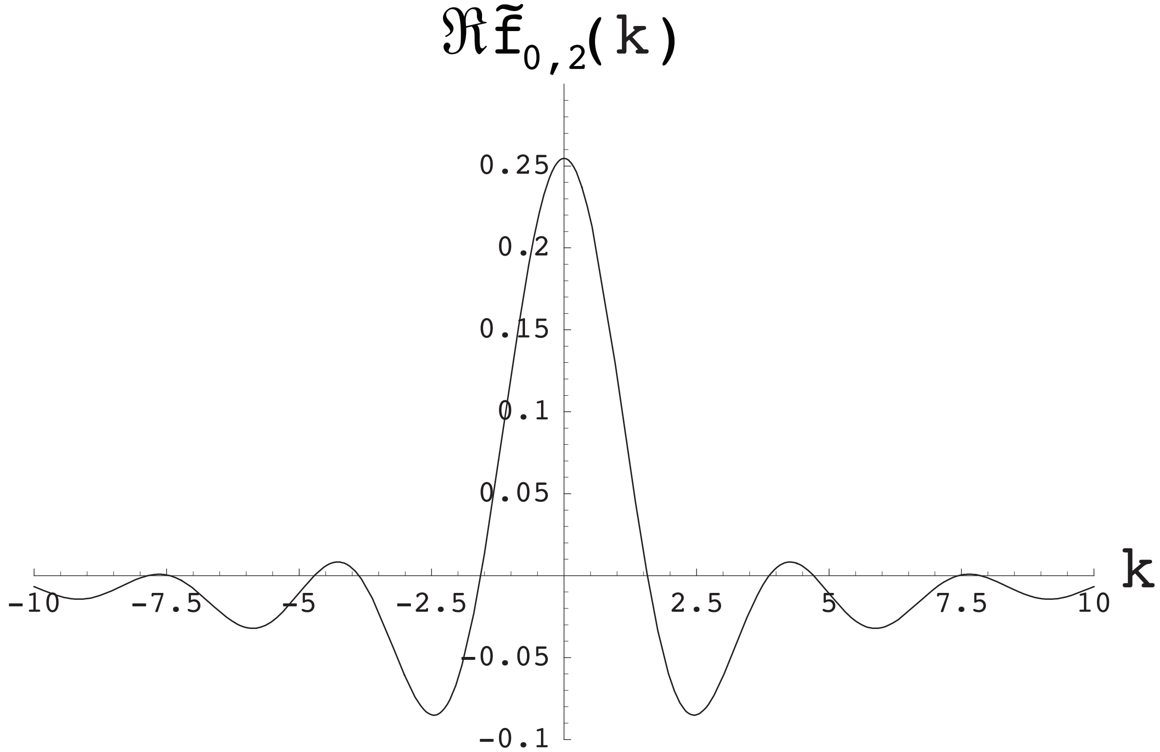

Figure 18.3.4: The function $\Re\tilde{f}_{0,2}(k)$.

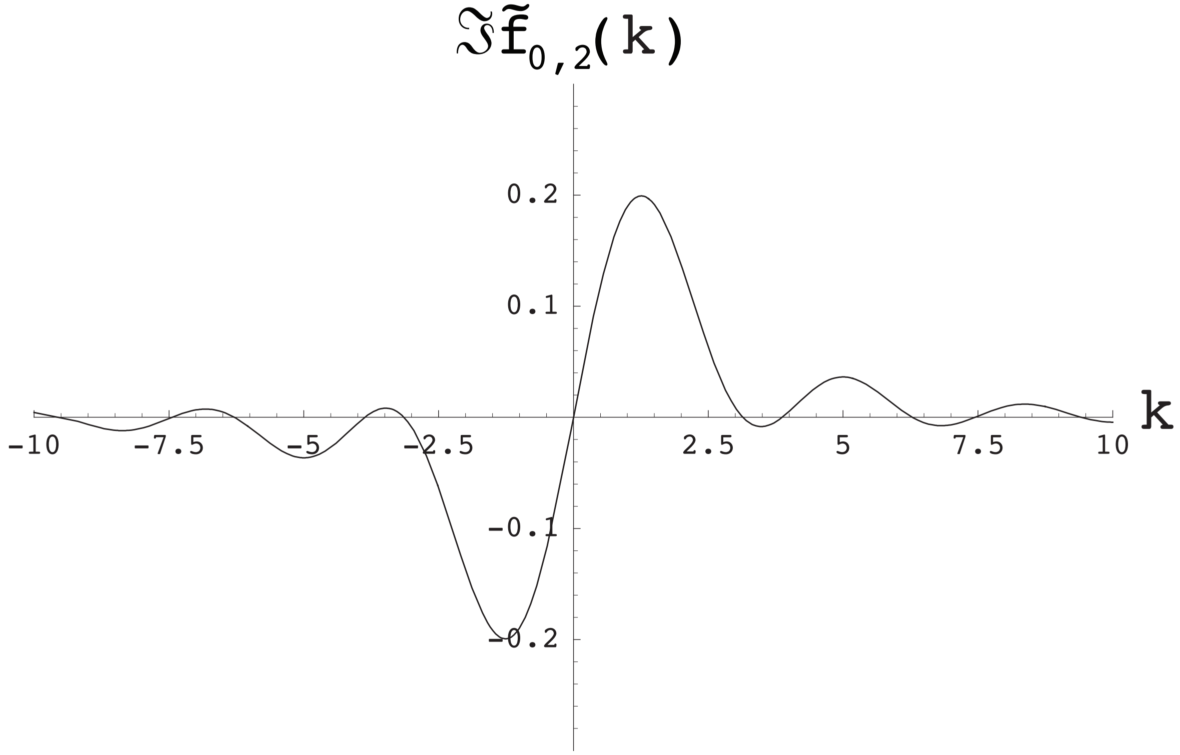

Figure 18.3.5: The function $\Im\tilde{f}_{0,2}(k)$.

18.3.3 Discrete Fourier Transform

Let us now turn to the task of evaluating $\tilde{f}$ numerically. Suppose the interval $[-Z_c, Z_c]$ is subdivided into N subintervals, each of length h, by writing

$$z_n = -Z_c + nh \text{ with } n = 0, 1, \cdots, N \tag{18.3.16}$$

where

$$h = 2Z_c/N \tag{18.3.17}$$

so that

$$z_0 = -Z_c \text{ and } z_N = Z_c. \tag{18.3.18}$$

See Figure 2.1.1 for an earlier analogous construction. Use this subdivision to approximate the integral (3.15) by the Riemann sum

$$\tilde{f}(k) \approx [1/(2\pi)]h\sum_{n=0}^{N-1} \exp(-ikz_n)f(z_n). \tag{18.3.19}$$

The quantity on the right side of (3.19) is called the *discrete* Fourier transform of f.

How accurate is the discrete Fourier transform? Let $g(z)$ be any twice differentiable function. Then, according to the *trapezoidal rule*, there is the result

$$\begin{aligned}\int_{-Z_c}^{Z_c} dz\; g(z) &= h[(1/2)g(z_0) + g(z_1) + g(z_2) + \cdots + g(z_{N-2}) + g(z_{N-1}) + (1/2)g(z_N)] \\ &- (1/6)h^2 g''(\zeta),\end{aligned} \tag{18.3.20}$$

which can be rewritten in the form

$$\begin{aligned}\int_{-Z_c}^{Z_c} dz\; g(z) &= h[g(z_0) + g(z_1) + g(z_2) + \cdots + g(z_{N-2}) + g(z_{N-1})] \\ &- (1/2)hg(z_0) + (1/2)hg(z_N) - (1/6)h^2 g''(\zeta).\end{aligned} \tag{18.3.21}$$

Here ζ is some point in the interval $[-Z_c, Z_c]$. In our case we have

$$g(z) = [1/(2\pi)]\exp(-ikz)f(z) \tag{18.3.22}$$

so that

$$g''(\zeta) = [1/(2\pi)][-k^2 f(\zeta) - 2ikf'(\zeta) + f''(\zeta)]\exp(-ik\zeta). \tag{18.3.23}$$

Thus, we have the result

$$\begin{aligned}\tilde{f}(k) &= [1/(2\pi)]h\sum_{n=0}^{N-1}\exp(-ikz_n)f(z_n) \\ &- (1/2)[1/(2\pi)]hf(-Z_c)\exp(ikZ_c) + (1/2)[1/(2\pi)]hf(Z_c)\exp(-ikZ_c) \\ &- (1/6)h^2[1/(2\pi)][-k^2 f(\zeta) - 2ikf'(\zeta) + f''(\zeta)]\exp(-ik\zeta).\end{aligned} \tag{18.3.24}$$

Upon comparing (3.19) and (3.24), we see that the discrete Fourier transform generally makes errors of order h. However, if $f(-Z_c) = 0$ and $f(Z_c) = 0$, which is often the case, then the discrete transform makes errors of order h^2. But, the errors of order h^2 can be very large if $|k|$ is large.

Let us explore the large $|k|$ behavior of the discrete Fourier transform. If we make use of (3.16), we see that (3.19) can also be written in the form

$$\tilde{f}(k) \approx [1/(2\pi)]h \exp(ikZ_c) \sum_{n=0}^{N-1} \exp(-iknh) f(z_n). \tag{18.3.25}$$

Observe that the function $\exp(-ikh)$ is *periodic* in k with a period K given by

$$K = 2\pi/h = N\pi/Z_c. \tag{18.3.26}$$

Consequently, if we define a function $F(k)$ by writing

$$F(k) = [1/(2\pi)]h \sum_{n=0}^{N-1} \exp(-iknh) f(z_n), \tag{18.3.27}$$

we have the relation

$$F(k + K) = F(k). \tag{18.3.28}$$

But (3.19) can be rewritten in terms of F. We find, using (3.25) and (3.27), the result

$$\tilde{f}(k) \approx \exp(ikZ_c)F(k). \tag{18.3.29}$$

We see that the discrete Fourier transform $\tilde{f}$ is *quasi-periodic* in k. It is a product of the function $\exp(ikZ_c)$, which has the period $2\pi/Z_c$ (so that $|\omega| = Z_c$), and the *envelope* function F which has period K. Thus, the discrete Fourier transform can never satisfy (3.5) or (3.6).[5] In general, the discrete Fourier transform is reliable only in the interval $k \in [-K/2, K/2]$. The quantity $K_{Ny} = K/2$ is called the *Nyquist critical frequency.*

As an example of the behavior of the discrete Fourier transform, consider again the function $f_{-1,1}(z)$ given by (3.9) and shown in Figure 3.1. We have already seen that it has the exact Fourier transform given by (3.11) and (3.12) and shown in Figure 3.3. Figure 3.6 shows both the exact Fourier transform, and the discrete and spline-based Fourier transforms for the case $h = .10$.[6] (The spline-based Fourier transform is discussed in a subsequent subsection.) In this case $K_{Ny} = \pi/h \simeq 31.4$. We observe that, as warned, the discrete Fourier transform results are not reliable for $|k| > K_{Ny}$. Figure 3.7 shows the difference between the exact and discrete Fourier transforms within and somewhat beyond the *Nyquist band* $|k| < K_{Ny}$. Note that, as expected from the quasi-periodicity of the discrete Fourier transform, see Figure 3.6, the error grows as k leaves the Nyquist band.

[5] Observe that the discrete Fourier transform (3.19) can be viewed as the *exact* Fourier transform of the function $h\sum_{n=0}^{N-1} f(z_n)\delta(z - z_n)$, and that this finite sum of *delta* functions must have all frequency components present.

[6] All these Fourier transforms are real because $f_{-1,1}(z)$ as given by (3.9) is an even function.

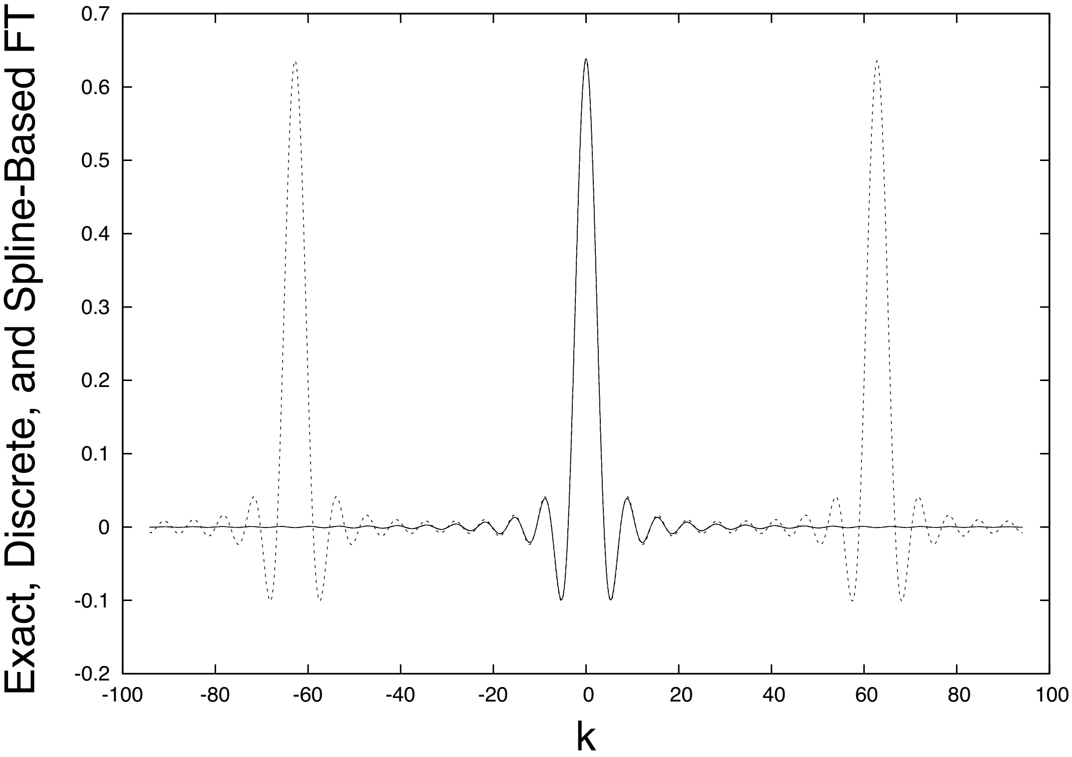

Figure 18.3.6: The exact, discrete, and spline-based Fourier transforms of $f_{-1,1}(z)$ for $h = .10$. On the scale of this figure the exact and spline-based Fourier transforms are indistinguishable. They are both shown as a solid line. The discrete Fourier transform is shown as a dashed line. Note that it is quasi-periodic while the exact and spline-based Fourier transforms fall to zero for large $|k|$.

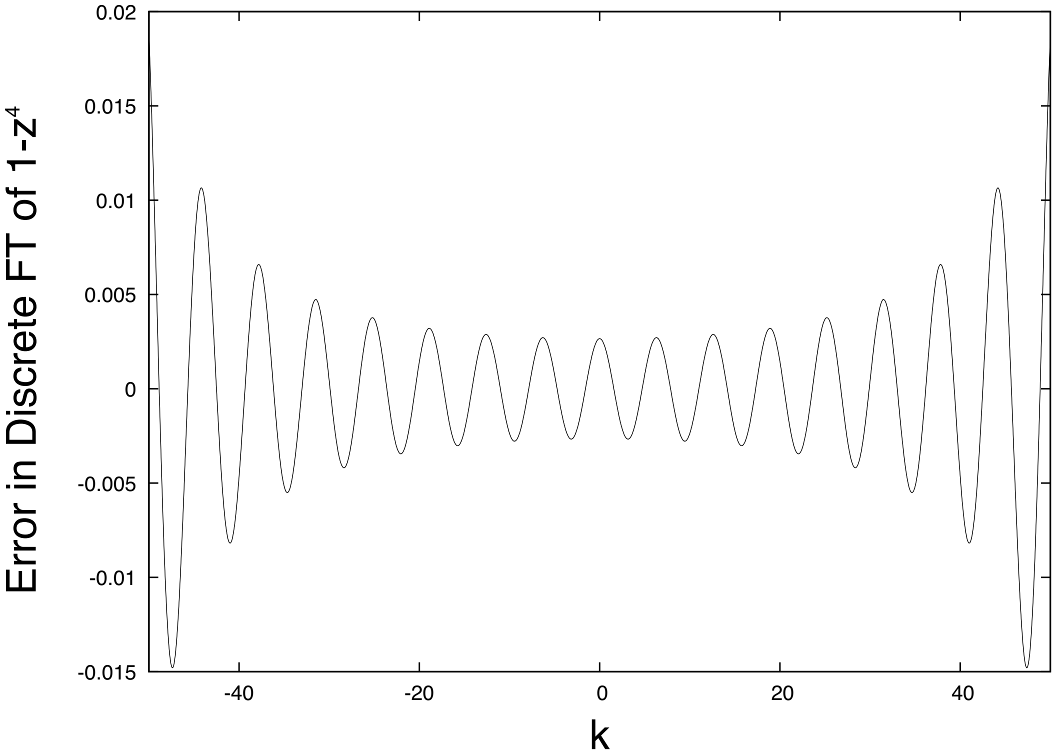

Figure 18.3.7: Difference between the exact and discrete Fourier transforms of $f_{-1,1}(z)$ for $h = .10$.

18.3.4 Discrete Inverse Fourier Transform

Consider again the inverse Fourier transform (3.8). Let us explore to what extent this inverse transform can also be made discrete and to what extent the discrete forward and inverse Fourier transforms are related. Discretize what so far has been the continuous variable k by writing

$$k_m = -K_c + mH \text{ for } m = 0, 1, \cdots, M \tag{18.3.30}$$

with

$$H = 2K_c/M \tag{18.3.31}$$

so that

$$k_0 = -K_c \text{ and } k_M = +K_c. \tag{18.3.32}$$

When this is done, the relation (3.8) can be approximated by the Riemann sum

$$f(z) \approx H \sum_{m=0}^{M-1} \exp(ik_m z)\tilde{f}(k_m). \tag{18.3.33}$$

Evidently both (3.19) and (3.33) are approximate, and presumably they become ever more accurate as $M \to \infty$ and $N \to \infty$. However, if $M = N$ and $K_c = K_{Ny}$, there are the *exact* relations

$$\tilde{f}(k_m) = [1/(2\pi)]h \sum_{n=0}^{N-1} \exp(-ik_m z_n) f(z_n), \tag{18.3.34}$$

and

$$f(z_n) = H \sum_{m=0}^{M-1} \exp(ik_m z_n)\tilde{f}(k_m). \tag{18.3.35}$$

Here (3.34) is taken to be the *definition* of the quantities $\tilde{f}(k_m)$. [They are *not* the exact values that would be found by doing the integral (3.15) exactly for the values $k = k_m$.] And when these approximate values $\tilde{f}(k_m)$ are employed in the (approximate) formula (3.35), the values $f(z_n)$ are recovered *exactly*. This a case where two wrongs do make a right![7] See Exercise 3.1.

18.3.5 Spline-Based Fourier Transforms

Let $f_{\rm sa}$ be a cubic spline approximation to the function f appearing in (3.15). Then we may make the definition

$$\tilde{f}_{\rm sa}(k) = [1/(2\pi)] \int_{-Z_c}^{Z_c} dz \exp(-ikz) f_{\rm sa}(z). \tag{18.3.36}$$

As described in Section 15.1.1, $f_{\rm sa}(z)$ can be constructed from the values $f(z_n)$ with $n \in [0, N]$. Moreover, observe that the definition (3.36) can be evaluated exactly (numerically to machine precision) for any value of k since the Fourier transforms of cubic polynomials

[7] The relation (3.35) does not give the exact values of $f(z)$ when $z \neq z_n$. Also note that (3.35) produces a function of z that is *quasi-periodic* with quasi-period $Z = 2\pi/H = 2$. By contrast, $f(z)$ is supposed to be zero for z outside the interval $[-1, 1]$.

can be found analytically and then evaluated numerically to machine precision. Thus, we have a relation of the form

$$\tilde{f}_{\rm sa}(k) = \sum_{n=0}^{N} g_n^-(k) f(z_n) \tag{18.3.37}$$

where the $g_n^-(k)$ are known functions of k that can be evaluated to machine precision.[8] Suppose we assume that $f(z)$ vanishes at the endpoints $\pm Z_c$. Then $f_{\rm sa}$ will be a differentiable function of z that vanishes at the endpoints. Therefore we expect that $\tilde{f}_{\rm sa}(k)$, unlike the $\tilde{f}$ given by (3.19), will have more nearly appropriate large $|k|$ behavior.[9] See (3.6). The accuracy of $\tilde{f}_{\rm sa}(k)$, namely the difference between $\tilde{f}_{\rm sa}(k)$ and the exact $\tilde{f}(k)$ given by (3.15), depends only on the quality of the spline fit $f_{\rm sa}(z)$, and not on any approximation to the Fourier integral.

As an example of the behavior of $\tilde{f}_{\rm sa}(k)$, consider again the $f_{-1,1}(z)$ given by (3.9). As already described earlier, Figure 3.6 shows the exact Fourier transform, the discrete Fourier transform, and $\tilde{f}_{\rm sa}$ for the case $h = .10$. [Here we have used (1.24) to estimate the end-point derivatives required to construct $f_{\rm sa}(z)$.] We have already noted that the exact and spline-based Fourier transforms appear identical on the scale shown. Figure 3.8 shows their difference. Note that their difference is small as expected from the error estimate (1.34) and the fact that the Fourier transform (3.36) of the spline approximation is evaluated exactly. In summary, as comparison of Figures 3.7 and 3.8 illustrates, for smooth functions the spline-based Fourier transform is much more accurate than the discrete Fourier transform.

What can be said about the inverse Fourier transform? Begin with (3.8). It is approximate because of the cutoff, but this cutoff K_c can in principle be made quite large to assure good accuracy. Next replace $\tilde{f}(k)$ by $\tilde{f}_{\rm sa}(k)$ using (3.36) to get the approximation

$$f(z) \approx \int_{-K_c}^{K_c} dk \exp(ikz)\tilde{f}_{\rm sa}(k). \tag{18.3.38}$$

The quality of this approximation depends on the quality of the spline fit $f_{\rm sa}(z)$. Also suppose we carry out the operation (3.36) for $M+1$ discrete values of k using the k_m values given by (3.30). That is, we compute the quantities $\tilde{f}_{\rm sa}(k_m)$ by the rule

$$\tilde{f}_{\rm sa}(k_m) = \sum_{n=0}^{N} g_n^-(k_m) f(z_n). \tag{18.3.39}$$

We may then use these quantities to try to reconstruct $f(z)$.

In particular, use the $M+1$ values $\tilde{f}_{\rm sa}(k_m)$ to construct a cubic spline approximation to $\tilde{f}_{\rm sa}(k)$ which we will call $\tilde{f}_{\rm sasa}(k)$. [Again we use (1.24), this time applied to the values $\tilde{f}_{\rm sa}(k_m)$, to estimate the required end-point derivatives.] Using this approximation in (3.38) gives the representation

$$f(z) \approx \int_{-K_c}^{K_c} dk \exp(ikz)\tilde{f}_{\rm sasa}(k). \tag{18.3.40}$$

[8] The superscript "$-$" indicates that $\exp(-ikz)$ appears in (3.36).

[9] The function $\tilde{f}_{\rm sa}(k)$ given by (3.36) cannot fall off any faster than $1/|k|^4$ at infinity because a cubic-spline has discontinuous third derivatives. See Exercise 3.2.

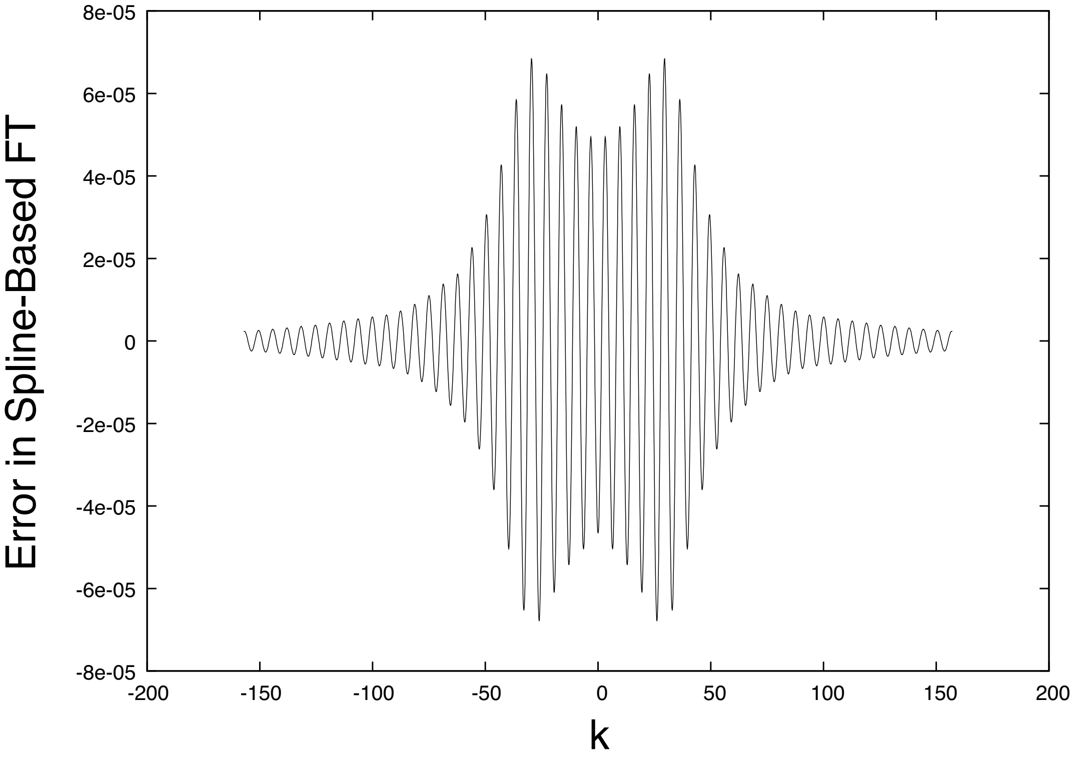

Figure 18.3.8: Difference between the exact and spline-based Fourier transforms of $f_{-1,1}(z)$ for $h = .10$.

Because $\tilde{f}_{\rm sasa}(k)$ is a cubic spline approximation, the integral (3.40) can again be done exactly. That is, there are known functions $g_m^+(z)$ such that[10]

$$f(z) \approx \int_{-K_c}^{K_c} dk \exp(ikz)\tilde{f}_{\rm sasa}(k) = \sum_{m=0}^{M} g_m^+(z)\tilde{f}_{\rm sa}(k_m). \tag{18.3.41}$$

The accuracy of this representation of f depends on how well $\tilde{f}_{\rm sasa}(k)$ approximates $\tilde{f}_{\rm sa}(k)$. In general it will not yield an f that vanishes outside $[-1, 1]$. However, unlike the f produced by (3.33), the f produced by (3.41) will be very small for z outside the interval $[-1, 1]$.

In summary, the accuracy of direct and inverse spline-based Fourier transforms is governed primarily by the quality of spline approximations, and not by how well various Fourier integrals are approximated. Put another way, the use of the discrete Fourier transform does not make any optimistic assumptions about the smoothness properties of $f(z)$. (Indeed, it assumes the worst, a sum of delta functions approximation.) By contrast, the use of spline-based Fourier transforms capitalizes on the assumption that $f(z)$ is not too badly behaved between sampling points z_n.

How well do the discrete and spline-based Fourier transforms work in reconstructing a function? Let us first consider the discrete case. As an example, will again consider the $f_{-1,1}$ given by (3.9). Figure 3.9 shows the reconstructed $f_{-1,1}(z)$ produced by (3.33) with the $\tilde{f}(k_m)$ given by (3.19) or, equivalently, (3.34). Figure 3.10 shows the difference between the exact $f_{-1,1}$ and the reconstructed $f_{-1,1}$. Here again we have used $h = .10$ so that $N = 20$; and we have set $K_c = K_{Ny}$ and $M = N$. We see from Figure 3.9 that the reconstructed $f_{-1,1}$ is quasi-periodic as expected. We see from Figure 3.10 that the error is zero at the sampling points as expected, but rises to as high as 2% elsewhere.

What happens if we instead use spline-based Fourier transforms? We have already seen that, for this example, the *forward* spline-based Fourier transform $\tilde{f}_{\rm sa}(k)$ is more accurate than the discrete Fourier transform. This is because of the high accuracy of the spline approximation $f_{\rm sa}(z)$ to $f(z)$, and the fact that the Fourier transform of the spline approximation is performed exactly. We expect to be able to carry out the *inverse* spline-based Fourier transform with good accuracy provided the spline approximation $\tilde{f}_{\rm sasa}(k)$ to $\tilde{f}_{\rm sa}(k)$ has good accuracy. But now there is a possible problem. Figure 3.11 shows the 21-point spline approximation $\tilde{f}_{\rm sasa}(k)$ over the interval $[-K_{Ny}, K_{Ny}]$ as well as $\tilde{f}_{\rm sa}(k)$ itself. We see that the 21-point spline approximation $\tilde{f}_{\rm sasa}(k)$ is not particularly good because of the oscillatory nature of $\tilde{f}_{\rm sa}(k)$. Figure 3.12 shows the exact $f_{-1,1}(z)$ and the reconstructed $f_{-1,1}(z)$ based on using $\tilde{f}_{\rm sasa}(k)$ in (3.41) with $K_c = K_{Ny}$. Evidently the agreement is not particularly good, reflecting the poor quality of the 21-point spline approximation $\tilde{f}_{\rm sasa}(k)$.

Suppose we instead make K_c somewhat larger than K_{Ny} by setting $K_c = 50$ and also use a 51-point spline approximation to $\tilde{f}_{\rm sasa}(k)$ over this interval $[-K_c, K_c]$. When this is done, it is found that the difference between $\tilde{f}_{\rm sa}(k)$ and its spline fit $\tilde{f}_{\rm sasa}(k)$ is less then 6×10^{-5}. Correspondingly we expect the reconstruction of $f_{-1,1}(z)$ to be much improved. This is indeed the case. Figure 3.13 shows the function $f_{-1,1}(z)$ and its reconstruction using, in (3.41), the 51-point spline approximation $\tilde{f}_{\rm sasa}(k)$ over the interval $k \in [-50, 50]$. The agreement is much improved, and is even good outside the interval $[-1, 1]$ where the discrete

[10] Here the superscript "+" indicates that $\exp(+ikz)$ appears in (3.40) and (3.41).

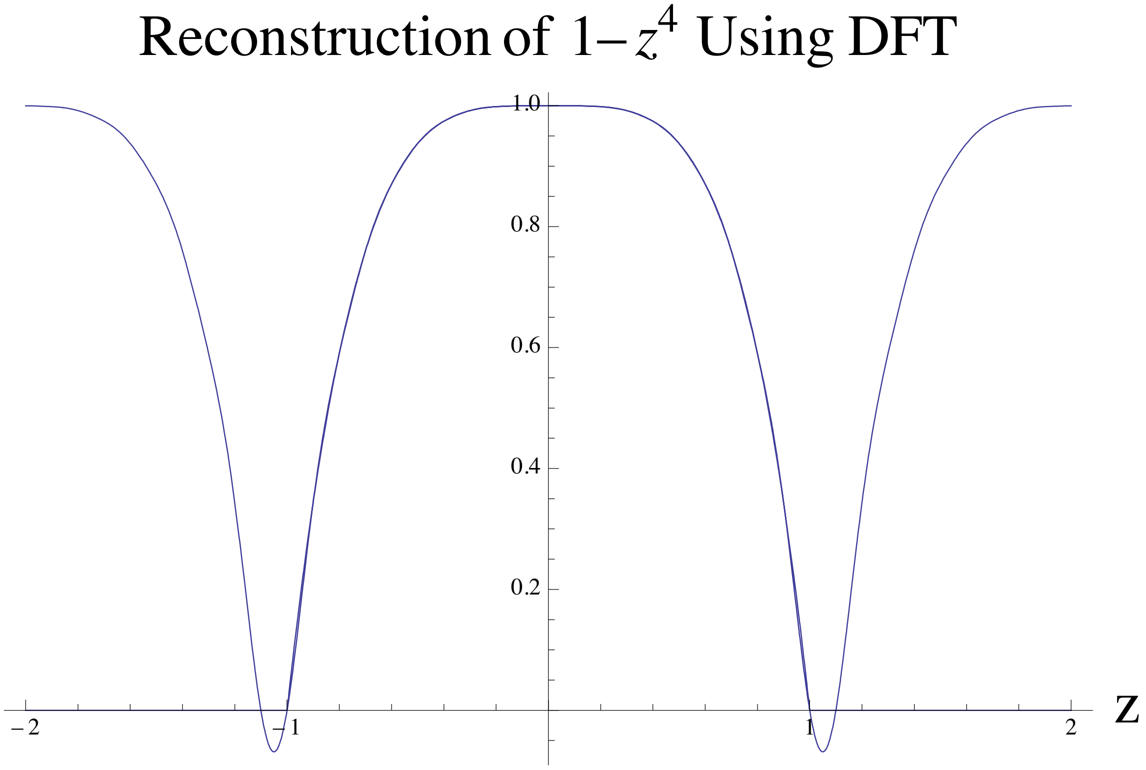

Figure 18.3.9: Reconstruction of $f_{-1,1} = 1 - z^4$ using forward and inverse discrete Fourier transforms.

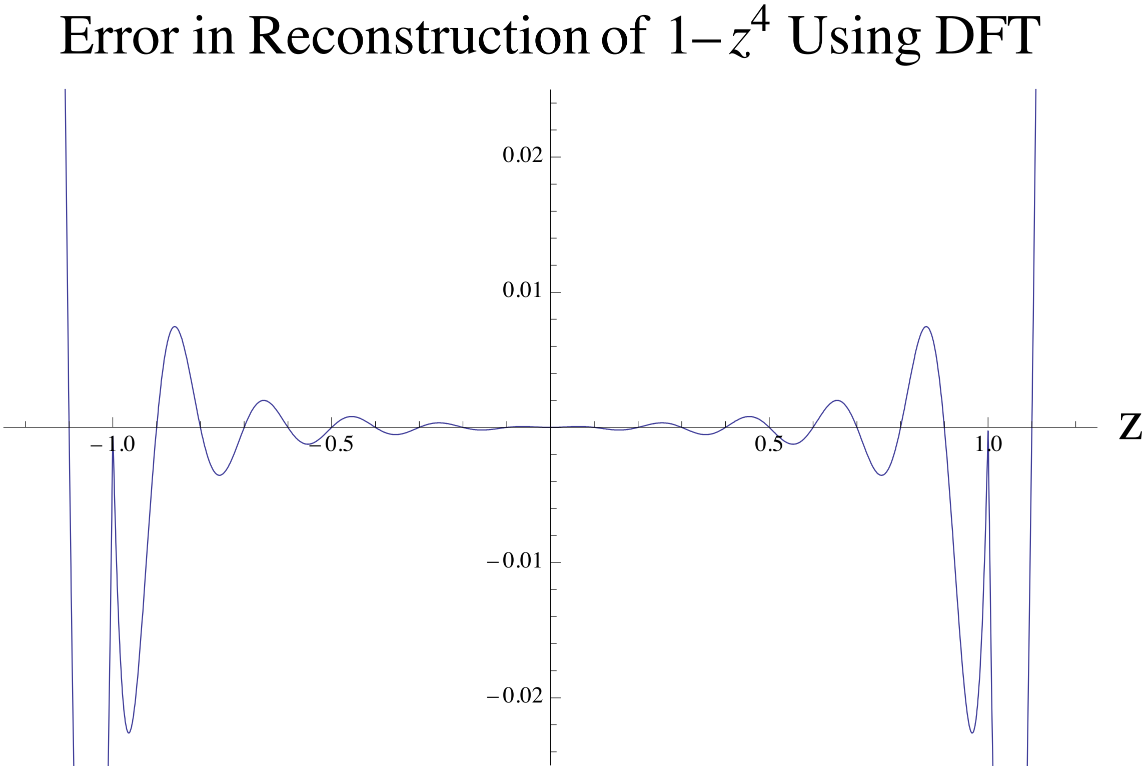

Figure 18.3.10: Error in reconstruction of $f_{-1,1} = 1 - z^4$ using forward and inverse discrete Fourier transforms.

Fourier reconstruction fails. To provide further insight into the error, Figure 3.14 displays the difference between the exact $f_{-1,1}(z)$ and the reconstructed $f_{-1,1}(z)$. Now the error is comparable to that for the discrete case, and, unlike the discrete case, is even small outside the interval $[-1, 1]$. Compare Figures 3.9, 3.10, 3.13, and 3.14. Of course, with more points the discrete-case error also decreases. But it decreases as a smaller power of h than in the spline-based case so that eventually the spline-based method wins.

Moreover, the apparent good performance of the discrete method is misleading. We already know from our previous discussion that its error when performing reconstructions must be zero at the sampling points due to the magic cancellation of errors in the forward and inverse discrete Fourier transformations at these points. But we are ultimately not interested in reconstruction. Rather, we are interested in forward Fourier transformation followed by inverse Fourier transformation with some k-dependent kernel. See (14.2.2), (14.2.6) and (14.3.1), (14.3.6) and (14.4.73), (14.4.74), (14.4.85), (14.4.86). In this context there is no reason to expect cancellation of errors when discrete Fourier transformations are employed. And, when spline-based Fourier transformations are employed, we may expect to see errors that are no worse then those encountered in the case of reconstruction. We conclude that as long as the spline approximations are done with care, the spline-based Fourier transforms should be superior to discrete Fourier transforms.

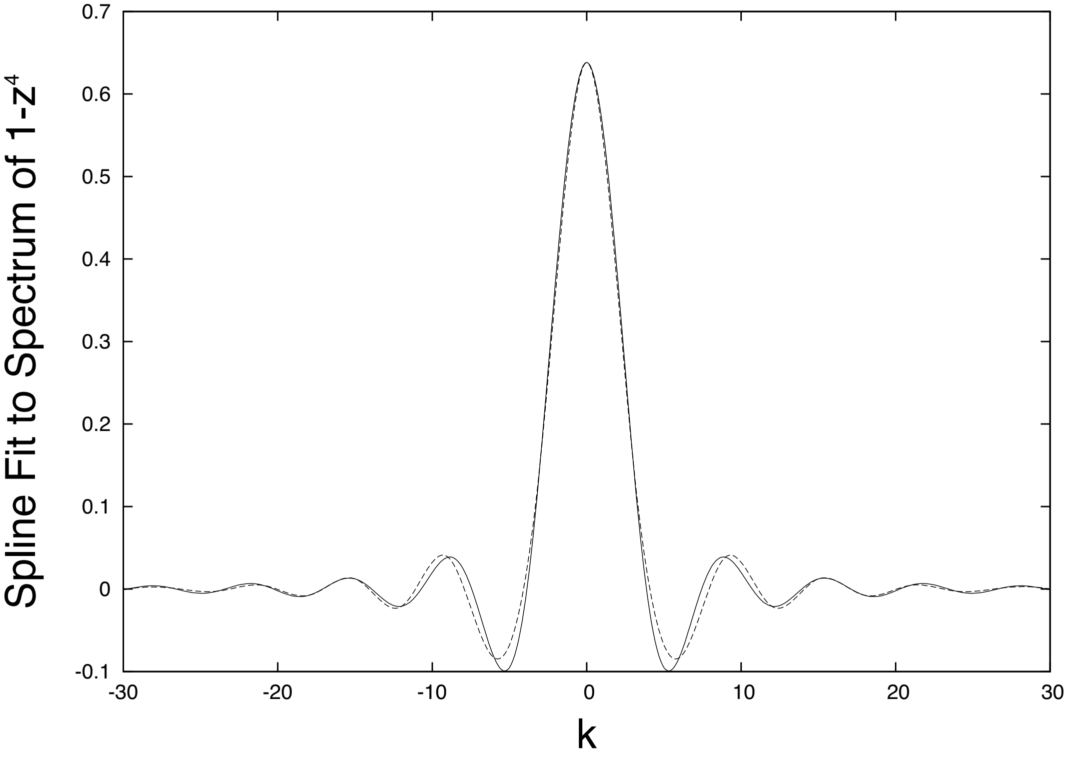

Figure 18.3.11: The function $\tilde{f}_{\text{sa}}(k)$ (solid line) and its 21-point spline approximation $\tilde{f}_{\text{sasa}}(k)$ (dashed line) over the Nyquist band $k \in [-K_{Ny}, K_{Ny}]$.

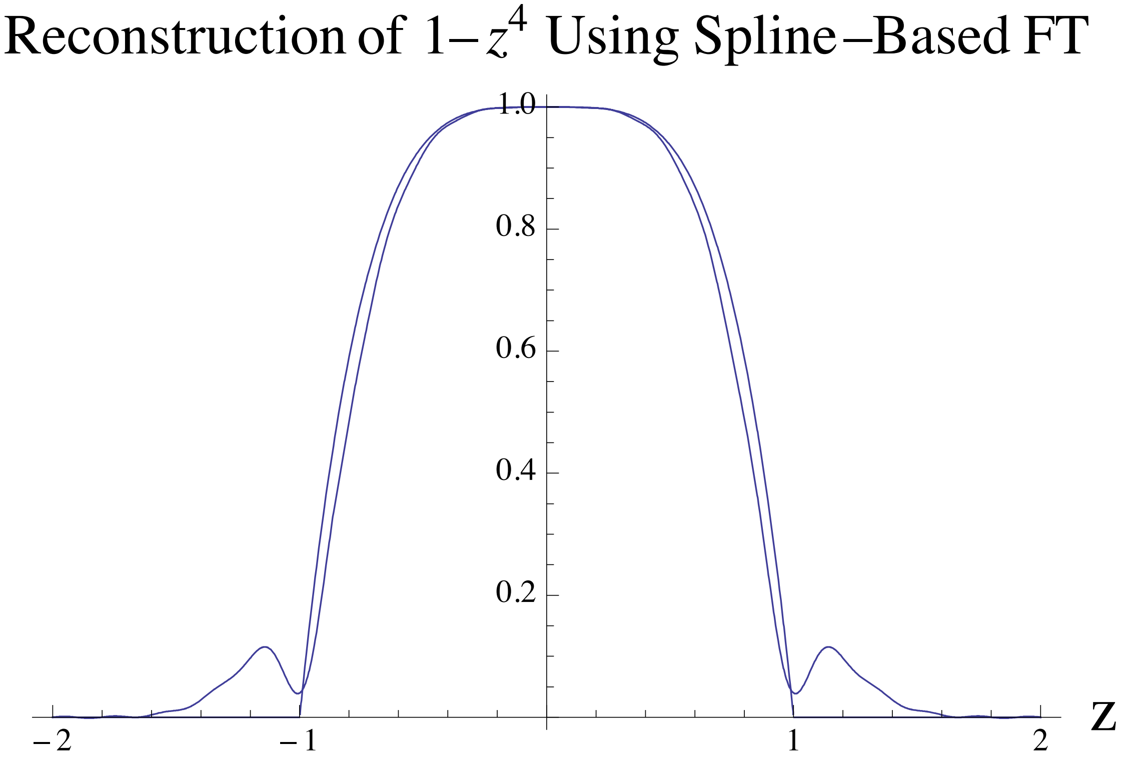

Figure 18.3.12: The function $f_{-1,1}(z) = 1 - z^4$ and its reconstruction using the 21-point spline approximation $\tilde{f}_{\text{sasa}}(k)$ in (3.41).

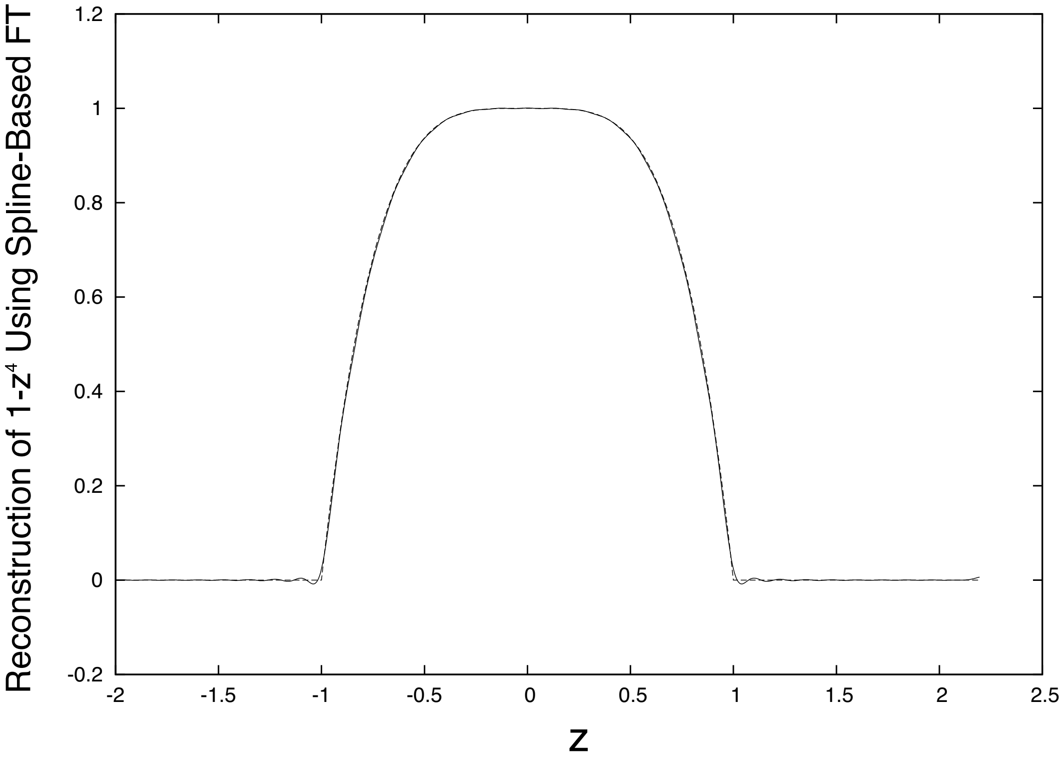

Figure 18.3.13: The function $f_{-1,1}(z) = 1 - z^4$ and its reconstruction using, in (3.41), the 51-point spline approximation $\tilde{f}_{\rm sasa}(k)$ over the interval $k \in [-50, 50]$.

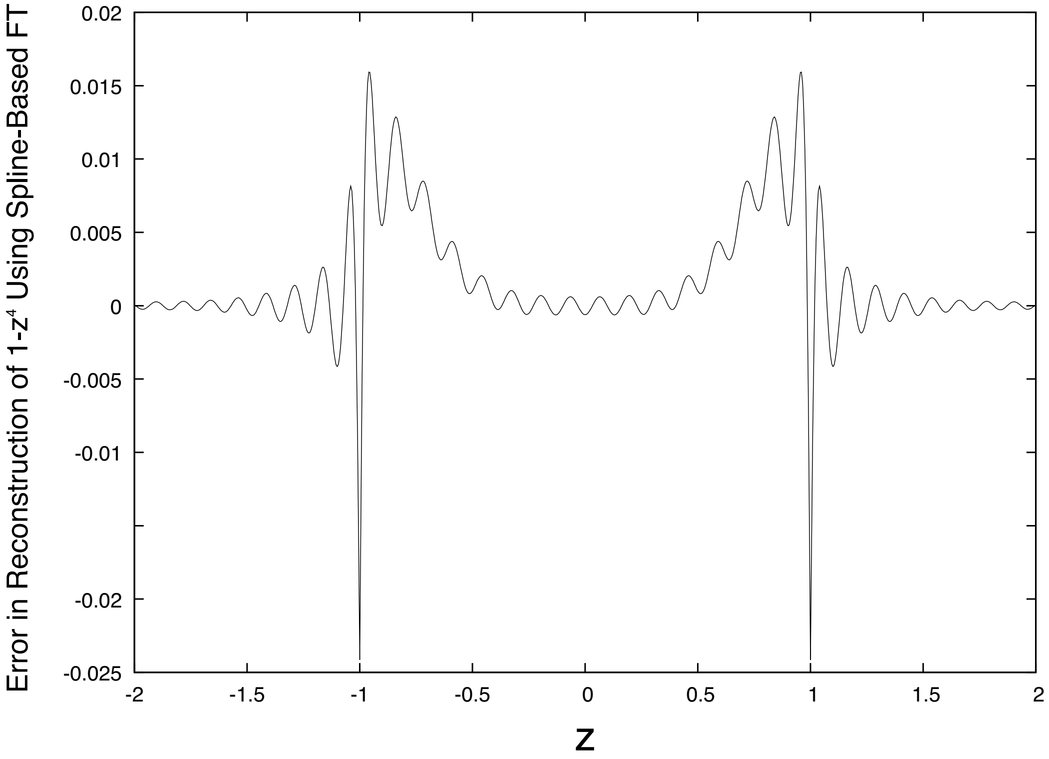

Figure 18.3.14: The difference between the exact function $f_{-1,1}(z) = 1 - z^4$ and its reconstruction using, in (3.41), the 51-point spline approximation $\tilde{f}_{\text{sasa}}(k)$ over the interval $k \in [-50, 50]$.

18.3.6 Fast Spline-Based Fourier Transforms

How much work is involved in computing Fourier transforms? Let M_{mn} be the matrix with entries

$$M_{mn} = [1/(2\pi)]h\exp(-ik_m z_n). \tag{18.3.42}$$

With this notation, the discrete Fourier transformation relation (3.34) can be written in the vector/matrix form

$$\tilde{f}(k_m) = \sum_{n=0}^{N-1} M_{mn} f(z_n). \tag{18.3.43}$$

Suppose we view the matrix M as being *precomputed*, so that we do not count its evaluation toward the work involved, but we do imagine carrying out (3.43) for a collection of k values. Then the major work involved will consist of N^2 multiplications because there are N multiplications in (3.43) for each value of m and there are N such values. Of course, additions are also involved, but they are much less expensive in machine time than multiplications, and so they will be ignored. Thus, it would seem that the work involved in computing discrete Fourier transforms scales as N^2.

One of the celebrated realizations of 20th century computational science is that there are certain *favored* values of N for which there is a *fast* Fourier transform (FFT) algorithm such that the work scales only as $N\log_2 N$ rather than N^2.[11] Although there are other possibilities, these favored values are most commonly taken to be integer powers of 2, $N = 2^\ell$ for some integer ℓ. The use of such N values does not cause any great complication because additional equally-spaced points z_n can added at both ends of the general interval $[a, b]$, and f can be assigned the value 0 at these additional points. (This is called *padding with zeros.*) So doing does not affect the values of the discrete Fourier transform, nor does it affect K_{Ny}. It does affect, however, the location of the sampling points k_m in k space. [See (3.30) with $M = N$ and $K_c = K_{Ny}$.] In fact, it makes the sampling points more finely spaced, which can be viewed as a virtue.

What can be said about the work involved in computing spline-based Fourier transforms? Examination of the logic involved in the construction of discrete FFT algorithms shows that exactly the same considerations apply to spline-based Fourier transforms. Therefore, for every favored value of N, there is also a fast spline-based Fourier transform algorithm for which the work also scales as $N\log_2 N$. Consequently, there is no computational penalty involved in the use of spline-based Fourier transforms.

Exercises

18.3.1. Verify ....

18.3.2. Verify ....

[11] We say *realization* rather than *discovery* because, after the extensive FFT work of Danielson, Lanczos, Cooley, Tukey, and others in the mid 20th century, it became clear in retrospect that their remarkable accomplishments had been anticipated earlier by others including Gauss in 1805.

18.4 Bessel Functions

Look again at Section 14.2. The computation of generalized gradients in terms of potential data on the surface of a circular cylinder required the calculation of Bessel functions $\mathrm{I_m}$, and the equivalent computation in Section 14.3 based on field data required a knowledge of I'_m. For small values of the argument, say $w \leq 1$, these calculations can done using the series (13.2.15). For larger argument values, and in view of the fact that the Bessel functions are needed for many equally-spaced argument values, it is convenient to to compute Bessel functions by integrating the differential equation for $\mathrm{I_m}$ numerically (using the methods of Chapter 2) in the form

$$\mathrm{I}''_\mathrm{m}(w) + (1/w)\mathrm{I}'_\mathrm{m}(w) - (m^2/w^2)\mathrm{I_m}(w) - \mathrm{I_m}(w) = 0. \tag{18.4.1}$$

Here, as initial conditions, we use the series (13.2.15) to evaluate $\mathrm{I_m}$ and I'_m for $w = 1$.

We remark that many of the standard familiar transcendental functions satisfy or are defined by differential equations with good analytic properties. If their values are required at many equally spaced points, these values can often be conveniently and reliably obtained by numerical integration of these differential equations. We will use this method in the next section for Mathieu functions.

18.5 Mathieu Functions

This subsection describes briefly tools needed for the computation of Mathieu functions. In 1914 Whittaker remarked about Mathieu functions that

> their actual analytical determination presents great difficulties.

He could have said the same thing about their numerical computation. Nearly 100 years later there still do not seem to be any open-source algorithms that are fully robust over the required range of the parameter q.

18.5.1 Calculation of Separation Constants $a_n(q)$ and $b_n(q)$

There is a fast algorithm, based on the use of continued fractions, for the computation of the separation constants $a_n(q)$ and $b_n(q)$. There are also algorithms based on matrix diagonalization. Unfortunately, no routines have yet been found that are completely robust. Samples of the existing routines are listed in Appendix M along with a description of their performance. Although much work has been done on this subject by many authors, there is yet more to be done.

18.5.2 Calculation of Mathieu Functions

The calculation of the Mathieu functions themselves is also a delicate matter. As an indication of the difficulty of computing Mathieu functions reliably, we have found that *Mathematica*, useful as it is, also does not compute them accurately for some values of q. However, for our purposes, since we need them only for a relatively few equally-spaced values of the arguments u and v, they can be obtained (with some care and recognition of their symmetry properties) by direct numerical integration (using the methods of Chapter 2) of their defining differential equations. Thus, for us, the major problem is accurate computation of the separation constants.

Specifically, for the $\mathrm{ce}_n(v,q)$, we integrate the equation (14.4.22) over the interval $[0,2\pi]$ with the initial conditions

$$Q_n^c(0,q)=1, \tag{18.5.1}$$

$$Q_n^{c\,\prime}(0,q)=0. \tag{18.5.2}$$

Here, and in what follows, a $\prime$ denotes differentiation with respect to v. Moreover, the notation $Q_n^c(v,q)$ indicates that q is to be computed using (14.4.23), that this resulting q value is next used to compute $a=a_n(q)$, and that these values of q and a are then used in (14.4.22). Simultaneously, we integrate the first-order differential equation

$$N_c'(v)=[Q_n^c(v,q)]^2, \tag{18.5.3}$$

again over the interval $[0,2\pi]$, with the initial condition

$$N_c(0)=0. \tag{18.5.4}$$

Finally, we find $\mathrm{ce}_n(v,q)$ from the relation

$$\mathrm{ce}_n(v,q)=[\sqrt{\pi/N_c(2\pi)}]Q_n^c(v,q). \tag{18.5.5}$$

In this way we generate a solution of (14.4.22) that is even in v, and also satisfies the normalization requirement (14.4.38) for $m=n$. Finally, we check numerically the periodicity requirements

$$Q_n^c(2\pi,q)=1,$$
$$Q_n^{c\,\prime}(2\pi,q)=0. \tag{18.5.6}$$

We require that the relations (5.6) are always satisfied to high precision. So doing provides a check on both the accuracy of the $a_n(q)$ and the numerical integration procedure. We remark that because of the symmetry conditions described at the end of Section 14.4.4, it is really only necessary to integrate over the interval $[0,\pi/2]$ and then verify that (4.54) or (4.57) are satisfied. Moreover, if the $a_n(q)$ are known to be accurate and there are strongly forbidden regions in v, it is only necessary to integrate over the still smaller interval $[0,v_{\mathrm{deep}}]$.

The calculation of the $\mathrm{se}_n(v,q)$ is done in a similar way. Now we set $a=b_n(q)$ and integrate (14.4.22) with the initial conditions

$$Q_n^s(0,q)=0, \tag{18.5.7}$$

$$Q_n^{s\,\prime}(0,q)=1. \tag{18.5.8}$$

At the same time we again integrate the differential equation

$$N_s'(v)=[Q_n^s(v,q)]^2 \tag{18.5.9}$$

with the initial condition

$$N_s(0)=0. \tag{18.5.10}$$

Then we define $\mathrm{se}_n(v,q)$ by the relation

$$\mathrm{se}_n(v,q) = [\sqrt{\pi/N_s(2\pi)}]Q_n^s(v,q). \tag{18.5.11}$$

Finally, we check numerically the periodicity requirements that now

$$Q_n^s(2\pi,q) = 0,$$

$$Q_n^s{}'(2\pi,q) = 1. \tag{18.5.12}$$

We require that (5.12) be satisfied to high precision thereby providing a check on the accuracy of both the $b_n(q)$ and, as before, the numerical integrator. Again, using symmetry it is really only necessary to integrate over the interval $[0,\pi/2]$. And if the $b_n(q)$ are known to be accurate and there are strongly forbidden regions in v, it is only necessary to integrate over the still smaller interval $[0,v_{\text{deep}}]$.

We still have to describe the computation of $\mathrm{Ce}_n(u,q)$ and $\mathrm{Se}_n(u,q)$. Now we will integrate (14.4.21) numerically. For the case of $\mathrm{Ce}_n(u,q)$ we find from (14.4.56) the initial condition

$$\mathrm{Ce}_n(0,q) = \mathrm{ce}_n(0,q) = \sqrt{\pi/N_c(2\pi)}. \tag{18.5.13}$$

Here we have also used (5.1) and (5.5). And, since $\mathrm{Ce}_n(u,q)$ is even in u, we have the second initial condition

$$\mathrm{Ce}_n'(0,q) = 0. \tag{18.5.14}$$

Thus, given k, we find q and $a = a_n(q)$. Then, having selected U, we integrate (14.4.21) over the interval $u \in [0,U]$ with the initial conditions

$$P_n^c(0,q) = \sqrt{\pi/N_c(2\pi)} \tag{18.5.15}$$

and

$$P_n^c{}'(0,q) = 0. \tag{18.5.16}$$

The result of this process is the value $\mathrm{Ce}_n(U,q) = P_n^c(U,q)$.

The computation of $\mathrm{Se}_n(u,q)$ proceeds similarly. From (14.4.57) we see that there are the initial conditions

$$\mathrm{Se}_n(0,q) = -i\mathrm{se}_n(0,q) = 0, \tag{18.5.17}$$

$$\mathrm{Se}_n'(u,q)|_{u=0} = -i\mathrm{se}_n'(iu,q)|_{u=0}(i) = \mathrm{se}_n'(0,q) = \sqrt{\pi/N_s(2\pi)}. \tag{18.5.18}$$

Here we have used (5.8) and (5.11). Thus, given k, we find q and $a = b_n(q)$. Then, having selected U, we integrate (14.4.21) over the interval $u \in [0,U]$ with the initial conditions

$$P_n^s(0,q) = 0 \tag{18.5.19}$$

and

$$P_n^s{}'(0,q) = \sqrt{\pi/N_s(2\pi)}. \tag{18.5.20}$$

The result of this process is the value $\mathrm{Se}_n(U,q) = P_n^s(U,q)$.

18.5.3 Calculation of Fourier and Mathieu-Bessel Connection Coefficients

The functions $\mathrm{ce}_r(v,q)$ and $\mathrm{se}_r(v,q)$ are periodic with period 2π and therefore have Fourier expansions in terms of the functions $\cos(mv)$ and $\sin(mv)$. See (14.4.52) through (14.4.55). As shown in Appendix N, the Fourier coefficients that appear in these expansions, which depend on q, are key to computing the Mathieu-Bessel connection coefficients $\alpha^r_m(k)$ and $\beta^r_m(k)$. See (14.4.78) and (14.4.79). In this subsection we describe how these Fourier coefficients can be computed numerically.

Let us begin with the functions $\mathrm{ce}_r(v,q)$. Since they are periodic and even, they have Fourier expansions of the form

$$\mathrm{ce}_r(v,q) = \sum_{m=0}^{\infty} A^r_m(q)\cos(mv). \tag{18.5.21}$$

There are known algorithms for the computation of the Fourier coefficients $A^r_m(q)$ but, as was the case with those for the computation of the $\mathrm{ce}_r(v,q)$, we have found that they are not robust. However, by the orthogonality property of the trigonometric functions, it follows that

$$A^r_0(q) = [1/(2\pi)]\int_0^{2\pi} dv\ \mathrm{ce}_r(v,q),$$

$$A^r_m(q) = (1/\pi)\int_0^{2\pi} dv\ \mathrm{ce}_r(v,q)\cos(mv) \text{ for } m \ge 1. \tag{18.5.22}$$

By (5.5) we may also write

$$A^r_0(q) = [1/(2\pi)][\sqrt{\pi/N_c(2\pi)}]\int_0^{2\pi} dv\ Q^c_r(v,q),$$

$$A^r_m(q) = (1/\pi)[\sqrt{\pi/N_c(2\pi)}]\int_0^{2\pi} dv\ Q^c_r(v,q)\cos(mv) \text{ for } m \ge 1. \tag{18.5.23}$$

Let $\hat{A}^r_m(v,q)$ be the functions defined for various values of m and r by the differential equations

$$\hat{A}^{r\,\prime}_0(v,q) = (1/2)Q^c_r(v,q),$$

$$\hat{A}^{r\,\prime}_m(v,q) = Q^c_r(v,q)\cos(mv) \text{ for } m \ge 1 \tag{18.5.24}$$

with the common initial conditions

$$\hat{A}^r_m(0,q) = 0. \tag{18.5.25}$$

The differential equations (5.24) can be integrated numerically over the interval $[0,2\pi]$ simultaneously with those for the $Q^c_r(v,q)$ and (5.3). Then we find that the $A^r_m(q)$ are given by the relations

$$A^r_m(q) = (1/\pi)[\sqrt{\pi/N_c(2\pi)}]\hat{A}^r_m(2\pi,q). \tag{18.5.26}$$

Similarly, for the functions $\mathrm{se}_r(v,q)$, there are Fourier expansions of the form

$$\mathrm{se}_r(v,q)=\sum_{m=1}^{\infty} B_m^r(q)\sin(mv). \tag{18.5.27}$$

And, again by the orthogonality property of the trigonometric functions, it follows that

$$B_m^r(q)=(1/\pi)\int_0^{2\pi} dv\ \mathrm{se}_r(v,q)\sin(mv). \tag{18.5.28}$$

With the aid of (5.11) this relation can also be written in the form

$$B_m^r(q)=(1/\pi)[\sqrt{\pi/N_s(2\pi)}]\int_0^{2\pi} dv\ Q_r^s(v,q)\sin(mv). \tag{18.5.29}$$

Now let $\hat{B}_m^r(v,q)$ be the functions defined for various values of m and r by the differential equations

$$\hat{B}_m^{r\,\prime}(v,q)=Q_r^s(v,q)\sin(mv) \tag{18.5.30}$$

with the common initial conditions

$$\hat{B}_m^r(0,q)=0. \tag{18.5.31}$$

Now we find that the $B_m^r(q)$ are given by the relations

$$B_m^r(q)=(1/\pi)[\sqrt{\pi/N_s(2\pi)}]\hat{B}_m^r(2\pi,q). \tag{18.5.32}$$

At this point we remark that the functions $\cos(mv)$ and $\sin(mv)$ required to integrate the differential equations (5.24) and (5.30), as well as the equations of the form (14.4.22) for the $Q_r^c(v,q)$ and the $Q_r^s(v,q)$, can also be computed on the fly by simultaneously integrating numerically the differential equations for the trigonometric functions. The needed hyperbolic functions in (14.4.21) can be calculated analogously. So doing is faster than using the built-in Fortran or C functions for the trigonometric functions.

Chapter 19

Numerical Benchmarks

How well do the surface methods of Chapter 14 work? To test them we need a problem that is sufficiently complex and challenging to fully exercise the numerical algorithms while at the same time being exactly soluble. In that way we will be able to gauge the accuracy of the numerical methods by comparing numerical results with exact analytic results. Such a test problem is that of the magnetic monopole doublet described in Section 13.7. For this problem we will assume that $a = 2.5$ cm and $g = 1$ Tesla-(cm)^2. See Section 13.7.1.

19.1 Circular Cylinder Numerical Results for Monopole Doublet

In this section we will apply the circular cylinder numerical method of Section 14.3 to the monopole doublet problem to investigate how accurately this method is able to reproduce the exact analytic results for the on-axis gradients found in Section 13.7.2.[1] For our benchmark calculation we will employ a cylinder with radius $R = 2$ cm. See Figure 13.7.1. We will work up to the desired numerical comparison by stages. In this way we will be able to judge the accuracy of various intermediate steps.

Observe that the integrands of (14.3.8) and (14.3.23), apart from multiplicative constants, consist of the *product* of a *kernel* $[k^{n+|m|-1}/I'_m(kR)]$ and the *Fourier coefficients* $[\tilde{\tilde{B}}_\rho(R, m', k')]$ or $[\tilde{\tilde{B}}^\alpha_\rho(R, m', k')]$. The kernels are *universal* (the same for all problems) and the Fourier coefficients are specific to each problem. In what follows we will be examining both. For convenience, we will use the Fourier coefficients $[\tilde{\tilde{B}}^\alpha_\rho(R, m', k')]$.

19.1.1 Testing the Spline-Based Inverse ($k \rightarrow z$) Fourier Transform

Suppose we know exactly the Fourier coefficients $\tilde{\tilde{B}}^\alpha_\rho(R, m', k')$ as given by (14.3.14). We will see in the next two paragraphs that, for the case of the monopole doublet, the $\tilde{\tilde{B}}^\alpha_\rho(R, m', k')$ can indeed be found exactly. We can insert these exact quantities into (14.3.23), and then

[1] A similar study could be made of the accuracy of the related method of Section 14.2, with analogous results.

perform the required integration numerically using the methods described in Section 15.3.5. In this way we will be able to test the accuracy of the numerical routines for $I_m'(w)$ and for spline-based inverse Fourier transforms. This test will be performed in later paragraphs.

Exact Fourier coefficients

To find the $\tilde{\tilde{B}}_\rho^\alpha(R, m', k')$ exactly, suppose the $C_{m,\alpha}^{[0]}(z)$ have the Fourier representation

$$C_{m,\alpha}^{[0]}(z) = \int_{-\infty}^{\infty} dk\ \tilde{C}_{m,\alpha}^{[0]}(k) \exp(ikz). \tag{19.1.1}$$

From (14.3.23) evaluated with $n = 0$ we have the result

$$C_{m,\alpha}^{[0]}(z) = (1/2)^m (1/m!) \int_{-\infty}^{\infty} dk [k^{m-1}/I_m'(kR)] \tilde{\tilde{B}}_\rho^\alpha(R, m, k) \exp(ikz). \tag{19.1.2}$$

It follows from the uniqueness of the Fourier representation that there are the relations

$$\tilde{C}_{m,\alpha}^{[0]}(k) = (1/2)^m (1/m!) [k^{m-1}/I_m'(kR)] \tilde{\tilde{B}}_\rho^\alpha(R, m, k), \tag{19.1.3}$$

which can be solved for the $\tilde{\tilde{B}}_\rho^\alpha(R, m, k)$ to give the relations

$$\tilde{\tilde{B}}_\rho^\alpha(R, m, k) = 2^m (m!) [I_m'(kR)/(k)^{m-1}] \tilde{C}_{m,\alpha}^{[0]}(k). \tag{19.1.4}$$

Of course, in view of (1.1), the $\tilde{C}_{m,\alpha}^{[0]}(k)$ are also given by the inverse Fourier transform

$$\tilde{C}_{m,\alpha}^{[0]}(k) = [1/(2\pi)] \int_{-\infty}^{\infty} dz\ C_{m,\alpha}^{[0]}(z) \exp(-ikz). \tag{19.1.5}$$

Therefore, from (13.7.9) and (13.7.33), we conclude that for the monopole doublet there are the results

$$\tilde{C}_{m=0}^{[0]}(k) = 0, \tag{19.1.6}$$

$$\tilde{C}_{m,c}^{[0]}(k) = 0, \tag{19.1.7}$$

$$\tilde{C}_{m,s}^{[0]}(k) = 0 \text{ for } m \text{ even}, \tag{19.1.8}$$

and the only nonzero integrals on the right side of (1.5) are of the form

$$\int_{-\infty}^{\infty} dz\ C_{m,s}^{[0]}(z) \exp(-ikz) \text{ with } m \text{ odd}. \tag{19.1.9}$$

From (13.7.33) we see that we need the integrals

$$\int_{-\infty}^{\infty} dz\ \exp(-ikz) \beta^{2m+1}(z) \text{ for } m \text{ odd}. \tag{19.1.10}$$

These integrals can be done analytically, and have the values

$$\int_{-\infty}^{\infty} dz\ \exp(-ikz) \beta^{2m+1}(z) = \{2/[1 \cdot 3 \cdot 5 \cdot 7 \cdots (2m-1)]\} a^{m+1} |k|^m K_m(a|k|). \tag{19.1.11}$$

Putting everything together gives the final result that the only nonzero $\tilde{\tilde{B}}_\rho^\alpha(R,m,k)$ are those given by the relations

$$\tilde{\tilde{B}}_\rho^s(R,m,k) = (-4g/\pi)(-1)^{(m-1)/2}|k|I'_m(kR)K_m(a|k|) \text{ for } m \text{ odd.} \tag{19.1.12}$$

We observe that the $\tilde{\tilde{B}}_\rho^s(R,m,k)$ for the monopole doublet are pure real and are even functions of k. The imaginary part vanishes because, for the monopole doublet, $B_\rho(R,\phi,z)$ is an even function of z. See (13.7.8) and (14.3.14) through (14.3.16).

As examples of the behavior of the $\tilde{\tilde{B}}_\rho^s(R,m,k)$, Figures 1.1 and 1.2 show the functions $\Re\tilde{\tilde{B}}_\rho^s(R,1,k)$ and $\Re\tilde{\tilde{B}}_\rho^s(R,7,k)$. As already described, $I'_m(kR)$ grows exponentially at infinity. See (14.3.7). By contrast, $K_m(a|k|)$ decays exponentially to zero at infinity,

$$|K_m(a|k|)| \sim \exp(-|k|a)(\pi)^{1/2}/\sqrt{2|k|a} \text{ as } |k| \to \infty. \tag{19.1.13}$$

Since $a > R$, it follows that the $\tilde{\tilde{B}}_\rho^s(R,m,k)$ are exponentially damped at infinity,

$$|\tilde{\tilde{B}}_\rho^s(R,m,k)| \sim \exp[-|k|(a-R)] \text{ as } |k| \to \infty. \tag{19.1.14}$$

The function $I'_m(kR)$ is an entire function of k. The function $K_m(a|k|)$ is singular at the origin. Analysis reveals that the product $|k|I'_m(kR)K_m(a|k|)$ is finite at the origin and has additionally a logarithmic singularity at the origin of the form $|k|^{2m}\log|k|$.[2] Thus the $\tilde{\tilde{B}}_\rho^s(R,m,k)$, with $m \geq 1$, are finite for all k and vanish exponentially at infinity.

Kernels

Since, as emphasized earlier, the integrand in (14.3.23) is the product of a kernel and a Fourier coefficient, we should also examine the kernels. Figures 1.3 through 1.5 display the kernels $[k^{n+m-1}/I'_m(kR)]$ for the representative cases (m,n)=(1,0), (1,6), and (7,0) when $R = 2$ cm. We see, as expected, that they fall off rapidly for large $|k|$. The intermediate cases give analogous results.

Exact Integrands

We are now ready to evaluate the integrals (14.3.23) to find the $C_{m,s}^{[n]}(z)$. Upon inserting (1.12) into (14.3.23), we find the results

$$C_{m,s}^{[n]}(z) = \left\{\frac{-4g(-1)^{(m-1)/2}}{\pi 2^m(m!)}\right\}\int_{-\infty}^{\infty} dk\ \exp(ikz)(ik)^n|k|^m K_m(|k|a). \tag{19.1.15}$$

Or, more directly and as an algebraic check, we may use (1.5) to yield the result

$$\begin{aligned}\tilde{C}_{m,s}^{[0]}(k) &= [1/2\pi]\int_{-\infty}^{\infty} dz\ C_{m,s}^{[0]}(z)\exp(-ikz) \\ &= \{-4g/[\pi 2^m(m!)]\}(-1)^{(m-1)/2}|k|^m K_m(|k|a).\end{aligned} \tag{19.1.16}$$

[2] It can be shown that this singularity in $\tilde{\tilde{B}}_\rho^s(R,m,k)$ is related to the $\sim 1/|z|^3$ behavior of $B_\rho(R,\phi,z)$ and the $\sim 1/|z|^{2m+1}$ behavior of the $C_{m,s}^{[0]}(z)$ for large $|z|$. See (13.7.8) and (13.7.34). In general, the faster the falloff at $|z| = \infty$, the milder the singularity at $k = 0$.

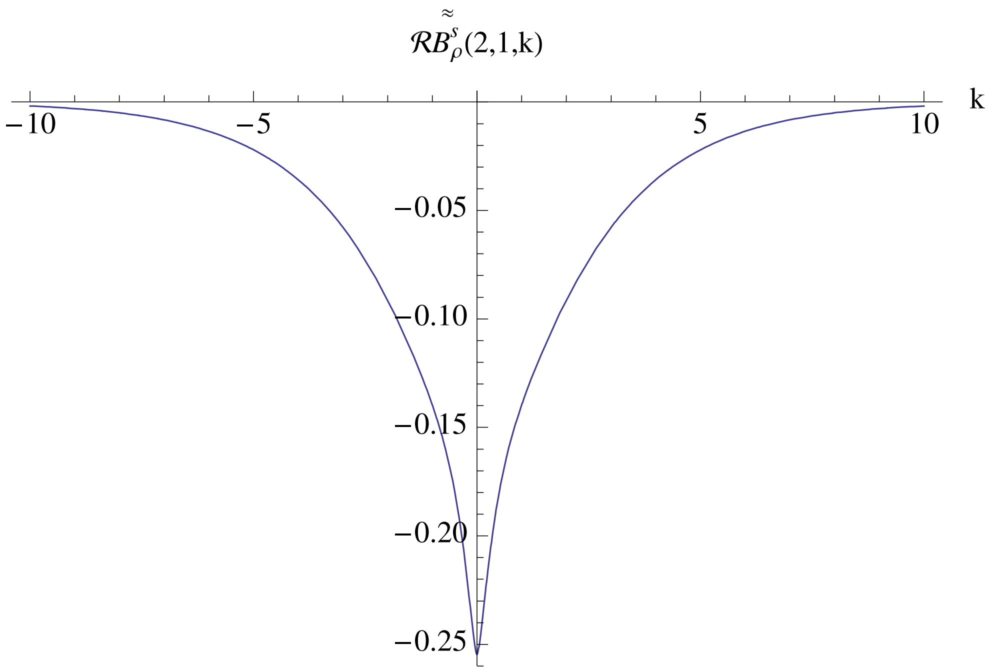

Figure 19.1.1: The real part of $\tilde{\tilde{B}}^s_\rho(R,1,k)$ as a function of k for the monopole doublet in the case that $R = 2$ cm and $a = 2.5$ cm. The imaginary part vanishes.

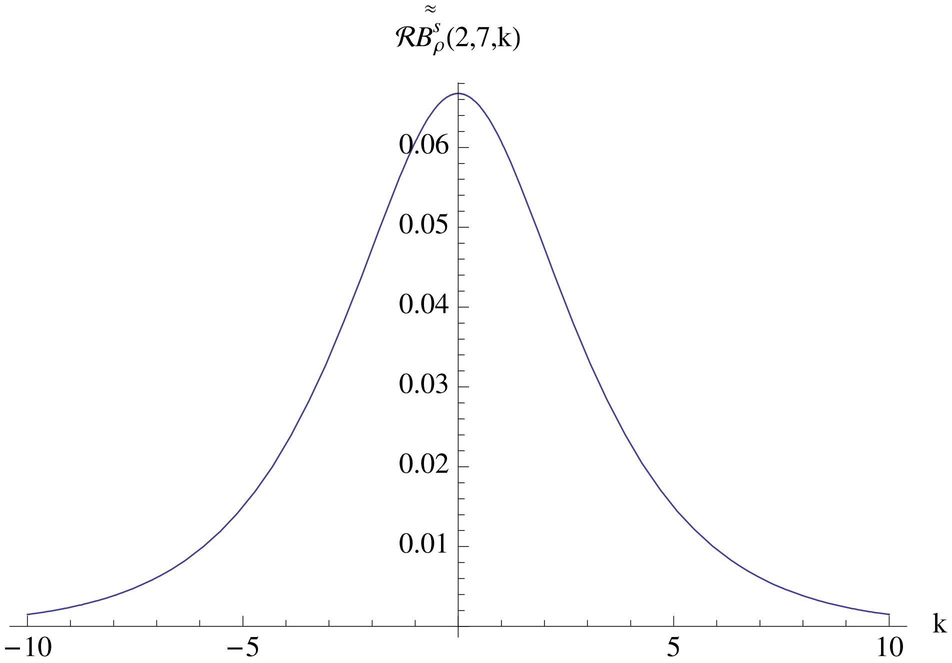

Figure 19.1.2: The real part of $\Re\tilde{\tilde{B}}^s_\rho(R,7,k)$ as a function of k for the monopole doublet in the case that $R = 2$ cm and $a = 2.5$ cm. The imaginary part vanishes.

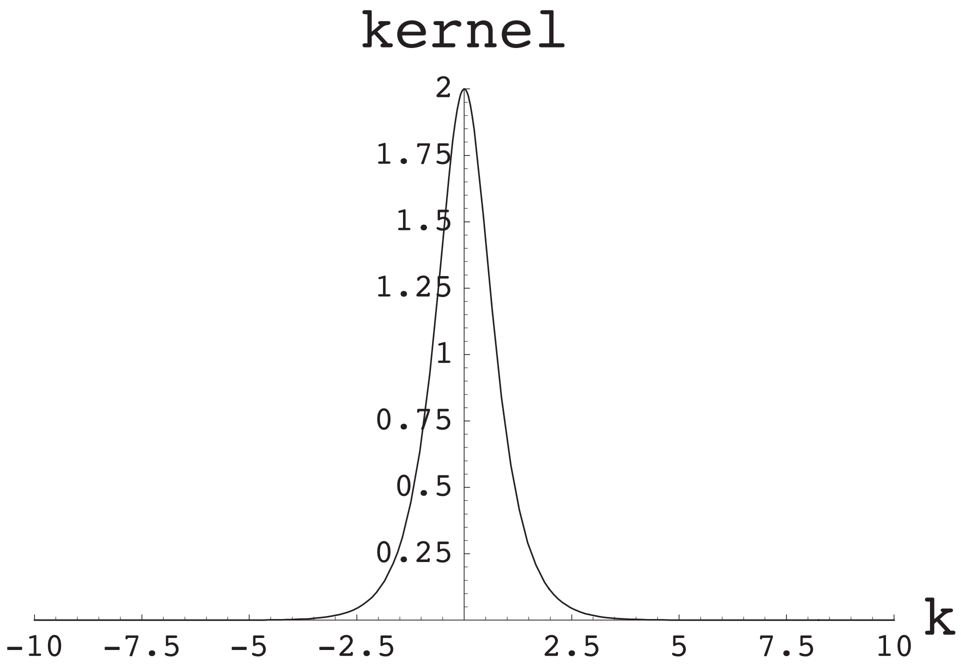

Figure 19.1.3: The kernel $[k^{n+m-1}/I'_m(kR)]$ as a function of k in the case that $m = 1$, $n = 0$, and $R = 2$ cm.

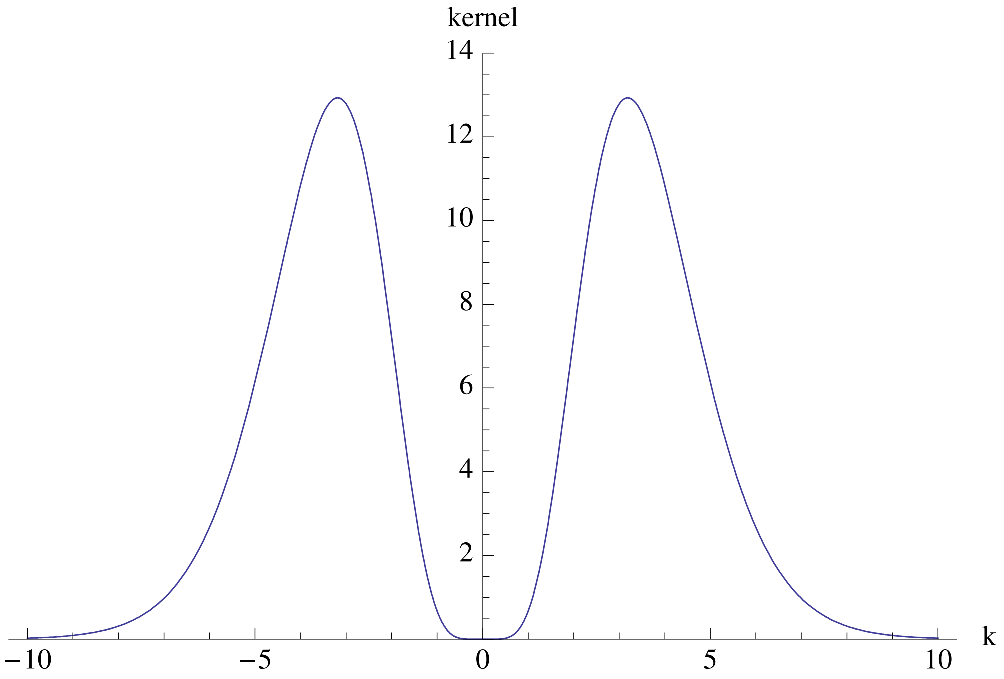

Figure 19.1.4: The kernel $[k^{n+m-1}/I'_m(kR)]$ as a function of k in the case that $m = 1$, $n = 6$, and $R = 2$ cm.

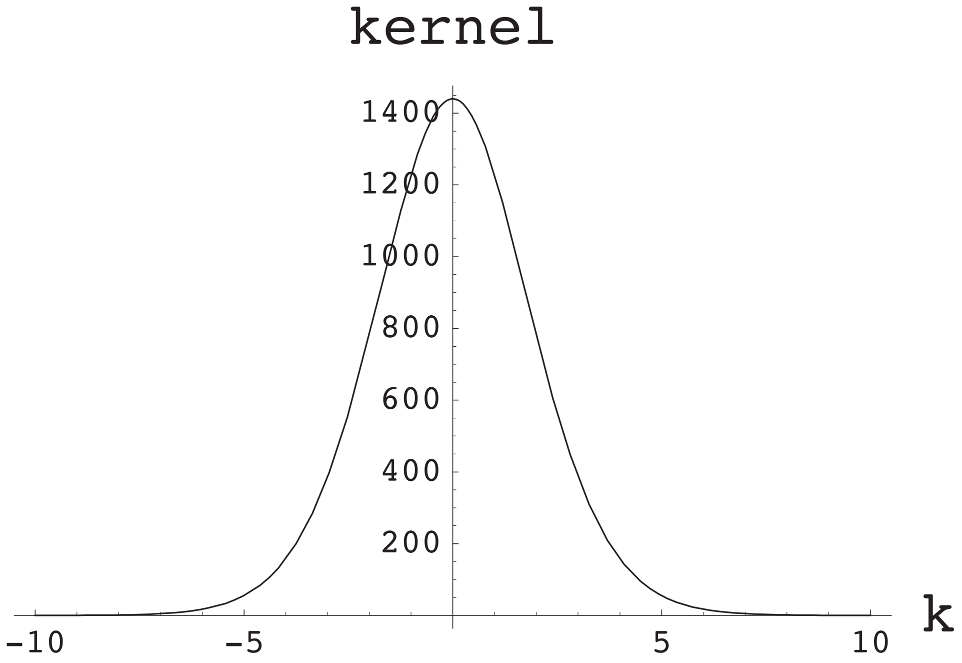

Figure 19.1.5: The kernel $[k^{n+m-1}/I'_m(kR)]$ as a function of k in the case that $m = 7$, $n = 0$, and $R = 2$ cm.

Note that the nonzero $\tilde{C}^{[0]}_{m,s}(k)$ for the monopole doublet are pure real because $C^{[0]}_{m,\alpha}(z)$ is real and, for the monopole doublet case, is an even function of z. Correspondingly, the $\tilde{C}^{[0]}_{m,s}(k)$ are even functions of k. Now, more compactly, we may write

$$C^{[n]}_{m,s}(z) = \int_{-\infty}^{\infty} dk\ (ik)^n \tilde{C}^{[0]}_{m,s}(k) \exp(ikz). \tag{19.1.17}$$

It is these integrals that we want to evaluate using spline-based inverse Fourier transforms in order to illustrate and verify the accuracy of this numerical method.

The integrands that are expected to be the hardest to integrate accurately are those for the extreme case $\{m = 1, n = 0\}$ because of its $|k|^2 \log |k|$ singularity at the origin and the extreme case $\{m = 1, n = 6\}$ because of its oscillatory behavior. These integrands, which are required to compute $C^{[0]}_{1,s}(z)$ and $C^{[6]}_{1,s}(z)$, respectively, are shown in Figures 1.6 and 1.7.

As expected, the integrands fall of rapidly for large $|k|$ because, as seen earlier, both the Fourier coefficients and the kernels fall of rapidly for large $|k|$. Indeed, inspection of Figures 1.6 and 1.7 shows that the integrands have effectively fallen to zero when $|k| > 10$. Therefore, and in order to be conservative, we will evaluate the integrals (14.3.23) using the somewhat larger cutoff $K_c = 20$. Moreover, we will use 401-point spline fits to the integrands over the interval $k \in [-K_c, K_c]$ so that $H = .1$. See (15.3.30).

Spline-Based Inverse Fourier Transform Results

Figures 1.8 and 1.9 show the functions $C^{[0]}_{1,s}(z)$ and $C^{[6]}_{1,s}(z)$ obtained in this way as well as the exact results given by (13.7.33) and its derivatives. Figures 1.10 and 1.11 show for these

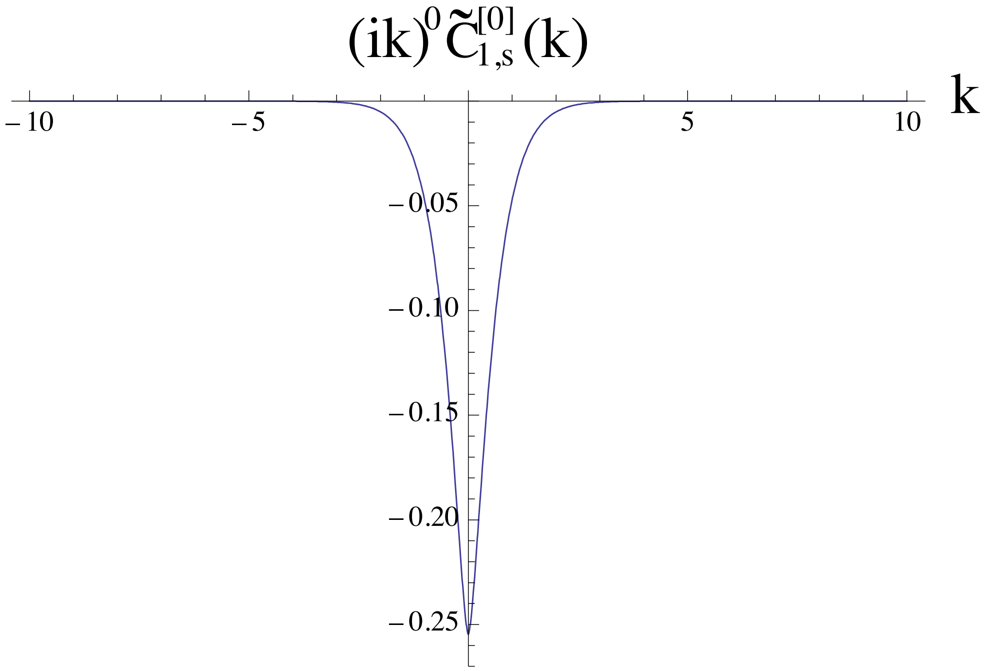

Figure 19.1.6: The integrand $(ik)^n\tilde{C}^{[0]}_{m,s}(k)$ for $m = 1$ and $n = 0$ as a function of k in the case that $R = 2$ cm. It is required to compute $C^{[0]}_{1,s}(z)$.

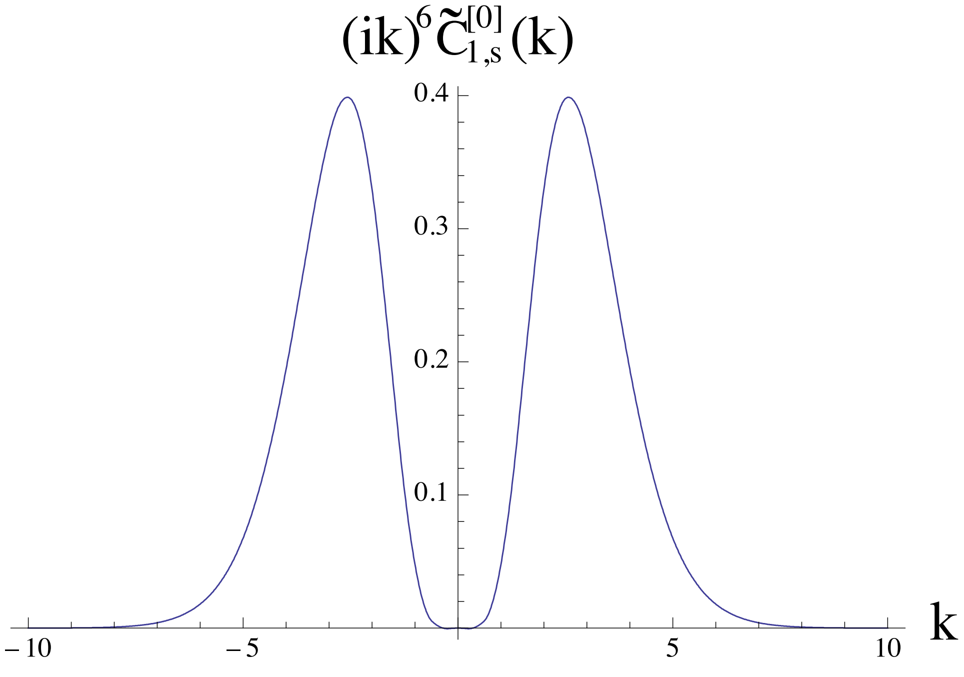

Figure 19.1.7: The integrand $(ik)^n\tilde{C}^{[0]}_{m,s}(k)$ for $m = 1$ and $n = 6$ as a function of k in the case that $R = 2$ cm. It is required to compute $C^{[6]}_{1,s}(z)$.

cases the differences between the exact and numerical results. Evidently the worst case is that of $C^{[0]}_{1,s}(z)$, and the error in this case is approximately 1.6 parts in 10^4. Further numerical study shows that the error is smaller for the other $C^{[n]}_{m,s}(z)$ listed in (13.7.35). Finally, further numerical study shows that the error can be made even smaller by increasing the number of points in the spline fit.[3] In this context we remark that the error in $C^{[0]}_{1,s}(z)$ decreases only as H^3 while the error in the other $C^{[n]}_{m,s}(z)$ decreases as H^4. This behavior is due to the $|k|^2 \log |k|$ singularity in $\tilde{C}^{[0]}_{1,s}(k)$ so that $\tilde{C}^{[0]}_{1,s}(k)$ does not have a finite fourth derivative at the origin. [See (15.1.34).] The integrands $(ik)^n \tilde{C}^{[0]}_{m,s}(k)$ for other values of m, n are less singular at the origin.

We conclude that if the integrand is computed to high precision (exactly, in this case), the spline-based inverse Fourier transform gives accurate results.

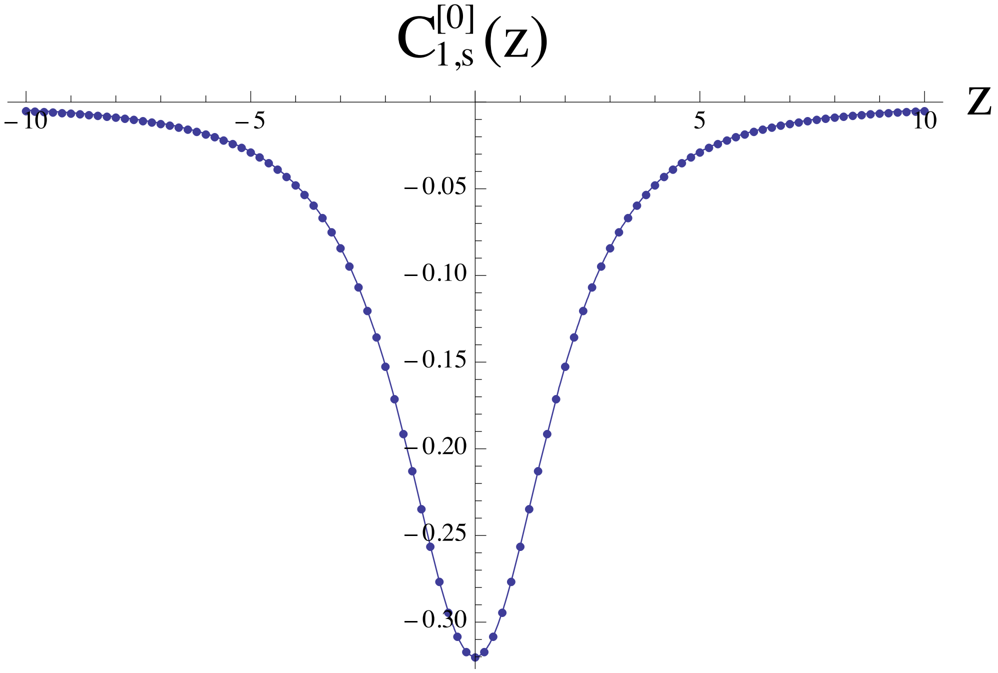

Figure 19.1.8: Exact and numerical results for $C^{[0]}_{1,s}(z)$. Exact results are shown as a solid line (see Figure 13.7.8), and numerical results are shown as dots.

19.1.2 Testing the Forward ($z \rightarrow k$) and ($\phi \rightarrow m$) Fourier Transforms

Having verified the accuracy of the spline-based inverse Fourier transform for carrying out the integration (14.3.23), let us also use splines to find $\tilde{\tilde{B}}_\rho(R, m', k')$. The radial component $B_\rho(\rho, \phi, z)$ of the magnetic field $\boldsymbol{B}$ is given by (13.7.8) and its behavior is displayed in Figures 13.7.6 and 13.7.7. According to (14.3.1), calculating $\tilde{\tilde{B}}_\rho(R, m', k')$ requires both a Fourier

[3] The value of K_c can also be increased. However, this does not seem to be necessary unless much higher accuracy is required.

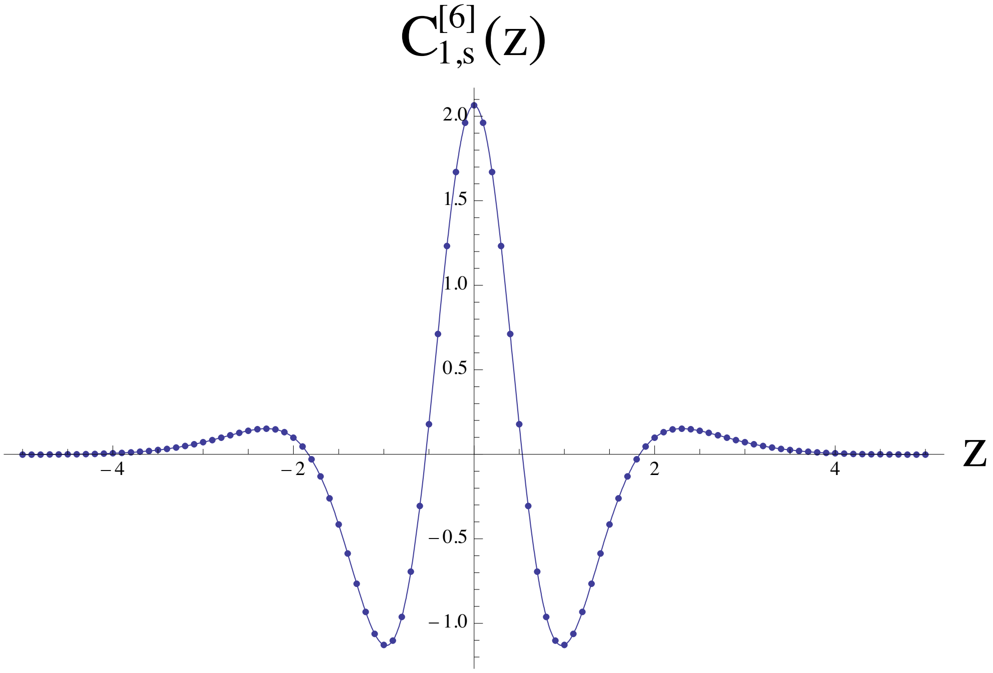

Figure 19.1.9: Exact and numerical results for $C_{1,s}^{[6]}(z)$. Exact results are shown as a solid line (see Figure 13.7.9), and numerical results are shown as dots.

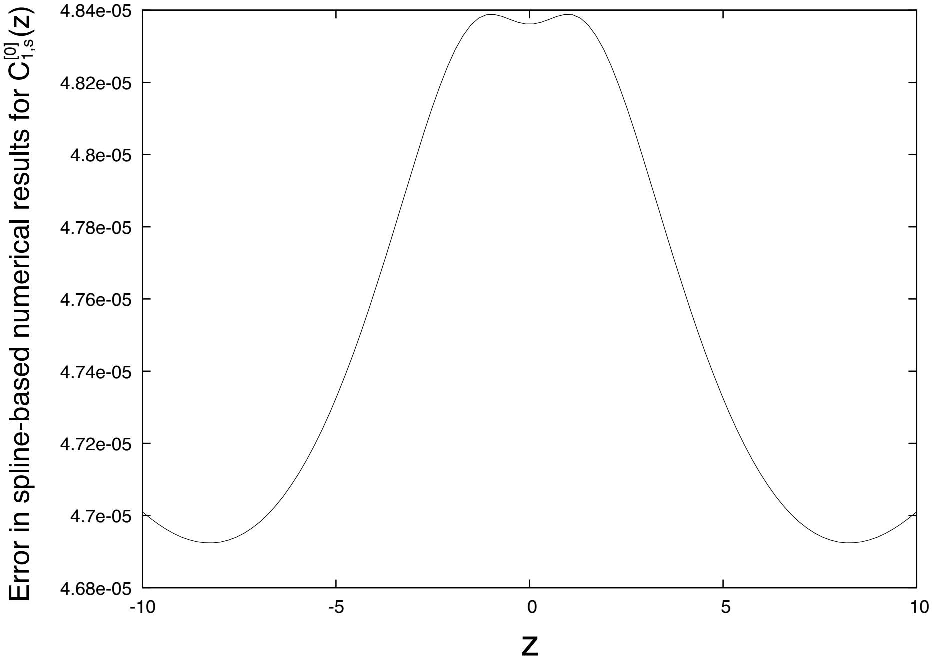

Figure 19.1.10: Difference between exact and spline-based numerical results for $C_{1,s}^{[0]}(z)$ using an exact integrand in (14.3.23).

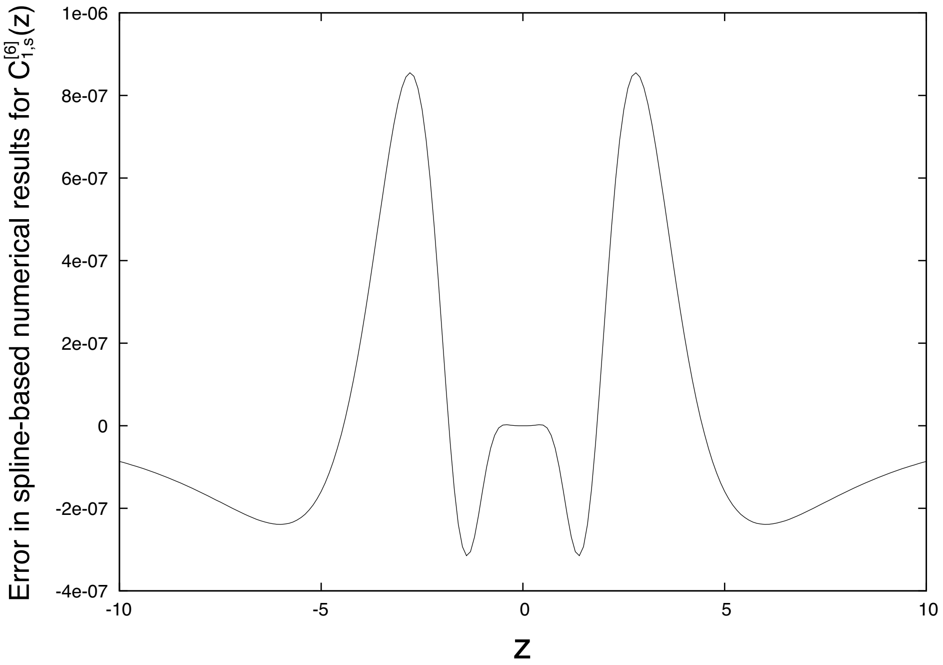

Figure 19.1.11: Difference between exact and spline-based numerical results for $C^{[6]}_{1,s}(z)$ using an exact integrand in (14.3.23).

transform involving integration over z, and the computation of Fourier coefficients involving integration over ϕ. The integrations may be performed in either order. Thus, we may define $\tilde{B}_\rho(R,\phi,k')$ by writing

$$\tilde{B}_\rho(R,\phi,k') = [1/(2\pi)] \int_{-\infty}^{\infty} dz\ \exp(-ik'z) B_\rho(R,\phi,z), \tag{19.1.18}$$

and then obtain $\tilde{\tilde{B}}_\rho(R,m',k')$ from the relation

$$\tilde{\tilde{B}}_\rho(R,m',k') = [1/(2\pi)] \int_0^{2\pi} d\phi\ \exp(-im'\phi) \tilde{B}_\rho(R,\phi,k'). \tag{19.1.19}$$

Performing the Forward ($z \to k$) Fourier Transform

Let us first attack the problem of evaluating (1.18). Based on inspection of Figure 13.7.7, we might imagine that we could safely cut off the Fourier transform integral (1.18) by setting the integrand to zero for $|z| > Z_c$ with $Z_c = 10$. However, in this case looks are deceiving. Examine (13.7.8) for the case $\phi = \pi/2$. The two terms within the first set of curly brackets tend to cancel for large $|z|$. The two terms within the second set of curly brackets do not. The term within the second set of curly brackets that falls of most slowly for large $|z|$ is given by the relation

$$\text{term with slowest falloff} = -ga[z^2 + (R+a)^2]^{-3/2} = -ga[z^2 + b^2]^{-3/2} \tag{19.1.20}$$

where

$$b = R + a. \tag{19.1.21}$$

If we are interested in evaluating $\tilde{B}_\rho(R,\phi,k)$ accurately for $\phi=\pi/2$ and $k=0$, then we must make the comparison

$$\int_{-\infty}^{\infty} dz\ [z^2+b^2]^{-3/2} \text{ versus} \int_{-Z_c}^{Z_c} dz\ [z^2+b^2]^{-3/2}. \tag{19.1.22}$$

These two integrals have the values

$$\int_{-\infty}^{\infty} dz\ [z^2+b^2]^{-3/2}\ = 2/b^2, \tag{19.1.23}$$

$$\int_{-Z_c}^{Z_c} dz\ [z^2+b^2]^{-3/2}\ = (2/b^2)\{Z_c/[Z_c^2+b^2]^{-1/2}\}. \tag{19.1.24}$$

Therefore the *fractional error* involved in imposing a cutoff is given by the relation

$$\text{fractional error} = 1 - Z_c/[Z_c^2+b^2]^{-1/2} \approx (1/2)(b/Z_c)^2. \tag{19.1.25}$$

Suppose we are willing to accept a fractional error on the order of 10^{-4}. Then we must have

$$Z_c \approx 100b/\sqrt{2}. \tag{19.1.26}$$

For $a=2.5$ and $R=2$, which yields $b=4.5$, this means that in reality we must have

$$Z_c \approx 300. \tag{19.1.27}$$

We remark that this is a worst case, where fringe fields fall off only as $1/|z|^3$. For cases where the fringe fields fall off more rapidly (e.g. quadrupoles, higher-order multipoles, dipoles with field clamps, etc.) the cutoff in z can be smaller.

Performing the Forward ($\phi \to m$) Fourier Transform

We are ready to carry out the spline-based calculation of $\tilde{\tilde{B}}_\rho(R,m',k')$. Let us select 4801 equally-spaced points z_j in the interval $z\in[-Z_c,Z_c]$ with $Z_c=300$, and let us select 49 equally-spaced values ϕ_ℓ in the interval $\phi\in[0,2\pi]$. Then, for each ϕ_ℓ, we carry out a 4801-point (in z) spline-based Fourier transform to find (for $R=2$) the quantities $\tilde{B}_\rho(R,\phi_\ell,k')$. Next we evaluate (1.19) using a 49-point (in ϕ) Riemann sum discrete angular Fourier transform to obtain $\tilde{\tilde{B}}_\rho(R,m',k')$. See Exercise 1.2 for an explanation of why 49 points should be adequate and, indeed, give good accuracy.

Spline-Based Forward and Inverse Fourier Transform Results

As a last step in this part of our exercise, let us use the integrands based on this $\tilde{\tilde{B}}_\rho(R,m',k')$ to carry out the same spline-based inverse Fourier transform described earlier. That is, we no longer work with exact integrands in (14.3.6), but rather use approximate integrands based on spline-based and discrete integrations over z and ϕ. However, we still do use exact values of $B_\rho(R,\phi,z)$ on the cylinder. The result of this process is an *almost completely* numerically calculated set of functions $C_{m,\alpha}^{[n]}(z)$. Examination of these numerically calculated functions shows that they also well approximate the exact functions $C^{[n]}_{m,\alpha}(z)$. For example, Figures 1.12 and 1.13 show the differences between the exact and numerically calculated $C^{[0]}_{1,s}(z)$ and $C^{[6]}_{1,s}(z)$. We see that Figure 1.12 resembles Figure 1.10. Surprisingly, the error in $C^{[0]}_{1,s}(z)$ is now slightly less than before, but remains approximately 1.6 parts in 10^4. Apparently in this case the errors involved in the approximate computation of $\tilde{\tilde{B}}_\rho(R, m', k')$ cancel to some extent the errors involved in the spline-based inverse Fourier transform. We also see that Figure 1.13 somewhat resembles Figure 1.11, but now the error in $C^{[6]}_{1,s}(z)$ is approximately 7 parts on 10^5 whereas it was 5 parts in 10^7 in Figure 1.11. In this case the errors involved in the approximate computation of $\tilde{\tilde{B}}_\rho(R, m', k')$ add to the overall error. (However the overall error is still acceptably small.) Indeed, we find that if we compute $\tilde{\tilde{B}}_\rho(R, m', k')$ more exactly by by increasing the number of points in ϕ beyond 49, increasing Z_c beyond 300, and increasing the number of points in z beyond 4801, then Figure 1.12 morphs into Figure 1.10, and Figure 1.13 morphs into Figure 1.11. With regard to the errors for the other nonzero $C^{[n]}_{m,s}(z)$, we find that they are also acceptably small. Finally, we find that the $C^{[0]}_{m,\alpha}(z)$ that should vanish are, in fact, numerically very small.

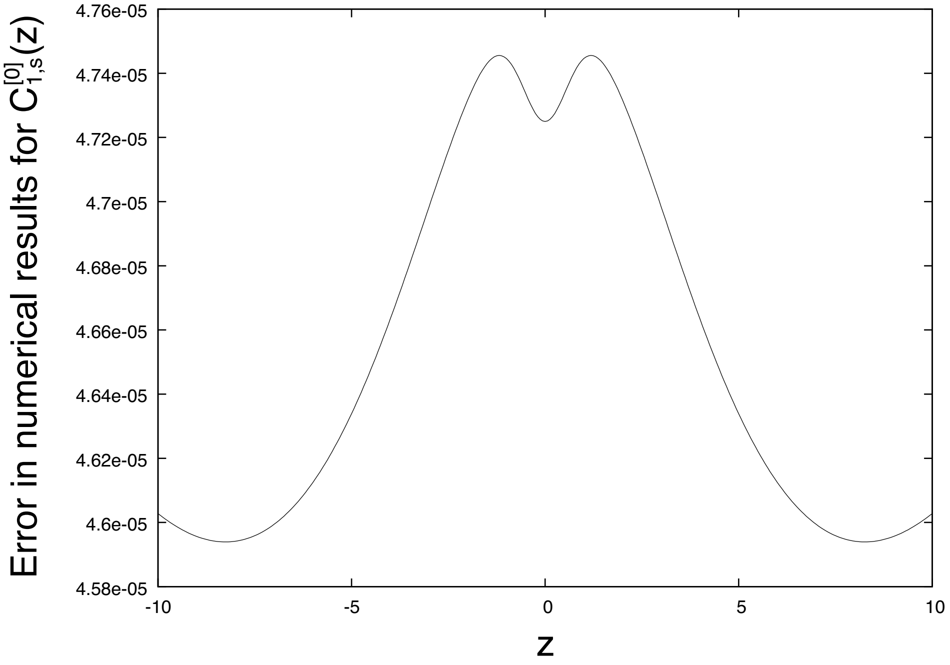

Figure 19.1.12: Difference between exact and numerical results for $C^{[0]}_{1,s}(z)$ using a spline-based integrand in (14.3.23) and exact values of $B_\rho(R, \phi, z)$ on the cylinder.

19.1.3 Test of Interpolation off a Grid

To complete our test, let us no longer use exact values of $B_\rho(R, \phi, z)$ on the cylinder. Rather, suppose we set up a regular grid in x, y, z space centered on the origin $(0, 0, 0)$. Let x and y range over the values $x \in [-2.4, 2.4]$ and $y \in [-2.4, 2.4]$, and (as before) let z range over the values $z \in [-300, 300]$. Use 49 grid points each in x and y so that $h_x = h_y = .1$,

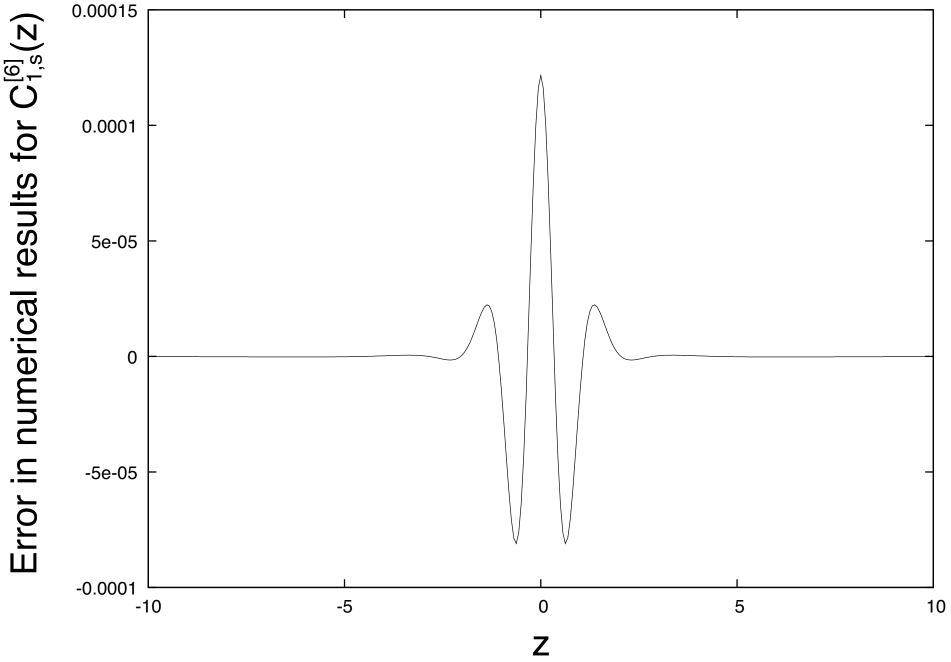

Figure 19.1.13: Difference between exact and numerical results for $C^{[6]}_{1,s}(z)$ using a spline-based integrand in (14.3.23) and exact values of $B_\rho(R, \phi, z)$ on the cylinder.

and (again as before) use 4801 grid points in z so that $h_z = .125$. Thus, use a total of $49 \times 49 \times 4801 = 11,527,201$ grid points. For each grid point specify the three components B_x, B_y, and B_z using (13.7.4) through (13.7.6) evaluated at these grid points. Employ bicubic interpolation (see Section 15.2.1) to interpolate $\boldsymbol{B}$ at these grid points onto the selected angular points on the cylinder $R = 2$, and then compute $B_\rho(R, \phi, z)$ at these angular points.[4] Finally, proceed as before using these approximate values of $B_\rho(R, \phi, z)$ on the cylinder. In particular, evaluate the angular Fourier transforms with a Riemann sum using 49 angular points and evaluate the forward linear transforms for 401 k values in the range $k \in [-K_c, K_c]$ with $K_c = 20$. Use these same points in k space to evaluate the inverse Fourier transforms. The result of this process is a *completely numerically* calculated set of functions $C^{[n]}_m(z)$.

Examination of these completely numerically calculated functions shows that they also well approximate the exact functions $C^{[n]}_{m,\alpha}(z)$. For example, Figures 1.14 and 1.15 show the differences between the exact and the completely numerically calculated $C^{[0]}_{1,s}(z)$ and $C^{[6]}_{1,s}(z)$. We see that Figure 1.14 is very similar to Figure 1.12, and Figure 1.15 is very similar to Figure 1.13. Consequently the error is little changed, and we conclude that interpolation from the grid onto the cylinder introduces little additional error. The errors for the other nonzero $C^{[n]}_{m,s}(z)$ listed in (13.7.35) are comparable. For example, Figure 1.16 shows the

[4] Alternatively, one could use bicubic spline interpolation. See Section 15.2.2. Note that the B_z component does not, in fact, contribute to $B_\rho(R, \phi, z)$. Note also that only a relatively small number of the 11,527,201 points are actually used because only values at those points relatively near the circular cylinder are needed to interpolate onto the cylinder. And, after interpolation onto the cylinder, only $49 \times 4801 = 235,249$ surface values of B_ρ are used in the remainder of the calculation.

exact and completely numerical results for $C^{[0]}_{7,s}(z)$, and Figure 1.17 shows the difference between the exact and completely numerical results for $C^{[0]}_{7,s}(z)$. We see that the error is approximately 4 parts in 10^4. Finally, the $C^{[0]}_{m,\alpha}(z)$ that should vanish are, in fact, again numerically very small.

We have demonstrated, for the monopole-doublet problem, that the steps in the first three boxes shown in Figure 14.1.1 can be carried out to yield results having good numerical accuracy. As remarked earlier, again see Figures 13.7.6 and 13.7.7, the surface field we have been working with is quite singular, more singular than fields likely to be encountered in practice. Thus the fact that the circular cylinder surface method has succeeded in this rather extreme case indicates that it is likely to work even better in actual physical applications.

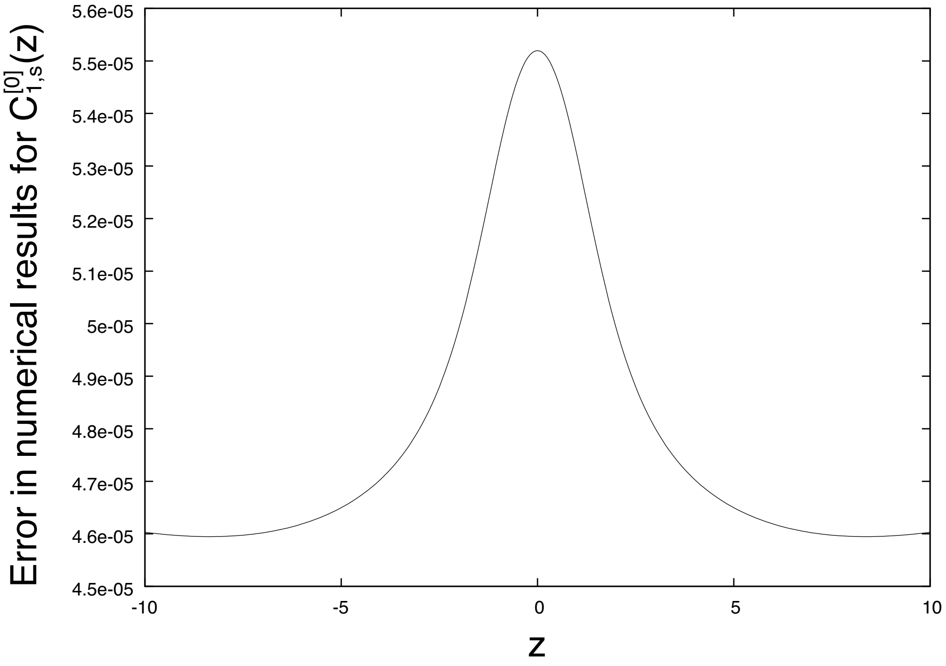

Figure 19.1.14: Difference between exact and completely numerical results for $C^{[0]}_{1,s}(z)$ using a spline-based integrand in (14.3.23) and interpolated values of $B_\rho(R, \phi, z)$ on the cylinder based on field data provided on a grid.

19.1.4 Reproduction of Interior Field Values

Another, but less stringent, test of accuracy is to use the completely numerically obtained on-axis gradients to compute $\boldsymbol{B}$ at the *interior* grid points with the aid of (13.2.69) through (13.2.71). These computed values can be compared with the known values of $\boldsymbol{B}$ at the interior grid points.[5] Before making such a comparison, some discussion is required.

[5] This test is less stringent because it does not compare derivatives.

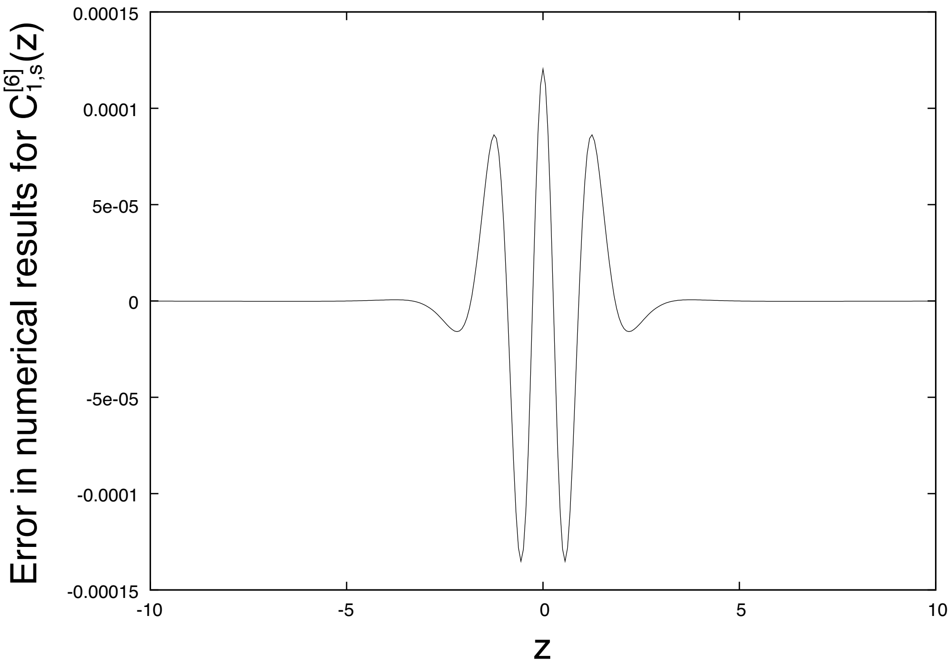

Figure 19.1.15: Difference between exact and completely numerical results for $C^{[6]}_{1,s}(z)$ using a spline-based integrand in (14.3.23) and interpolated values of $B_\rho(R, \phi, z)$ on the cylinder based on field data provided on a grid.

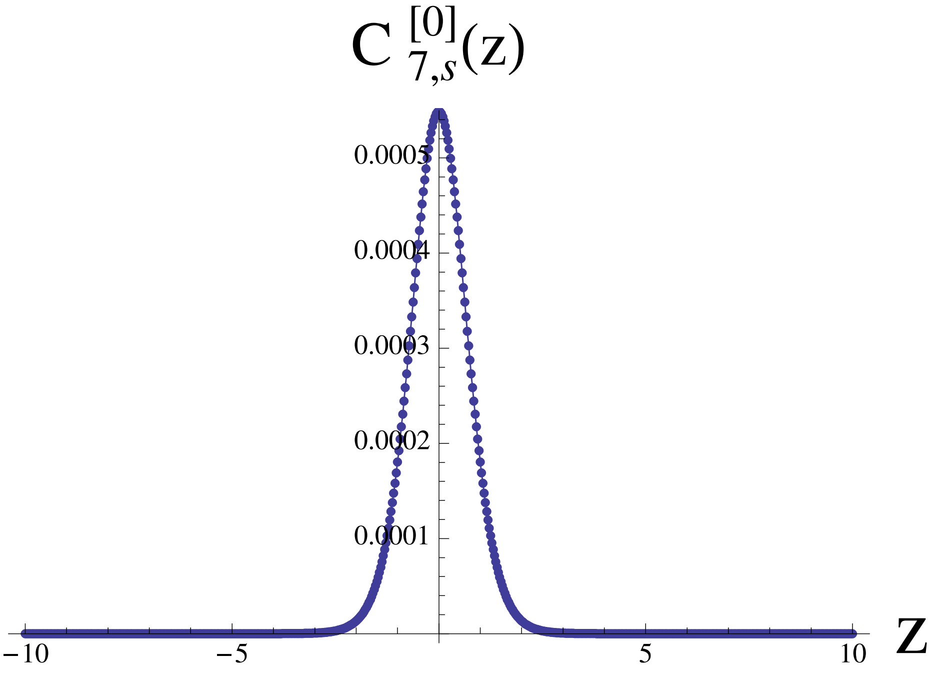

Figure 19.1.16: Exact and completely numerical results for $C^{[0]}_{7,s}(z)$. Exact results are shown as a solid line (see Figure 13.7.15), and numerical results are shown as dots.

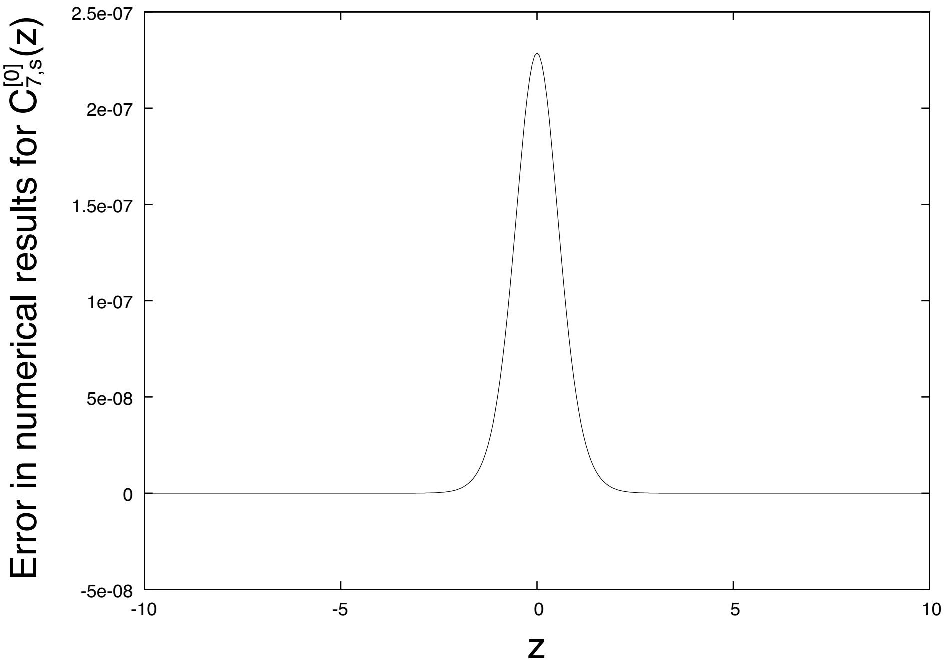

Figure 19.1.17: Difference between exact and completely numerical results for $C_{7,s}^{[0]}(z)$ using a spline-based integrand in (14.3.23) and interpolated values of $B_\rho(R, \phi, z)$ on the cylinder based on field data provided on a grid.

What to Hope for

First, since the surface fields we have been working with are quite singular, let us investigate the region over which the $C_{m,s}^{[n]}(z)$ that we have decided to employ, see (13.7.35), can be expected to give a good representation of $\boldsymbol{B}(x, y, z)$. As an initial exploration, let us consider the behavior of the Fourier series representation

$$B_\rho(R = 2, \phi, z = 0) = \sum_{m=-\infty}^{\infty} a_m \exp(im\phi) \tag{19.1.28}$$

for the function $B_\rho(R = 2, \phi, z = 0)$ shown in Figure 13.7.6. Suppose this series is *truncated* so that only terms for which $|m| \leq 7$ are retained. See Exercise 1.3. Call the resulting function $B_\rho^{\rm Tr}(R = 2, \phi, z = 0)$. Figure 1.18 displays $B_\rho^{\rm Tr}(R = 2, \phi, z = 0)$ as a function of ϕ, and Figure 1.19 shows the difference between $B_\rho(R = 2, \phi, z = 0)$ and $B_\rho^{\rm Tr}(R = 2, \phi, z = 0)$. Evidently terms well beyond $|m| = 7$ must be retained in (1.28) to adequately represent the surface field. See also the table of Fourier coefficients in Exercise 1.3. It follows that many $C_{m,s}^{[n]}(z)$ beyond those listed in (13.7.35) are required to represent the field near the surface $R = 2$.

As an illustration of this conclusion, let $\boldsymbol{B}^{\rm TrA}$ denote the field computed using the series (13.2.69) through (13.2.71) *truncated* so that only the $C_{m,s}^{[n]}(z)$ listed in (13.7.35) are retained, and using the *analytic* expressions (13.7.33) and their z derivatives for these $C_{m,s}^{[n]}(z)$.[6] Also,

[6] Note that the use of only the $C_{m,s}^{[n]}(z)$ listed in (13.7.35) to compute $\boldsymbol{B}^{\rm TrA}$ amounts to using 6th-order

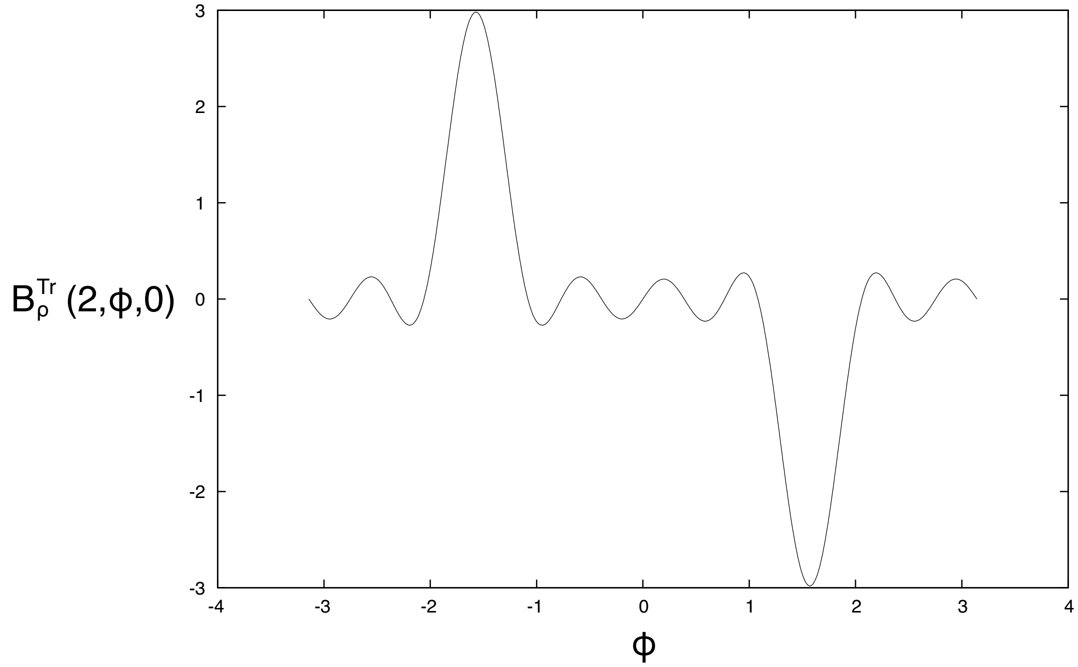

Figure 19.1.18: The quantity $B_\rho^{\mathrm{Tr}}(R = 2, \phi, z = 0)$ for the monopole doublet in the case that $a = 2.5$ cm and $g = 1$ Tesla-(cm)^2.

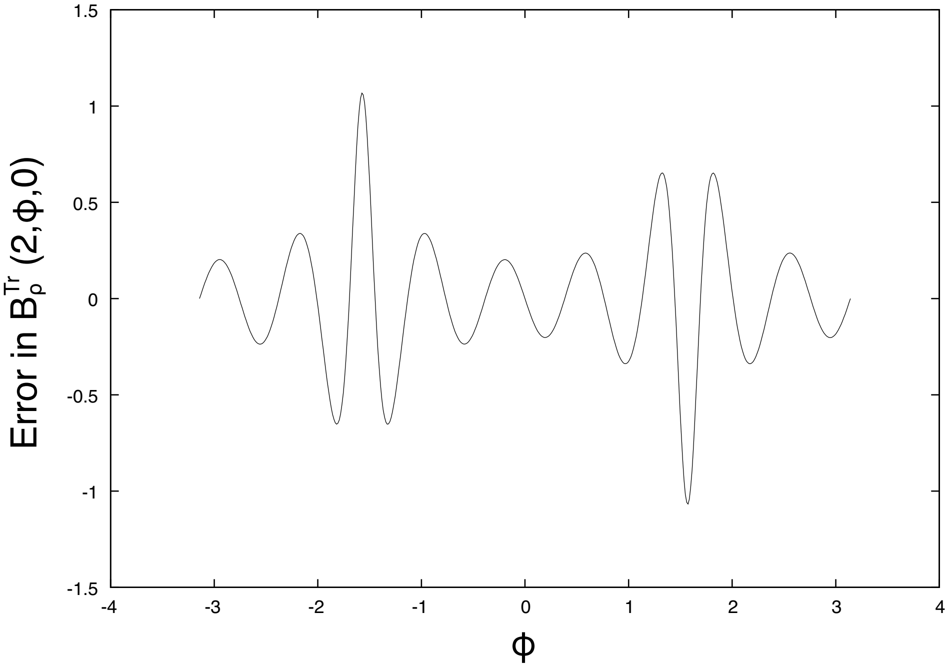

Figure 19.1.19: Difference between $B_\rho(R = 2, \phi, z = 0)$ and $B_\rho^{\mathrm{Tr}}(R = 2, \phi, z = 0)$ for the monopole doublet in the case that $a = 2.5$ cm and $g = 1$ Tesla-(cm)^2.

let $\boldsymbol{B}^{\rm Exact}$ denote the known *exact* values of $\boldsymbol{B}$ computed using (13.7.4) through (13.7.6). Figures 1.20 through 1.22 show, as a function of ϕ, the quantity $||\boldsymbol{B}^{\rm TrA} - \boldsymbol{B}^{\rm Exact}||/||\boldsymbol{B}||^{\rm Max}$ for various values of ρ and z. Here $||\boldsymbol{B}||^{\rm Max}$ is the *maximum* value of $||\boldsymbol{B}||$ within the cylinder with radius ρ. We conclude that within the cylinder $\rho \leq 1/2$ the relative error in the field due to truncating the cylindrical multipole expansion is less than a few parts in 10^5. Note also that the domain of good approximation opens up as z leaves the plane $z = 0$. This behavior is to be expected based on the analytic properties of $\psi(x, y, z)$ when x, y, z are treated as three *complex* variables. See Examples 2.1 and 2.2 in Section 31.2; and Examples 3.1 and 3.2 in Section 31.3.

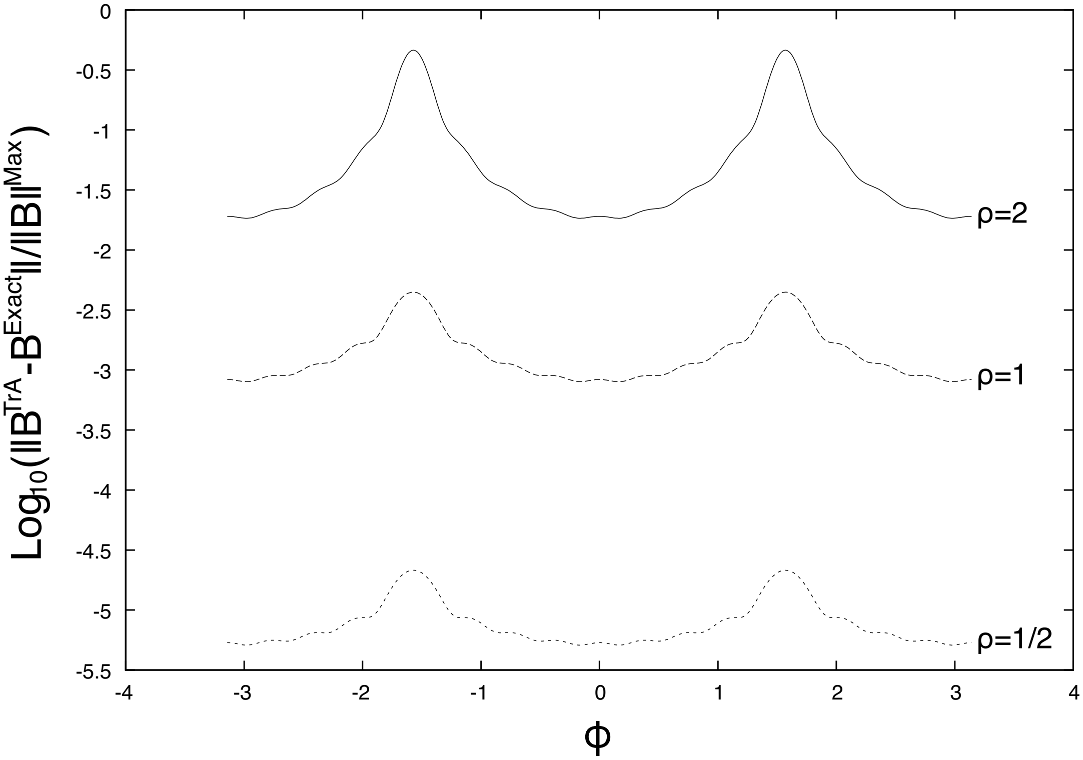

Figure 19.1.20: The logarithm base 10 of the quantity $||\boldsymbol{B}^{\rm TrA} - \boldsymbol{B}^{\rm Exact}||/||\boldsymbol{B}||^{\rm Max}$ as a function of ϕ for three ρ values and $z = 0$, for the monopole doublet, in the case that $a = 2.5$ cm and $g = 1$ Tesla-(cm)^2. The solid line corresponds to $\rho = 2$, the dashed line to $\rho = 1$, and the dotted line to $\rho = 1/2$.

Test of Field Reproduction within the Cylinder $\rho \leq 1/2$

The previous discussion has determined (for the case of a monopole doublet) the region where the truncated cylindrical multipole expansion, which retains only the terms listed in (13.7.35), is expected to be accurate assuming the listed $C_{m,s}^{[n]}(z)$ are known exactly. For real

polynomials in the x, y variables (with z-dependent coefficients) for the components B_x and B_y, and a 5th-order polynomial in x, y for B_z.

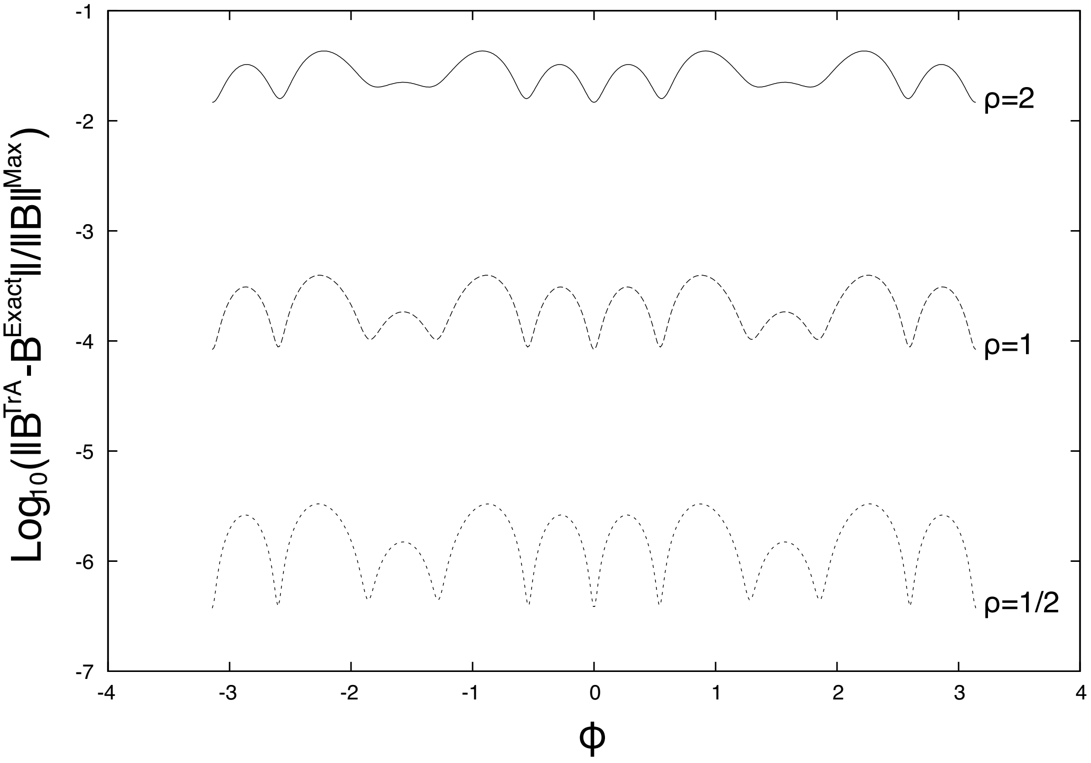

Figure 19.1.21: The logarithm base 10 of the quantity $||\boldsymbol{B}^{\mathrm{TrA}} - \boldsymbol{B}^{\mathrm{Exact}}||/||\boldsymbol{B}||^{\mathrm{Max}}$ as a function of ϕ for three ρ values and $z = 2.5$, for the monopole doublet, in the case that $a = 2.5$ cm and $g = 1$ Tesla-(cm)^2. The solid line corresponds to $\rho = 2$, the dashed line to $\rho = 1$, and the dotted line to $\rho = 1/2$.

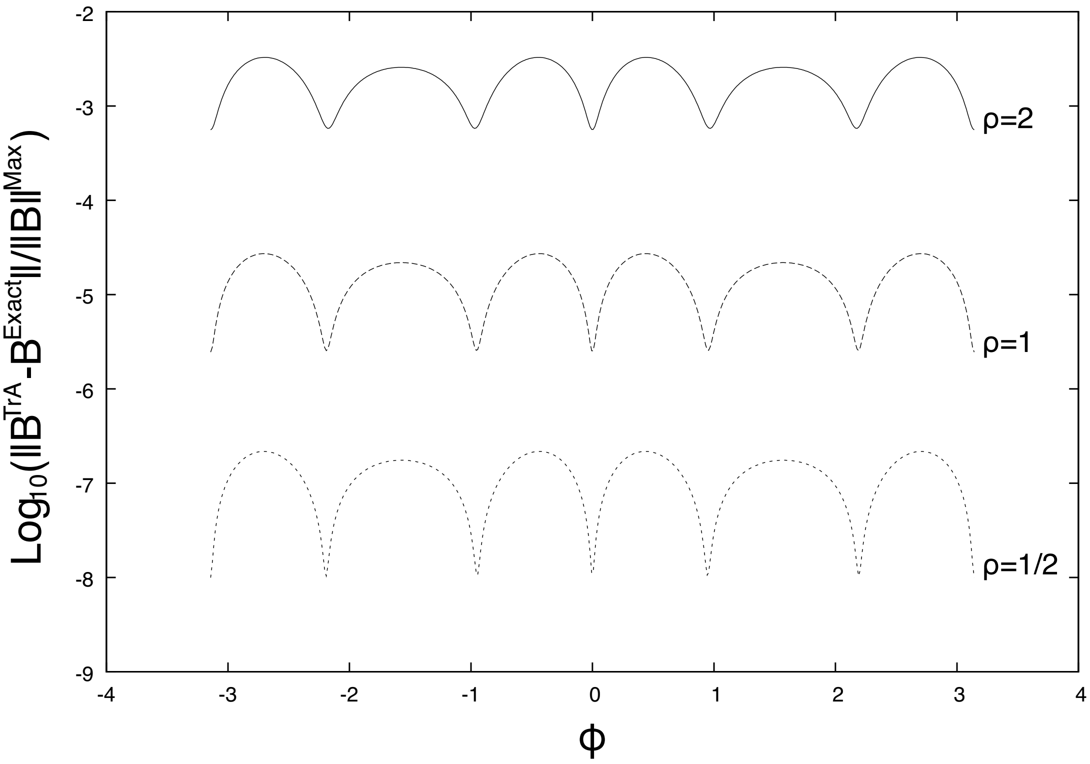

Figure 19.1.22: The logarithm base 10 of the quantity $||\boldsymbol{B}^{\rm TrA} - \boldsymbol{B}^{\rm Exact}||/||\boldsymbol{B}||^{\rm Max}$ as a function of ϕ for three ρ values and $z = 5$, for the monopole doublet, in the case that $a = 2.5$ cm and $g = 1$ Tesla-(cm)^2. The solid line corresponds to $\rho = 2$, the dashed line to $\rho = 1$, and the dotted line to $\rho = 1/2$.

problems we only know the $C^{[n]}_{m,\alpha}(z)$ as calculated numerically based on grid data interpolated onto a surface, and only have the values of $\boldsymbol{B}$ at the grid points. Let $\boldsymbol{B}^{\rm Num}$ denote the completely *numerically* calculated values of $\boldsymbol{B}$ based on the completely numerically calculated $C^{[n]}_{m,\alpha}(z)$ with $(m+n) \leq 7$, and let $\boldsymbol{B}^{\rm Grid}$ now denote the values of $\boldsymbol{B}$ at the *grid* points obtained using (13.7.4) through (13.7.6). Examination of the completely numerically calculated values and the corresponding grid values shows that

$$||\boldsymbol{B}^{\rm Num} - \boldsymbol{B}^{\rm Grid}|| < 6 \times 10^{-5} \tag{19.1.29}$$

for all grid points within the cylinder $\rho \leq (1/2)$. Observe that, according to Figure 13.7.3, the magnitude of the maximum on-axis field is .32. Thus, the maximum error within the cylinder $\rho = 1/2$ compared to the maximum on-axis field is approximately 2 parts in 10^4. The smallness of this error again illustrates the accuracy of the method.[7] It also is a data-based indication that the cylindrical harmonic expansion is converging well for the interior $\rho \leq 1/2$ and that the Maxwell equations are well satisfied by the interior values of $\boldsymbol{B}^{\rm Grid}$.[8]

Exercises

19.1.1. Verify (1.11), (1.12), (1.15), and (1.16). You may need the identity

$$(2m)! = 2^m m![1 \cdot 3 \cdot 5 \cdot 7 \cdots (2m-1)]. \tag{19.1.30}$$

Prove this identity, say, by induction.

19.1.2. This exercise studies the discrete Fourier transform of a periodic function. Suppose $f(\phi)$ is a 2π periodic function and therefore has a Fourier expansion of the form

$$f(\phi) = \sum_{m=-\infty}^{\infty} a_m \exp(im\phi). \tag{19.1.31}$$

We know that the coefficients a_j are given by the relation

$$a_j = [1/(2\pi)] \int_0^{2\pi} d\phi \; f(\phi) \exp(-ij\phi). \tag{19.1.32}$$

Select N discrete phi values ϕ_n according to the rule

$$\phi_n = n(2\pi/N) \text{ for } n = 0, 1, \cdots, N-1. \tag{19.1.33}$$

[7] This small error means, among other things, that Figures 13.7.3 through 13.7.5 are well reproduced by $\boldsymbol{B}^{\rm Num}$. Note that *only* the values of $B^{\rm Grid}_x$ and $B^{\rm Grid}_y$ on grid points near the surface of the cylinder $R = 2$ were used to determine all three components of $\boldsymbol{B}^{\rm Num}$ at all grid points within the cylinder.

[8] By construction, the $\boldsymbol{B}^{\rm Num}$ satisfy the Maxwell equations to good precision. And, in this case, the $\boldsymbol{B}^{\rm Grid}$ also satisfy the Maxwell equations since they were obtained by evaluating the Maxwell solution (13.7.4) through (13.7.6) at the grid points. However, in the general case, the $\boldsymbol{B}^{\rm Grid}$ are supplied by some 3-D electromagnetic code, and the 'Maxwellian goodness' of these quantities depends on the quality of the 3-D electromagnetic code.

Next define quantities A_j by the rule

$$A_j = (1/N)\sum_{n=0}^{N-1} f(\phi_n)\exp(-ij\phi_n). \tag{19.1.34}$$

Verify that (1.34) is the discrete version of (1.32).

Show that combining (1.31), (1.33), and (1.34) gives the result

$$\begin{aligned} A_j &= \sum_{m=-\infty}^{\infty} a_m\{(1/N)\sum_{n=0}^{N-1}\exp[inm(2\pi/N)]\exp[-ijn(2\pi/N)]\} \\ &= \sum_{m=-\infty}^{\infty} a_m\{(1/N)\sum_{n=0}^{N-1}\exp[in(m-j)(2\pi/N)]\}. \end{aligned} \tag{19.1.35}$$

However, there is the identity

$$\sum_{n=0}^{N-1} x^n = (1-x^N)/(1-x). \tag{19.1.36}$$

Using this identity, show that

$$(1/N)\sum_{n=0}^{N-1}\exp[in(m-j)(2\pi/N)] = (1/N)\{1-\exp[i(m-j)2\pi]\}/\{1-\exp[i(m-j)(2\pi/N)]\}. \tag{19.1.37}$$

From (1.37), show that

$$(1/N)\sum_{n=0}^{N-1}\exp[in(m-j)(2\pi/N)] = 0 \text{ if } (m-j)/N \text{ is not an integer,} \tag{19.1.38}$$

and

$$(1/N)\sum_{n=0}^{N-1}\exp[in(m-j)(2\pi/N)] = 1 \text{ if } (m-j)/N \text{ is an integer.} \tag{19.1.39}$$

[Note that $(m-j)$ is always an integer.] Verify that these results can be written more compactly in the form

$$(1/N)\sum_{n=0}^{N-1}\exp[in(m-j)(2\pi/N)] = \sum_{\ell=-\infty}^{\infty}\delta_{m,j+\ell N}. \tag{19.1.40}$$

Employ (1.35) and (1.40) to get the final result

$$A_j = \sum_{\ell=-\infty}^{\infty} a_{j+\ell N}. \tag{19.1.41}$$

Verify that (1.41) implies the periodicity relation

$$A_{j+N} = A_j. \tag{19.1.42}$$

The relation (1.41) can be rewritten in the form

$$A_j = a_j + \sum_{\ell \neq 0}^{\infty} a_{j+\ell N}. \tag{19.1.43}$$

Thus, A_j is a good approximation to a_j provided N is large enough that the $a_{j+\ell N}$ are small for $\ell = \pm 1, \pm 2, \cdots$ in such a way that the sum in (1.43) is also small.

Note that under the assumptions made, namely periodicity and rapid falloff of the Fourier coefficients, the discrete angular Fourier transform is much more accurate than the estimate (15.3.24) would promise.

19.1.3. This exercise is a continuation of Exercise 1.2. It shows that good performance of the discrete Fourier transform for periodic functions can be assured under the the assumption of suitable *analyticity*. As an application, it justifies the use of the $N = 49$ discrete Fourier transform to obtain $\tilde{B}_\rho(R, m', k')$ in the case of the monopole doublet.

As in (1.28), let $f(\phi)$ be the function $B_\rho(R = 2, \phi, z = 0)$ shown in Figure 13.7.6. Its first few nonzero Fourier coefficients, obtained by accurate numerical integration of (1.32) using *Mathematica*, are listed below in Table 1.1. As shown in Figure 1.23, they fall of exponentially with increasing j in the fashion

$$|a_j| \sim (.8)^j. \tag{19.1.44}$$

Consequently, the contribution of the sum in (1.43) will be small provided N is reasonably large and j is considerably smaller than N. Table 1.1 also lists the first few nonzero values of A_j obtained from (1.34) with $N = 49$. We see from the table that (when $N = 49$) the A_j are good approximations to the a_j for $j \leq 7$, as advertised.

Table 19.1.1: The exact and discrete (with $N = 49$) Fourier coefficients of $f(\phi)$.

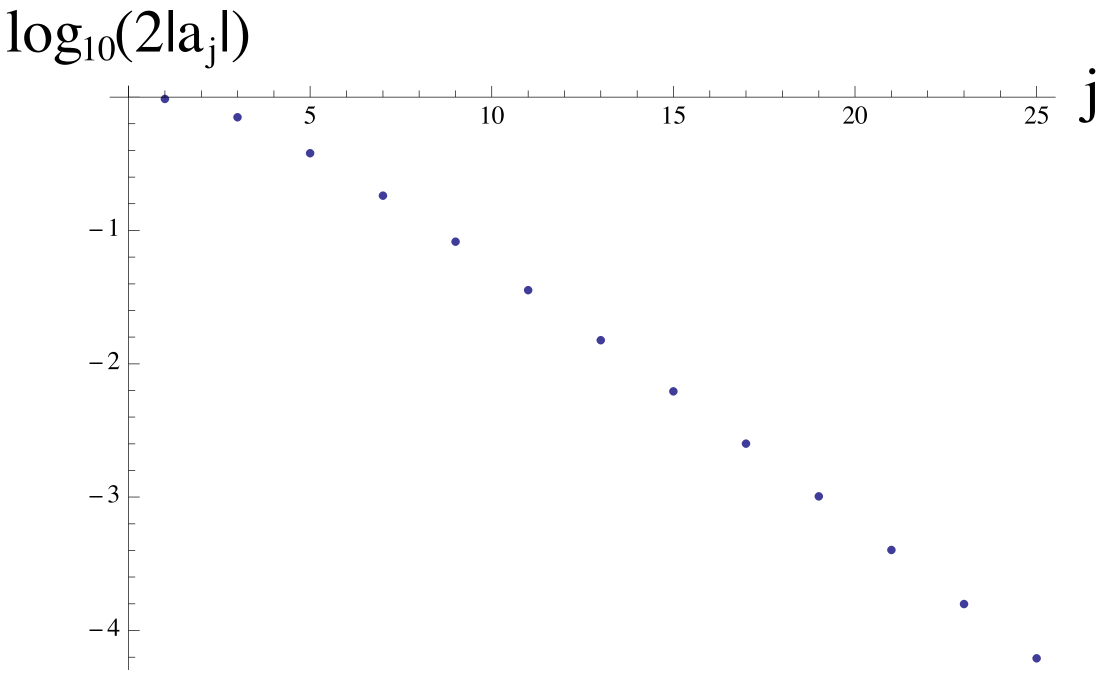

Figure 19.1.23: The quantities $\log_{10}(2|a_j|)$ as a function of j. For large j the points fall on a straight line having slope $\log_{10}(.8)$.

Similar considerations apply to the function $\tilde{B}_\rho(R,\phi,k)$. Figures 1.24 and 1.25 illustrate the cases $\tilde{B}_\rho(R=2,\phi,k=0)$ and $\tilde{B}_\rho(R=2,\phi,k=20)$, and Figures 1.26 and 1.27 display their Fourier coefficients. Again the Fourier coefficients fall of as $(.8)^j$. This behavior can be understood as follows: It can be shown that the Fourier coefficients of $B_\rho(R,\phi,z)$ for $z \neq 0$ fall off even more rapidly than (1.44). We conclude that since the Fourier coefficients of $B_\rho(R,\phi,z)$ fall off at least as rapidly as (1.44) for all z, then the Fourier coefficients of $\tilde{B}_\rho(R,\phi,k)$ must also fall off in this fashion, because $\tilde{B}_\rho(R,\phi,k)$ may be viewed as a linear combination of the $B_\rho(R,\phi,z)$. See (1.22).

How might one anticipate the relation (1.44)? Introduce the complex variable λ by writing

$$\lambda = \exp i\phi. \tag{19.1.45}$$

With this change of variable the integral (1.32) becomes

$$a_j = [-i/(2\pi)] \oint_C d\lambda\, f(-i\log\lambda)\lambda^{-(j+1)} \tag{19.1.46}$$

where the contour C is the unit circle. Now deform the contour to make C as large a circle as possible without encountering singularities of $f(-i\log\lambda)$. Suppose this circle has radius Λ. Then the integral (1.46) has the asymptotic behavior

$$|a_j| \sim (1/\Lambda)^j. \tag{19.1.47}$$

Evidently (13.7.8), when evaluated at $z=0$, is singular when

$$\sin\phi = \pm[(R^2+a^2)/(2aR)]. \tag{19.1.48}$$

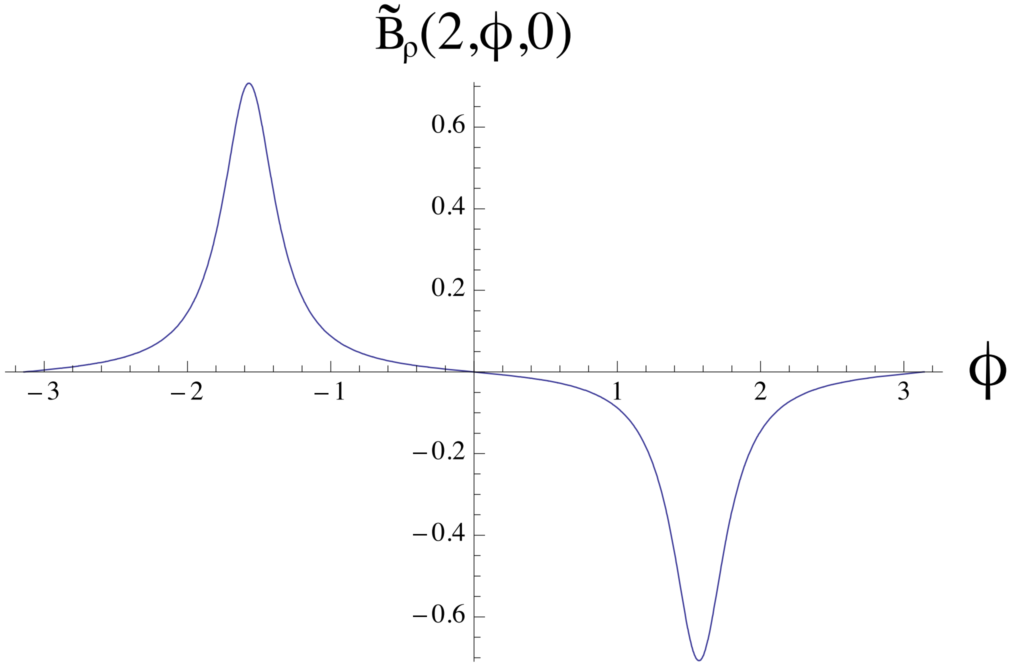

Figure 19.1.24: The real part of $\tilde{B}_\rho(R = 2, \phi, k = 0)$ for the monopole doublet in the case that $a = 2.5$ cm and $g = 1$ Tesla-(cm)^2. The imaginary part vanishes.

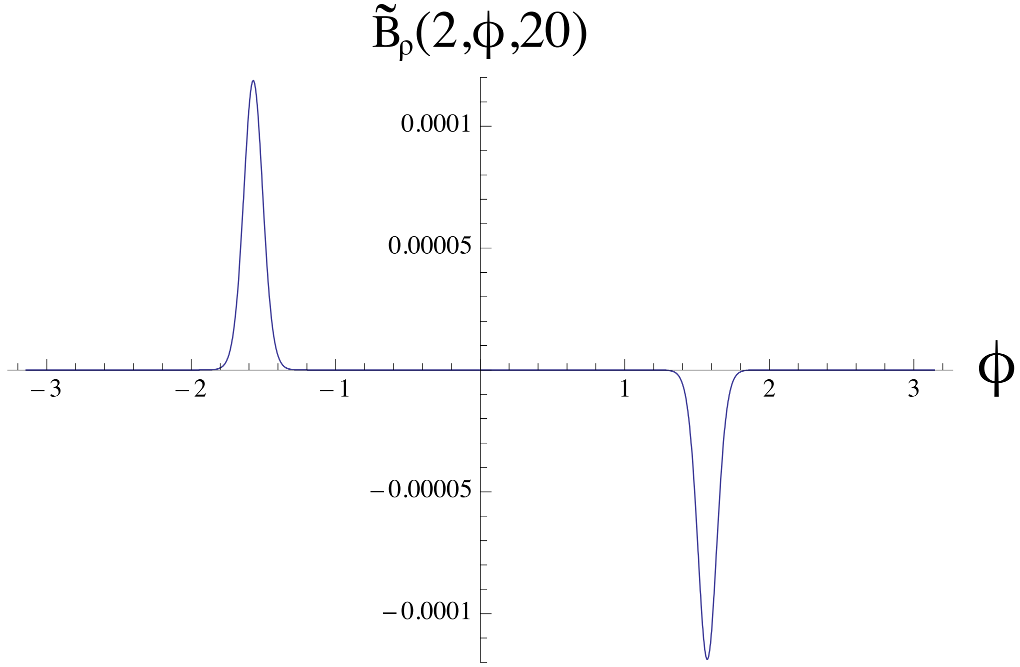

Figure 19.1.25: The real part of $\tilde{B}_\rho(R = 2, \phi, k = 20)$ for the monopole doublet in the case that $a = 2.5$ cm and $g = 1$ Tesla-(cm)^2. The imaginary part vanishes.

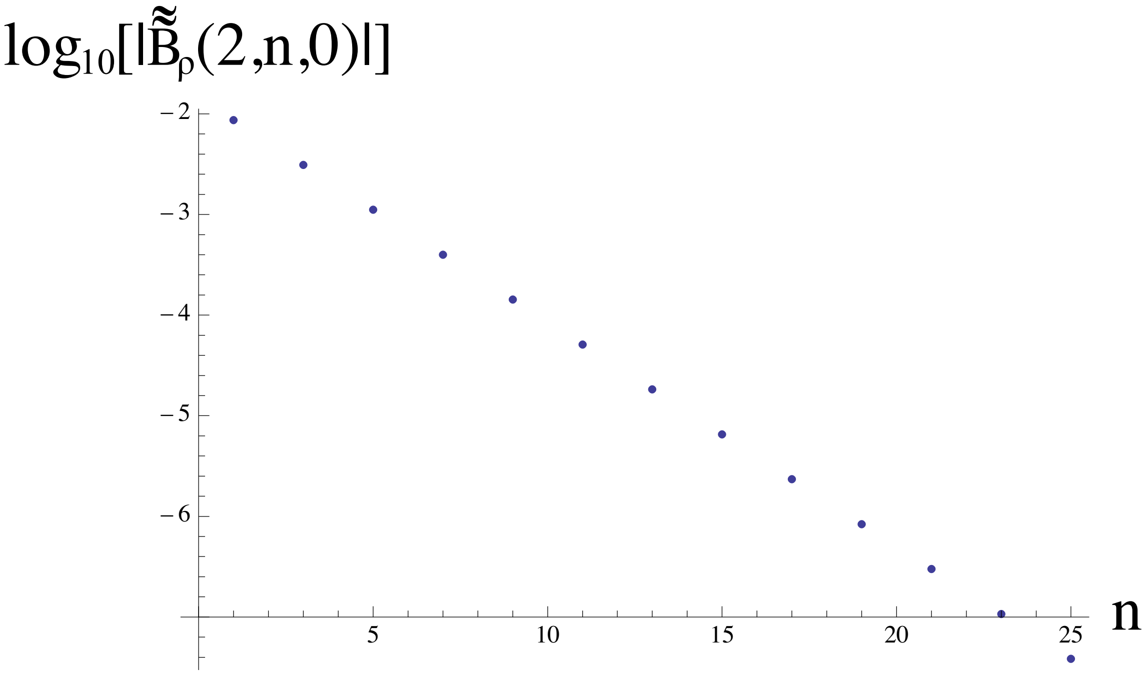

Figure 19.1.26: The quantities $\log_{10}[|\tilde{\tilde{B}}_\rho(R = 2, n, k = 0)|]$ as a function of n. For large n the points fall on a straight line having slope $\log_{10}(.8)$.

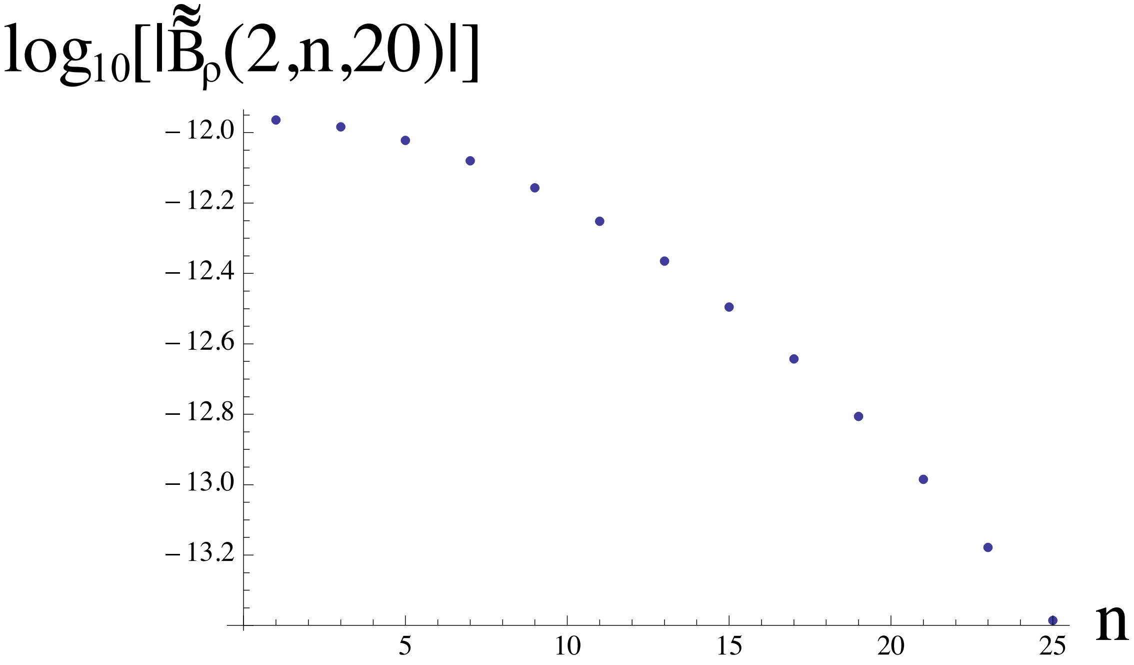

Figure 19.1.27: The quantities $\log_{10}[|\tilde{\tilde{B}}_\rho(R = 2, n, k = 20)|]$ as a function of n. For large n the points fall on a straight line having slope $\log_{10}(.8)$.

Show that (1.48) yields the relation

$$1/\Lambda = R/a = 2/2.5 = .8. \tag{19.1.49}$$

Suppose $z \neq 0$ in (13.7.8). Show that then Λ is larger than the value given in (1.49). Thus, we have analyzed the worst case, the case with the slowest falloff with increasing j.

19.1.4. Review Exercise 1.3. Look at the relation (14.3.2), the expansion (13.2.37), and the monopole doublet results (13.7.19), (13.7.29), and (13.7.33). Use these quantities to find explicit expressions for the Fourier Coefficients $\tilde{B}_\rho(R, m, z)$, and find their large m behavior.

19.2 Elliptical Cylinder Numerical Results for Monopole Doublet

In this subsection we will benchmark the numerical method of Section 14.4 to demonstrate the use of an elliptical cylinder. Here we have two goals: First, as a practical matter, the infinite sums over r that occur in (14.4.83) through (14.4.86) must be truncated, and we must establish that this can be done while still achieving a desired accuracy. Second, we must demonstrate that all our numerical machinery actually works.

As just done for the case of a circular cylinder, we will again try to reproduce the exact results for the on-axis gradients of the same monopole doublet. But now, as an example, we will use as our surface that of an elliptical cylinder for which the ellipse has a semi-major axis ($x^{\max}$) of 4 cm in the x direction and a semi-minor axis ($y^{\max}$) of 2 cm in the y direction. See Figure 14.4.2. This is achieved by setting

$$u = U = \tanh^{-1}(y^{\max}/x^{\max}) = \tanh^{-1}(2/4) = .549306144 \tag{19.2.1}$$

and

$$f = 4/\cosh(U) = \sqrt{12} = 3.464101615 \text{ cm} \tag{19.2.2}$$

in equations (14.4.1) and (14.4.2) so that we have the relations

$$x^{\max} = f \cosh U = 4 \text{ cm}, \tag{19.2.3}$$

$$y^{\max} = f \sinh U = 2 \text{ cm}. \tag{19.2.4}$$

19.2.1 Finding the Mathieu Coefficients

In the elliptical cylinder case there are fewer calculations we can carry out exactly compared to the circular cylinder case. However, some of the routines we will be using in the elliptic case will be the same as in the circular case, and we have already benchmarked them in the circular case.

Exact Results for the Forward ($z \rightarrow k$) Fourier Transform

There is a quantity we can still compute exactly for the elliptic cylinder when applied to the monopole doublet case, and that is the function $\tilde{F}(v, k)$. See (14.4.72).[9] Upon combining (14.4.67) and (14.4.72) we see that

$$\tilde{F}(v, k) = (f \sinh U \cos v)\tilde{B}_x(U, v, k) + (f \cosh U \sin v)\tilde{B}_y(U, v, k) \tag{19.2.5}$$

where

$$\tilde{B}_x(U, v, k) = [1/(2\pi)] \int_{-\infty}^{\infty} dz \exp(-ikz) B_x(U, v, z), \tag{19.2.6}$$

$$\tilde{B}_y(U, v, k) = [1/(2\pi)] \int_{-\infty}^{\infty} dz \exp(-ikz) B_y(U, v, z). \tag{19.2.7}$$

Examine $B_x(U, v, z)$ and $B_y(U, v, z)$ as given by (14.4.1), (14.4.2), (13.7.4), and (13.7.5). Define quantities $b_\pm(v)$ by the rule

$$b_\pm(v) = [x^2 + (y \pm a)^2]^{1/2} = \{[f \cosh(U) \cos(v)]^2 + [f \sinh(U) \sin(v) \pm a]^2\}^{1/2}. \tag{19.2.8}$$

Using this definition we may write

$$[x^2 + (y \pm a)^2 + z^2] = [z^2 + b_\pm^2(v)], \tag{19.2.9}$$

and $B_x(U, v, z)$ and $B_y(U, v, z)$ take the form

$$\begin{aligned} B_x(U, v, z) \quad &= \quad gf \cosh(U) \cos(v)[z^2 + b_-^2(v)]^{-3/2} \\ &\quad -gf \cosh(U) \cos(v)[z^2 + b_+^2(v)]^{-3/2}, \end{aligned} \tag{19.2.10}$$

$$\begin{aligned} B_y(U, v, z) \quad &= \quad g[f \sinh(U) \sin(v) - a][z^2 + b_-^2(v)]^{-3/2} \\ &\quad -g[f \sinh(U) \sin(v) + a][z^2 + b_+^2(v)]^{-3/2}. \end{aligned} \tag{19.2.11}$$

Next recall the Fourier transform relation

$$[1/(2\pi)] \int_{-\infty}^{\infty} dz \;\; \exp(-ikz)[z^2 + b_\pm^2(v)]^{-3/2} = (1/\pi)[|k|/b_\pm(v)]K_1[|k|b_\pm(v)]. \tag{19.2.12}$$

For convenience, define the functions $F_\pm(v, k)$ by the rule

$$F_\pm(v, k) = (1/\pi)[|k|/b_\pm(v)]K_1[|k|b_\pm(v)]. \tag{19.2.13}$$

Then, in terms of these functions, we have the relations

$$\begin{aligned} \tilde{B}_x(U, v, k) \quad &= \quad gf \cosh(U) \cos(v)F_-(v, k) \\ &\quad -gf \cosh(U) \cos(v)F_+(v, k), \end{aligned} \tag{19.2.14}$$

[9] Of course, we will eventually want to demonstrate that we can compute this function numerically with high accuracy using field data on grid points.

$$\begin{aligned}\tilde{B}_y(U,v,k) &= g[f\sinh(U)\sin(v)-a]F_-(v,k) \\ &\quad -g[f\sinh(U)\sin(v)+a]F_+(v,k). \qquad (19.2.15)\end{aligned}$$

Combining (2.5), (2.8), and (2.13) through (2.15) gives a final expression for $\tilde{F}(v,k)$,

$$\tilde{F}(v,k) = . \qquad (19.2.16)$$

Note that for the magnetic monopole doublet the functions $F_\pm(v,k)$ and $\tilde{F}(v,k)$ are pure real and are even functions of k.

Let us pause to study the functions $F_\pm(v,k)$. The function $K_1(w)$ has, at the origin, the behavior

$$K_1(w) \approx (1/w) + (w/2)\log(w/2); \qquad (19.2.17)$$

and therefore

$$wK_1(w) \approx 1 + (w^2/2)\log(w/2) \qquad (19.2.18)$$

at the origin. At $w = +\infty$, $K_1(w)$ has the behavior

$$K_1(w) \approx [\pi/(2w)]^{1/2}\exp(-w). \qquad (19.2.19)$$

Consequently $F_\pm(v,k)$, and therefore also $\tilde{F}(v,k)$, are well behaved for all k, but are not analytic at the origin because of the log term.[10]

Exact Results for the Mathieu Coefficients

According to (14.4.73) and (14.4.74), the next step is to compute the Mathieu coefficients by performing the angular integrals[11]

$$\tilde{\tilde{F}}_r^c(k) = (1/\pi)\int_0^{2\pi} dv\ \mathrm{ce}_r(v,q)\tilde{F}(v,k), \qquad (19.2.20)$$

$$\tilde{\tilde{F}}_r^s(k) = (1/\pi)\int_0^{2\pi} dv\ \mathrm{se}_r(v,q)\tilde{F}(v,k). \qquad (19.2.21)$$

For the monopole doublet, because the transverse field components are even in z, the functions $\tilde{\tilde{F}}_r^\alpha(k)$ will be real and even in k. Unfortunately, unlike the circular cylinder case for which we were able to find the $\tilde{\tilde{B}}_\rho(R,m,k)$ analytically, see (1.14) through (1.16), we do not have analytic results for the $\tilde{\tilde{F}}_r^\alpha(k)$. However, since we do know $\tilde{F}(v,k)$ analytically, we can compute the $\tilde{\tilde{F}}_r^\alpha(k)$ numerically.[12] With these functions in hand, we will be able to explore how many of them need to be retained in the sums (14.4.85) and (14.4.86).

[10] As emphasized earlier, this lack of analyticity at the origin is related to the fact that $\boldsymbol{B}$ for the monopole doublet falls off only as $|z|^{-3}$ at $\pm\infty$.

[11] Note that, unlike the circular cylinder case where the $(z \to k)$ and $(\phi \to m)$ Fourier transforms can be performed in either order, see Section 16.1.2, in the elliptic cylinder case we must first perform the $(z \to k)$ transform and then the $(v \to r)$ transform. This is because $\mathrm{ce}_r(v,q)$ and $\mathrm{se}_r(v,q)$ depend on k through (14.4.23).

[12] Of course, we will eventually want to demonstrate that we can also compute these functions to high accuracy using only data on grid points.

To see what we might expect for the Mathieu coefficients, $\tilde{\tilde{F}}_r^\alpha(k)$, it is useful to examine the angular dependence of $\tilde{F}(v,k)$. As examples, Figures 2.1 and 2.2 display the functions $\Re\tilde{F}(v,k=0)$ and $\Re\tilde{F}(v,k=20)$. Also shown, in Figure 2.3, is the quantity $\Re\tilde{F}(v=\pi/2,k)$. Note that the maximum amplitude of $\tilde{F}(v,k)$ decreases dramatically as k increases, in accord with (2.19), and the peaks become sharper. As is evident from Figures 2.1 and 2.2, and can also be seen from (2.16), $\tilde{F}(v,k)$ is an odd function of v. Therefore we immediately know, in this monopole doublet case, that

$$\tilde{\tilde{F}}_r^c(k) = 0 \tag{19.2.22}$$

since the $\mathrm{ce}_r(v,q)$ are even functions of v. Moreover, these figures and (2.16) show that $\tilde{F}(v,k)$ is symmetric about the values $v=\pm\pi/2$. Since the $\mathrm{se}_r(v,q)$ for even r are antisymmetric about $v=\pm\pi/2$, we conclude, again in this monopole doublet case, that the only nonvanishing angular integrals will be

$$\tilde{\tilde{F}}_r^s(k) = (1/\pi)\int_0^{2\pi} dv\ \mathrm{se}_r(v,q)\tilde{F}(v,k) \tag{19.2.23}$$

with $r = 1,3,5,7\cdots$.

Finally, what range of q values is of interest? According to (14.4.23) and (2.2), q and k are connected in this instance by the relation

$$q = -k^2f^2/4 = -3k^2. \tag{19.2.24}$$

If we use k values in the range $k\in[-K_c,K_c]$, q will lie in the range $q\in[q_{\min},0]$ with

$$q_{\min} = -3K_c^2. \tag{19.2.25}$$

Since the fields on the surface of the elliptical cylinder are no more singular than those on the surface of the circular cylinder, we could set $K_c=20$ as done before for the circular cylinder case. Doing so yields $q_{\min}=-1200$. Or, being less conservative, we might use $K_c=10$, in which case $q_{\min}=-300$. This is the extreme q value used in making Figures 14.4.13 through 14.4.21.

With this background in mind, examine Figures 2.4 and 2.5. They show the Mathieu coefficients $\tilde{\tilde{F}}_r^s(k)$ as a function of k for the cases $r=1$ through $r=11$ and $r=17$ through $r=25$. The curves for the intervening values $r=13$ and $r=15$ behave analogously. We see that all the $\tilde{\tilde{F}}_r^s(k)$ tend to zero with increasing $|k|$.

This large $|k|$ behavior can be understood as follows: Suppose $f(v)$ and $g(v)$ are any two 2π periodic functions. Into the vector space of such functions introduce a scalar product by the usual rule

$$(f,g) = [1/(2\pi)]\int_0^{2\pi} dv\ \bar{f}(v)g(v) \tag{19.2.26}$$

where a bar denotes complex conjugation. Also define a norm by the usual rule

$$(||f||)^2 = (f,f). \tag{19.2.27}$$

Then, by the Schwarz inequaltiy, there is the result

$$|(f,g)| \le ||f||\ ||g||. \tag{19.2.28}$$

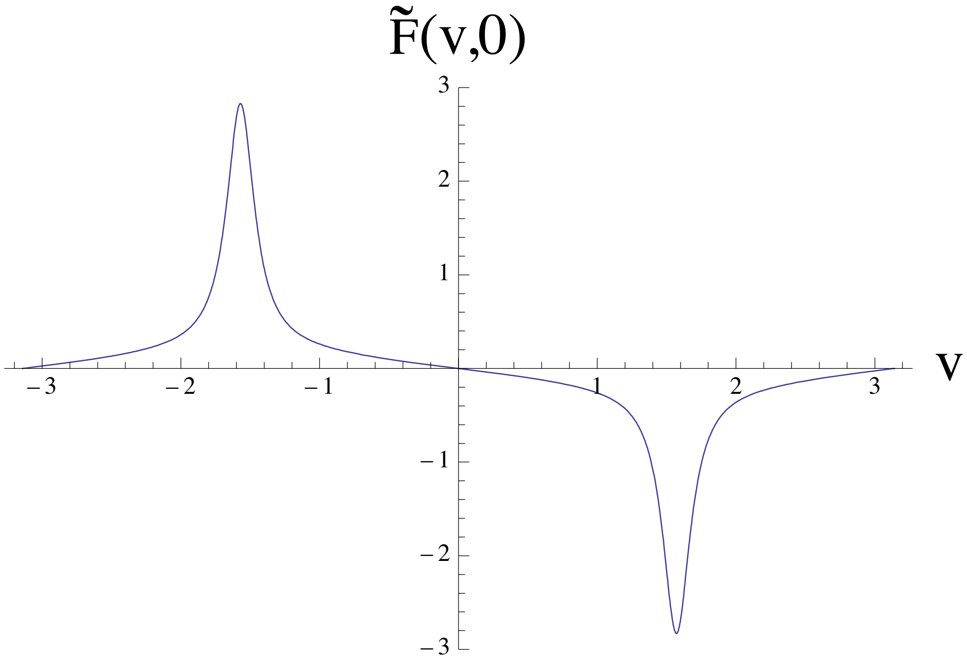

Figure 19.2.1: The real part of $\tilde{F}(v, k = 0)$ for the monopole doublet in the case that $x^{\max} = 4$ cm, $y^{\max} = 2$ cm, $a = 2.5$ cm, and $g = 1$ Tesla-(cm)^2. The imaginary part vanishes.

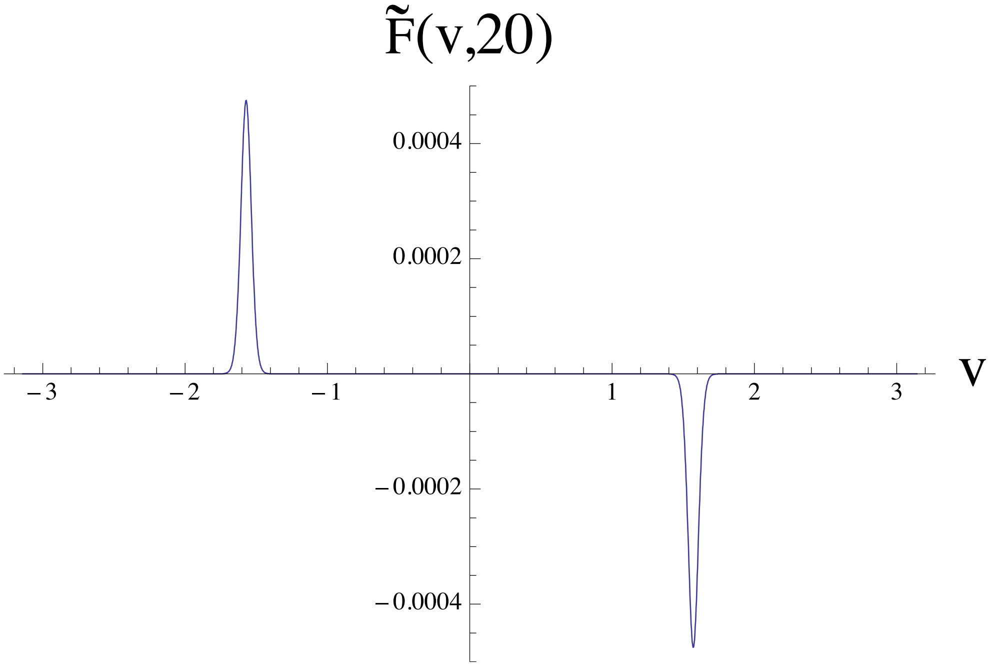

Figure 19.2.2: The real part of $\tilde{F}(v, k = 20)$ for the monopole doublet in the case that $x^{\max} = 4$ cm, $y^{\max} = 2$ cm, $a = 2.5$ cm, and $g = 1$ Tesla-(cm)^2. The imaginary part vanishes.

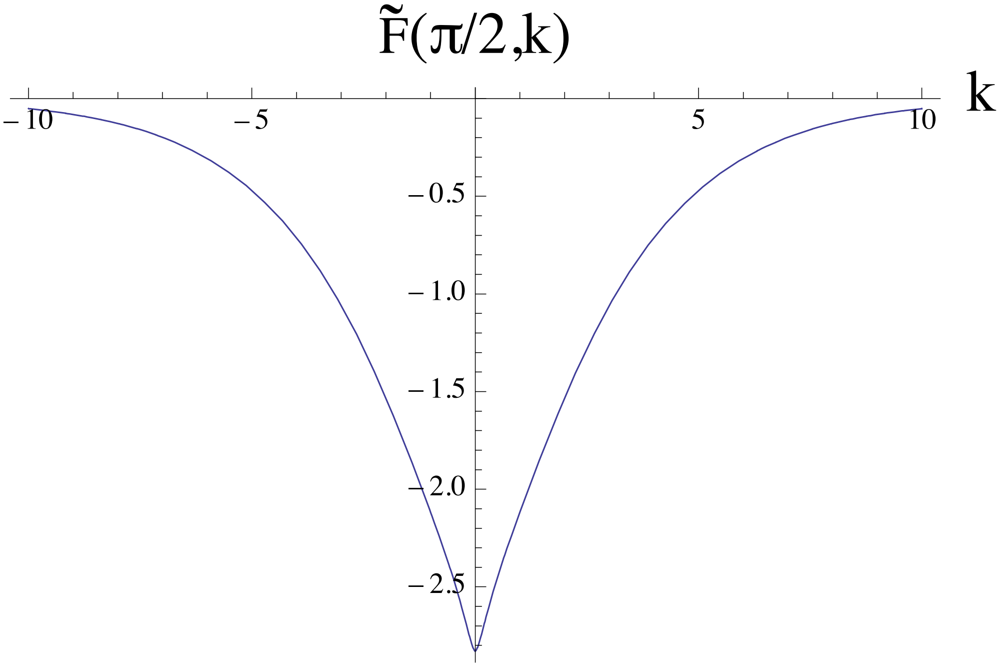

Figure 19.2.3: The real part of $\tilde{F}(v=\pi/2,k)$ for the monopole doublet in the case that $x^{\max}=4$ cm, $y^{\max}=2$ cm, $a=2.5$ cm, and $g=1$ Tesla-(cm)^2. The imaginary part vanishes.

With this notation in mind, we see that (2.23) can be rewritten in the form

$$\tilde{\tilde{F}}_r^s(k)=2(\mathrm{se}_r,\tilde{F}). \tag{19.2.29}$$

Therefore, using (2.28), we have the inequality

$$|\tilde{\tilde{F}}_r^s(k)|\leq 2||\mathrm{se}_r||\ ||\tilde{F}||. \tag{19.2.30}$$

Also, from the normalization (14.4.39), we see that

$$||\mathrm{se}_r||=1/\sqrt{2}. \tag{19.2.31}$$

We conclude that there is the r *independent* bound

$$|\tilde{\tilde{F}}_r^s(k)|\leq\sqrt{2}\ ||\tilde{F}|| \tag{19.2.32}$$

where

$$(||\tilde{F}||)^2=[1/(2\pi)]\int_0^{2\pi}dv\ [\tilde{F}(v,k)]^2. \tag{19.2.33}$$

(See also Exercise 2.1.) Figure 2.6 displays the quantity $\sqrt{2}\ ||\tilde{F}||$ as a function of k. Evidently it also decreases with increasing $|k|$. In fact, we can get a loose bound on $||\tilde{F}||$ from its definition (2.33) by estimating the integral,

$$(||\tilde{F}||)^2=[1/(2\pi)]\int_0^{2\pi}dv\ [\tilde{F}(v,k)]^2\leq[\tilde{F}(\pi/2,k)]^2 \tag{19.2.34}$$

from which it follows that

$$||\tilde{F}|| \leq |\tilde{F}(\pi/2, k)|. \tag{19.2.35}$$

Here we have used the fact that $[\tilde{F}(v, k)]^2$ takes its maxima at $v = \pm\pi/2$. See Figures 2.1 and 2.2. We already know that $|\tilde{F}(\pi/2, k)|$ decreases exponentially with increasing $|k|$. Again see Figure 2.3 and (2.16) through (2.19). We conclude that the $|\tilde{\tilde{F}}_r^s(k)|$ must all decrease at least this rapidly as well.

In fact there are two reasons why, for fixed r, the $|\tilde{\tilde{F}}_r^s(k)|$ must eventually decrease even more rapidly as $|k| \to \infty$. First, as comparison of Figures 2.1 and 2.2 indicates, the peaks in $\tilde{F}(v, k)$ at $v = \pm\pi/2$ become more narrow with increasing $|k|$. Second, look at (2.21). We expect that the greatest contribution to this integral will come from $v = \pm\pi/2$ because $\tilde{F}(v, k)$ is peaked there. But it is precisely at these v values that the $\mathrm{se}_r(v, q)$ vanish rapidly as $q \to -\infty$ since these v values are in the middle of the forbidden region. See, for example, Figures 14.4.19 and 14.4.20. To observe these considerations in action for the case of $|\tilde{\tilde{F}}_r^s(k)|$ with $r = 29$, see Figure 2.30 in Exercise 2.4.

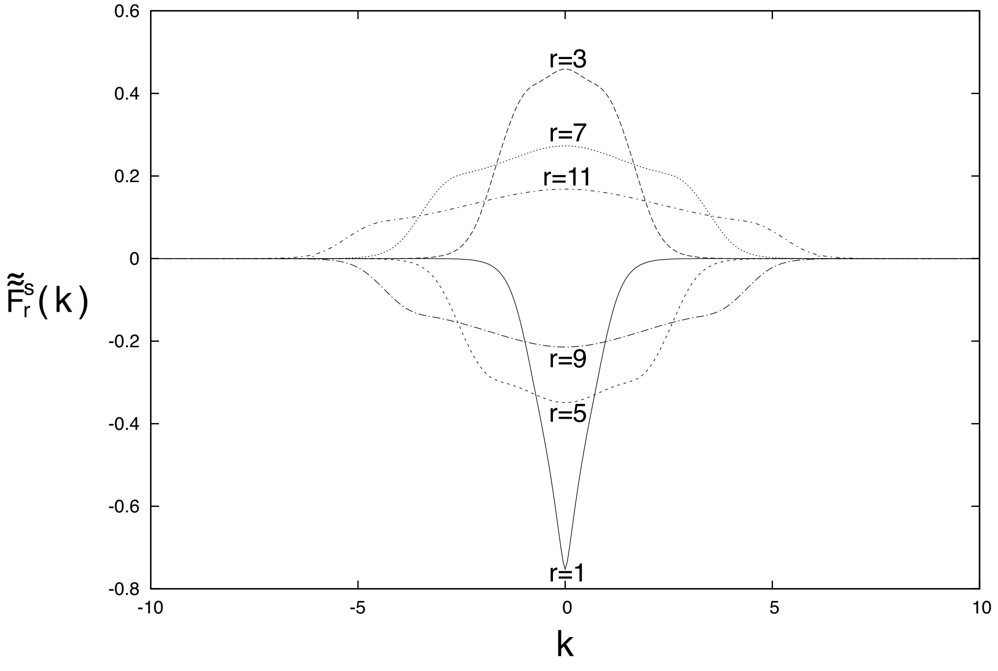

Figure 19.2.4: The real parts of the Mathieu coefficients $\tilde{\tilde{F}}_r^s(k)$ as a function of k, with $r = 1, 3, 5, 7, 9, 11$, for the monopole doublet in the case that $x^{\max} = 4$ cm, $y^{\max} = 2$ cm, $a = 2.5$ cm, and $g = 1$ Tesla-(cm)^2. The imaginary parts vanish. The solid curve, the one with the largest negative excursion at $k = 0$, is that for $r = 1$. The curves alternate in sign, and the magnitudes of their values at $k = 0$ decrease, for each successive value of r. For example, the curve with the largest positive excursion at $k = 0$ is that for $r = 3$.

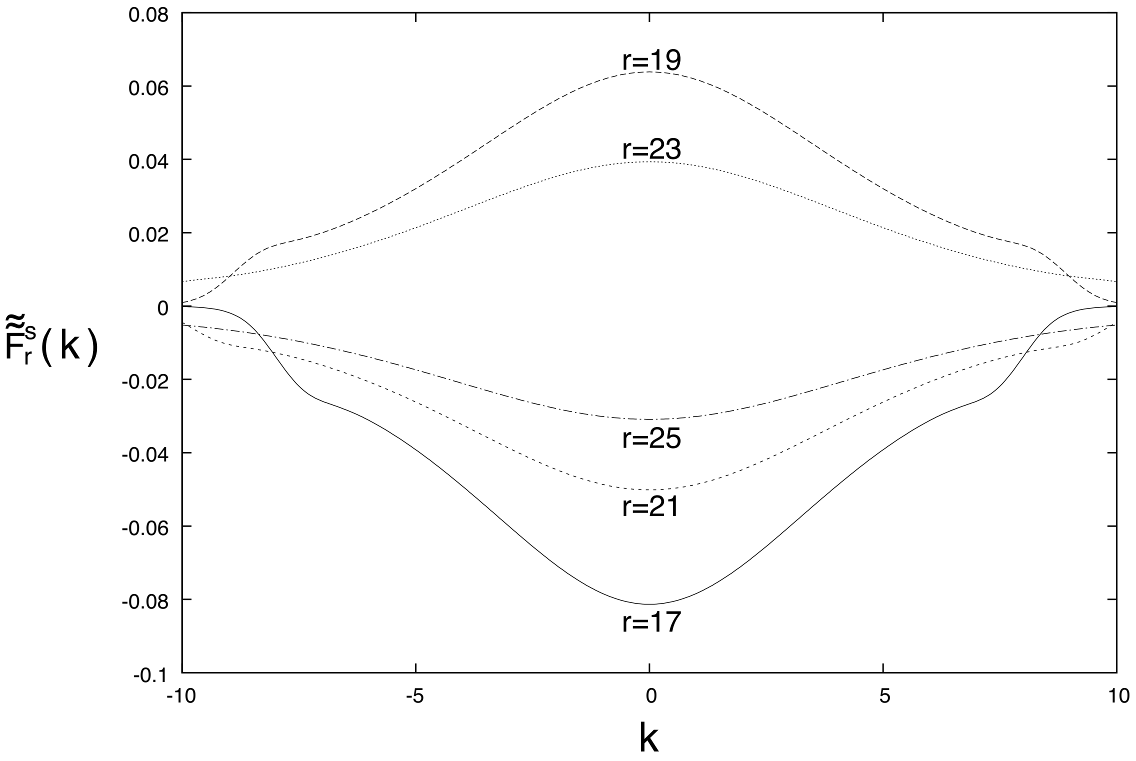

Figure 19.2.5: The real parts of the Mathieu coefficients $\tilde{\tilde{F}}^s_r(k)$ as a function of k, with $r = 17, 19, 21, 23, 25$, for the monopole doublet in the case that $x^{\max} = 4$ cm, $y^{\max} = 2$ cm, $a = 2.5$ cm, and $g = 1$ Tesla-(cm)^2. The imaginary parts vanish. The solid curve, the one with the largest negative excursion at $k = 0$, is that for $r = 17$. The curves alternate in sign, and the magnitudes of their values at $k = 0$ decrease for each successive value of r. For example, the curve with the largest positive excursion at $k = 0$ is that for $r = 19$.

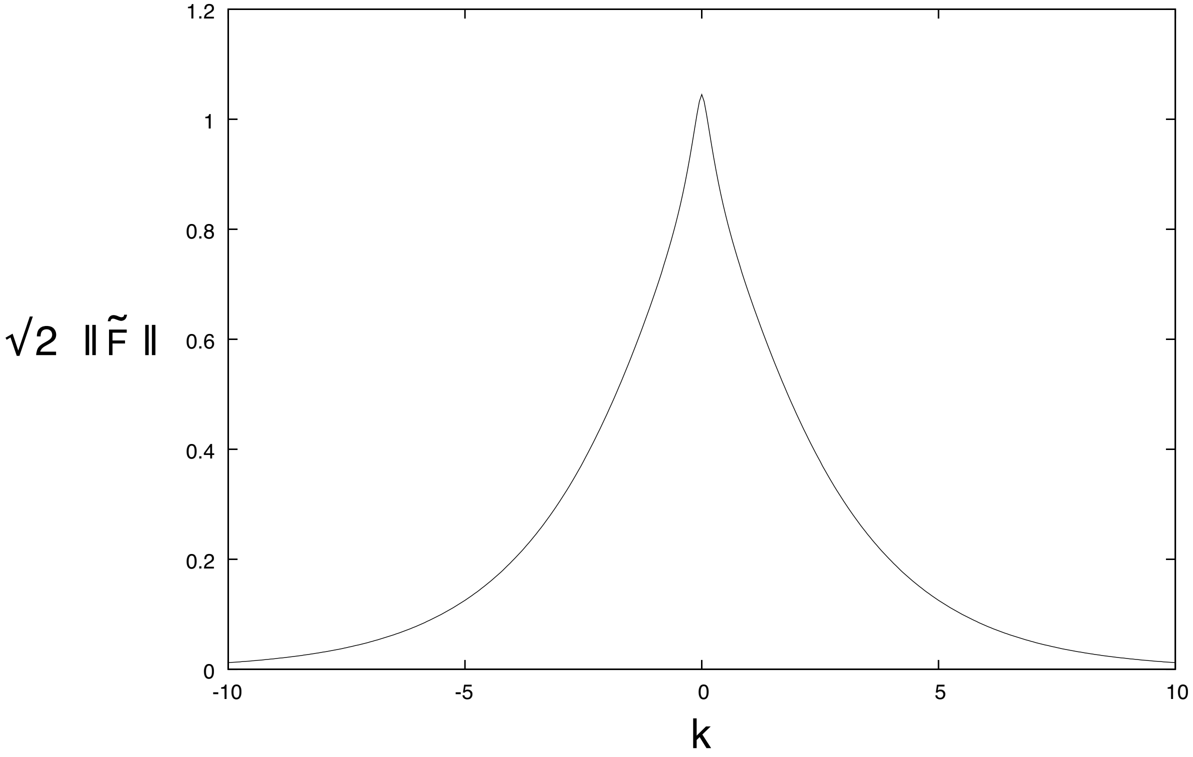

Figure 19.2.6: The quantity $\sqrt{2}\ ||\tilde{F}||$ as a function of k for the monopole doublet in the case that $x^{\max} = 4$ cm, $y^{\max} = 2$ cm, $a = 2.5$ cm, and $g = 1$ Tesla-(cm)^2.

19.2.2 Behavior of Kernels

We have determined the behavior of the Mathieu coefficients $\tilde{\tilde{F}}_r^s(k)$ for the case of the monopole doublet. In analogy with our previous discussion of the circular cylinder case in Section 16.1.1, let us next examine the kernels $k^m\beta_m^r(k)/\mathrm{Se}_r'(U,q)$ that appear in (14.4.86). Figure 2.7 shows the kernels $k^m\beta_m^r(k)/\mathrm{Se}_r'(U,q)$ for the case $m=1$ and $r=1,3,5,7,9,11$. We see that each kernel has constant sign and the absolute value of each goes monotonically to 0 as $|k|\to\infty$. Also, as Figure 2.8 shows, their absolute values at $k=0$ go monotonically to zero as r increases.

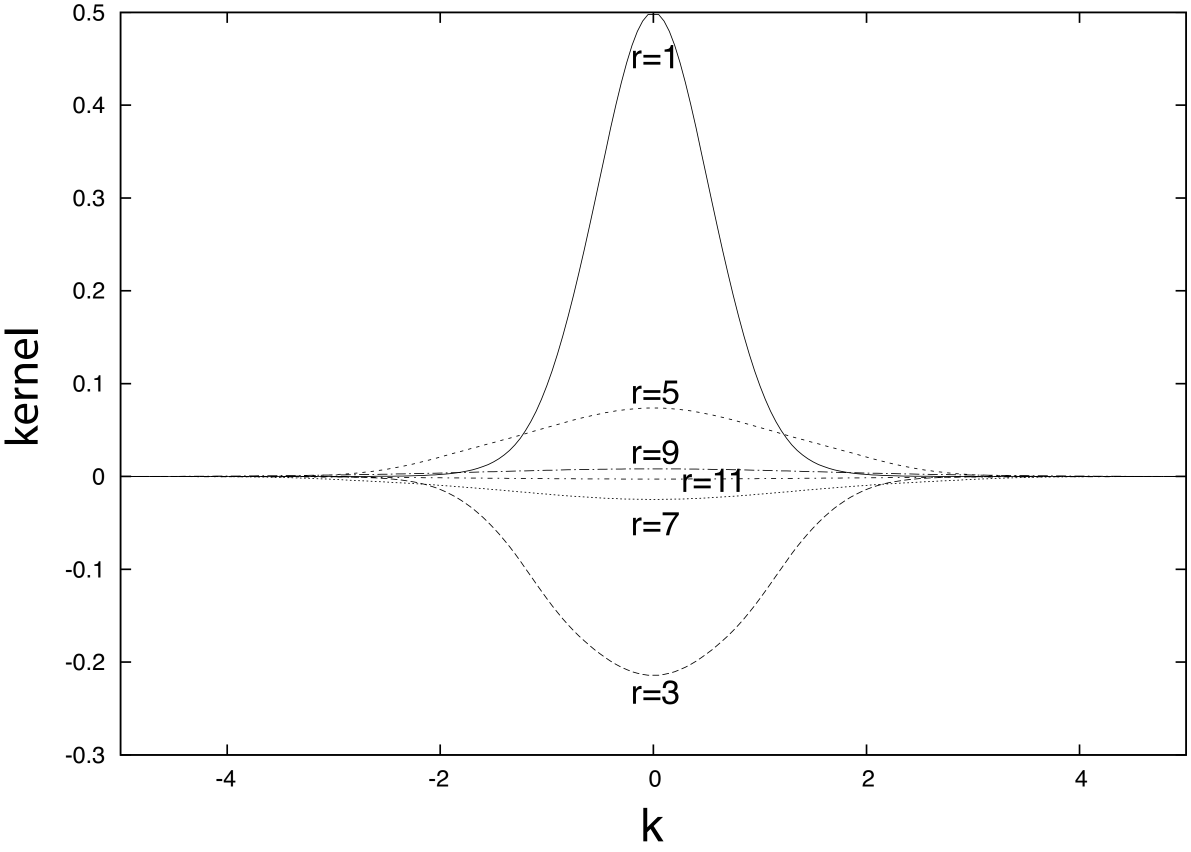

Figure 19.2.7: The kernels $k^m\beta_m^r(k)/\mathrm{Se}_r'(U,q)$ for the case $m=1$ and $r=1,3,5,7,9,11$, as a function of k, with q and k related by (2.24) and U given by (2.1). The kernel for $r=1$ is the one with the largest positive value at $k=0$. Kernels for successive values of r alternate in sign. Their absolute values at $k=0$ decrease monotonically with increasing r.

Figure 2.9 shows the kernels $k^m\beta_m^r(k)/\mathrm{Se}_r'(U,q)$ for the case $m=7$ and $r=1,3,5$. Figure 2.10 shows the kernels $k^m\beta_m^r(k)/\mathrm{Se}_r'(U,q)$ for the case $m=7$ and $r=7,9,11$. Figure 2.11 shows the kernels $k^m\beta_m^r(k)/\mathrm{Se}_r'(U,q)$ for the case $m=7$ and $r=13,15,17,21,23$. We see that the kernels for $r<m$ vanish at $k=0$. Those with $r\geq m$ are finite at $k=0$, but ultimately go to 0 as $r\to\infty$. See Figure 2.12. Finally, all kernels go rapidly to zero as $|k|\to\infty$. We have documented the extreme cases $m=1$ and $m=7$. The intermediate cases $m=3$ and $m=5$ are similar to the $m=7$ case: the kernels for $r<m$ vanish at

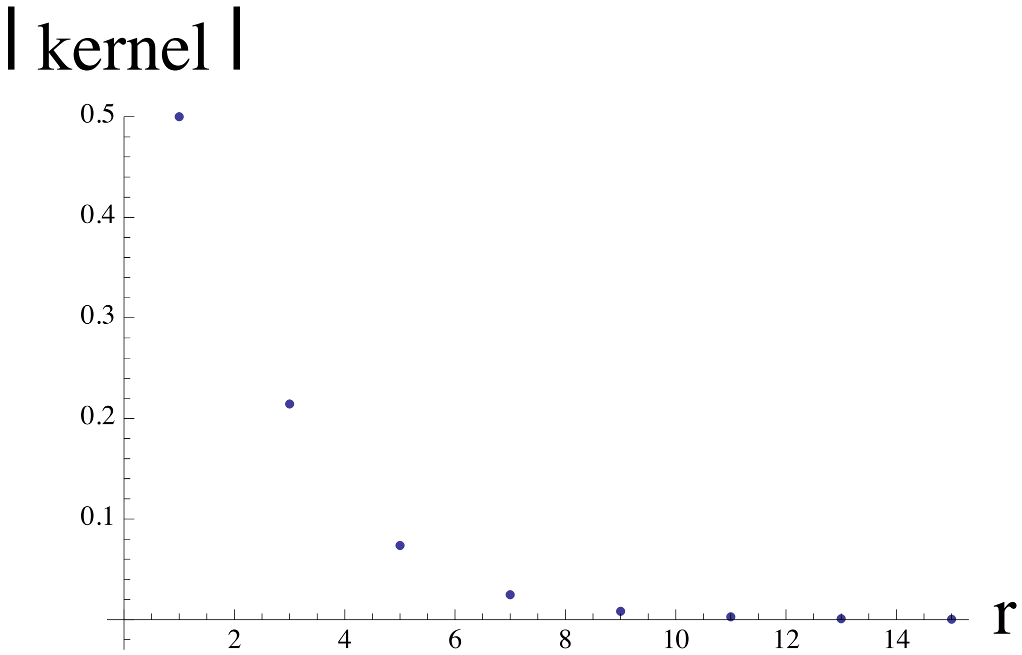

Figure 19.2.8: Absolute values of the kernels $k^m\beta^r_m(k)/\mathrm{Se}'_r(U,q)$ evaluated at $k=0$ for the case $m=1$ and $r\in[1,15]$ with U given by (2.1).

$k=0$; those with $r\geq m$ are finite at $k=0$, but ultimately go to 0 as $r\to\infty$; all kernels go rapidly to zero as $|k|\to\infty$.

19.2.3 Truncation of Series

We have studied the Mathieu coefficients $\tilde{\tilde{F}}^s_r(k)$ and the kernels $k^m\beta^r_m(k)/\mathrm{Se}'_r(U,q)$. Next, we need to study their combinations as they occur in (14.4.84) and (14.4.86). In particular, let us look at the quantities $(1/2)^m(1/m!)k^mG_{m,s}(k)$. Of course, in the monopole doublet case, we also know exactly what the result should be. Comparison of (14.4.86) and (1.1) gives the relation

$$(1/2)^m(1/m!)k^mG_{m,s}(k)=\tilde{C}^{[0]}_{m,s}(k), \tag{19.2.36}$$

and we know the right side of (2.36) from (1.20).

Figure 2.13 shows their values for the cases $m=1,3,5,7$. Figures 2.14 through 2.16 show their values for the cases $m=3,5,7$ separately. These are the cases that we need for our magnet monopole doublet example.

As described in the beginning of this subsection, we must truncate the infinite sums over r that occur in (14.4.83) through (14.4.86) in order to obtain practical results. We will do this by assuming that the truncation error is comparable to the size of the last retained term.[13] By this criterion, we retained all terms with values of r through $r=r_{\max}(m)$ with $r_{\max}(m)=11,19,25,29$ for the cases $m=1,3,5,7$, respectively. Figures 2.17 through

[13] This assumption is justified because both the Mathieu coefficients $\tilde{\tilde{F}}^s_r(k)$ and the kernels $k^m\beta^r_m(k)/\mathrm{Se}'_r(U,q)$ fall off exponentially in r for large r.

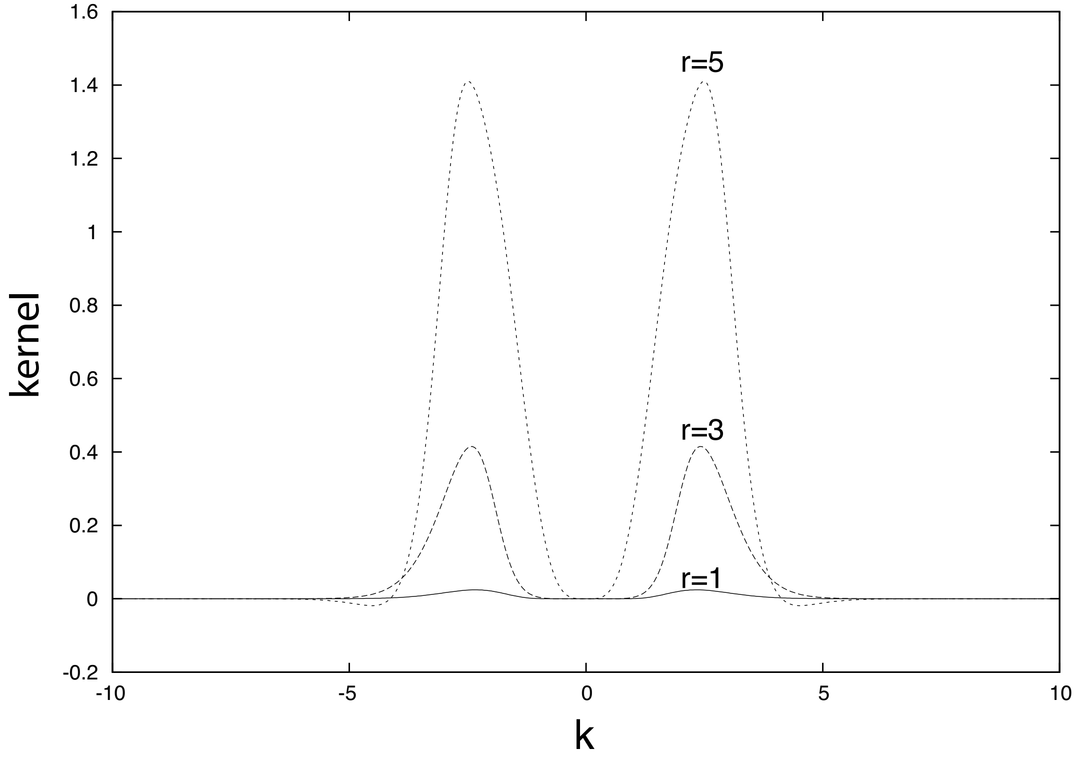

Figure 19.2.9: The kernels $k^m \beta_m^r(k)/\mathrm{Se}_r'(U,q)$ for the case $m = 7$ and $r = 1, 3, 5$, as a function of k, with q and k related by (2.24) and U given by (2.1). The kernel that has the largest positive value is that for $r = 5$. The kernel with the next largest positive value is that for $r = 3$. The remaining kernel is that for $r = 1$.

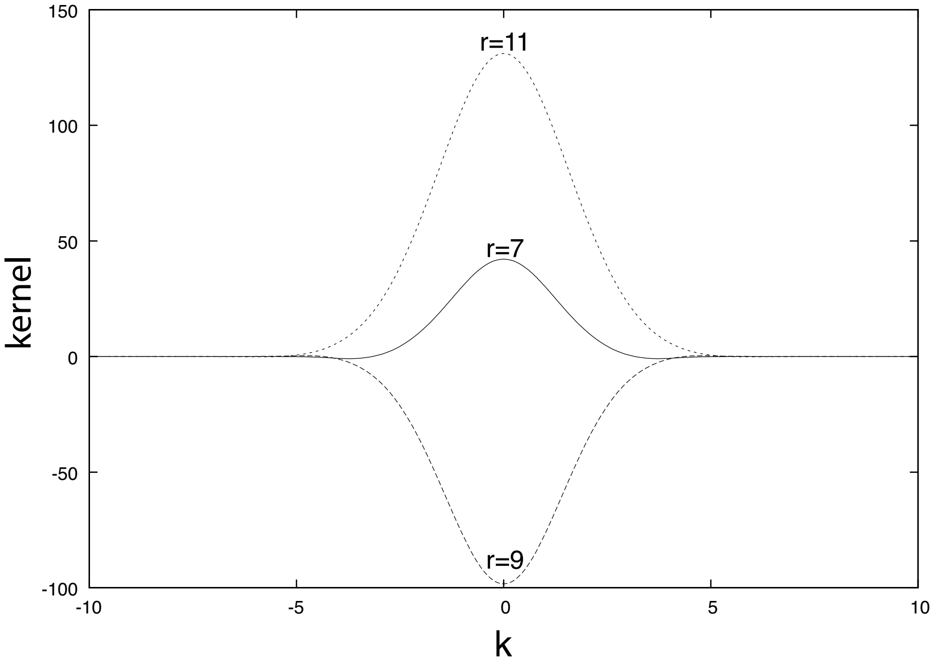

Figure 19.2.10: The kernels $k^m \beta_m^r(k)/\mathrm{Se}_r'(U,q)$ for the case $m = 7$ and $r = 7, 9, 11$, as a function of k, with q and k related by (2.24) and U given by (2.1). The kernel for $r = 7$ is the one with the smallest positive value at $k = 0$. Kernels for successive values of r alternate in sign. Their magnitudes at $k = 0$ increase monotonically with increasing r in the range $r \in [7, 11]$.

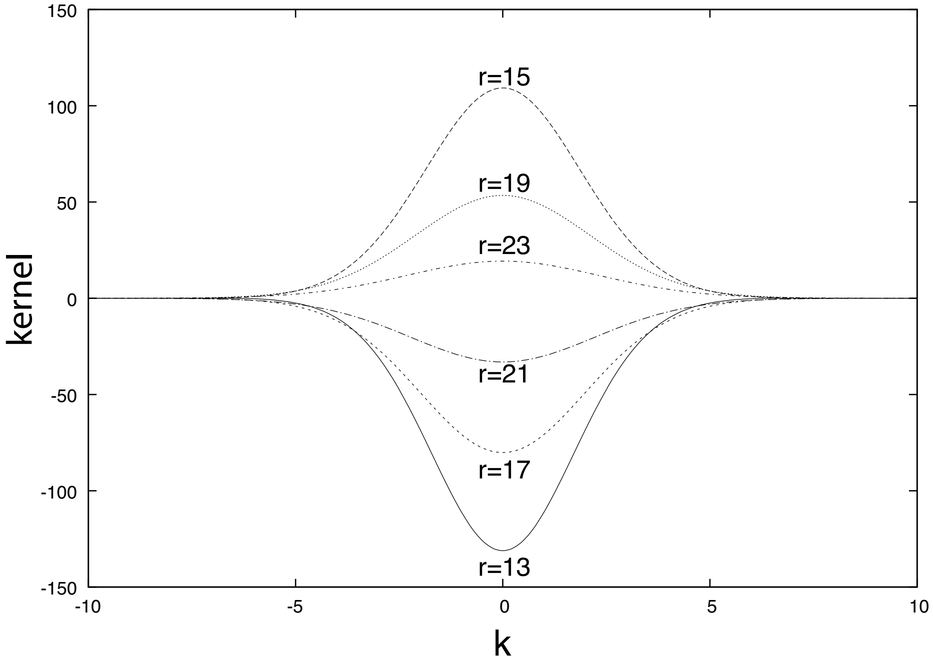

Figure 19.2.11: The kernels $k^m\beta^r_m(k)/\mathrm{Se}'_r(U,q)$ for the case $m = 7$ and $r = 13, 15, 17, 19, 21, 23$, as a function of k, with q and k related by (2.24) and U given by (2.1). The kernel for $r = 13$ is the one with the largest negative value at $k = 0$. Kernels for successive values of r alternate in sign. Their magnitudes at $k = 0$ decrease monotonically with increasing r in the range $r \in [13, 23]$.

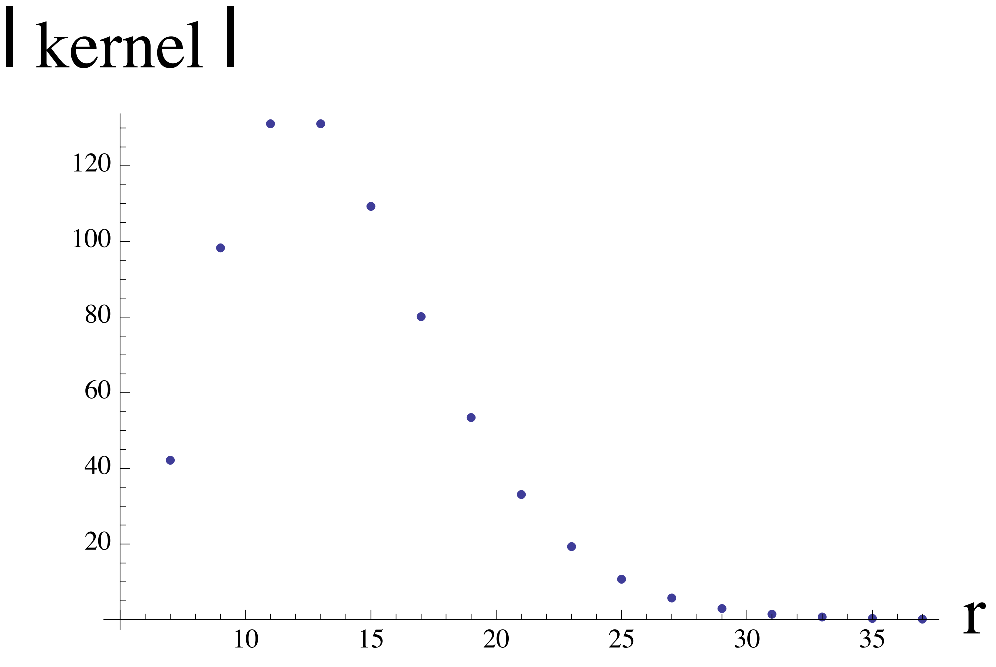

Figure 19.2.12: Absolute values of the kernels $k^m\beta^r_m(k)/\mathrm{Se}'_r(U,q)$ evaluated at $k = 0$ for the case $m = 7$ and $r \in [7, 37]$ with U given by (2.1).

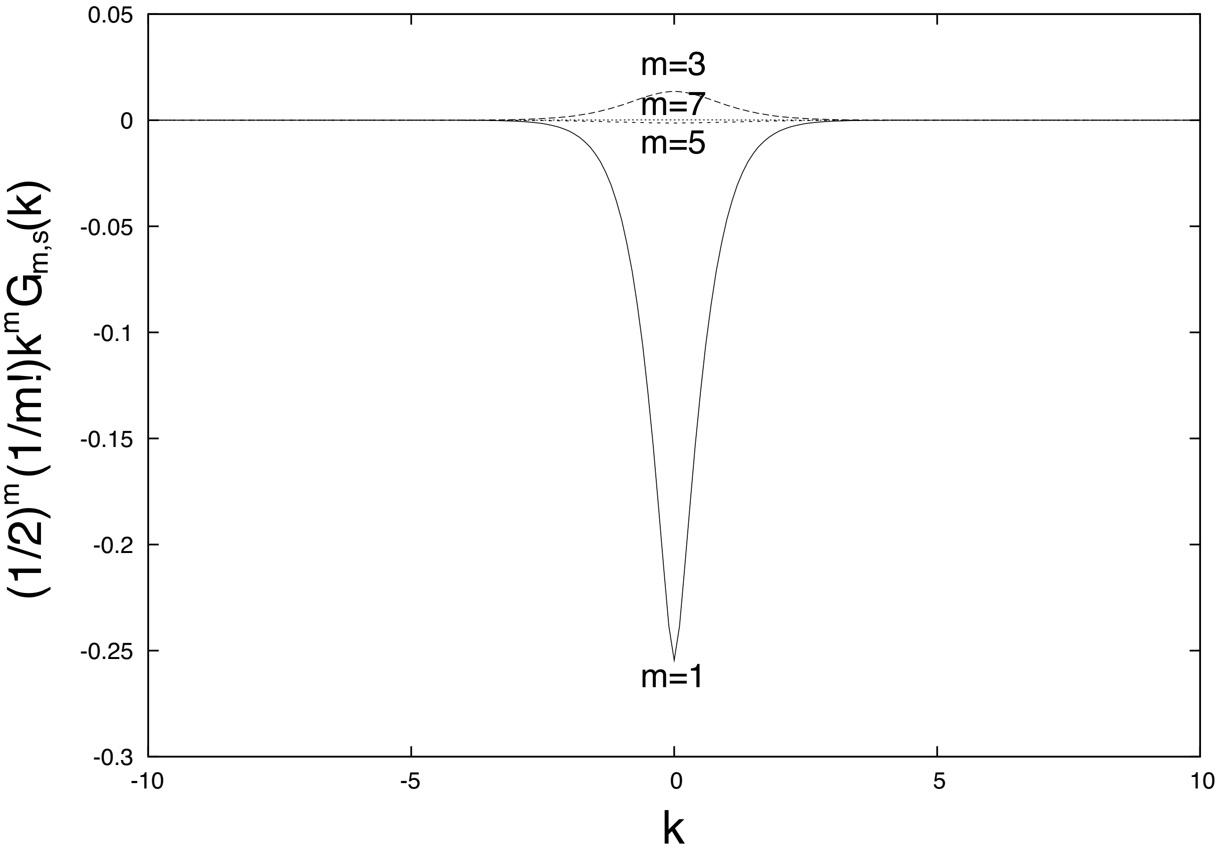

Figure 19.2.13: The real parts of $(1/2)^m(1/m!)k^m G_{m,s}(k)$ for the monopole doublet when $m = 1, 3, 5, 7$. The imaginary parts vanish. The quantities decrease in magnitude with increasing m. For example, the curve with the largest negative value at $k = 0$ is that for $m = 1$.

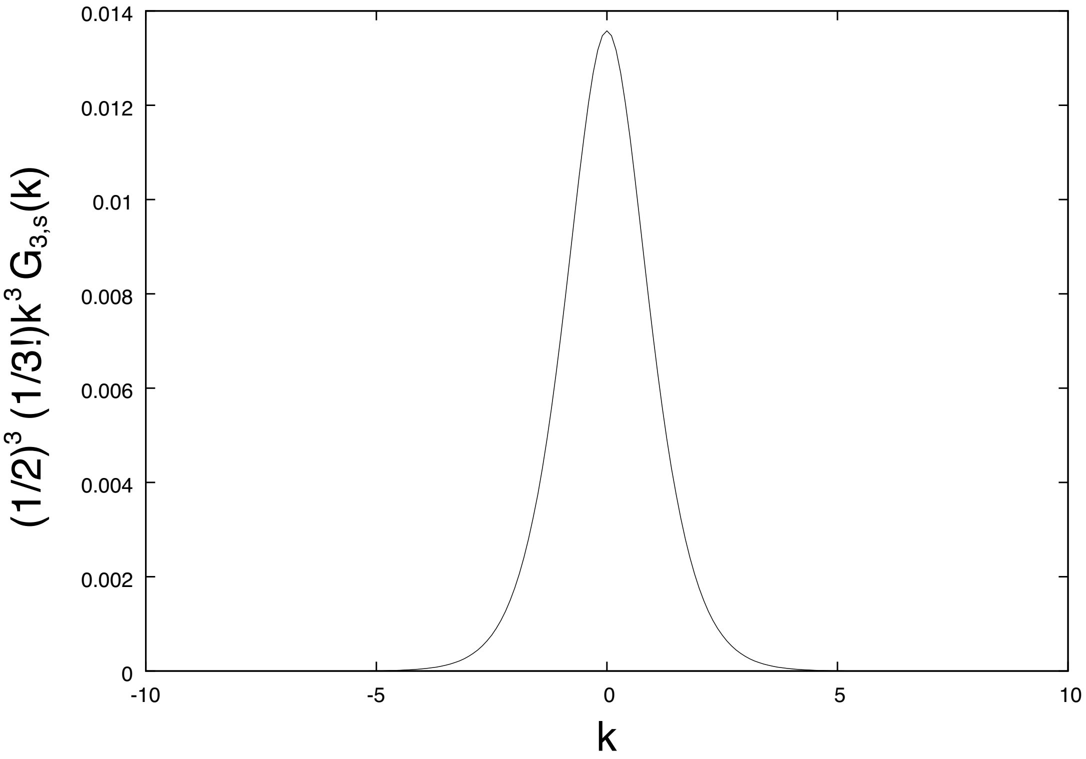

Figure 19.2.14: The real part of $(1/2)^m(1/m!)k^m G_{m,s}(k)$ for $m = 3$.

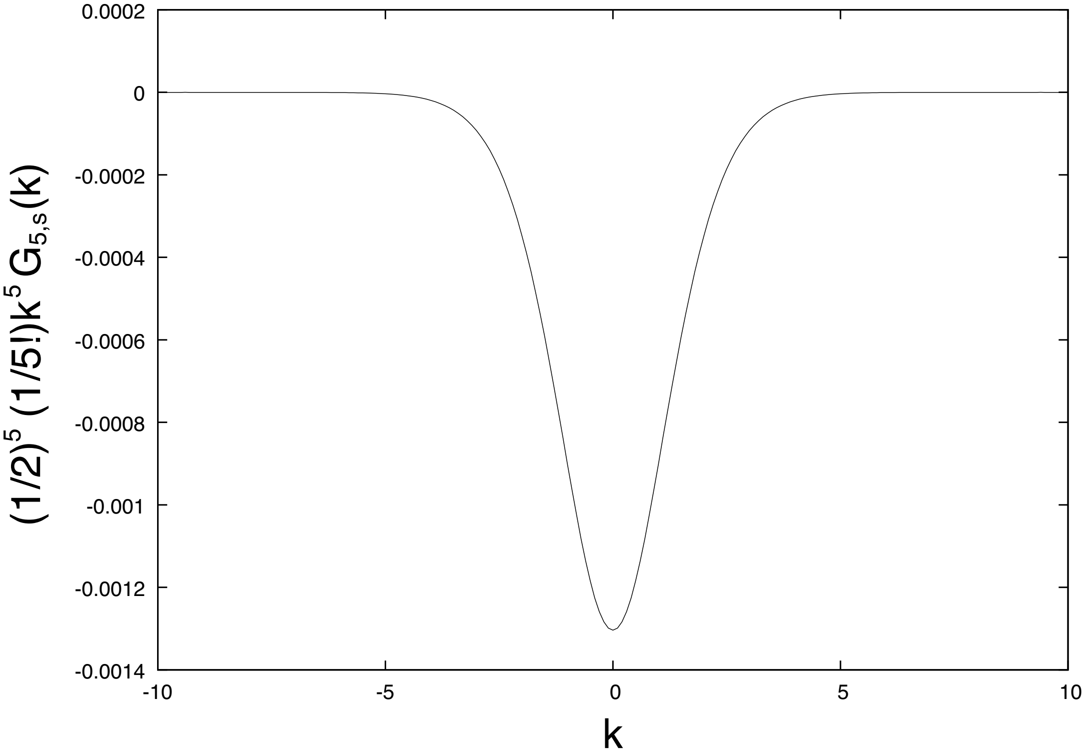

Figure 19.2.15: The real part of $(1/2)^m(1/m!)k^m G_{m,s}(k)$ for $m = 5$.

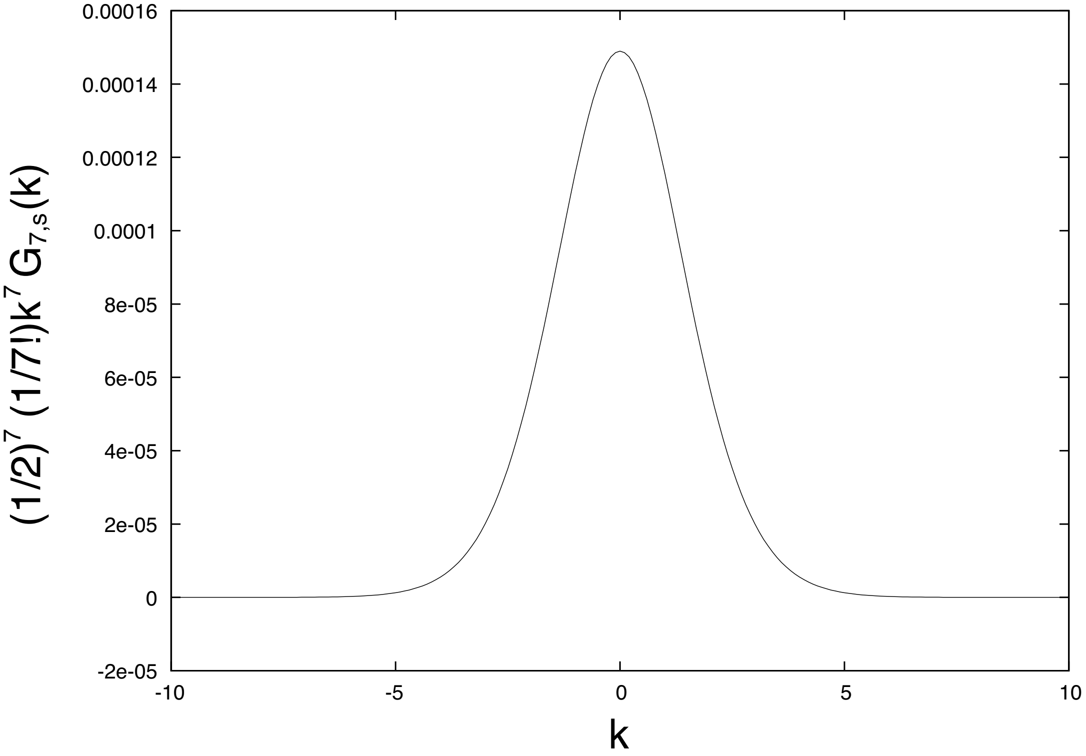

Figure 19.2.16: The real part of $(1/2)^m(1/m!)k^mG_{m,s}(k)$ for $m = 7$.

2.20 show the last retained term in each case. Judging from Figures 2.13 through 2.16, we estimate the errors to be 10,4,3,6 parts in 10^4 for the cases $m = 1, 3, 5, 7$ respectively.

Figures 2.21 through 2.24 show the actual truncation error, the difference between the truncated result and the exact result (2.36). Comparison of Figures 2.13 through 2.16 and Figures 2.21 through 2.24 shows that the actual truncation errors are 3,2,2,4 parts in 10^4 for $m = 1, 3, 5, 7$, respectively.

19.2.4 Approximation of Angular Integrals by Riemann Sums

At this point we have verified that the truncation criterion is adequate and that the routines used to compute the Mathieu functions and the Mathieu-Bessel function connection coefficients are working properly. The next step is to explore the replacement of angular integrals by Riemann sums.

Select N discrete v values v_n according to the rule

$$v_n = n(2\pi/N) \text{ for } n = 0, 1, \cdots, N-1. \tag{19.2.37}$$

What we want to do is to approximate the integrals (2.20) and (2.21) by the Riemann sums

$$\tilde{\tilde{F}}_r^c(k) \approx (2/N)\sum_{n=0}^{N-1} \mathrm{ce}_r(v_n, q)\tilde{F}(v_n, k), \tag{19.2.38}$$

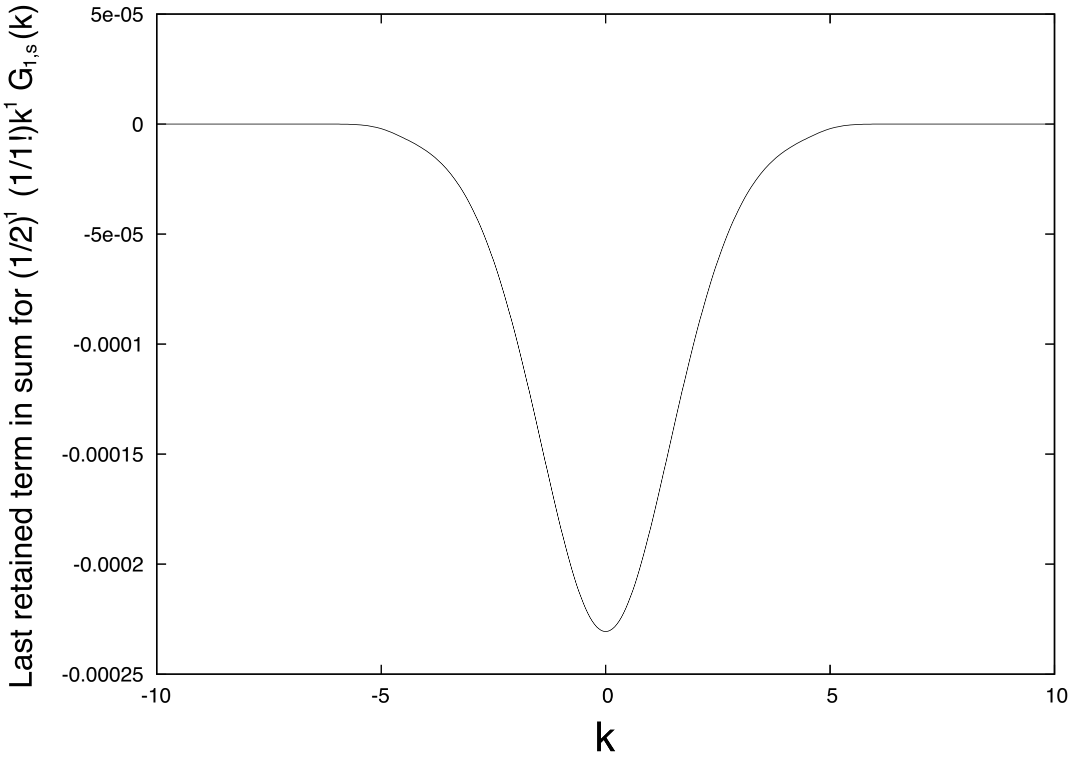

Figure 19.2.17: The real part of the last retained term in the sum for $(1/2)^m(1/m!)k^mG_{m,s}(k)$ with $m = 1$ based on truncating the series (14.4.84) beyond $r = r_{\max}(1) = 11$. The imaginary part vanishes.

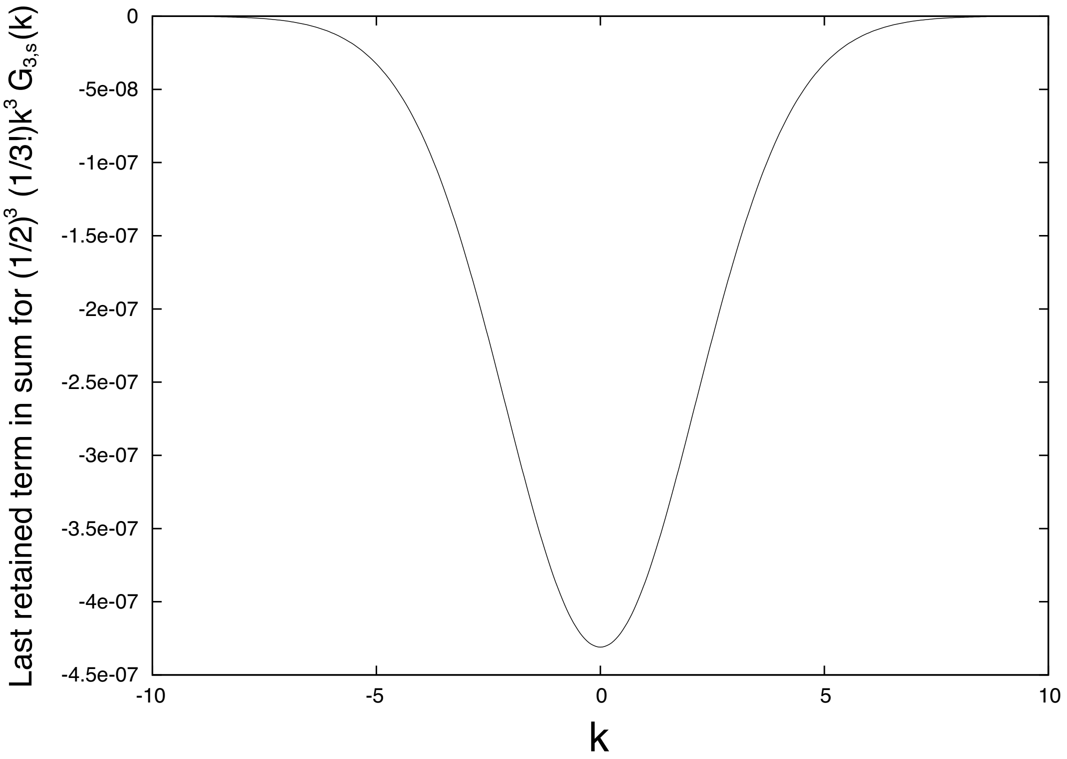

Figure 19.2.18: The real part of the last retained term in the sum for $(1/2)^m(1/m!)k^mG_{m,s}(k)$ with $m = 3$ based on truncating the series (14.4.84) beyond $r = r_{\max}(3) = 19$. The imaginary part vanishes.

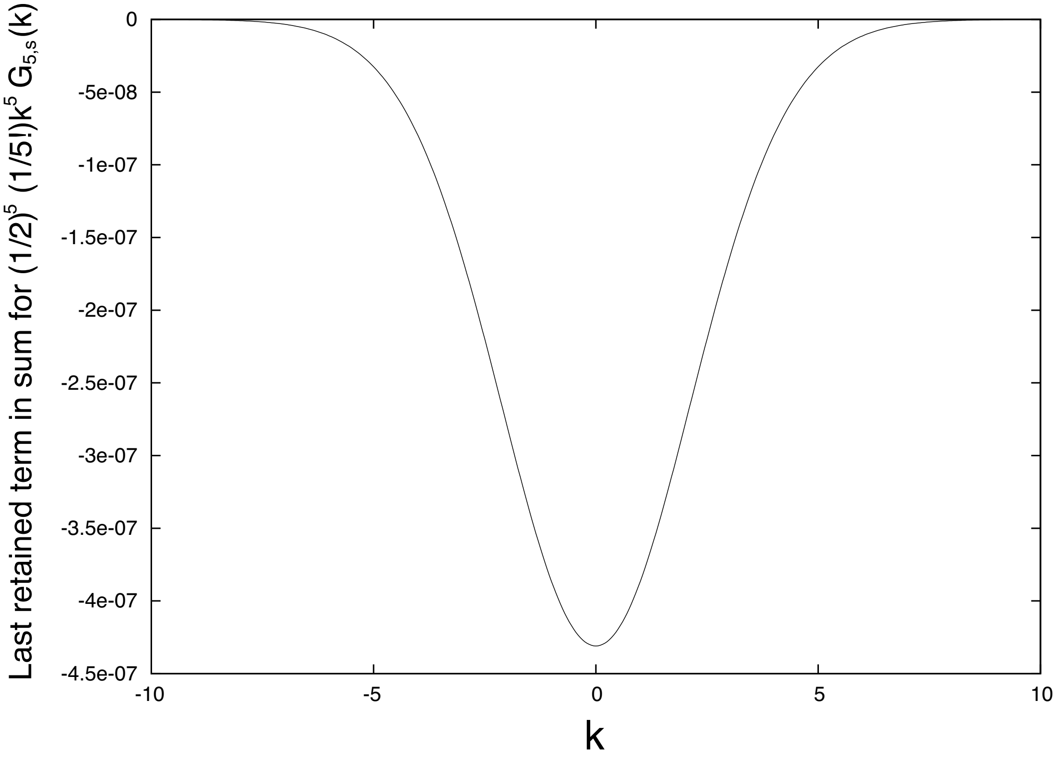

Figure 19.2.19: The real part of the last retained term in the sum for $(1/2)^m(1/m!)k^mG_{m,s}(k)$ with $m = 5$ based on truncating the series (14.4.84) beyond $r = r_{\max}(5) = 25$. The imaginary part vanishes.

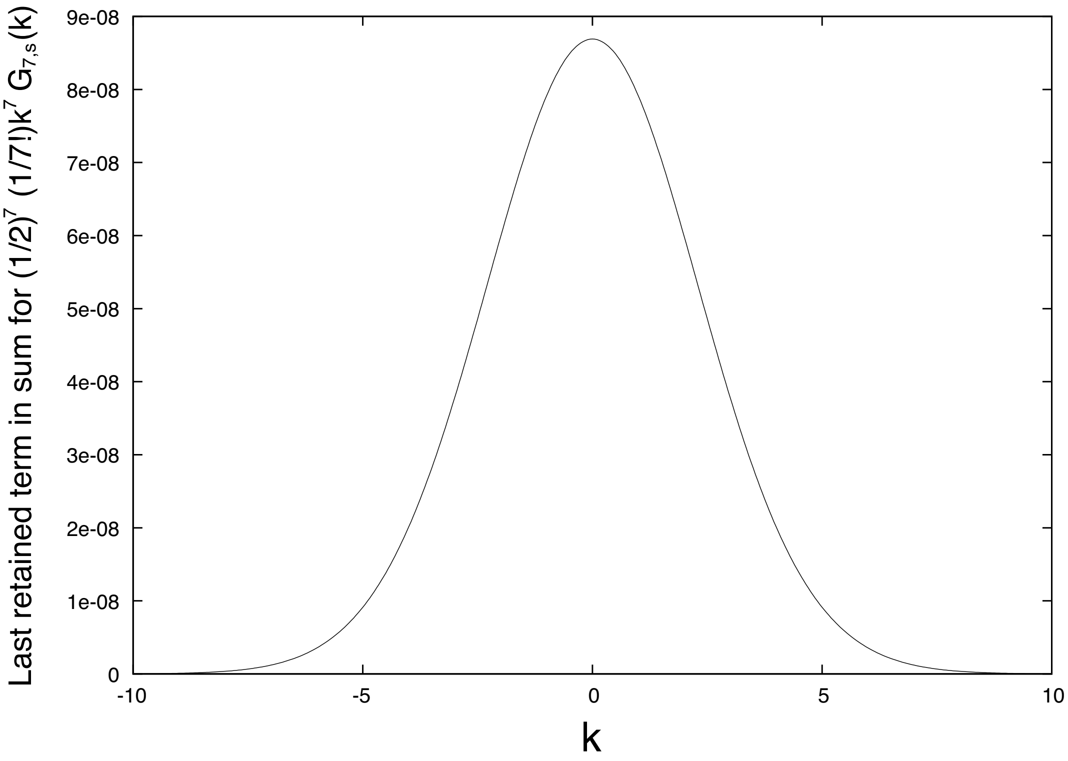

Figure 19.2.20: The real part of the last retained term in the sum for $(1/2)^m(1/m!)k^m G_{m,s}(k)$ with $m = 7$ based on truncating the series (14.4.84) beyond $r = r_{\max}(7) = 29$. The imaginary part vanishes.

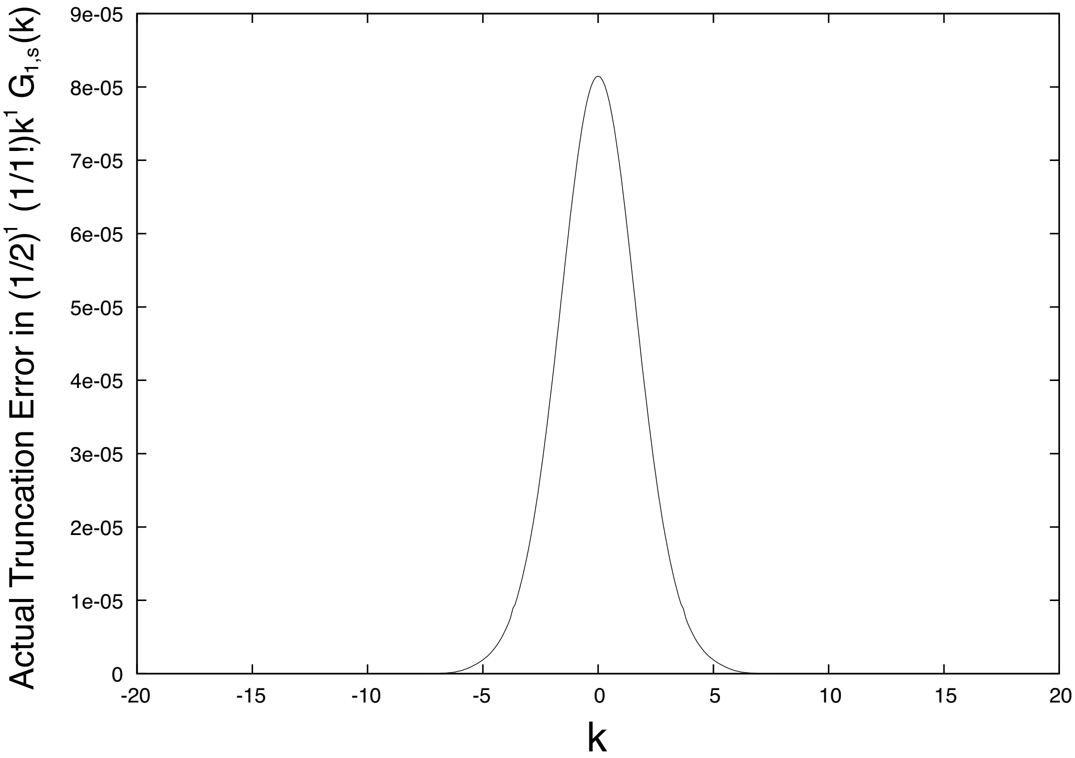

Figure 19.2.21: Real part of actual truncation error in $(1/2)^m(1/m!)k^m G_{m,s}(k)$ for $m = 1$ produced by truncating the series (14.4.84) beyond $r = r_{\max}(1) = 11$. The imaginary part vanishes.

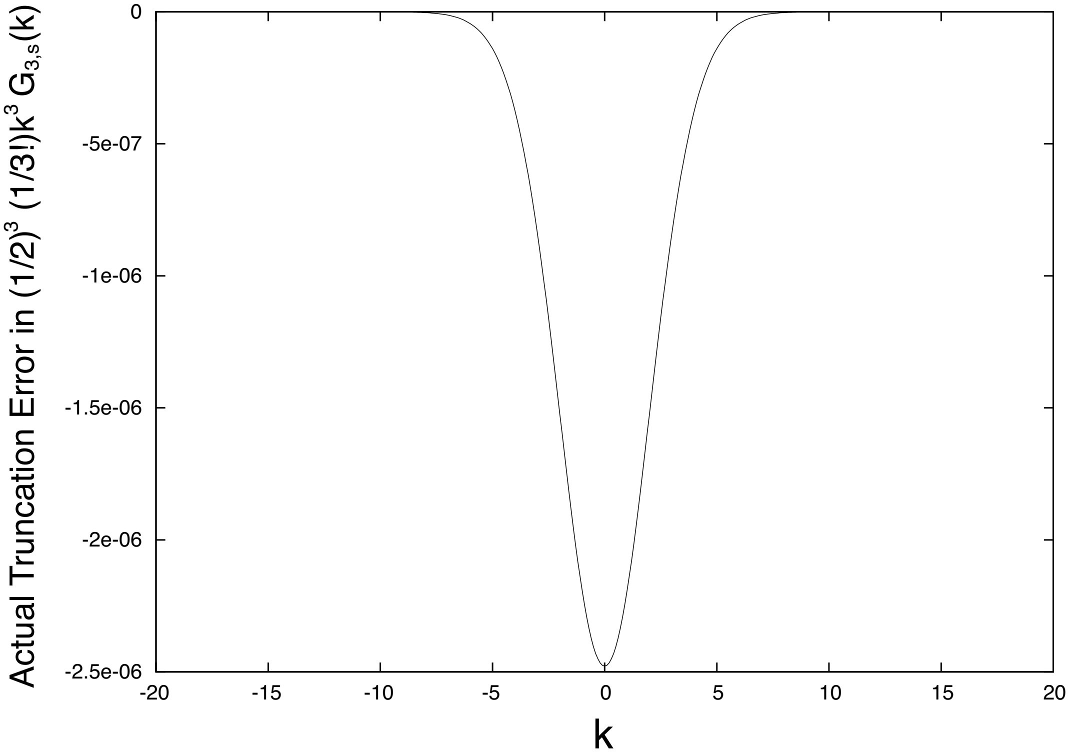

Figure 19.2.22: Real part of actual truncation error in $(1/2)^m(1/m!)k^mG_{m,s}(k)$ for $m = 3$ produced by truncating the series (14.4.84) beyond $r = r_{\max}(3) = 19$. The imaginary part vanishes.

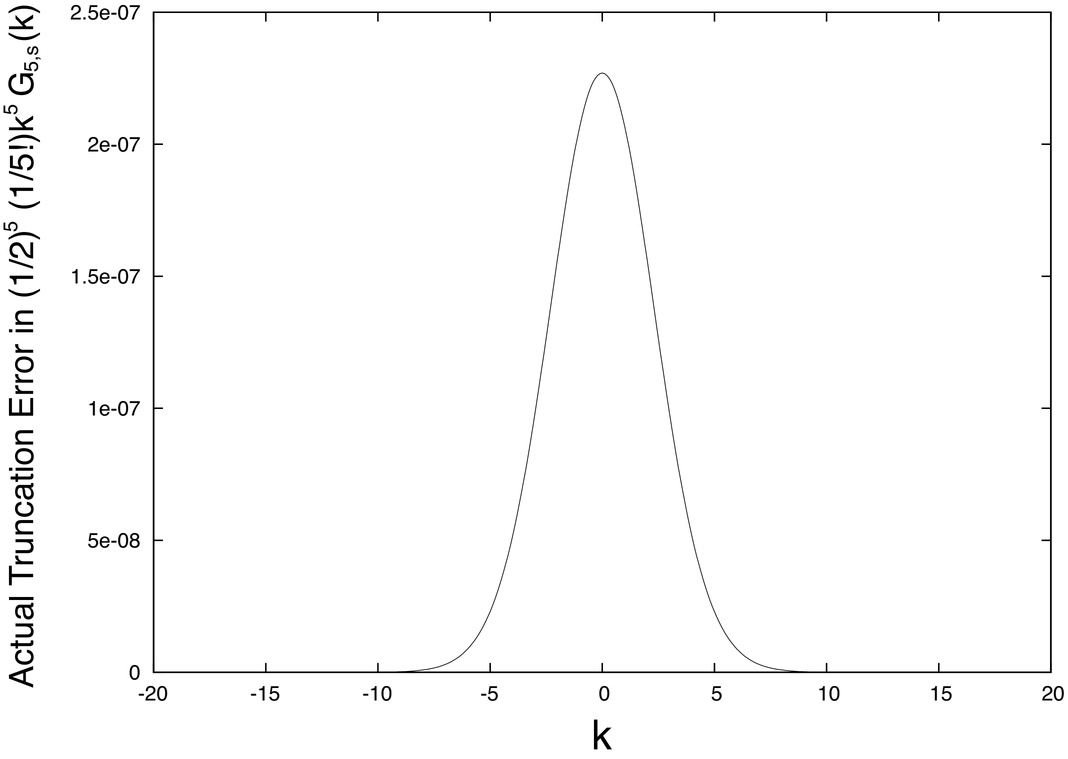

Figure 19.2.23: Real part of actual truncation error in $(1/2)^m(1/m!)k^m G_{m,s}(k)$ for $m = 5$ produced by truncating the series (14.4.84) beyond $r = r_{\max}(5) = 25$. The imaginary part vanishes.

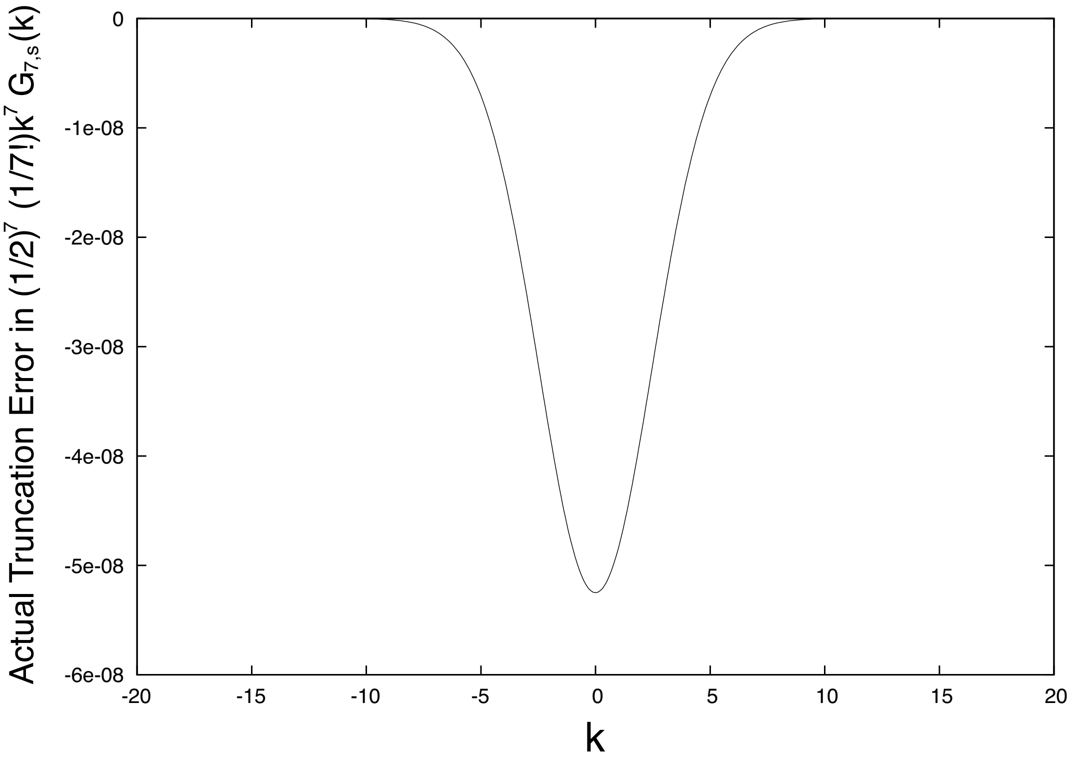

Figure 19.2.24: Real part of actual truncation error in $(1/2)^m(1/m!)k^mG_{m,s}(k)$ for $m = 7$ produced by truncating the series (14.4.84) beyond $r = r_{\max}(7) = 29$. The imaginary part vanishes.

$$\tilde{\tilde{F}}_r^s(k) \approx (2/N) \sum_{n=0}^{N-1} \mathrm{se}_r(v_n, q)\tilde{F}(v_n, k). \tag{19.2.39}$$

The accuracy of these approximations depends on the large m behavior of the Fourier coefficients for $\tilde{F}(v, k)$ and the Fourier coefficients for the Mathieu functions $\mathrm{ce}_r(v, q)$ and $\mathrm{se}_r(v, q)$. See Exercise 2.2. There it is shown that (2.38) and (2.39) are good approximations providing the Fourier coefficients are sufficiently small for $m \geq N$. For the monopole doublet case this proves to be true for $N \geq 120$. See Exercises 2.3 and 2.4. In that case the use of (2.38) and (2.39) with $N = 120$ is accurate to 5 parts in 10^4 for all k and r values of interest. Indeed, the $\tilde{\tilde{F}}_r^s(k)$ used in making Figures 2.4 and 2.5 were obtained using (2.39) with $N = 120$.

19.2.5 Further Tests

Following the pattern established in the circular cylinder case, the next items we should verify are these:

- So far, we have been using exact results for $\tilde{F}(v_n, k)$. We should verify that sufficiently accurate results for $\tilde{F}(v_n, k)$ can be obtained by evaluating (14.4.72) numerically using splines.

- With the use of this spline-computed $\tilde{F}(v_n, k)$ and the related Riemann sum $\tilde{\tilde{F}}_r^s(k)$ derived from it employing (2.39), we should verify that (2.36) is still well satisfied.

- Assuming that (2.36) is well satisfied, we should verify that inserting these results into (14.4.86) and then carrying out the indicated inverse Fourier transform, again numerically using splines, yields sufficiently accurate approximations to the functions $C_{m,s}^{[n]}(z)$.

- Finally, all these procedures should also yield satisfactory results when data is taken from a grid and interpolated onto the elliptic cylinder. See Figures 13.7.2 and 14.4.3.

The first three items above depend on the accuracy of the numerical spline-based Fourier transform routines. Since this accuracy has already been established in the circular cylinder case, and the demands made of the spline-based routines are no more stringent in the elliptic cylinder case, it seems sensible to proceed directly to verifying the last item. Moreover, its verification also provides added evidence of the veracity of the first three.

19.2.6 Completion of Test

Therefore, to complete our test, we again set up a regular grid in x, y, z space. We again let y and z range over the intervals $y \in [-2.4, 2.4]$ with $h_y = .1$ and $z \in [-300, 300]$ with $h_z = .125$. However, for x we will use the interval $x \in [-4.4, 4.4]$ with $h_x = .1$ in order to ensure that all the ellipse given by (2.1) and (2.2) lies within the grid. Thus, we use 89 grid points in x, 49 grid points in y, and 4801 grid points in z for a total of $89 \times 49 \times 4801 = 20,937,161$ grid points.[14] As before, we evaluate the angular integrals using a Riemann sum with $N = 120$. Doing so requires interpolation off the grid onto the elliptical cylinder at 120 angular points for each of the 4801 selected values of z. And we evaluate the forward linear transforms for 401 k values in the range $k \in [-K_c, K_c]$ with $K_c = 20$. We also use these same points in k space to evaluate the inverse Fourier transforms. That is, $H = .1$. Finally we use the same values for $r_{\max}(m)$ as before. The result of this process is a *completely numerically* calculated set of functions $C_m^{[n]}(z)$.

We find that the results so obtained for the $C_m^{[n]}(z)$ are to the eye indistinguishable, for example, from Figures 1.7, 1.8, and 1.15. As more precise indicators of accuracy, Figures 2.25 through 2.27 show differences between exact and grid-value based completely numerically computed results for $C_{1,s}^{[0]}(z)$, $C_{1,s}^{[6]}(z)$, and $C_{7,s}^{[0]}(z)$. We see that the error is between 4 and 5 parts in 10^4, which is just slightly larger than the circular cylinder error result.

We have demonstrated, for the monopole-doublet problem, that the steps in the first three boxes shown in Figure 14.1.1 can also be carried out to yield results having good numerical accuracy for the case of a cylinder with elliptical cross section. As remarked earlier, again see Figure 13.7.7 and now also Figure 2.28, the surface field we have been working with is quite singular, more singular than fields likely to be encountered in practice. Thus the fact that the elliptical cylinder surface method has succeeded in this rather extreme case indicates that it is likely to work even better in actual physical applications.

Exercises

19.2.1. From (2.20) through (2.22) we know that $\tilde{F}(v, k)$ must have an expansion of the form

$$\tilde{F}(v,k) = \sum_r \tilde{\tilde{F}}_r^s(k)\mathrm{se}_r(v,q). \tag{19.2.40}$$

Use this expansion to show that there is the relation

$$||\tilde{F}||^2 = (1/2)\sum_n |\tilde{\tilde{F}}_n^s(k)|^2, \tag{19.2.41}$$

which is a form of *Parseval's* theorem applied to Mathieu expansions. From (2.41) conclude that

$$|\tilde{\tilde{F}}_r^s(k)| = \sqrt{2}[||\tilde{F}||^2 - \sum_{n \neq r} |\tilde{\tilde{F}}_n^s(k)|^2]^{1/2} \leq \sqrt{2}||\tilde{F}||]. \tag{19.2.42}$$

19.2.2. This exercise is a generalization of Exercise 1.2. Suppose $f(\phi)$ and $g(\phi)$ are 2π periodic functions and therefore have Fourier expansions of the form

$$f(\phi) = \sum_{m=-\infty}^{\infty} f_m \exp(im\phi), \tag{19.2.43}$$

[14] Of course, as in the circular cylinder case, most of these grid points are actually unused since only relatively few are sufficiently near the surface of the elliptic cylinder to be employed in the interpolation procedure. After interpolation onto the surface of the elliptic cylinder, $120 \times 4801 = 576,120$ surface values of $F(U, v, z)$ are used in the remainder of the calculation.

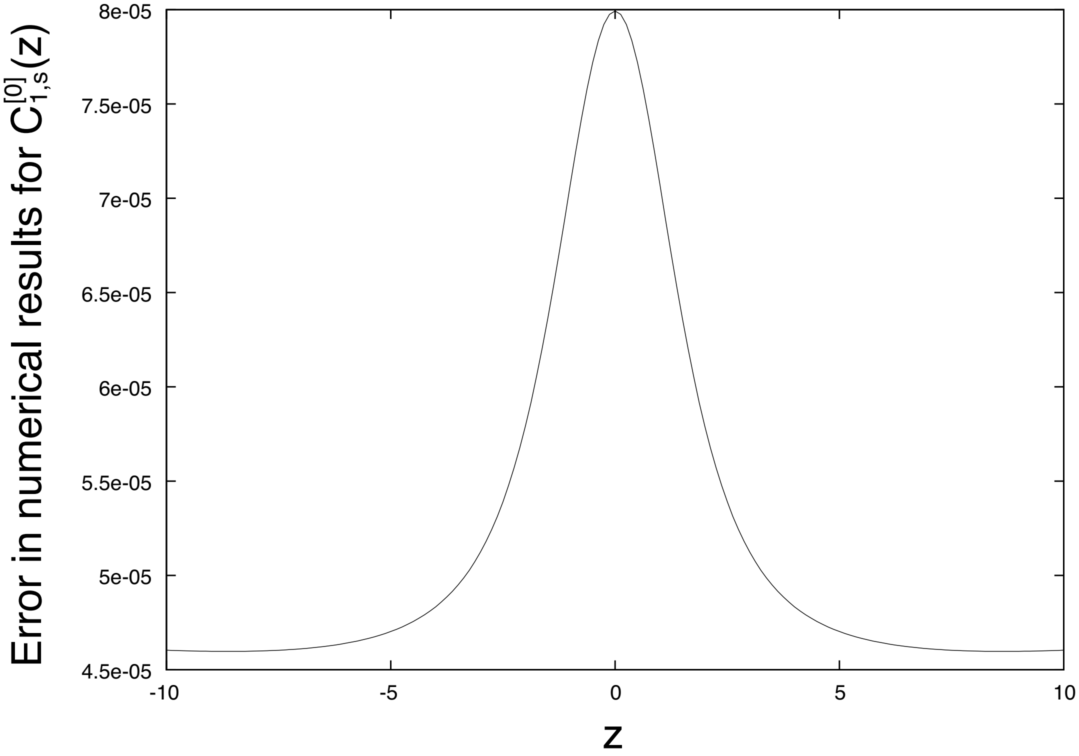

Figure 19.2.25: Difference between exact and completely numerically computed results for $C_{1,s}^{[0]}(z)$ based on field data provided on a grid and interpolated onto an elliptic cylinder with $x_{\max} = 4$ cm and $y_{\max} = 2$ cm.

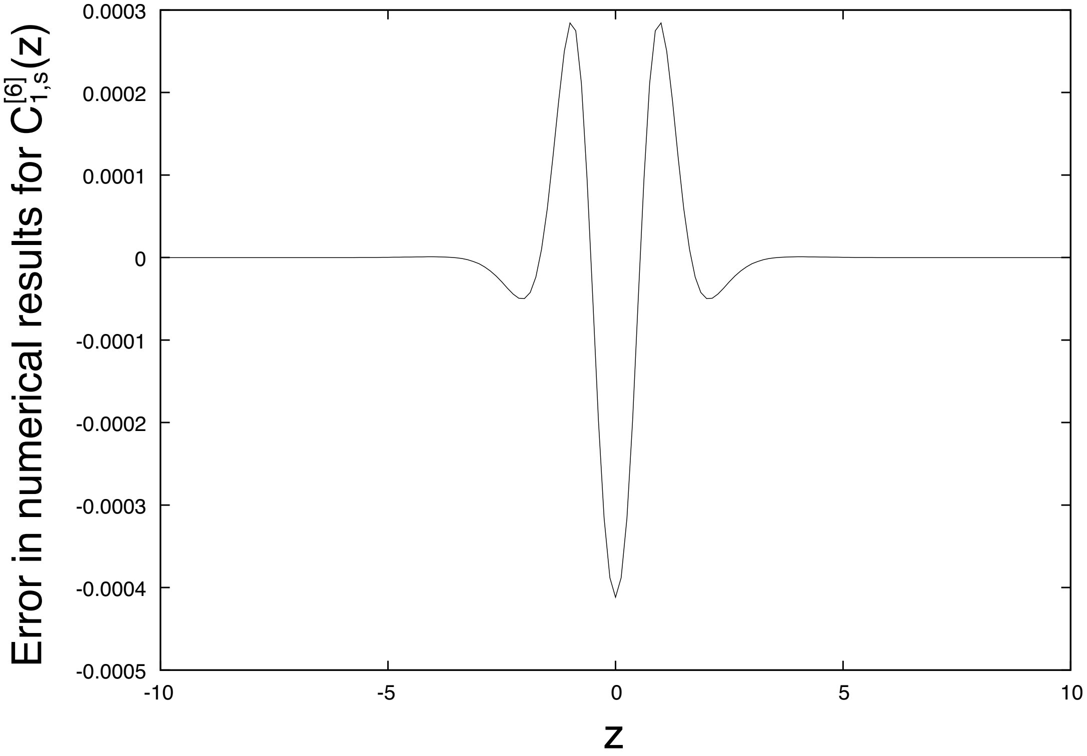

Figure 19.2.26: Difference between exact and completely numerically computed results for $C^{[6]}_{1,s}(z)$ based on field data provided on a grid and interpolated onto an elliptic cylinder with $x_{\rm max} = 4$ cm and $y_{\rm max} = 2$ cm.

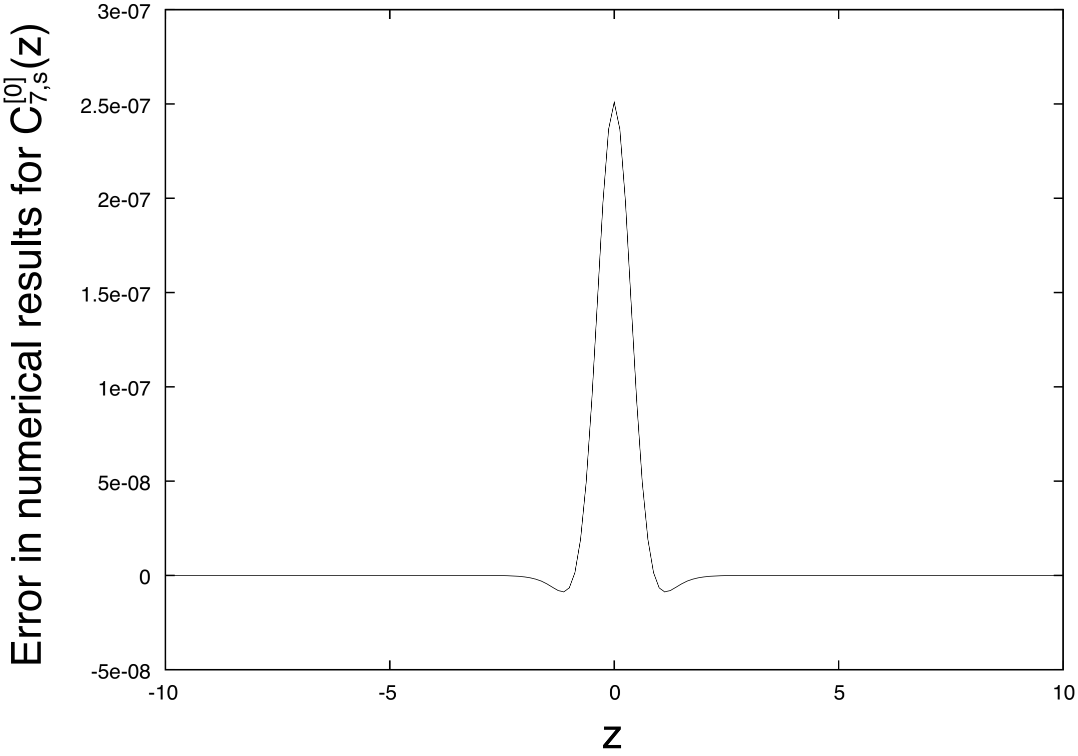

Figure 19.2.27: Difference between exact and completely numerically computed results for $C_{7,s}^{[0]}(z)$ based on field data provided on a grid and interpolated onto an elliptic cylinder with $x_{\max} = 4$ cm and $y_{\max} = 2$ cm..

$$g(\phi) = \sum_{m=-\infty}^{\infty} g_m \exp(im\phi). \tag{19.2.44}$$

Into the vector space of such functions introduce a scalar product by the usual rule

$$(f, g) = [1/(2\pi)] \int_0^{2\pi} d\phi \ \bar{f}(\phi) g(\phi) \tag{19.2.45}$$

where a bar denotes complex conjugation. Show that

$$(f, g) = \sum_{m=-\infty}^{\infty} \bar{f}_m g_m, \tag{19.2.46}$$

which is *Parseval's* theorem for Fourier expansions. Again select N discrete phi values ϕ_n according to the rule (6.1.37), and use these discrete values to define a *discrete* scalar product by the rule

$$(f, g)_{\rm d} = (1/N) \sum_{n=0}^{N-1} \bar{f}(\phi_n) g(\phi_n). \tag{19.2.47}$$

Verify that (2.47) is the discrete version of (2.45). Show that

$$(f, g)_{\rm d} = \sum_{m=-\infty}^{\infty} \sum_{\ell=-\infty}^{\infty} \bar{f}_m g_{m+\ell N}, \tag{19.2.48}$$

which can be rewritten in the form

$$\begin{aligned} (f, g)_{\rm d} &= \sum_{m=-\infty}^{\infty} \bar{f}_m g_m + \sum_{m=-\infty}^{\infty} \sum_{\ell \neq 0} \bar{f}_m g_{m+\ell N} \\ &= (f, g) + \sum_{m=-\infty}^{\infty} \sum_{\ell \neq 0} \bar{f}_m g_{m+\ell N}. \end{aligned} \tag{19.2.49}$$

Thus, $(f, g)_{\rm d}$ is a good approximation to (f, g) provided the f_m and g_m fall off sufficiently rapidly for large $|m|$, and N is sufficiently large, so that the sum in (2.49) can be neglected.

Let us apply these results to the computation of the $\tilde{\tilde{F}}{}_r^s(k)$ as given by (2.21). Employing scalar product notation, we may write (2.21) in the form

$$\tilde{\tilde{F}}{}_r^s(k) = 2({\rm se}_r, \tilde{F}). \tag{19.2.50}$$

We know that the ${\rm se}_r$ have the Fourier expansion(15.5.27), which we rewrite in the complex form

$${\rm se}_r(v, q) = \sum_{m=-\infty}^{\infty} \hat{B}_m^r(q) \exp(imv). \tag{19.2.51}$$

Also, let $\tilde{\tilde{F}}{}^F(m, k)$ denote the *Fourier* coefficients of $\tilde{F}(v, k)$ so that we may write

$$\tilde{F}(v, k) = \sum_{m=-\infty}^{\infty} \tilde{\tilde{F}}{}^F(m, k) \exp(imv). \tag{19.2.52}$$

Then we have the result

$$(\mathrm{se}_r, \tilde{F})_{\mathrm{d}} = (\mathrm{se}_r, \tilde{F}) + \sum_{m=-\infty}^{\infty} \sum_{\ell \neq 0} \bar{\hat{B}}_m^r(q) \tilde{\tilde{F}}^F(m + \ell N, k). \tag{19.2.53}$$

In the next two exercises we will study the large $|m|$ behavior of the Fourier coeficients $\tilde{\tilde{F}}^F(m,k)$ and $\hat{B}_m^r(q)$.

19.2.3. This exercise is a continuation of Exercise 2.2. Here we will examine the falloff of the *Fourier* coefficients of $F(U, v, z)$ and $\tilde{F}(v, k)$ for the monopole doublet example. If you have not already done so, read Exercise 1.3. Here in analogy, we want to view $F(U, v, z)$ as a function of λ, with

$$\lambda = \exp iv, \tag{19.2.54}$$

and locate its singularities in λ.

From (14.4.67) we see that F is analytic in v save for those points where $B_x(U, v, z)$ and $B_y(U, v, z)$ have singularities in v. And from (13.7.4) and (13.7.5) we see that these singularities occur where $\psi(x, y, z)$ as given by (13.7.3) is singular, namely the points where

$$x^2 + (y \pm a)^2 + z^2 = 0. \tag{19.2.55}$$

Use (14.4.1), (14.4.2), and (2.1) through (2.4) to show that (2.25) is equivalent to the condition

$$\sin^2(v) \pm (2a/f)\sinh(U)\sin(v) - \{[f\cosh(U)]^2 + a^2 + z^2\}/f^2 = 0, \tag{19.2.56}$$

which can also be written in the form

$$\sin^2(v) \pm (2ay^{\max}/f^2)\sin(v) - [(x^{\max})^2 + a^2 + z^2]/f^2 = 0. \tag{19.2.57}$$

For the given values of f, $x^{\max}$, $y^{\max}$, and $a = 2.5$, and setting $z = 0$ as before, verify that (2.57) has the solutions

$$\sin(v) = \pm 1.0073, \ \pm 1.84067 \tag{19.2.58}$$

Correspondingly, verify that λ has the values

$$\lambda = \pm 1.12863i, \ \pm .88603i, \ \pm .29533i, \ \pm 3.38601i, \tag{19.2.59}$$

and therefore Λ has the value

$$\Lambda = 1.12863 \tag{19.2.60}$$

and $1/\Lambda$ has the value

$$1/\Lambda = 1/1.12863 = .88603. \tag{19.2.61}$$

Upon comparing (2.61) with (1.53), we see that the Fourier coefficients of $F(U, v, z = 0)$ are expected to fall off less rapidly that those of $B_\rho(R = 2, \phi, z = 0)$. Figure 2.28 displays the function $F(U, v, z = 0)$, with U given by (2.1). Observe that the peaks at $v = \pm\pi/2$ are sharper than those in Figure 13.7.6 for the corresponding case of a circular cylinder. Sharper peaks imply the existence of greater high 'frequency' content, which is consistent with the slower falloff of the Fourier coefficients.

Finally, it can be shown that, like the circular case, Λ is larger when $z \neq 0$. It follows, because the $\tilde{F}(v,k)$ may be viewed as linear combinations of the $F(U,v,z)$, that the $\tilde{\tilde{F}}^F(m,k)$ must also have the asymptotic behavior

$$|\tilde{\tilde{F}}^F(m,k)| \sim (.88603)^{|m|}. \tag{19.2.62}$$

This slower falloff is also consistent with the properties of $\tilde{F}(v,k)$. Figures 2.1 and 2.2 display the functions $\tilde{F}(v,k=0)$ and $\tilde{F}(v,k=20)$. For comparison, Figures 1.23 and 1.24 show $\tilde{B}_\rho(R,\phi,k=0)$ and $\tilde{B}_\rho(R,\phi,k=20)$ for the case of the circular cylinder. We see that the angular behavior is similar, but more peaked in the case of the elliptic cylinder. Since $\tilde{F}(v,k)$ and $\tilde{B}_\rho(R,\phi,k)$ have similar angular behavior, we conclude that the large m behavior of $\tilde{\tilde{F}}^F(m,k)$ and $\tilde{\tilde{B}}_\rho(R,m,k)$ should be similar. However, since the elliptic case is more peaked, we expect the falloff with m will be slower, as observed.

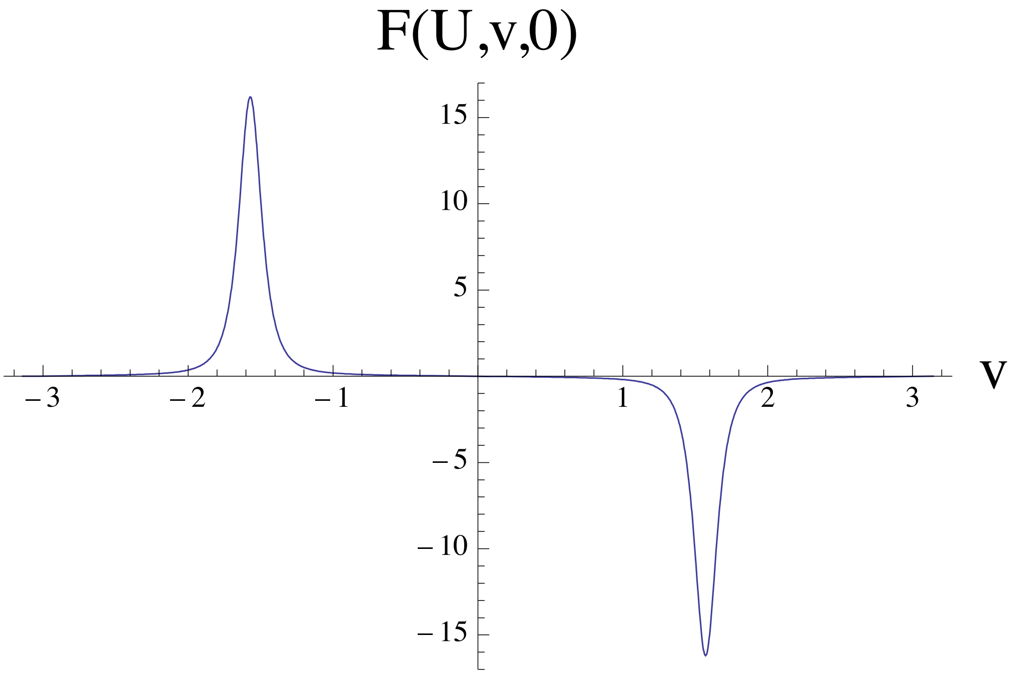

Figure 19.2.28: The quantity $F(U,v,z=0)$ for the monopole doublet in the case that $x^{\max}=4$ cm, $y^{\max}=2$ cm, $a=2.5$ cm, and $g=1$ Tesla-(cm)^2.

19.2.4. This exercise is a continuation of Exercise 2.2. Here we will examine the Fourier coefficients for the Mathieu functions $\mathrm{ce}_r(v,q)$ and $\mathrm{se}_r(v,q)$. That is, we want to study the functions $A^r_m(q)$ and $B^r_m(q)$ given in (15.5.21) and (15.5.27).

When $q=0$ the Mathieu functions become the trigonometric functions. See (14.4.35) through (14.4.37). Consequently, we have the results

$$A^r_m(0) = \delta_{mr} \text{ when } m \neq 0, \tag{19.2.63}$$

$$A^r_m(0) = \sqrt{2}\delta_{mr} \text{ when } m = 0, \tag{19.2.64}$$

$$B_m^r(0) = \delta_{mr} \text{ with } m, r \geq 1. \tag{19.2.65}$$

For $q \neq 0$ the $A_m^r(q)$ and $B_m^r(q)$ need to be computed numerically, and the methods of Section 15.5.3 are convenient for doing so.

From (15.5.22) and (15.5.28), and applying the logic of Exercise 1.3, we see that as $m \to \infty$ the $A_m^r(q)$ and $B_m^r(q)$, for fixed q and r, must fall off faster than $(1/\Lambda)^m$ for any $\Lambda > 1$ because the Mathieu functions $\mathrm{ce}_r(v, q)$ and $\mathrm{se}_r(v, q)$ are entire functions of v. This is good news, but we still would like to know how large m must be for this asymptotic behavior to set in. We will see that the answer to this question depends on q.

For simplicity, let us study the behavior of $B_m^r(q)$ as a function of m and q for the case $r = 7$, which is relevant to the case of the magnetic monopole doublet. Table 2.1 lists the values of $B_m^7(q)$ for various values of m and q. We see that, as q becomes more negative, the m value for which $|B_m^7(q)|$ peaks becomes ever larger. This is because, as q becomes ever more negative, more and more of the v axis is forbidden. See Section 14.4.4. However, we also know that $\mathrm{se}_7(v, q)$ must have 7 zeroes in the half-open interval $v \in [0, \pi)$. Thus, these oscillations are crowded into an ever smaller regions about 0 and $\pm\pi$, therefore leading to ever higher effective frequencies of oscillation.

Table 19.2.1: The coefficients $B_m^7(q)$.

We saw on Exercise 2.2 that the discrete scalar product (discrete angular Riemann sum) is a good approximation to the true scalar product if N is sufficiently large such that

$$\tilde{\tilde{F}}^F(m, k) \approx 0 \text{ for } m \geq N \tag{19.2.66}$$

and

$$B_m^r(q) \approx 0 \text{ for } m \geq N \tag{19.2.67}$$

with $k \in [-K_c, K_c]$ and r being within its required range. See (2.53). In our benchmarking we have set $N = 120$. Verify that $(.88603)^{120} = 4.9 \times 10^{-7}$ so that, in view of (2.62), (2.66) is well satisfied. We next have to worry about the condition (2.67). From Table 2.1 we infer that $B_m^7(q = -50)$ begins to fall off rapidly with increasing m for m somewhat greater than 17, and $B_m^7(q = -300)$ begins to fall off rapidly with increasing m for m somewhat greater than 29. Assuming this trend continues as q becomes ever more negative, estimate by linear extrapolation that $B_m^7(q = -1200)$ begins to fall off rapidly with increasing m for m somewhat greater than 72. Also, we know that the largest r value we are interested in is $r_{\max}(7) = 29$. Therefore we might infer that $B_m^{29}(q = -1200)$ begins to fall of rapidly for m somewhat larger than $72 + (29 - 7) = 94$. Since 120 is significantly larger than 94, we infer that (2.67) should also be well satisfied for the choice $N = 120$.

These expectations are verified by the following calculations: Let ${}^N\tilde{\tilde{F}}_r^s(k)$ denote the result of the Riemann sum (2.93), and let

$$ {}^\infty\tilde{\tilde{F}}_r^s(k) = \tilde{\tilde{F}}_r^s(k) \tag{19.2.68}$$

denote its $N \to \infty$ limit given by the integral (2.21). Figure 2.29 shows the quantity ${}^\infty\tilde{\tilde{F}}_{29}^s(k)$ obtained by careful numerical evaluation of the integral in (2.21) when $r = 29$. En passant, we also take this opportunity to show in Figure 2.30 the base 10 logarithm of the three quantities $[-{}^\infty\tilde{\tilde{F}}_{29}^s(k)]$, $[\sqrt{2}||\tilde{F}||]$, and $[\sqrt{2}|\tilde{F}(\pi/2, k)|]$ to illustrate the inequalities (2.32) and (2.35). More to the point of this exercise, Figures 2.31 through 2.33 show the error quantities

$$ {}^N\tilde{\tilde{F}}_{29}^s(k) \; - \; {}^\infty\tilde{\tilde{F}}_{29}^s(k) $$

for $N = 40, 80,$ and 120. We see that the error decreases rapidly with increasing N, and is less than 6 parts in 10^4 when $N = 120$. Indeed, further calculation shows that the error is approximately 4 parts in 10^6 when $N = 160$.

19.2.5. Show that the quantities B_m^n comprise the entries of an infinite orthogonal matrix.

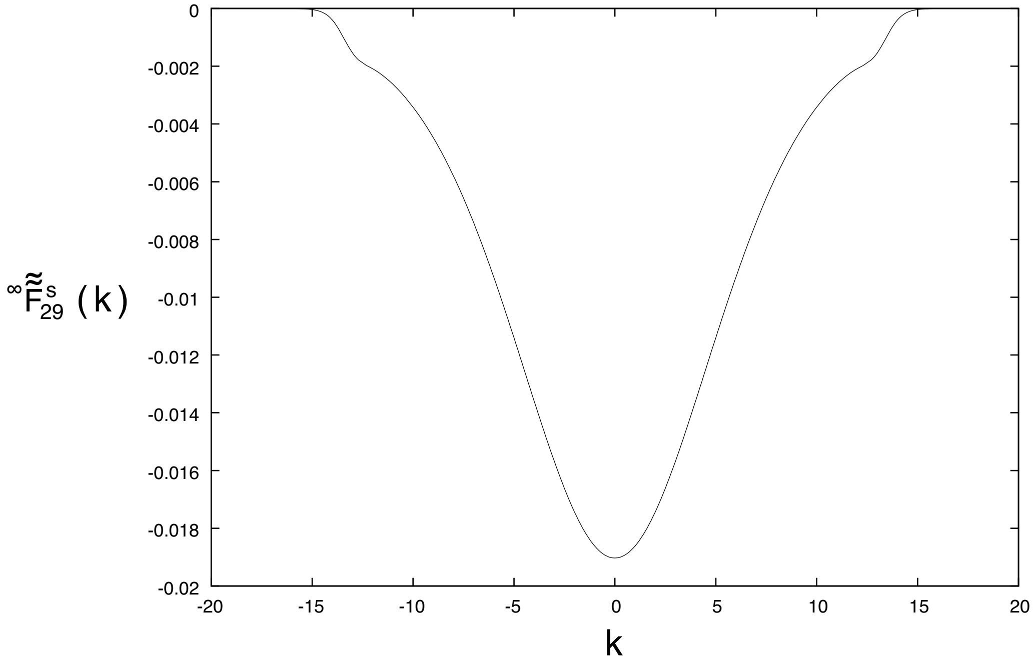

Figure 19.2.29: Real part of $^{\infty}\tilde{\tilde{F}}^{s}_{29}(k)$. The imaginary part vanishes.

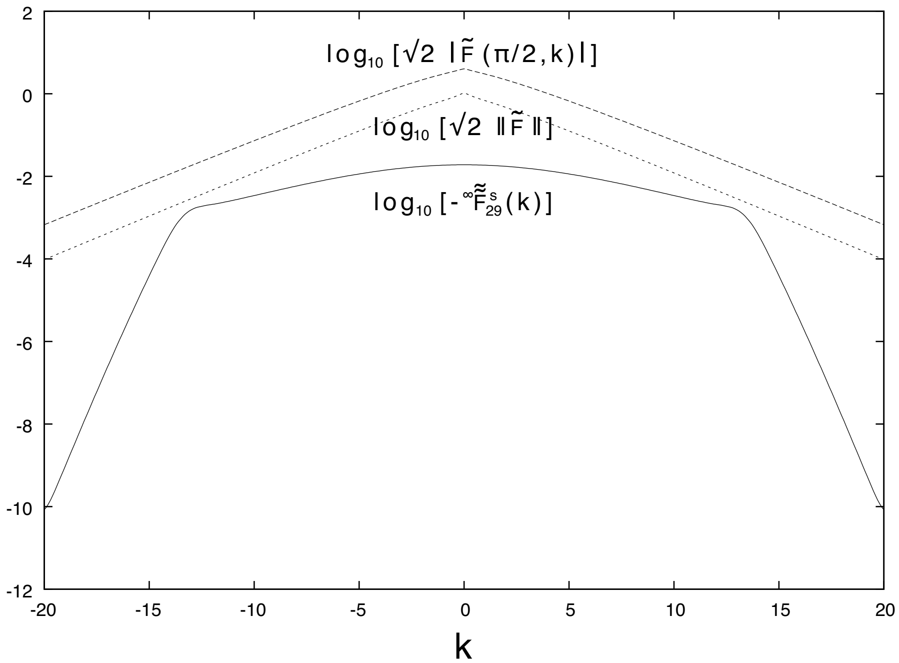

Figure 19.2.30: The base 10 logarithm of three quantities. The quantity $\log_{10}[\sqrt{2}|\tilde{F}(\pi/2,k)|]$ is the top curve. The middle curve is the quantity $\log_{10}[\sqrt{2}||\tilde{F}||]$, and the bottom curve is $\log_{10}[-^{\infty}\tilde{\tilde{F}}^{s}_{29}(k)]$. Together they illustrate the inequalities (2.32) and (2.35).

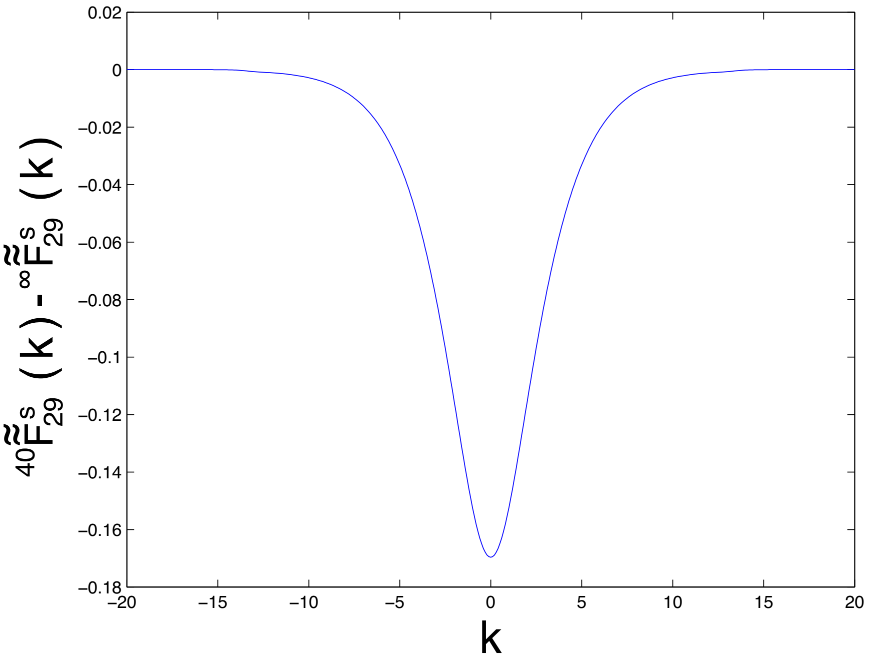

Figure 19.2.31: Real part of the error quantity ${}^{N}\tilde{\tilde{F}}^{s}_{29}(k) - {}^{\infty}\tilde{\tilde{F}}^{s}_{29}(k)$ for $N = 40$. The imaginary part vanishes.

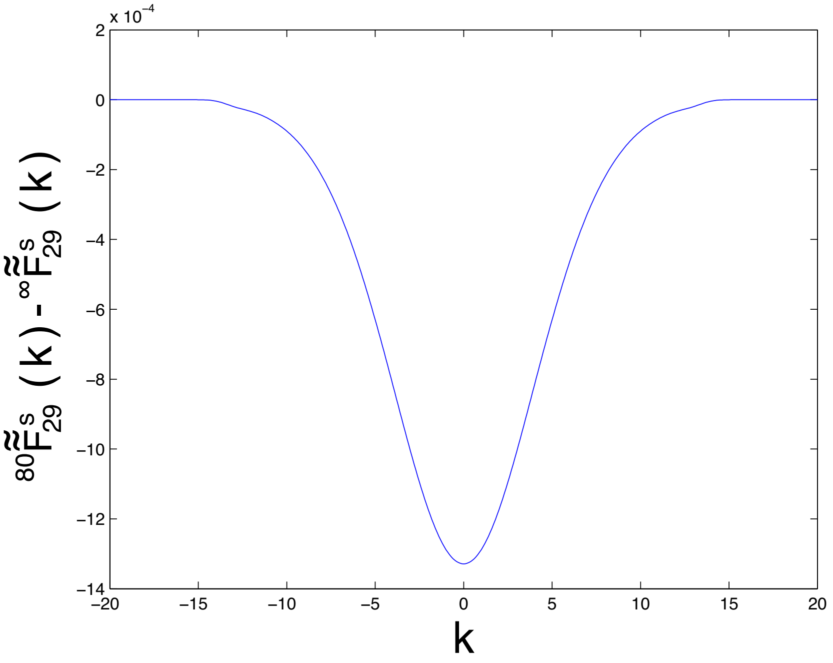

Figure 19.2.32: Real part of the error quantity ${}^{N}\tilde{\tilde{F}}^{s}_{29}(k) - {}^{\infty}\tilde{\tilde{F}}^{s}_{29}(k)$ for $N = 80$. The imaginary part vanishes.

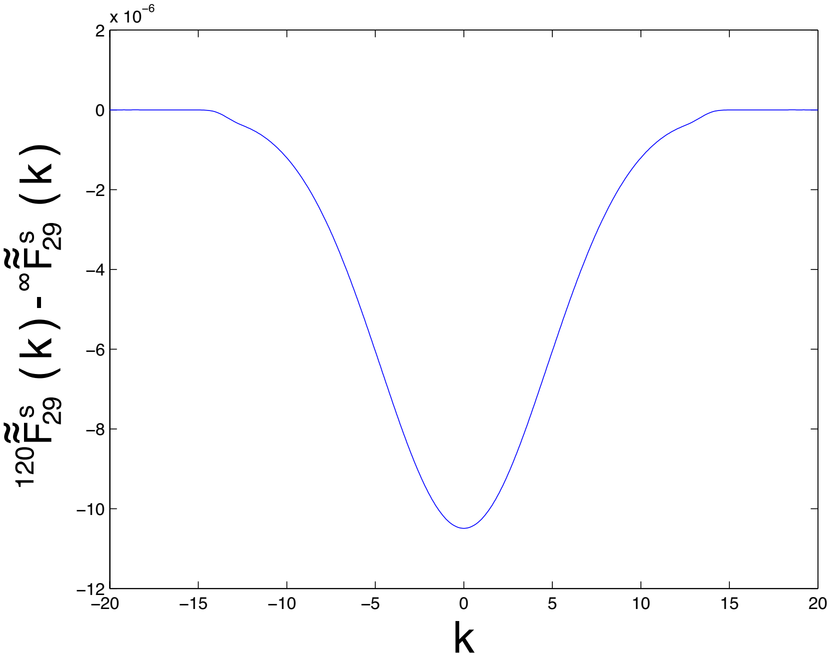

Figure 19.2.33: Real part of the error quantity ${}^{N}\tilde{\tilde{F}}^{s}_{29}(k) - {}^{\infty}\tilde{\tilde{F}}^{s}_{29}(k)$ for $N = 120$. The imaginary part vanishes.

Chapter 20

Smoothing and Insensitivity to Errors

20.1 Introduction

In the previous Chapters 13 and 14 mention was made of the smoothing feature of surface methods. In this chapter we will explore the smoothing behavior of surface methods in more detail.

By way of introduction, imagine for simplicity that we initially use the surface of a circular cylinder. Suppose there are measurement or computational errors in the radial surface field values $B_\rho(\rho = R, \phi, z)$. What effect do these errors have on the determination of the generalized on-axis gradients and their derivatives? We will see that due to smoothing the effect of these errors is rather mild.

20.1.1 Preliminary Considerations

The relative insensitivity of surface methods to errors arises from a basic property of solutions to Laplace's equation: the value of ψ at some interior point is an appropriately weighted average of its values over any surrounding boundary. Consequently, ψ is smoother in the interior of a region than it may be on a boundary of this region. Correspondingly, errors in boundary values are averaged.

Something can also be said about surface methods and fitting errors. Suppose ψ is a *harmonic* function (satisfies $\nabla^2\psi = 0$) in some domain $\mathcal{D}$. Then, it can be shown that ψ assumes its maxima and minima on the *boundary* of $\mathcal{D}$. Imagine that $\psi^{\rm exact}$ is the true scalar potential and $\psi^{\rm approx}$ is some approximation to it. We know that $\psi^{\rm exact}$ is harmonic, and suppose that $\psi^{\rm approx}$ has been constructed to be harmonic. Then we know that $\psi^{\rm error} = \psi^{\rm approx} - \psi^{\rm exact}$ is harmonic. Therefore the magnitude of the error must be largest on the boundary of $\mathcal{D}$. However, if we do a good job of fitting $\psi^{\rm exact}$ by $\psi^{\rm approx}$ on the boundary of $\mathcal{D}$, then the error on the boundary will be small. And, thanks to $\psi^{\rm error}$ being harmonic, the error in the interior of $\mathcal{D}$ will be even smaller.

20.1.2 Analyticity

For a preliminary exploration of smoothing, suppose, for example, that the magnetic field is produced by an iron-dominated magnet, and is therefore localized in space. In this case the integrals (14.3.2) can be considered to have, in practice, finite limits of integration. With some care, an effective cut-off can also be found even if the fields extend to infinity since they fall off sufficiently rapidly at infinity. Also, since the generalized Bessel function I_m' increases exponentially as described by (14.3.9), there is also, in effect, a cut-off in k for the integrals (14.3.8) defining the generalized gradients.

Next suppose that the $\tilde{B}_\rho(R, m', z)$ are absolutely integrable,

$$\int_{-\infty}^{\infty} dz |\tilde{B}_\rho(R, m', z)| < \infty. \tag{20.1.1}$$

This will certainly be the case if $B_\rho(R, \phi, z)$ and hence the $\tilde{B}_\rho(R, m', z)$ are localized in z space. It follows from (14.3.2) that the Fourier transforms $\tilde{\tilde{B}}_\rho(R, m', k')$ are then bounded,

$$|\tilde{\tilde{B}}_\rho(R, m', k')| < [1/(2\pi)] \int_{-\infty}^{\infty} dz |\tilde{B}_\rho(R, m', z)| < \infty. \tag{20.1.2}$$

Now look at the integral representations (14.3.8) for the generalized gradients. We see that, due to the bounds (1.2) and the fall off in k at infinity produced by the $I_m'(kR)$ denominators, the integrals (14.3.8) are absolutely convergent in the domain

$$\Re(z) \in (-\infty, \infty)\ ,\ \Im(z) \in (-R, R). \tag{20.1.3}$$

Thus, under very mild assumptions about the surface data $B_\rho(\rho = R, \phi, z)$, including the possibility of errors, we conclude that the generalized gradients are *analytic* in the strip (1.3). Note that commonly used fringe-field models, those that assume constant (z independent) fields for z within the body of a magnet, zero fields outside beyond the fringe-field regions, and interpolating linear ramps in the fringe-field regions, violate this analyticity property because of singularities in the first derivative at the beginnings and ends of the ramps. These models are therefore unphysical, and their use could lead to erroneous conclusions.

20.1.3 Equivalent Spatial Kernel

In Section 14.3 the on-axis gradients were related to fields on the surface of a circular cylinder by various Fourier transform operations. We will now see that, for the circular cylinder case, they can also be viewed as being related by integration against a spatial kernel. Later, analogous results will be found for the cases of elliptic and rectangular cylinders.

Begin by relabeling variables so that (14.3.14) through (14.3.16) take (for $m > 0$) the form

$$\tilde{\tilde{B}}_\rho^\alpha(R, m, k) = [1/(2\pi)] \int_{-\infty}^{\infty} dz' \exp(-ikz') \tilde{B}_\rho^\alpha(R, m, z') \tag{20.1.4}$$

with

$$\tilde{B}_\rho^s(R, m, z') = (1/\pi) \int_0^{2\pi} d\phi \sin(m\phi) B_\rho(R, \phi, z'), \tag{20.1.5}$$

$$\tilde{B}_\rho^c(R, m, z') = (1/\pi) \int_0^{2\pi} d\phi \cos(m\phi) B_\rho(R, \phi, z'), \tag{20.1.6}$$

and (again for $m > 0$) (14.3.23) takes the form

$$C_{m,\alpha}^{[n]}(z) = i^n(1/2)^m(1/m!)\int_{-\infty}^{\infty} dk[k^{n+m-1}/I_m'(kR)]\tilde{\tilde{B}}_\rho^\alpha(R,m,k)\exp(ikz). \quad (20.1.7)$$

Our goal is to re-express the relations (1.4) and (1.7) in terms of a spatial kernel.

To do this, insert (1.4) into (1.7) to find the relation

$$\begin{aligned}
&C_{m,\alpha}^{[n]}(z) = [1/(2\pi)]i^n(1/2)^m(1/m!) \times \\
&\int_{-\infty}^{\infty} dk[k^{n+m-1}/I_m'(kR)]\exp(ikz)\int_{-\infty}^{\infty} dz'\exp(-ikz')\tilde{B}_\rho^\alpha(R,m,z') \\
&= [1/(2\pi)]i^n(1/2)^m(1/m!) \times \\
&\int_{-\infty}^{\infty} dz'\tilde{B}_\rho^\alpha(R,m,z')\int_{-\infty}^{\infty} dk[k^{n+m-1}/I_m'(kR)]\exp(ikz)\exp(-ikz') \\
&= [1/(2\pi)]i^n(1/2)^m(1/m!) \times \\
&\int_{-\infty}^{\infty} dz'\tilde{B}_\rho^\alpha(R,m,z')\int_{-\infty}^{\infty} dk[k^{n+m-1}/I_m'(kR)]\exp[ik(z-z')]. \quad (20.1.8)
\end{aligned}$$

Define the kernel $K_m^{[n]}$ by the rule

$$K_m^{[n]}(z,z') = [1/(2\pi)]i^n(1/2)^m(1/m!)\int_{-\infty}^{\infty} dk[k^{n+m-1}/I_m'(kR)]\exp[ik(z-z')]. \quad (20.1.9)$$

With this definition, we may rewrite (1.8) in the form

$$C_{m,\alpha}^{[n]}(z) = \int_{-\infty}^{\infty} dz' K_m^{[n]}(z,z')\tilde{B}_\rho^\alpha(R,m,z'). \quad (20.1.10)$$

That is, $C_{m,\alpha}^{[n]}(z)$ has been expressed as the result of integrating $\tilde{B}_\rho^\alpha(R,m,z')$ against the spatial kernel $K_m^{[n]}(z,z')$.

Let us now explore the properties of $K_m^{[n]}$. In the definition (1.9) make the substitution

$$\lambda = kR \text{ or } k = \lambda/R. \quad (20.1.11)$$

So doing gives the result

$$K_m^{[n]}(z,z') = [1/(2\pi)]i^n(1/2)^m(1/m!)(1/R)^{n+m}\int_{-\infty}^{\infty} d\lambda[\lambda^{n+m-1}/I_m'(\lambda)]\exp[i\lambda(z-z')/R]. \quad (20.1.12)$$

Staring at (1.12) suggests writing

$$K_m^{[n]}(z,z') = (1/R)^{n+m}L_m^{[n]}(\Delta) \quad (20.1.13)$$

where

$$\Delta = (z-z')/R \quad (20.1.14)$$

and

$$L_m^{[n]}(\Delta) = [1/(2\pi)]i^n(1/2)^m(1/m!)\int_{-\infty}^{\infty} d\lambda[\lambda^{n+m-1}/I'_m(\lambda)]\exp(i\lambda\Delta). \tag{20.1.15}$$

We observe, consistent with the notation being employed, that there is the relation

$$L_m^{[n]}(\Delta) = (\partial_\Delta)^n L_m^{[0]}(\Delta). \tag{20.1.16}$$

We also observe that the integrand factor $[\lambda^{m-1}/I'_m(\lambda)]$ appearing in

$$L_m^{[0]}(\Delta) = [1/(2\pi)](1/2)^m(1/m!)\int_{-\infty}^{\infty} d\lambda[\lambda^{m-1}/I'_m(\lambda)]\exp(i\lambda\Delta) \tag{20.1.17}$$

is *even* in λ. It follows that the $L_m^{[n]}(\Delta)$, and hence also the $K_m^{[n]}(z,z')$, are purely real. Moreover, the $L_m^{[0]}(\Delta)$ are even in Δ.

Graphs of some of the functions $L_m^{[n]}(\Delta)$ are shown in Figures 1.1 through 1.3 below. Before commenting on them, it is also useful to examine the integrands $\tilde{L}_m^{[0]}(\lambda)$, which are the Fourier transforms of the $L_m^{[0]}(\Delta)$, defined by the relations

$$\tilde{L}_m^{[0]}(\lambda) = [1/(2\pi)](1/2)^m(1/m!)[\lambda^{m-1}/I'_m(\lambda)]. \tag{20.1.18}$$

Some of them are displayed in Figures 1.4 and 1.5. Again we recall the asymptotic behavior

$$|I'_m(\lambda)| \sim \exp(|\lambda|)/\sqrt{2\pi|\lambda|} \text{ as } |\lambda| \to \infty, \tag{20.1.19}$$

from which we conclude that the $\tilde{L}_m^{[0]}(\lambda)$ essentially vanish exponentially at infinity.

What insights can be gained from examining Figures 1.1 through 1.5? First, we observe from Figure 1.3 that the $L_m^{[0]}$ become ever narrower with increasing m. Correspondingly, in accord with the uncertainty principle relating Fourier transform pairs, Figure 1.5 shows that the $\tilde{L}_m^{[0]}$ become ever broader with increasing m.

Next, from (1.10), we see that it is desirable that the $K_m^{[0]}(z,z')$ be slowly varying in z', because then noise in $\tilde{B}_\rho^\alpha(R,m,z')$ will be averaged over a large interval in z'. From (1.14) and Figure 1.3 we see that the $K_m^{[0]}(z,z')$ will be more nearly constant in z' the larger the value of R, and therefore there is ever more smoothing in z' as R is increased. We have already observed that the $L_m^{[0]}$ become somewhat narrower as m increases. Therefore there is somewhat less smoothing in z' for larger m. However, there is still ever more smoothing in z' as R is increased. Also, inspection of (1.13) shows that there is a $(1/R)^{n+m}$ factor relating $K_m^{[n]}$ and $L_m^{[n]}$. When the associated $C_{m,\alpha}^{[n]}$ are used in (13.2.37) or analogous expansions for $\boldsymbol{A}$, it is evident that the effective dimensionless expansion factor is $(\rho/R)^{n+m}$. Thus, although there is somewhat less smoothing in z' for larger m, there is increased suppression of high angular harmonic noise, and moreover this suppression is enhanced as R is increased. We also observe that there is increased suppression of high angular harmonic noise as n is increased.

Finally, let us examine smoothing from the perspective of k space. In the integral (1.7) make the change of variables

$$\lambda = kR \tag{20.1.20}$$

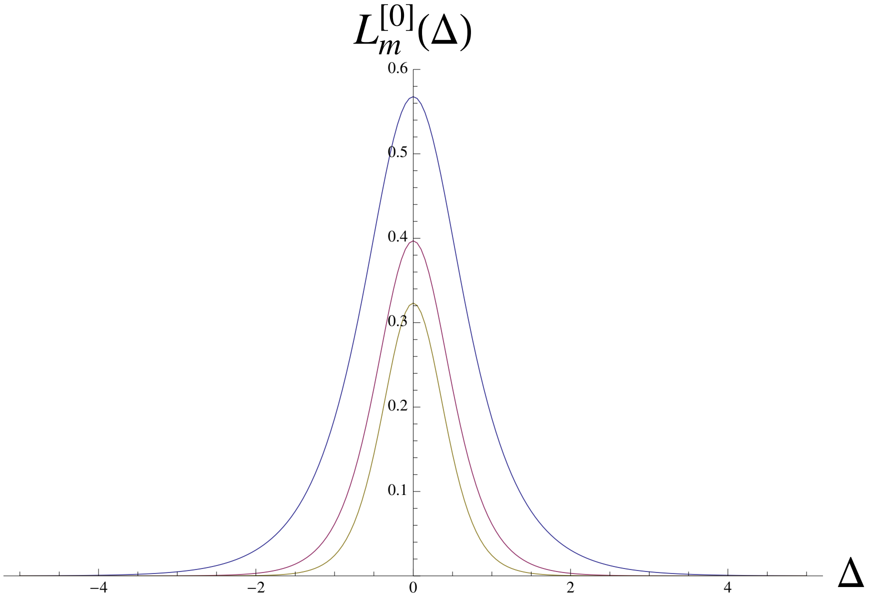

Figure 20.1.1: The spatial kernels $L_1^{[0]}(\Delta)$ through $L_3^{[0]}(\Delta)$. For $\Delta = 0$, the kernels $L_m^{[0]}(\Delta)$ decrease with increasing m.

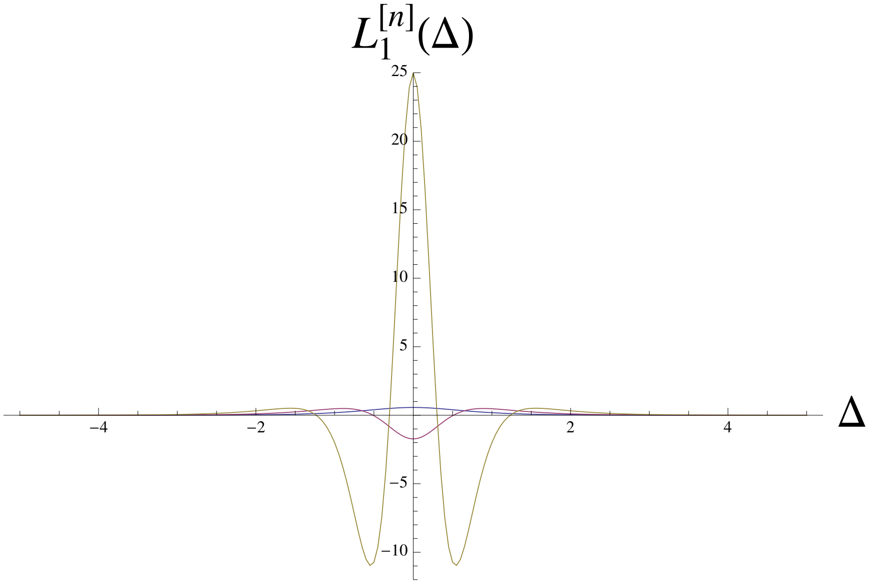

Figure 20.1.2: The spatial kernels $L_1^{[n]}(\Delta)$ for $n = 0, 2, 4$. Note that they satisfy (1.16). In particular, they have n zeroes.

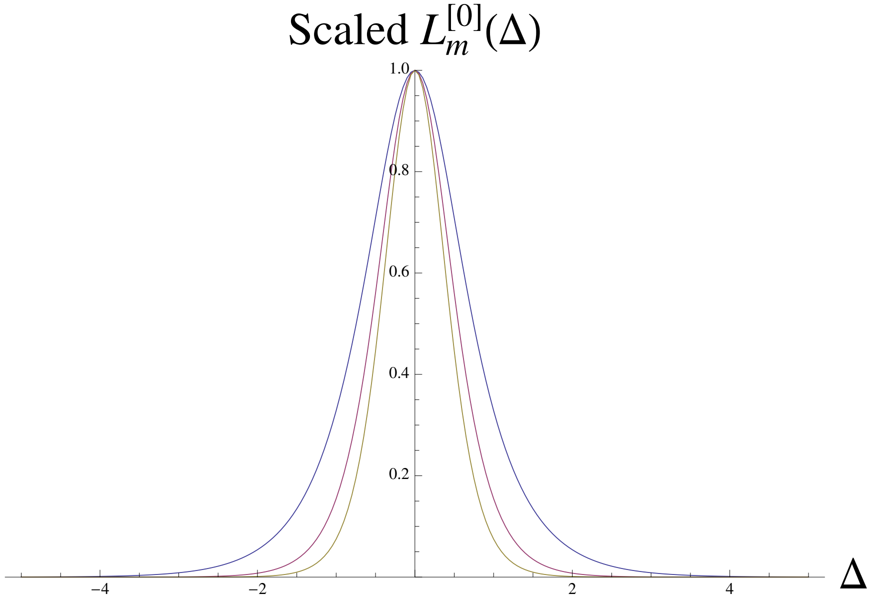

Figure 20.1.3: The *scaled* spatial kernels $L_1^{[0]}(\Delta)$ through $L_3^{[0]}(\Delta)$, all normalized to 1 at $\Delta = 0$. The scaled $L_m^{[0]}$ become ever narrower with increasing m.

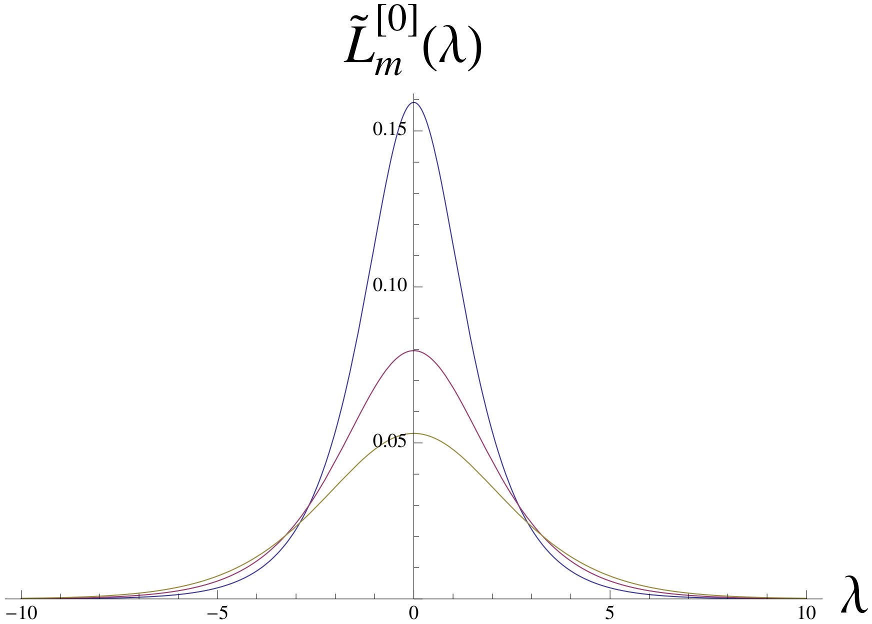

Figure 20.1.4: The integrands $\tilde{L}_m^{[0]}(\lambda)$ for $m = 1, 2, 3$. For $\lambda = 0$, the integrands decrease with increasing m.

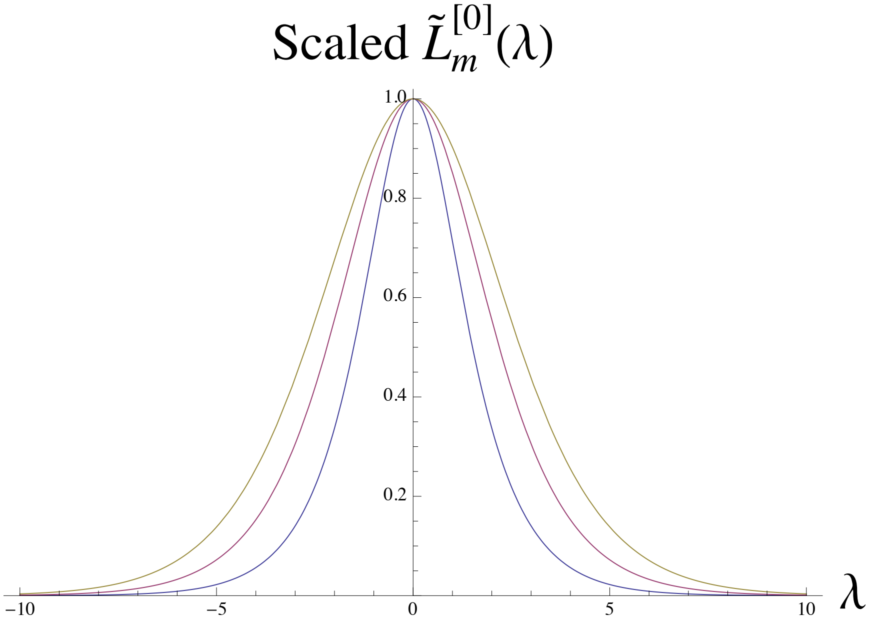

Figure 20.1.5: The *scaled* integrands $\tilde{L}_m^{[0]}(\lambda)$ for $m = 1, 2, 3$, all normalized to 1 at $\lambda = 0$. The scaled integrands become ever broader with increasing m.

to find the result

$$C_{m,\alpha}^{[n]}(z) = (1/R)^{n+m} i^n (1/2)^m (1/m!) \int_{-\infty}^{\infty} d\lambda [\lambda^{n+m-1}/I'_m(\lambda)] \tilde{\tilde{B}}_\rho^\alpha(R, m, \lambda/R) \exp(i\lambda z/R). \tag{20.1.21}$$

With the aid of the definition (1.18) this result can be rewritten in the form

$$C_{m,\alpha}^{[n]}(z) = 2\pi i^n (1/R)^{n+m} \int_{-\infty}^{\infty} d\lambda \tilde{L}_m^{[n]}(\lambda) \tilde{\tilde{B}}_\rho^\alpha(R, m, \lambda/R) \exp(i\lambda z/R). \tag{20.1.22}$$

Consider, for example, the case $n = 0$. Since the $\tilde{L}_m^{[0]}(\lambda)$ are peaked about $\lambda = 0$, we have the approximate result

$$\tilde{L}_m^{[0]}(\lambda) \tilde{\tilde{B}}_\rho^\alpha(R, m, \lambda/R) \approx \tilde{L}_m^{[0]}(\lambda) \tilde{\tilde{B}}_\rho^\alpha(R, m, 0), \tag{20.1.23}$$

and this result becomes ever more exact the larger the value of R. From (1.4) we see that evaluating $\tilde{\tilde{B}}_\rho^\alpha(R, m, k)$ for $k \approx 0$ essentially amounts to averaging $\tilde{B}_\rho^\alpha(R, m, z')$ over z', thereby suppressing the effect of noise. From Figure 1.5 we see that this smoothing in z' becomes somewhat less effective with increasing m because then the $\tilde{L}_m^{[0]}(\lambda)$ are less peaked about $\lambda = 0$. But again there is a $(1/R)^{n+m}$ factor that comes into play so that the effective dimensionless expansion factor is again $(\rho/R)^{n+m}$. Thus, although there is somewhat less smoothing in z' for larger m, there is increased suppression of high angular harmonic noise as n and m are increased, and again this suppression is further enhanced as R is increased.

20.1.4 What Work Lies Ahead

We will now study smoothing and insensitivity to errors in more detail depending on what surface is used. We will do so for the monopole-doublet examples treated in Sections 16.1 through 16.3, but our conclusions will be general. Section 17.2 treats the use of circular cylinders, and Sections 17.3 and 17.4 treat the use of elliptic and rectangular cylinders.

Exercises

20.1.1. Show that the on-axis gradients associated with the magnetic monopole doublet and given by (13.7.33) are analytic in the domain (1.3), and have singularities on the boundary. Show that the same is true for the on-axis gradient associated with the air-core solenoid of Section 11.11.

20.1.2. Verify that that the integrand factor $[\lambda^{m-1}/I'_m(\lambda)]$ is *even* in λ, and therefore the $L_m^{[n]}(\Delta)$, and also the $K_m^{[n]}(z,z')$, are purely real. Verify that the $L_m^{[0]}(\Delta)$ are even in Δ.

20.2 Circular Cylinders

Review Section 16.1.3 that described, for the monopole-doublet test case and the use of the surface of a circular cylinder, the calculation of on-axis gradients based on field data provided on a grid. Suppose we add to the field data at each grid point small random field components in the x and y directions.[1] What will be the effect of this noise on the on-axis gradients? We could use the noisy data to compute the on-axis gradients, and compare the results with those obtained in the absence of noise (and which we know agree very well with exact results). However, observe that the on-axis gradients are *linear* functions of the input field values on the grid points. Therefore, we can just as well compute the on-axis gradients that arise from *pure* noise without any background field. Doing so will give us better insight. If these purely noise-generated on-axis gradients are small compared to those for the noise-free data, then we will know that the effect of noise is small.

How shall we assign random field values to each grid point? Suppose the grid points are numbered from 1 to N. For example, in the calculation described in Section 16.1.3, $N = 11,527,201$. Let (x_j, y_j, z_j) be the coordinates of the j^{th} grid point. Let $B_y(0,0,z)$ be the vertical on-axis field arising from the monopole doublet and displayed in Figure 13.7.3. To model noise we make the Ansätze

$$B_x^{\text{noise}}(x_j, y_j, z_j) = \epsilon B_y(0,0,z_j)\delta_x(j), \tag{20.2.1}$$

$$B_y^{\text{noise}}(x_j, y_j, z_j) = \epsilon B_y(0,0,z_j)\delta_y(j). \tag{20.2.2}$$

Here the $\delta_x(j)$ and $\delta_y(j)$ are random numbers uniformly distributed in the interval $[-1, 1]$, and we set $\epsilon = .01$. By this prescription we produce a random field that is proportional, at

[1] Note, as observed earlier, that the z component of the field makes no contributions to the on-axis gradients.

the 1% level, to the strength of the monopole-doublet on-axis vertical field.[2]

The first step in the purely numerical calculation is to interpolate the field onto the surface of the cylinder and find its normal component at each of the cylinder sampling points. Figures 2.1 and 2.2 show the resulting $B_\rho(R, \phi, z = 0)$ for two different random number seeds. Compare with Figure 13.7.6. Correspondingly, Figures 2.3 and 2.4 show $B_\rho(R, \phi = \pi/2, z)$. Compare with Figure 13.7.7. We see that the surface field is noisy as expected, and the noise field falls to zero as $z \to \pm\infty$ because $B_y(0, 0, z)$ does so.

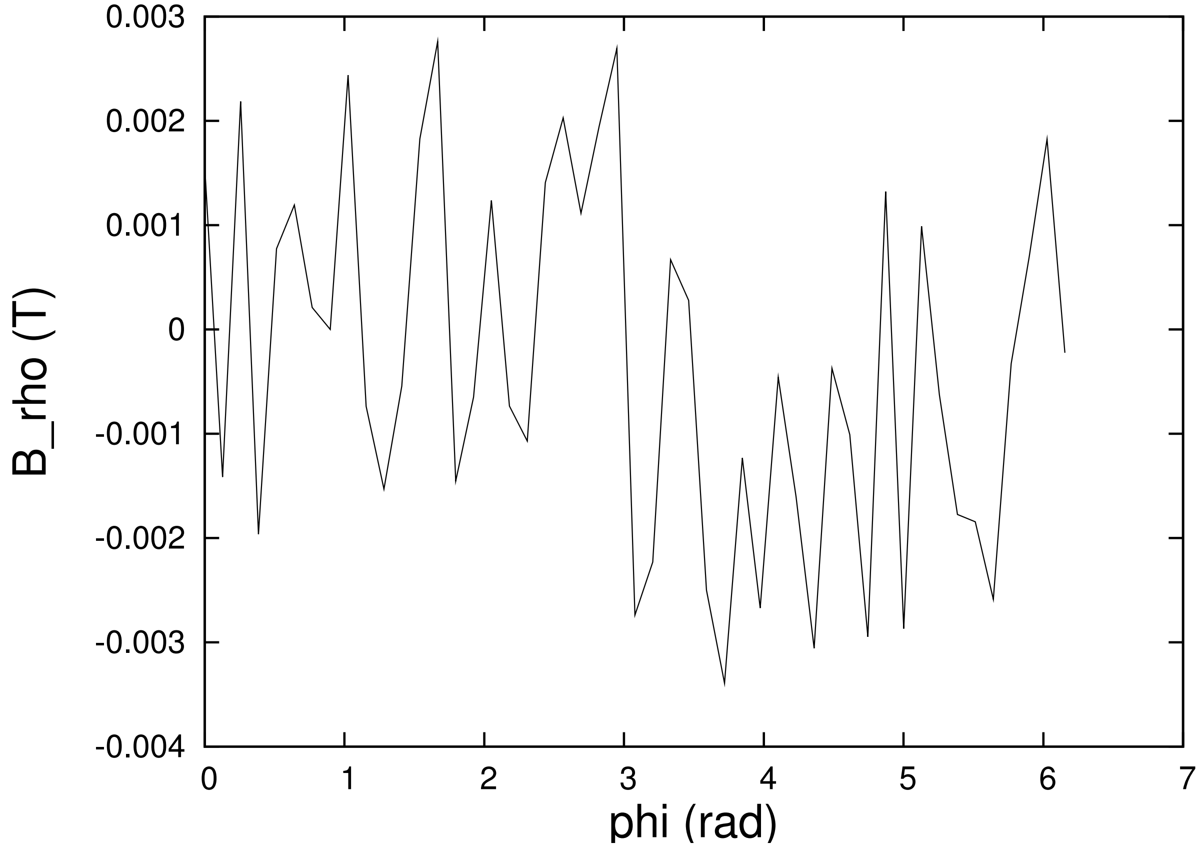

Figure 20.2.1: The function $B_\rho(R, \phi, z = 0)$ produced by a pure noise field.

Suppose, for example, that we now wish to compute the $C^{[0]}_{1,s}(z)$ produced by the pure noise field. Then, according to (14.3.23), we first need to compute $\tilde{\tilde{B}}^s_\rho(R, m = 1, k)$. And, because no particular symmetry is assumed for the noise, $\tilde{\tilde{B}}^s_\rho(R, m = 1, k)$ will have both real and imaginary parts. Figures 2.5 and 2.6 display the real parts for the two different choices of random number seed. [The imaginary parts behave analogously. They no longer vanish because $\tilde{B}^s_\rho(R, m = 1, z)$ for the noise is not assumed to be even in z.] In both cases

[2] This would be the general procedure. Actually, for this study, we generate a random field at all the $N = 20, 937, 161$ points described in Section 16.2.6; but, of course, only those required for interpolation onto the surface of the circular cylinder are actually used. We do this because in Section 17.3 we want to compare the use of circular and elliptic cylinders, and for this purpose we want to have a common data base. Note that the grid points described in Section 16.1.3 are a subset of those described in Section 16.2.6.

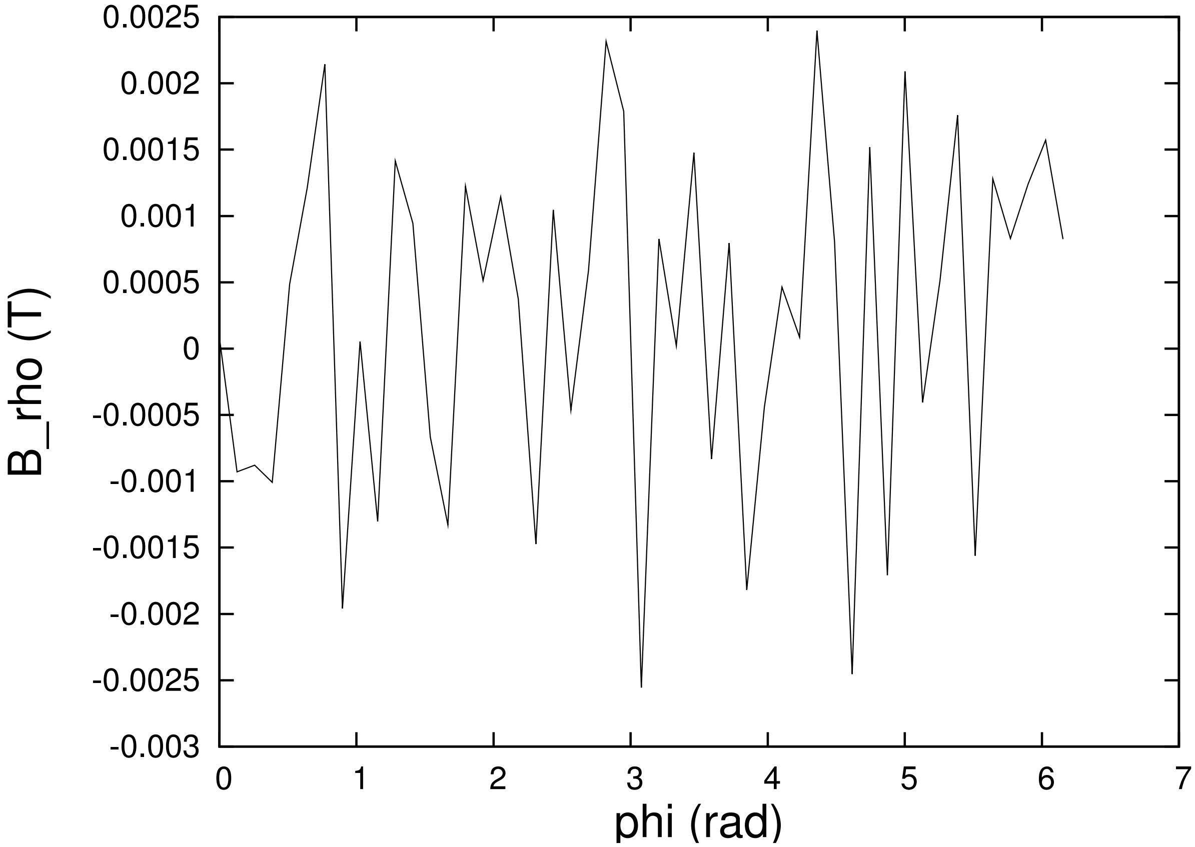

Figure 20.2.2: The function $B_\rho(R, \phi, z = 0)$ produced by a pure noise field arising from a second different random number seed.

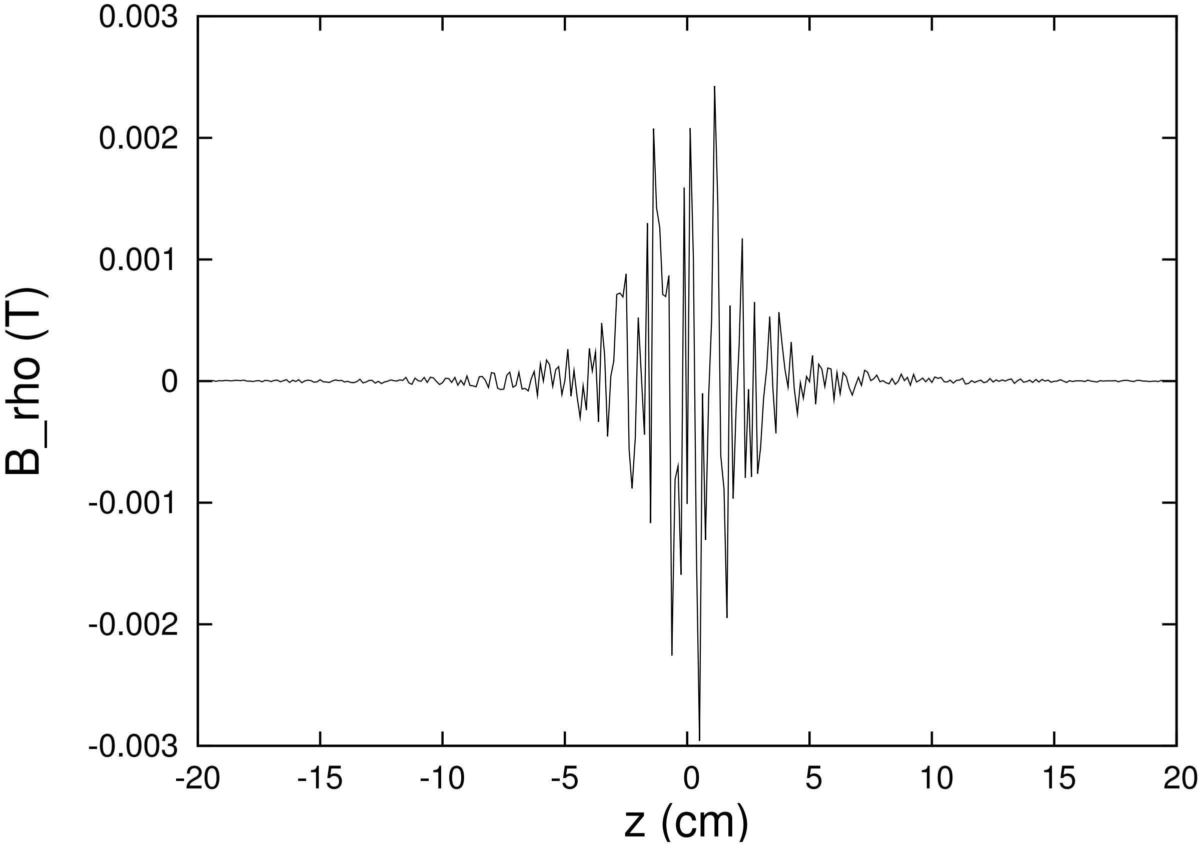

Figure 20.2.3: The function $B_\rho(R, \phi = \pi/2, z)$ produced by a pure noise field.

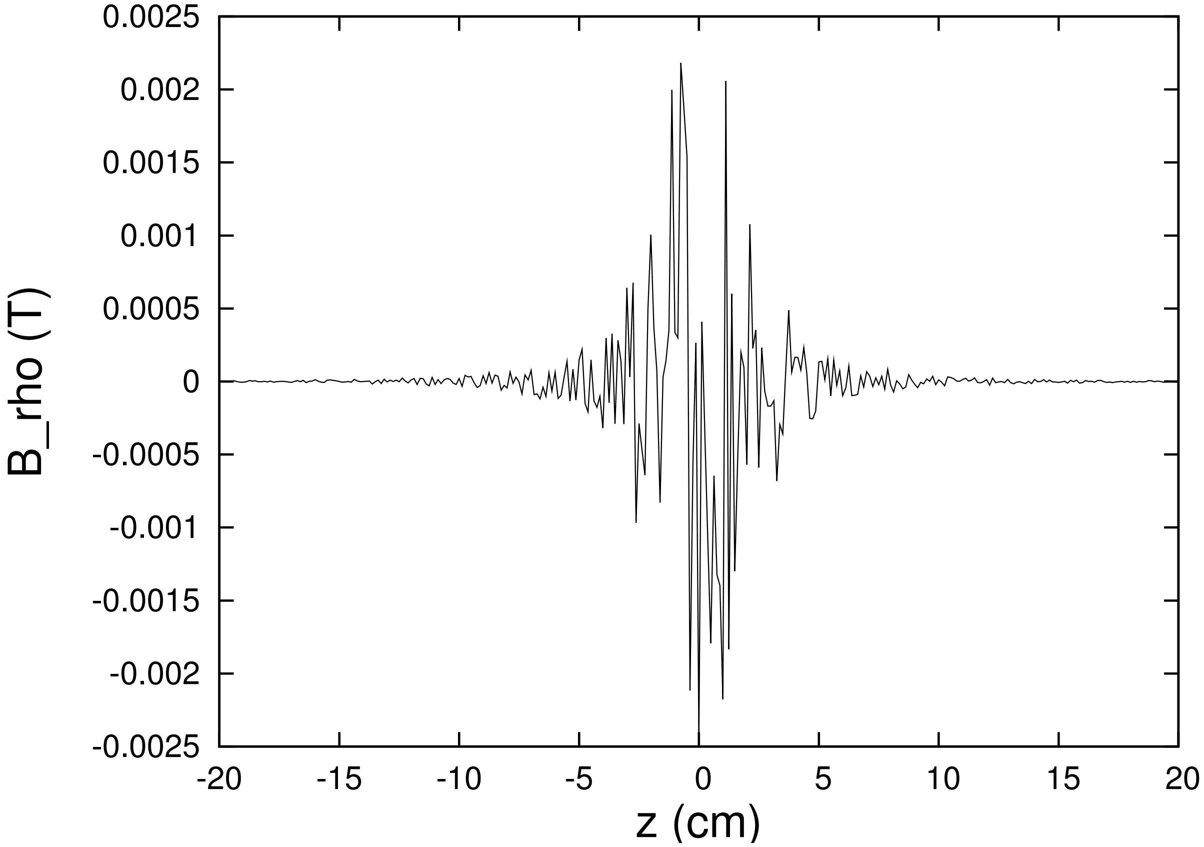

Figure 20.2.4: The function $B_\rho(R, \phi = \pi/2, z)$ produced by a pure noise field arising from a second different random number seed.

they have support for large values of $|k|$ as expected due to noise. Compare with Figure 16.1.1. In fact, because $h_z = .125$, we expect the noise to have Fourier contributions out to $K_{Ny} = \pi/h_z = 8\pi$, which is consistent with what is displayed.

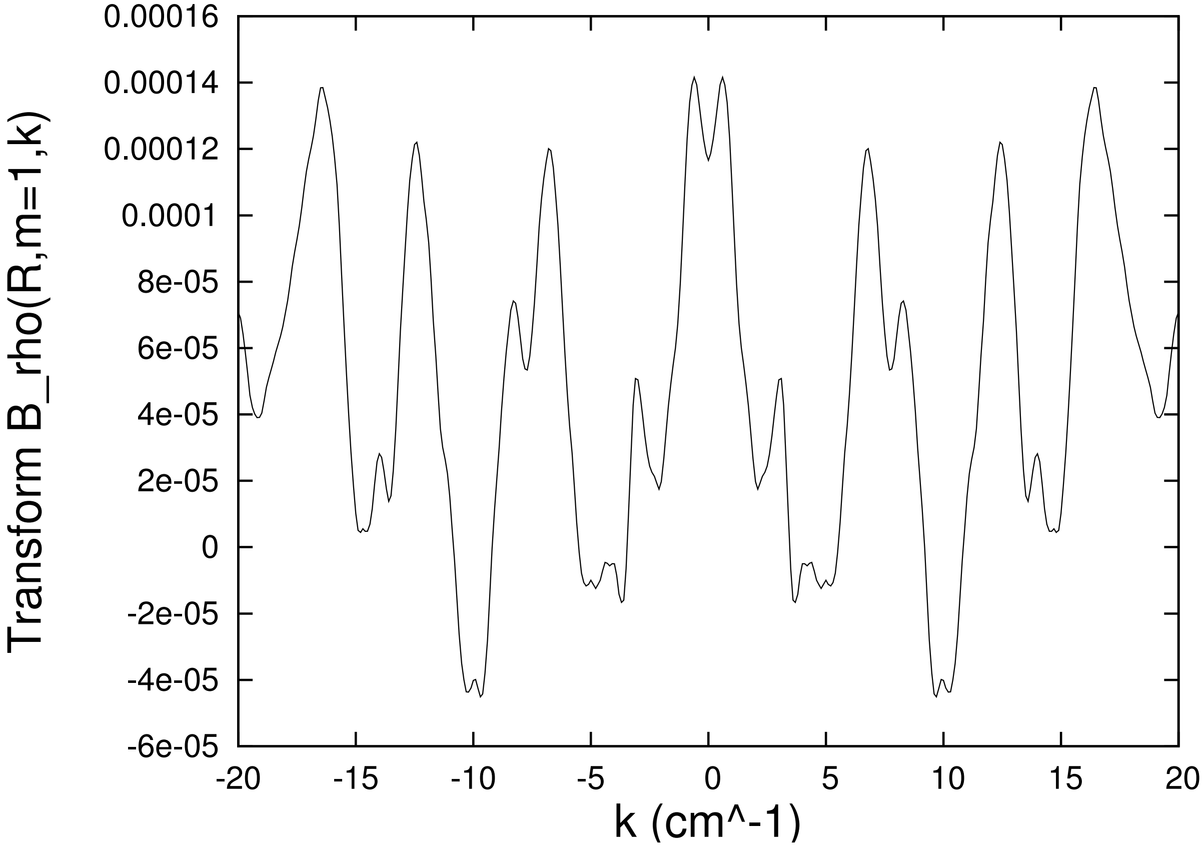

Figure 20.2.5: Real part of $\tilde{\tilde{B}}^s_\rho(R, m = 1, k)$ produced by a pure noise field. The imaginary part is comparable.

Next, again according to (14.3.23), we need to multiply $\tilde{\tilde{B}}^s_\rho(R, m = 1, k)$ by the kernel shown in Figure 16.1.3. Figures 2.7 and 2.8 show (for the real part) the results of this multiplication for the two different seed cases. We see, in both cases, that high spatial frequency noise is filtered out by the kernel.

Finally, we need to carry out the integration in (14.3.23). Figures 2.9 and 2.10 show the $C^{[0]}_{1,s}(z)$ so obtained for each noise realization. Comparison of these figures with Figure 16.1.7 shows that in this study a 1% noise in field data produces at most a .03% error in $C^{[0]}_{1,s}(z)$. Note that, unlike the case of Figure 16.1.7, $C^{[0]}_{1,s}(z)$ in Figures 2.9 and 2.10 is not symmetric about $z = 0$. There is no assumed symmetry for the noise.

What can be said about the other $C^{[n]}_{m,s}(z)$? They too are small. For example, Figures 2.11 through 2.14 show the functions $C^{[6]}_{1,s}(z)$ and $C^{[0]}_{7,s}(z)$. Comparison with Figures 16.1.8 and 16.1.15 shows that in this case a 1% noise in field data produces at most a .02% error in $C^{[6]}_{1,s}(z)$ and a .08% error in $C^{[0]}_{7,s}(z)$. It is remarkable that the error in the on-axis gradients is considerably smaller than that in the field data. It seems particularly remarkable that

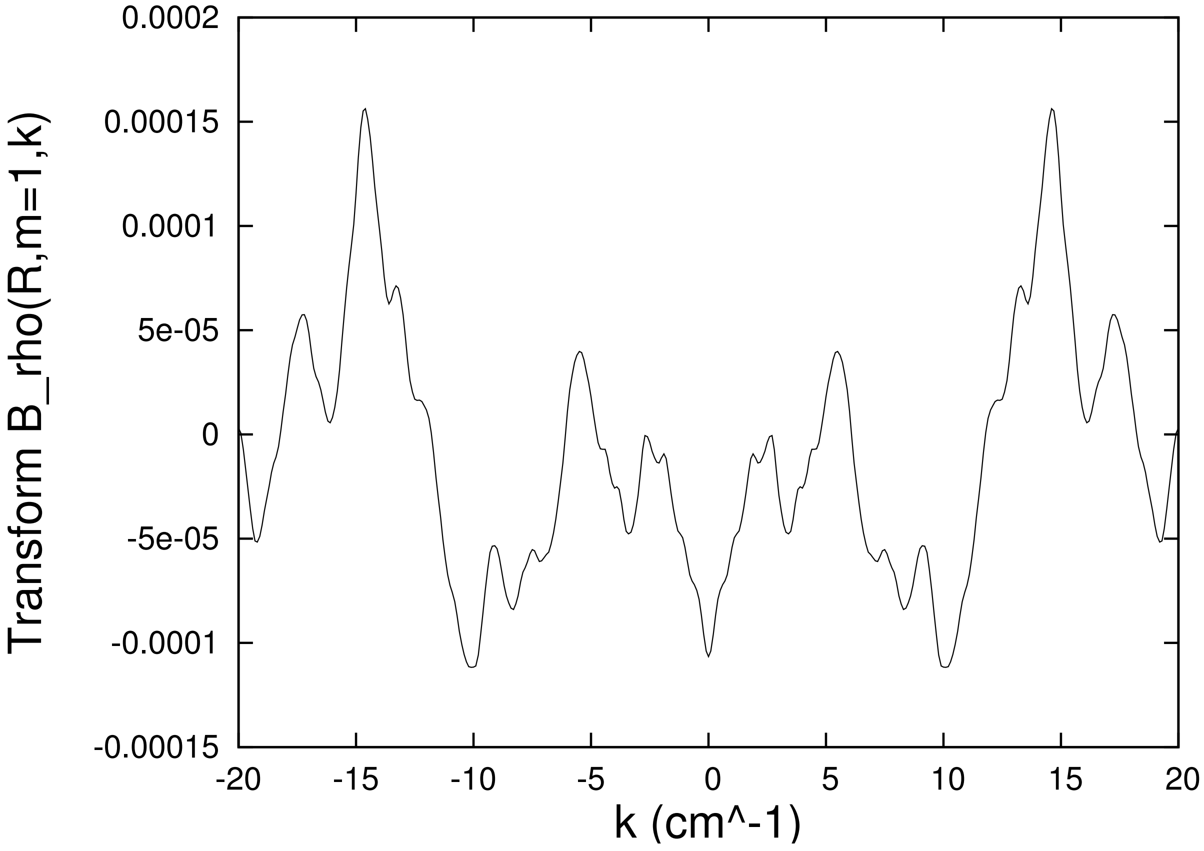

Figure 20.2.6: Real part of $\tilde{\tilde{B}}_\rho(R, m = 1, k)$ produced by a pure noise field arising from a second different random number seed. The imaginary part is comparable.

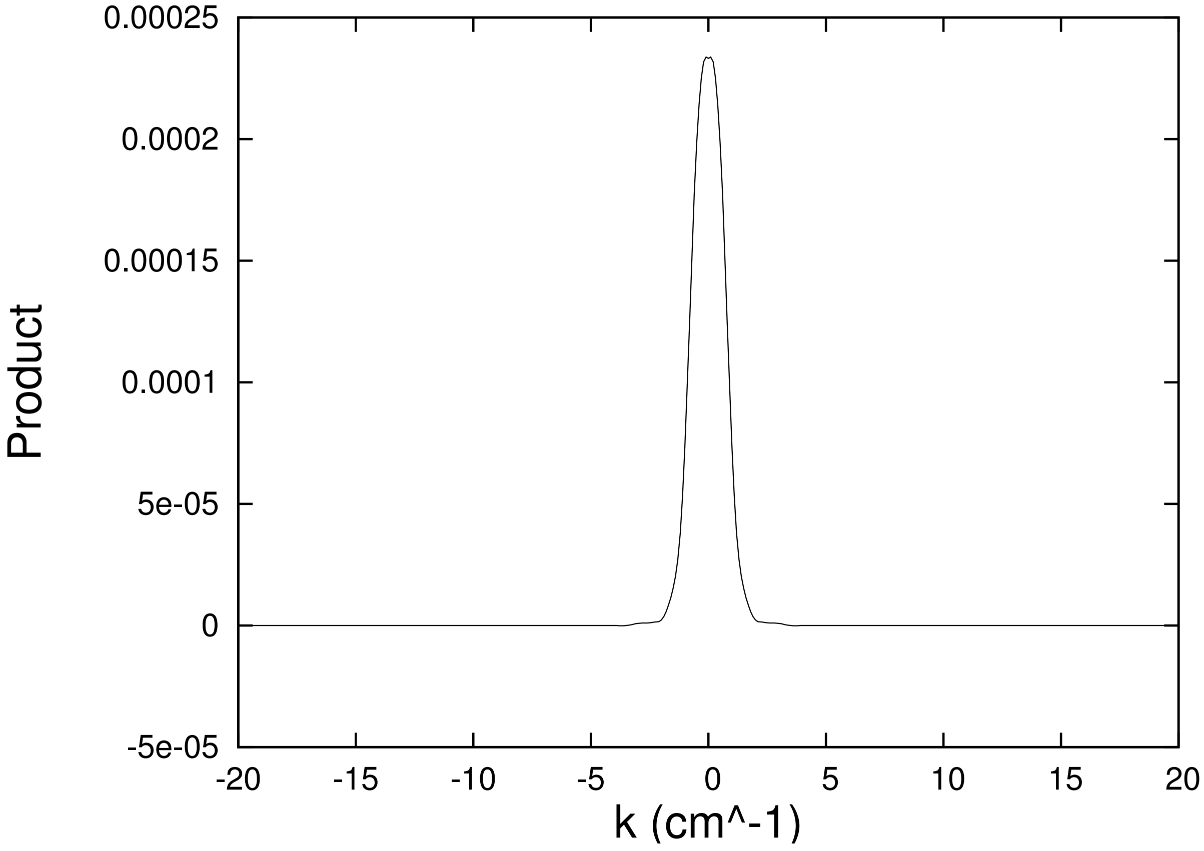

Figure 20.2.7: The product of $\Re\tilde{\tilde{B}}_\rho(R, m = 1, k)$ for the first random number seed and the kernel of Figure 16.1.3.

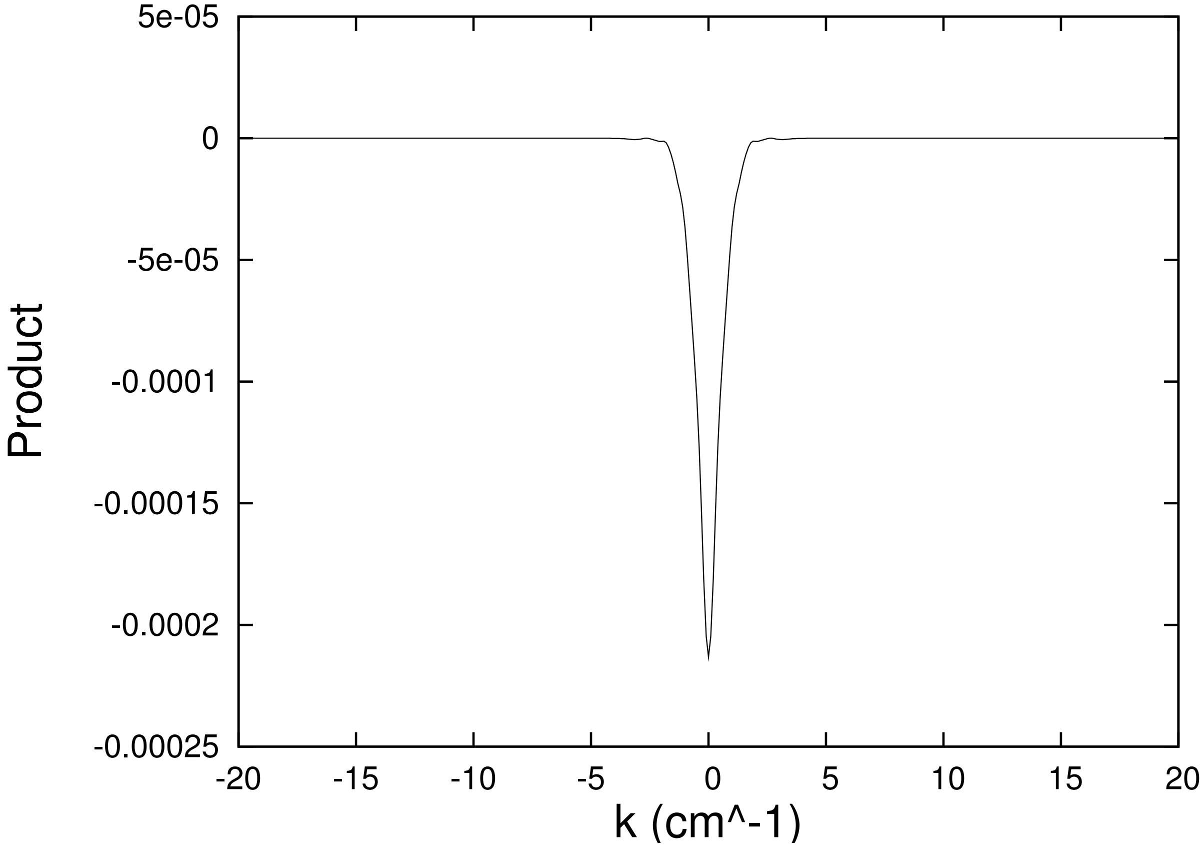

Figure 20.2.8: The product of $\Re\tilde{\tilde{B}}_\rho(R, m = 1, k)$ for the second different random number seed and the kernel of Figure 16.1.3.

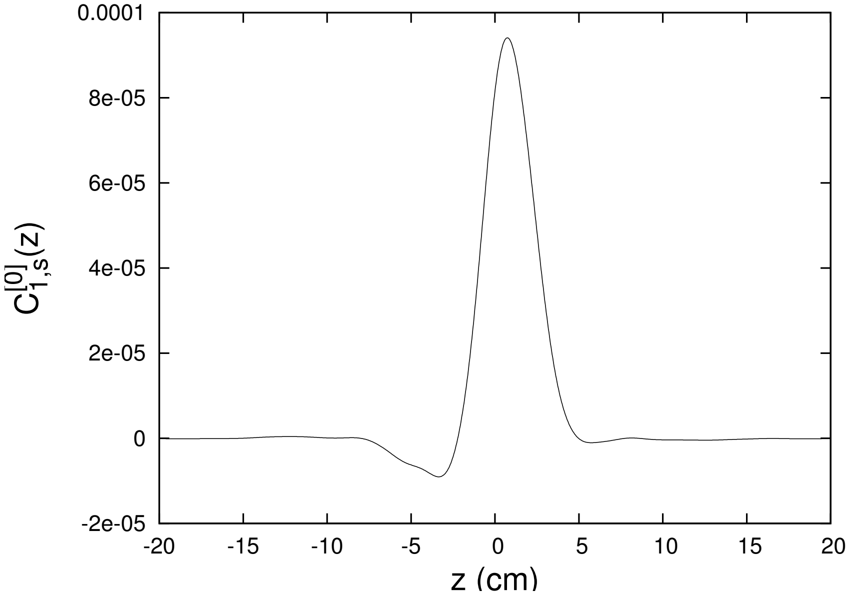

Figure 20.2.9: The function $C^{[0]}_{1,s}(z)$ produced by a pure noise field.

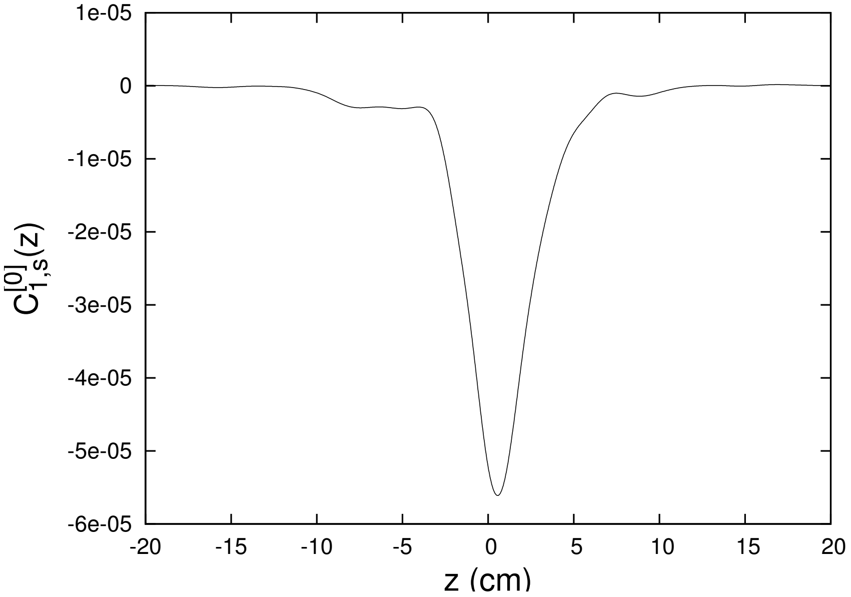

Figure 20.2.10: The function $C^{[0]}_{1,s}(z)$ produced by a pure noise field arising from a second different random number seed.

the error in $C^{[6]}_{1,s}(z)$ is so small because it involves 6 derivatives and the interpolated surface data, as evidenced by Figures 2.3 through 2.6, essentially has no derivatives.

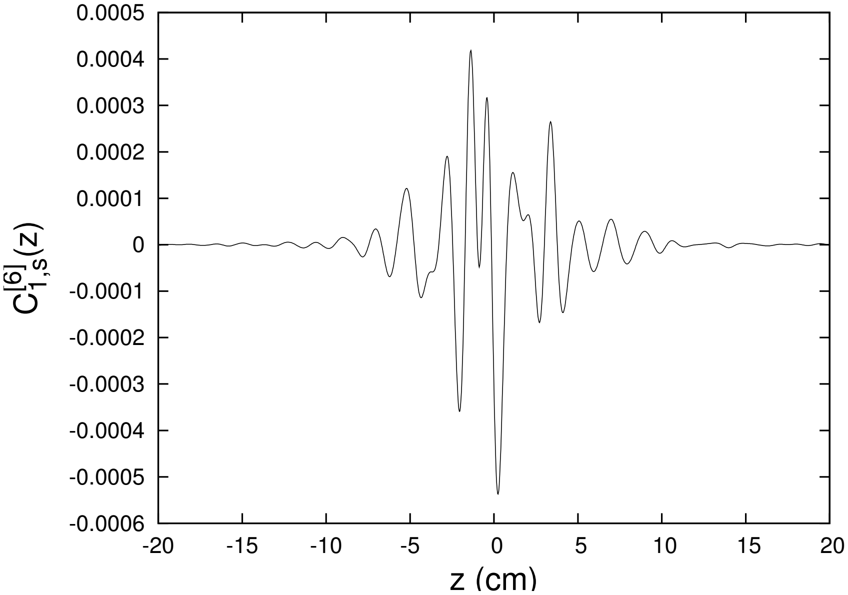

Figure 20.2.11: The function $C^{[6]}_{1,s}(z)$ produced by a pure noise field.

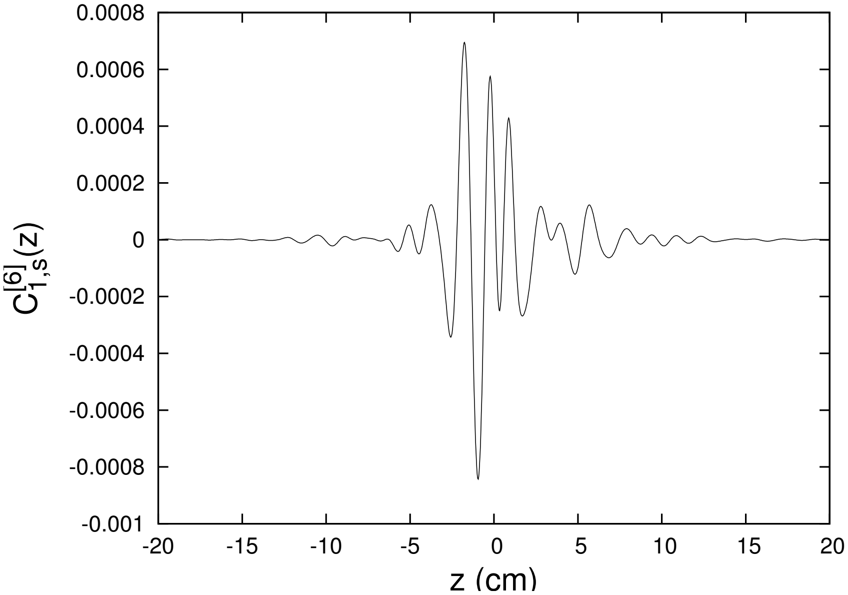

Figure 20.2.12: The function $C^{[6]}_{1,s}(z)$ produced by a pure noise field arising from a second different random number seed.

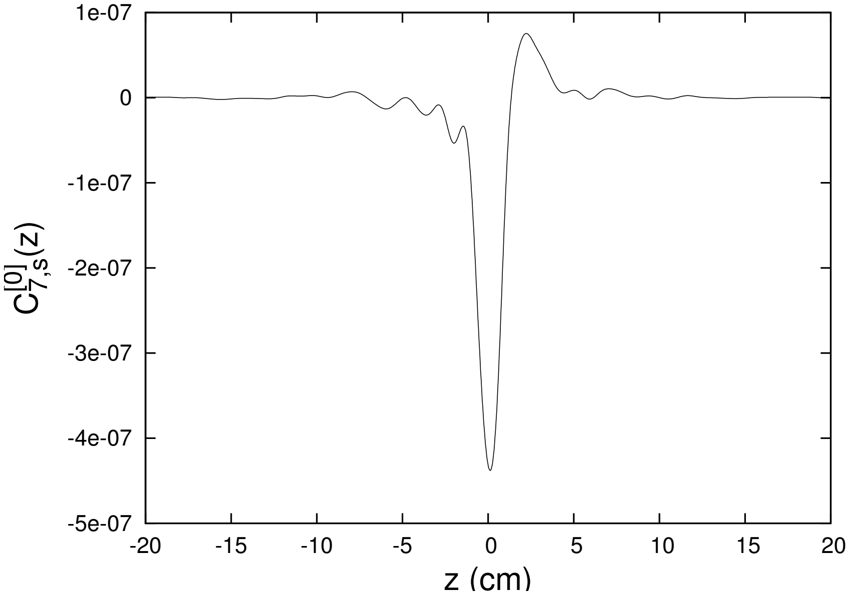

Figure 20.2.13: The function $C^{[0]}_{7,s}(z)$ produced by a pure noise field.

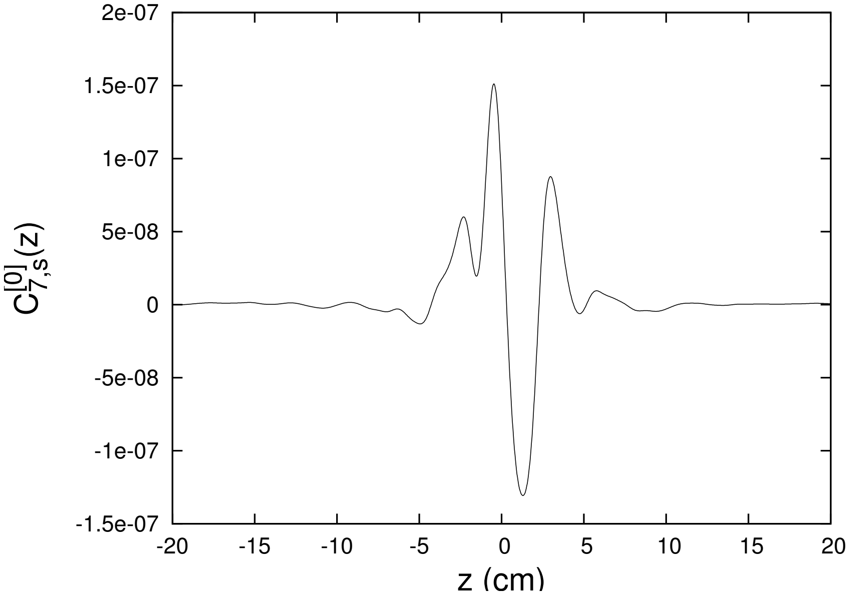

Figure 20.2.14: The function $C^{[0]}_{7,s}(z)$ produced by a pure noise field arising from a second different random number seed.

We end this section by exploring how smoothing depends on the radius of the circular cylinder. Figures 2.9 through 2.14 presented results for the case of a circular cylinder having radius $R = 2$. What if we had instead used a circular cylinder with $R = 1$? Presumably the effect of noise will be larger because there will then be less filtering. See (14.2.7).

Let us make a simple model of what to expect. Look at (14.3.23). Consistent with arising from a noise source, suppose the associated $\tilde{\tilde{B}}_\rho(R, m, k)$ is essentially independent of k. Then we have the bound

$$|C_{m,\alpha}^{[n]}(z)| \leq |\tilde{\tilde{B}}_\rho^\alpha(R, m, k \approx 0)|[(1/2)^m(1/m!)] \int_{-\infty}^{\infty} dk[|k|^{n+m-1}/|I_m'(kR)|]. \tag{20.2.3}$$

By the change of variables (1.20), the integral appearing in (2.3) can be brought to the form

$$\int_{-\infty}^{\infty} dk[|k|^{n+m-1}/|I_m'(kR)|] = (1/R)^{n+m} \int_{-\infty}^{\infty} d\lambda[|\lambda|^{n+m-1}/|I_m'(\lambda)|]. \tag{20.2.4}$$

Correspondingly, the bound (2.3) now takes the form

$$|C_{m,\alpha}^{[n]}(z)| \leq |\tilde{\tilde{B}}_\rho^\alpha(R, m, k \approx 0)|[(1/2)^m(1/m!)](1/R)^{n+m} \int_{-\infty}^{\infty} d\lambda[|\lambda|^{n+m-1}/|I_m'(\lambda)|]. \tag{20.2.5}$$

On the assumption that the noise itself is independent of R, we see that because of smoothing the $C_{m,\alpha}^{[n]}(z)$ due to noise may be expected to decrease with increasing R as $(1/R)^{n+m}$.

What actually happens? Figures 2.15 through 2.20 compare the results for $R = 1$ and $R = 2$. We see that, as a general trend, noise indeed has a larger effect when the smaller cylinder is employed. This is particularly true, as expected, for large values of $n + m$. But, in the case of Figure 2.15, the $C_{1,s}^{[0]}(z)$ computed from noise on the $R = 1$ cylinder is smaller than that computed from noise on the $R = 2$ cylinder. How can this be? As explained in the beginning of this section, see (2.1) and (2.2), in our model the noise values at the various grid points are independent. It can happen, through statistical fluctuations, that the net noise on the $R = 1$ cylinder is considerably less than on the $R = 2$ cylinder, so much so that this fluctuation effect more than compensates the poorer smoothing supplied by the smaller cylinder.

As a check on this explanation, suppose we attempt to make the noise on the $R = 1$ cylinder nearly the same as that on the $R = 2$ cylinder. One way to do this is the following: Suppose a noise value is required at some point on the $R = 1$ cylinder having angle ϕ. Instead of interpolating off nearby grid points, we may find the point on the $R = 2$ cylinder having the same ϕ value, and then interpolate off grid points near this $R = 2$ point. Figure 2.21 shows what happens when this done. Evidently the effect of noise on the $R = 1$ cylinder is now larger than the effect of essentially the same noise on the $R = 2$ cylinder.

We conclude that, as hoped, expected, and advertised, the use of surface methods (in this case the surface of a circular cylinder) does indeed yield results that are relatively insensitive to noise, and that this insensitivity is improved by placing the surface farther from the axis.

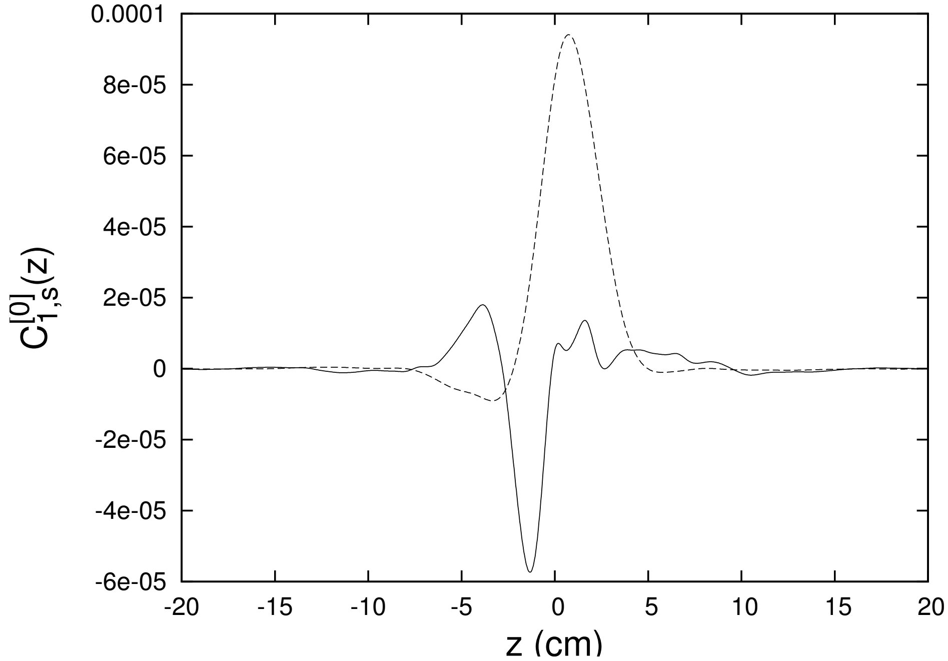

Figure 20.2.15: The functions $C_{1,s}^{[0]}(z)$ produced by a pure noise field on circular cylinders having $R = 1$ (solid line) and $R = 2$ (dashed line).

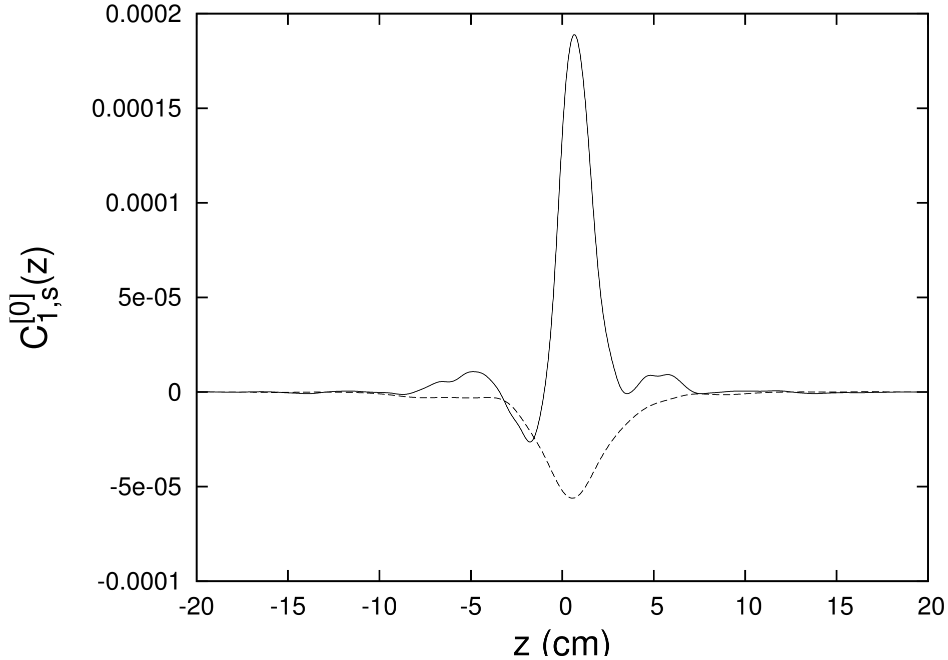

Figure 20.2.16: The functions $C_{1,s}^{[0]}(z)$ produced by a pure noise field on circular cylinders having $R = 1$ (solid line) and $R = 2$ (dashed line) and arising from a second different random number seed.

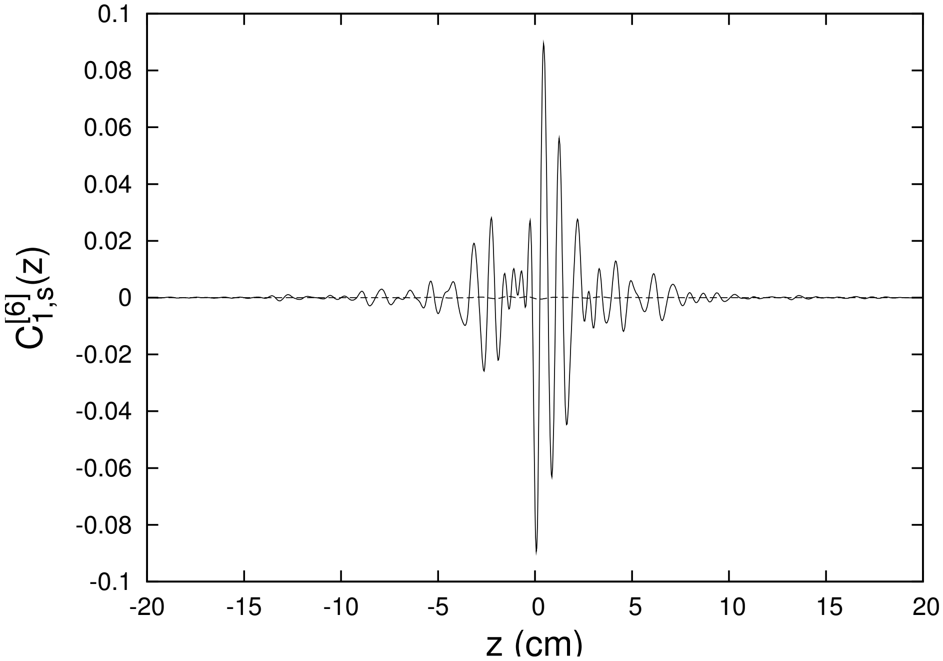

Figure 20.2.17: The functions $C^{[6]}_{1,s}(z)$ produced by a pure noise field on circular cylinders having $R = 1$ (solid line) and $R = 2$ (dashed line).

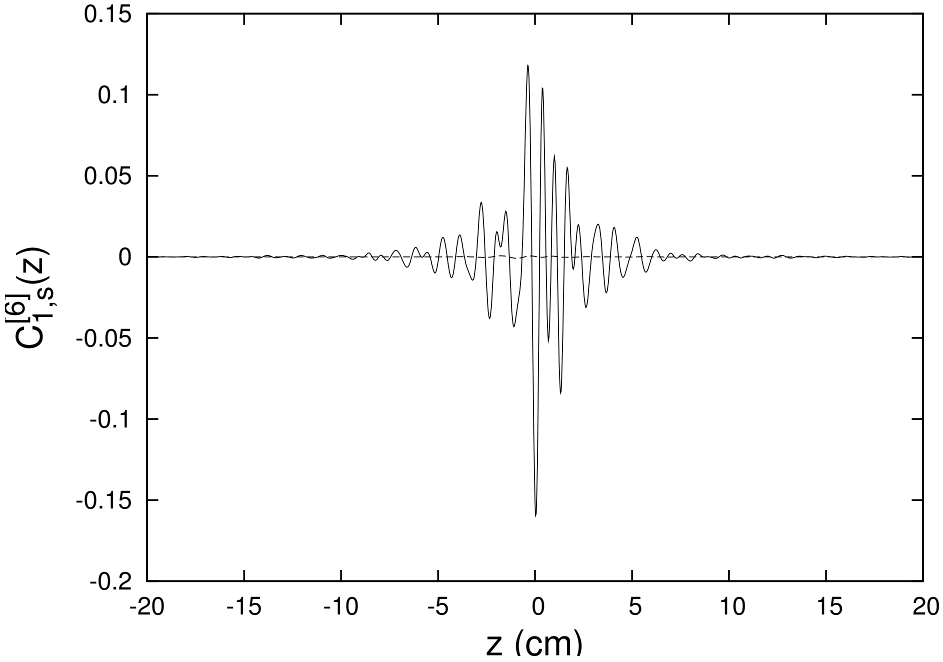

Figure 20.2.18: The functions $C^{[6]}_{1,s}(z)$ produced by a pure noise field on circular cylinders having $R = 1$ (solid line) and $R = 2$ (dashed line) and arising from a second different random number seed.

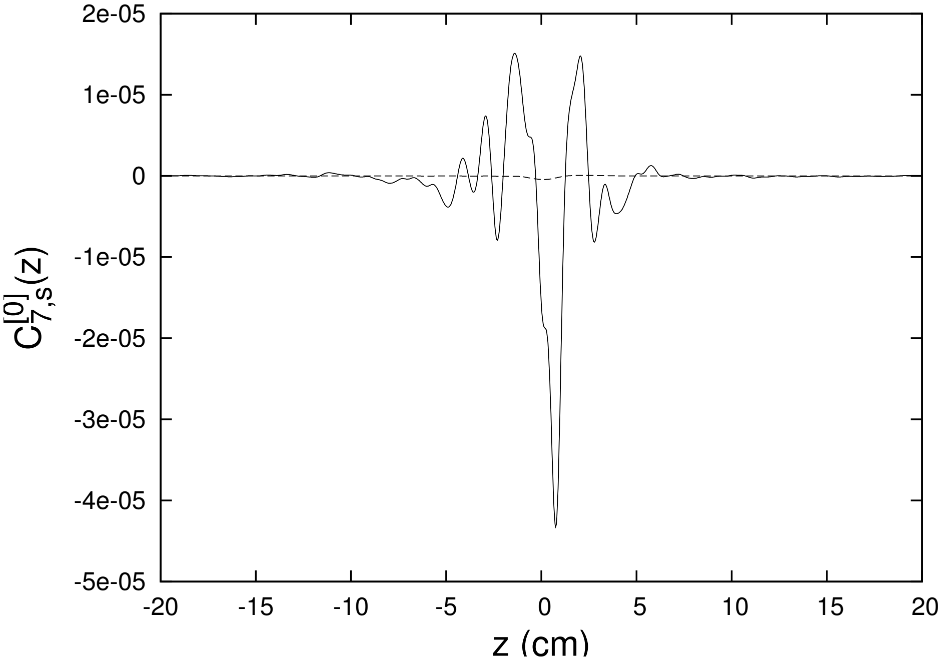

Figure 20.2.19: The functions $C^{[0]}_{7,s}(z)$ produced by a pure noise field on circular cylinders having $R = 1$ (solid line) and $R = 2$ (dashed line).

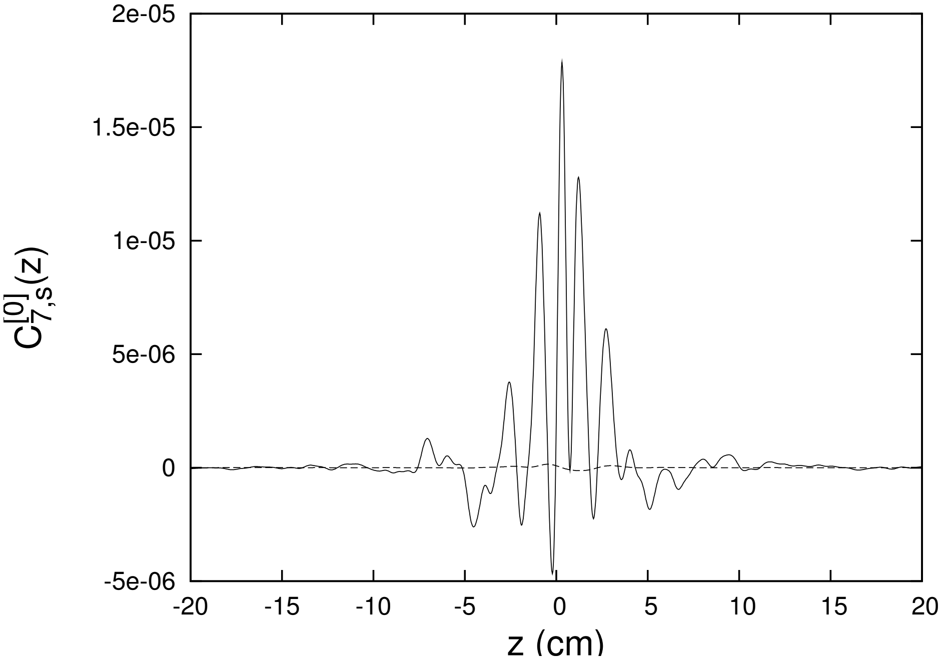

Figure 20.2.20: The functions $C^{[0]}_{7,s}(z)$ produced by a pure noise field on circular cylinders having $R = 1$ (solid line) and $R = 2$ (dashed line) and arising from a second different random number seed.

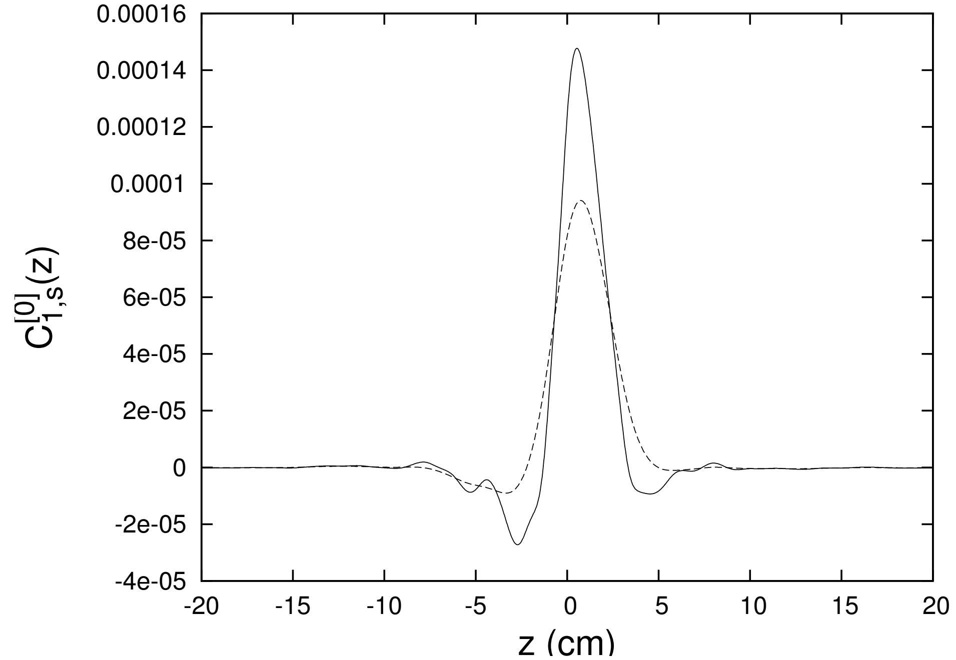

Figure 20.2.21: The functions $C^{[0]}_{1,s}(z)$ produced by nearly the same pure noise fields on circular cylinders having $R = 1$ (solid line) and $R = 2$ (dashed line).

20.3 Elliptic Cylinders

The discussion of this section parallels that of the previous section, but now deals with the monopole-doublet test case and the use of the surface of an elliptic cylinder as described in Section 16.2.6. We use the same noise model as that of the previous section.

Now the first step in the purely numerical calculation is to interpolate the field onto the surface of the elliptic cylinder and to find the function $F(U, v, z)$ given by (14.4.67). Figures 3.1 and 3.2 show the resulting $F(U, v, z = 0)$ for two different random number seeds. Compare with Figure 16.2.28. Correspondingly, Figures 3.3 and 3.4 show $F(U, v = \pi/2, z)$. In view of (14.4.66), this quantity is proportional to the normal component of B when $\phi = \pi/2$ so that these figures should be compared with Figure 13.7.7. Observe that the surface field is noisy as expected.

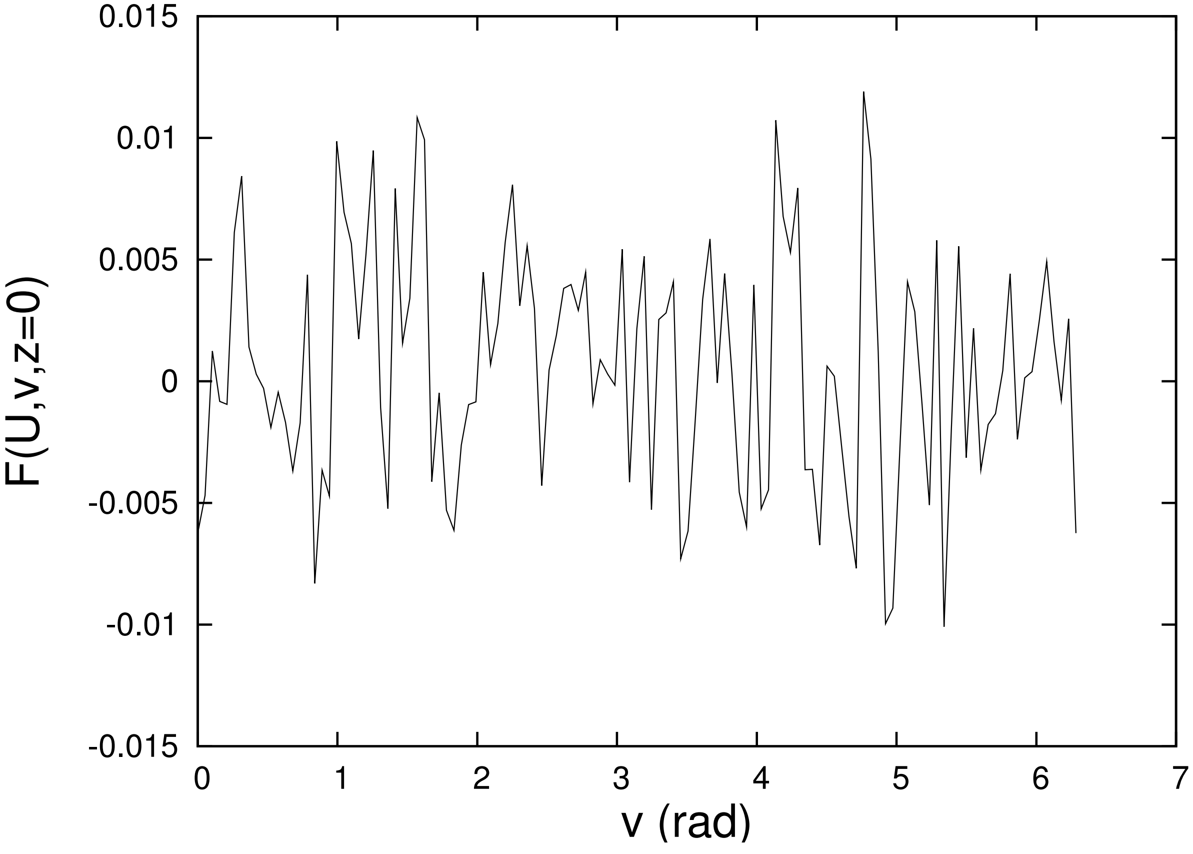

Figure 20.3.1: The function $F(U, v, z = 0)$ produced by a pure noise field.

According to (14.4.72) the second step is to perform a Fourier transform to produce $\tilde{F}(v, k)$. Figures 3.5 and 3.6 display the real parts of $\tilde{F}(v = \pi/2, k)$ for the two different seeds. The imaginary parts are comparable. Compare with Figure 16.2.3. In both cases $\tilde{F}(v = \pi/2, k)$ has support for large $|k|$ as is expected for noisy data.

The third step is to compute the Mathieu coefficients defined by (16.2.20) and (16.2.21). As described in Section 16.2.1, for the monopole doublet we are particularly interested in the coefficients $\tilde{\tilde{F}}_r^s(k)$ for odd r. Figures 3.7 and 3.8 display the real parts of the first few

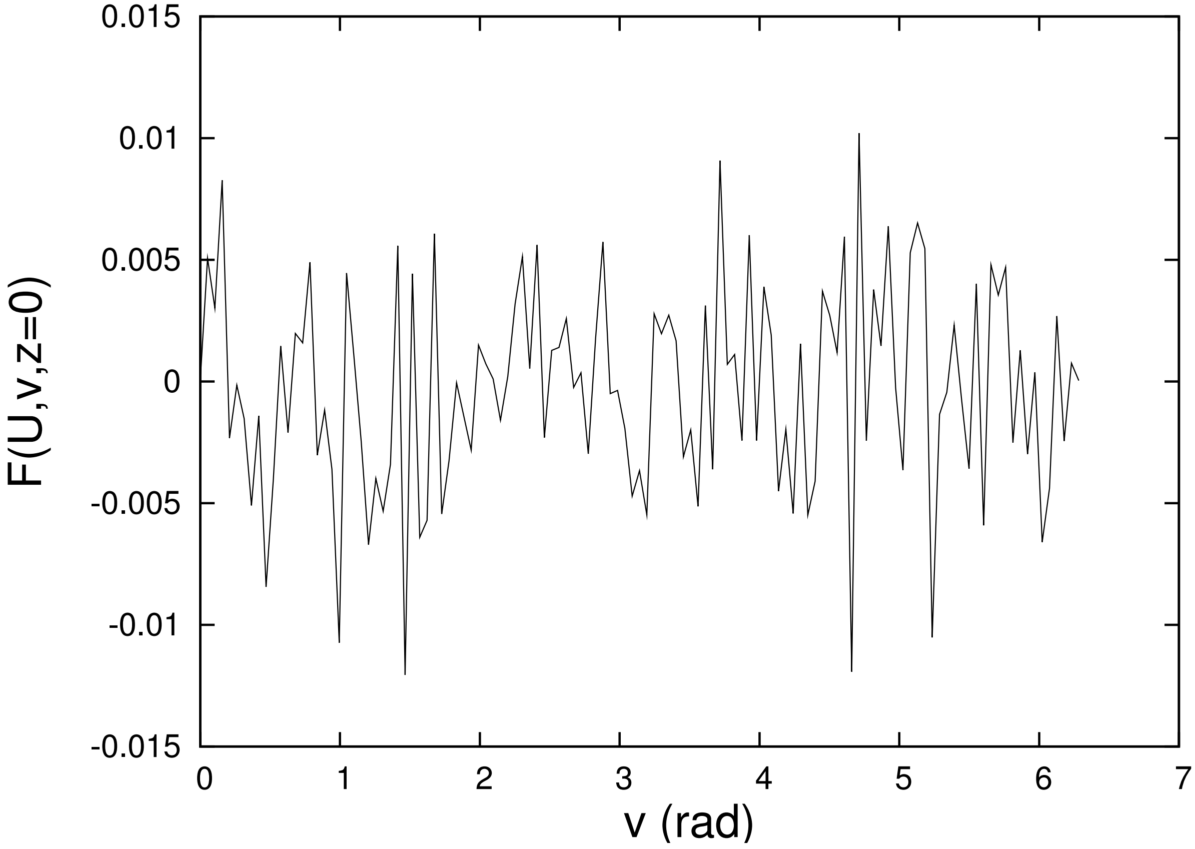

Figure 20.3.2: The function $F(U, v, z = 0)$ produced by a pure noise field arising from a second different random number seed.

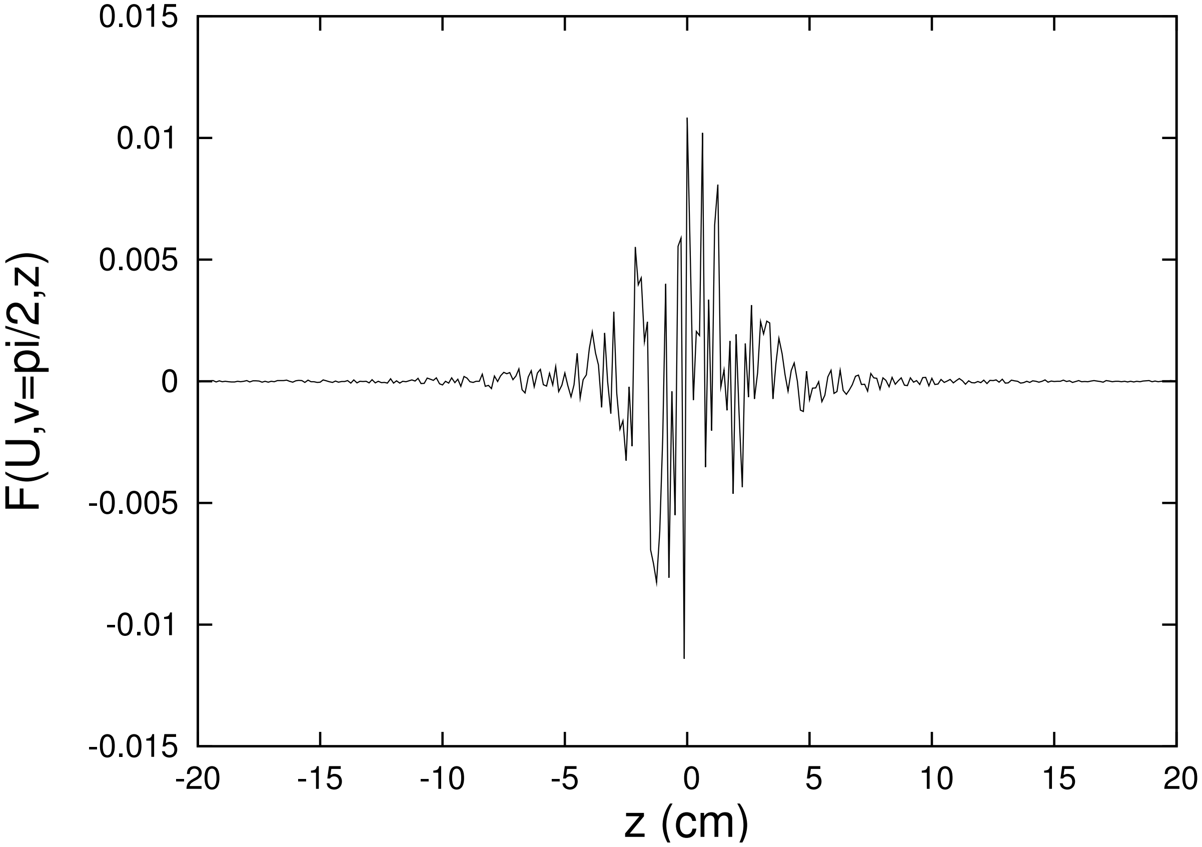

Figure 20.3.3: The function $F(U, v = \pi/2, z)$ produced by a pure noise field.

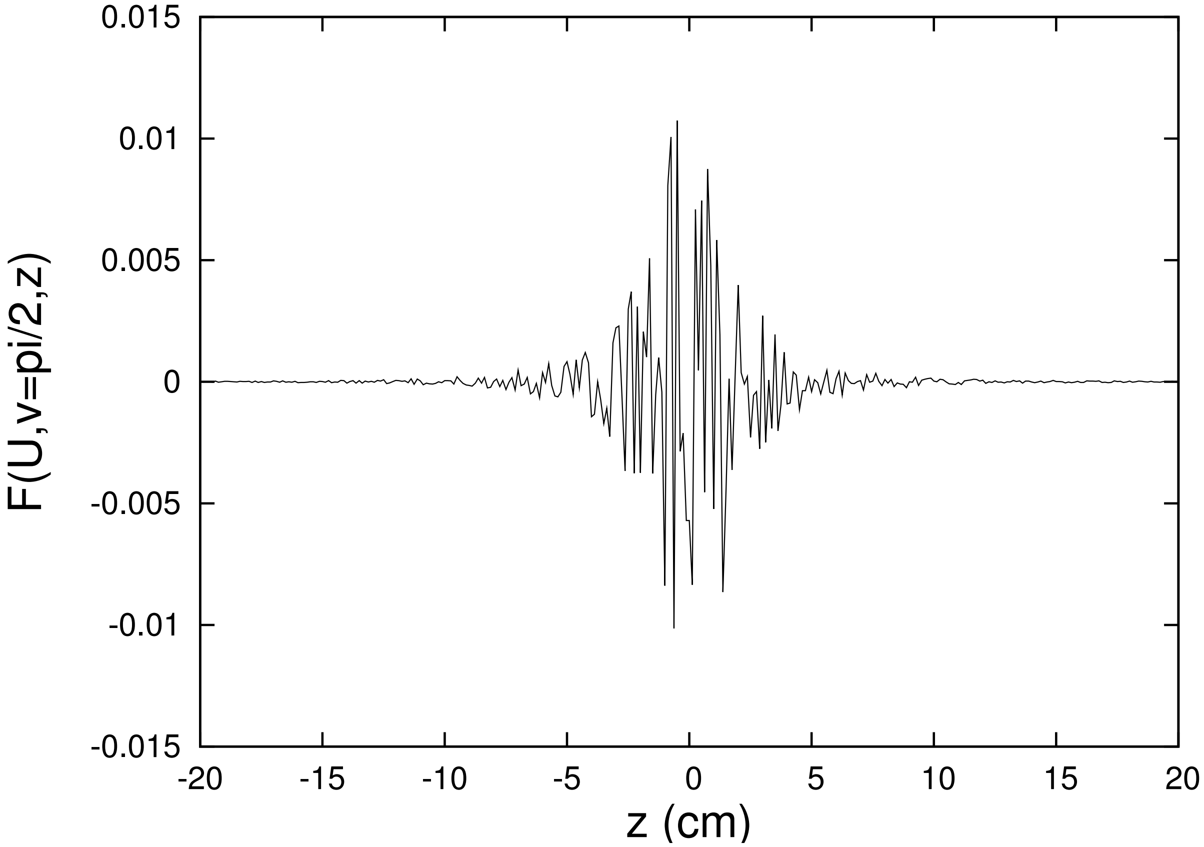

Figure 20.3.4: The function $F(U, v = \pi/2, z)$ produced by a pure noise field arising from a second different random number seed.

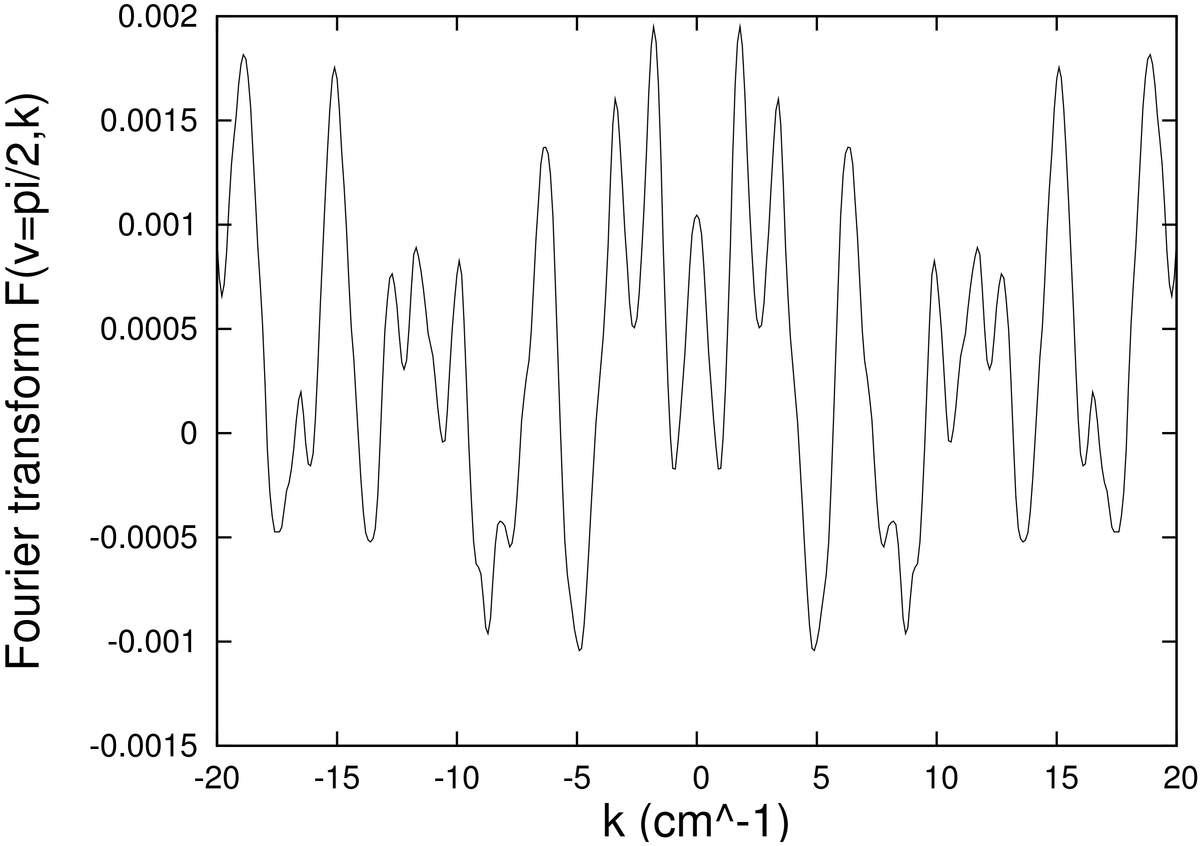

Figure 20.3.5: Real part of $\tilde{F}(v = \pi/2, k)$ produced by a pure noise field. The imaginary part is comparable.

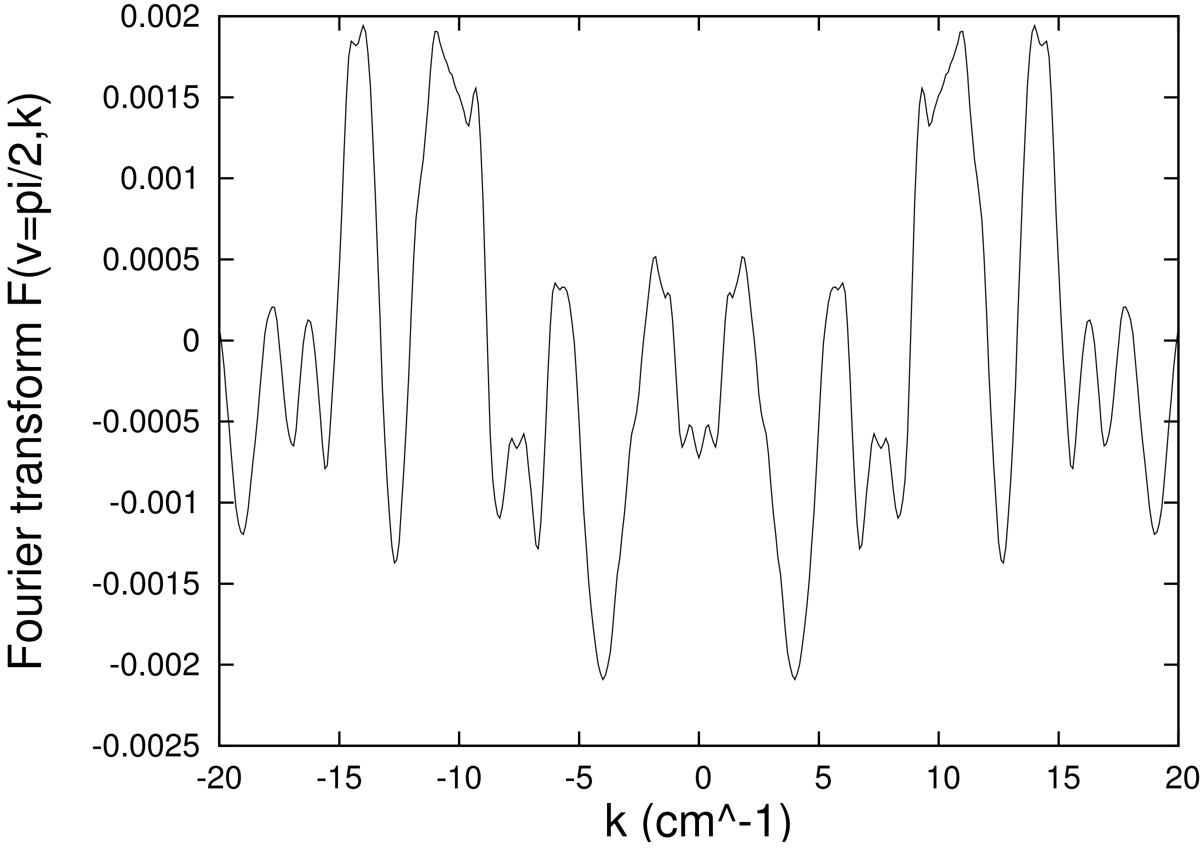

Figure 20.3.6: Real part of $\tilde{F}(v = \pi/2, k)$ produced by a pure noise field arising from a second different random number seed. The imaginary part is comparable.

of these, namely those for $r = 1, 3$, and 5, for the two different seeds. Compare with Figure 16.2.4. Note that they also have support for large $|k|$.

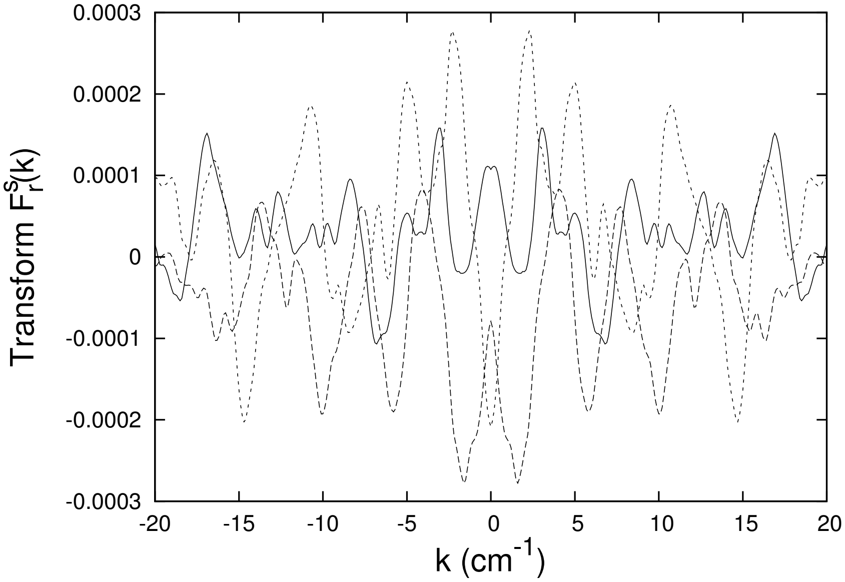

Figure 20.3.7: Real parts of the first few functions $\tilde{\tilde{F}}_r^s(k)$, those for $r = 1, 3$, and 5, produced by a pure noise field. The imaginary parts are comparable.

Suppose, for example, that we now again wish to compute the $C_{1,s}^{[0]}(z)$ produced by the pure noise field. Then, according to (14.8.86) and (14.8.84), we must compute the quantity $kG_{1,s}(k)$ by multiplying the $\tilde{\tilde{F}}_r^s(k)$ by the kernels $k\beta_1^r(k)/Se_r'(U, q)$ shown in Figure 16.2.7, and then summing over r. As described in Section 16.2.3, this sum is terminated at $r_{\max}(1) = 11$. Figures 3.9 and 3.10 display the real parts of the $kG_{1,s}(k)$ for the two different choices of random number seed. The imaginary parts are comparable. Note that, like the circular cylinder case, the kernels effectively filter out all the high frequency components.

This is a good place to compare the filtering provided by the use of an elliptic cylinder with that provided by the use of a circular cylinder. Figure 3.11 shows the circular cylinder $m = 1$ kernel $[1/I_1'(kR)]$ and the first few elliptical cylinder $m = 1$ kernels $[k\beta_1^r(k)/Se_r'(U, q)]$, and Figure 3.12 shows the same kernels all normalized to 1 at $k = 0$. From Figure 3.12 we see that the elliptic kernels for $r = 1$ and $r = 3$ fall off more rapidly with $|k|$ than the circular kernel, but that they fall off less rapidly for $r \geq 5$. The r value for which this transition occurs depends on the eccentricity of the ellipse: the larger the eccentricity the larger the transition r. Moreover, we see from Figure 3.11 that the elliptic kernels for small r dominate.

Finally, we need to carry out the integration in (14.4.86). Figures 3.13 and 3.14 show, as dashed lines, the $C_{1,s}^{[0]}(z)$ so obtained for each noise realization. Also shown, as solid lines, are the $C_{1,s}^{[0]}(z)$ obtained using a circular cylinder. (See Figures 2.9 and 2.10). Evidently use of the elliptic cylinder, in this case, has reduced the effect of noise by another factor of ~ 2.5 compared to the use of a circular cylinder. Comparison of these figures with Figure 16.1.8 shows that in this study a 1% noise in field data produces about .01% error in $C_{1,s}^{[0]}(z)$ when

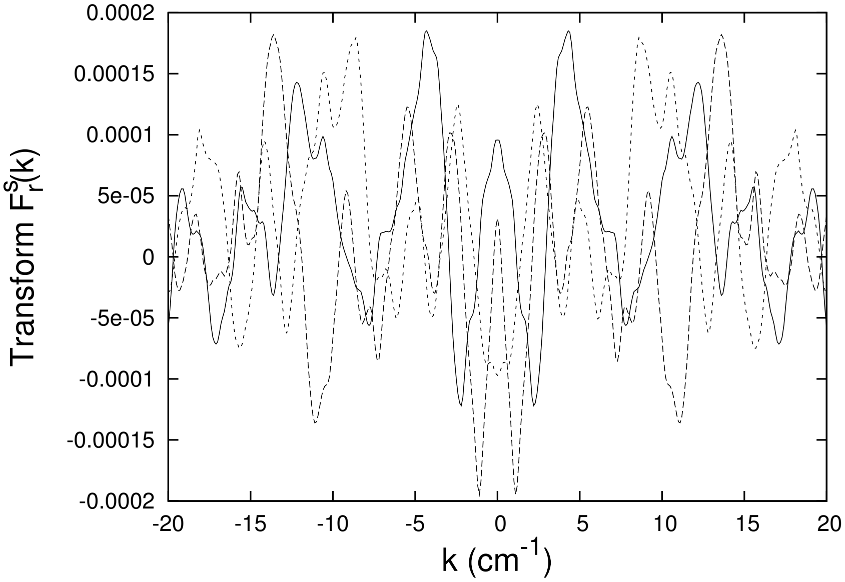

Figure 20.3.8: Real parts of the first few functions $\tilde{\tilde{F}}_r^s(k)$, those for $r = 1, 3$, and 5, produced by a pure noise field arising from a second different random number seed. The imaginary parts are comparable.

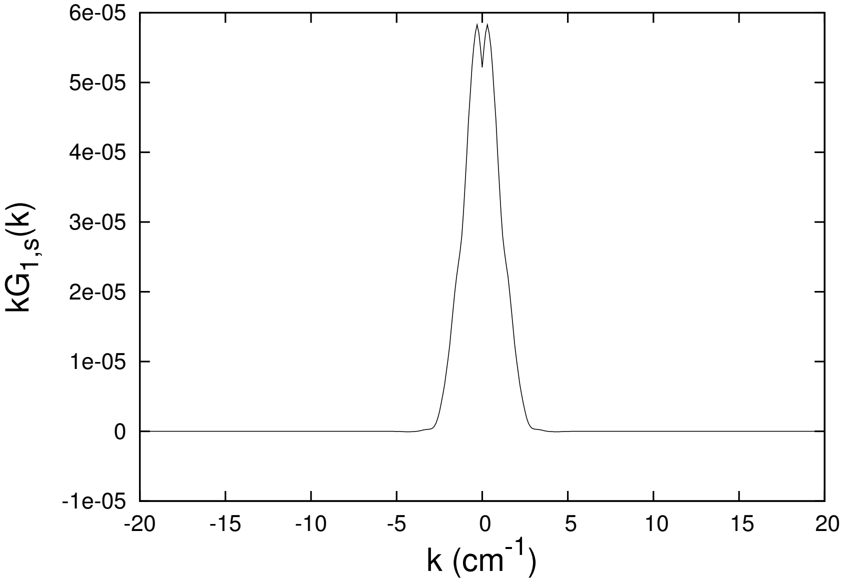

Figure 20.3.9: Real part of $kG_{1,s}(k)$ computed from $\tilde{\tilde{F}}_r^s(k)$ associated with the first seed. The imaginary part is comparable.

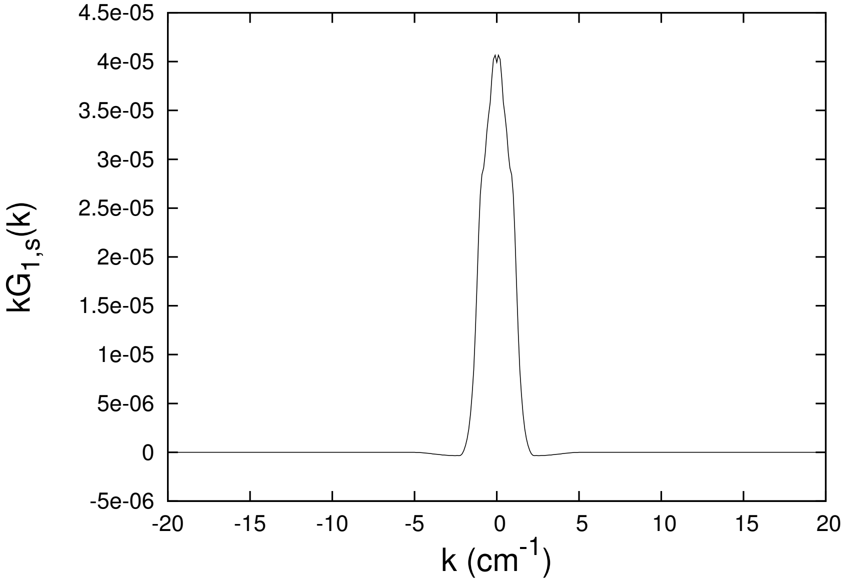

Figure 20.3.10: Real part of $kG_{1,s}(k)$ computed from $\tilde{\tilde{F}}_r^s(k)$ associated with the second seed. The imaginary part is comparable.

the elliptic cylinder is used.

What can be said about the other $C_{m,s}^{[n]}(z)$? Generally the use of an elliptic cylinder gives better results. But in some cases the circular and elliptic cylinder results are comparable, and sometimes the circular cylinder error is somewhat smaller. Results vary from seed to seed. For example, Figures 3.15 through 3.18 show the functions $C_{1,s}^{[6]}(z)$ and $C_{7,s}^{[0]}(z)$ computed using both elliptic and circular cylinders.

There are at least two remarks to be made. First, just as in the cases in Section 17.2 where the results of using circular cylinders with different radii were compared, statistical fluctuations can mask the effects of improved smoothing. Second, it is primarily the vertical magnetic field that contributes to the $C_{1,s}^{[n]}(z)$, $C_{3,s}^{[n]}(z)$, $C_{5,s}^{[n]}(z) \cdots$. However, what enters our calculation is the component of the magnetic field that is perpendicular to the surface. Although the elliptical cylinder surface has points that are farther from the axis than the circular cylinder, at these points the normal to the surface is primarily in the horizontal direction. Consequently, the points on the elliptical surface for which the field values actually contribute to the $C_{m,\alpha}^{[n]}(z)$ thus far examined are not very much farther from the axis than points on the circular surface.

We should also examine, for example, the quantities $C_{1,c}^{[n]}(z)$, $C_{3,c}^{[n]}(z)$, $C_{5,c}^{[n]}(z) \cdots$ for which the horizontal magnetic field makes substantial contributions. For these quantities we expect that noise results for circular and elliptic cylinders should be noticeably different. As a first exploratory step, let us again examine the relevant kernels. Figure 3.19 shows the circular cylinder $m = 1$ kernel $[1/I_1'(kR)]$ and the first few elliptical cylinder $m = 1$ kernels $[k\alpha_1^r(k)/Ce_r'(U,q)]$, and Figure 3.20 shows the same kernels all normalized to 1 at $k = 0$. From Figure 3.20 we see that the elliptic kernels for $r = 1$ and $r = 3$ fall off more rapidly with $|k|$ than the circular kernel, but that they fall off less rapidly for $r \geq 5$. The r value for which this transition occurs depends on the eccentricity of the ellipse: the larger the

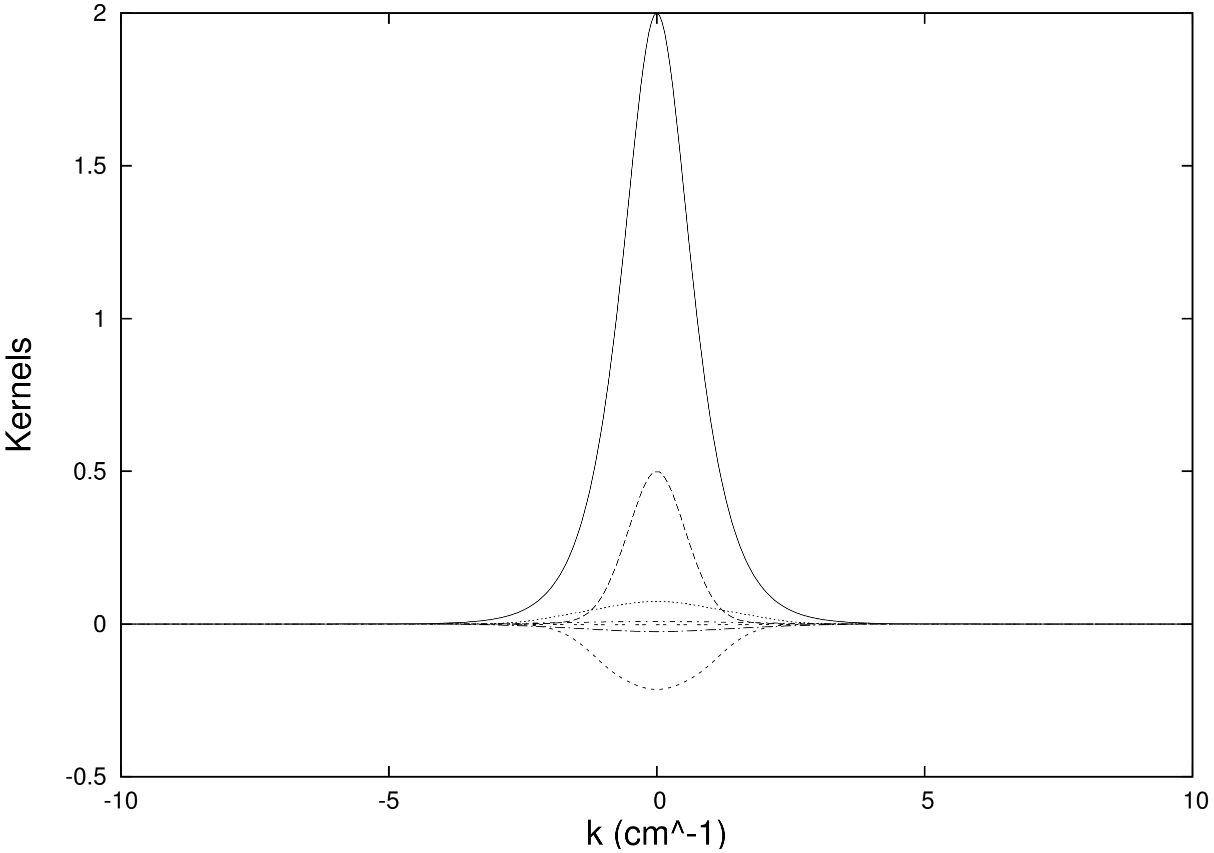

Figure 20.3.11: A comparison of the circular cylinder $m = 1$ kernel $[1/I_1'(kR)]$, shown as a solid line, and the first few relevant elliptical cylinder $m = 1$ kernels $[k\beta_1^r(k)/Se_r'(U,q)]$, namely those for $r = 1, 3, 5, 7, 9,$ and 11, shown as a dashed lines. The elliptic kernels alternate in sign, and their magnitude at $k = 0$ decreases with increasing r. See Figure 16.2.7.

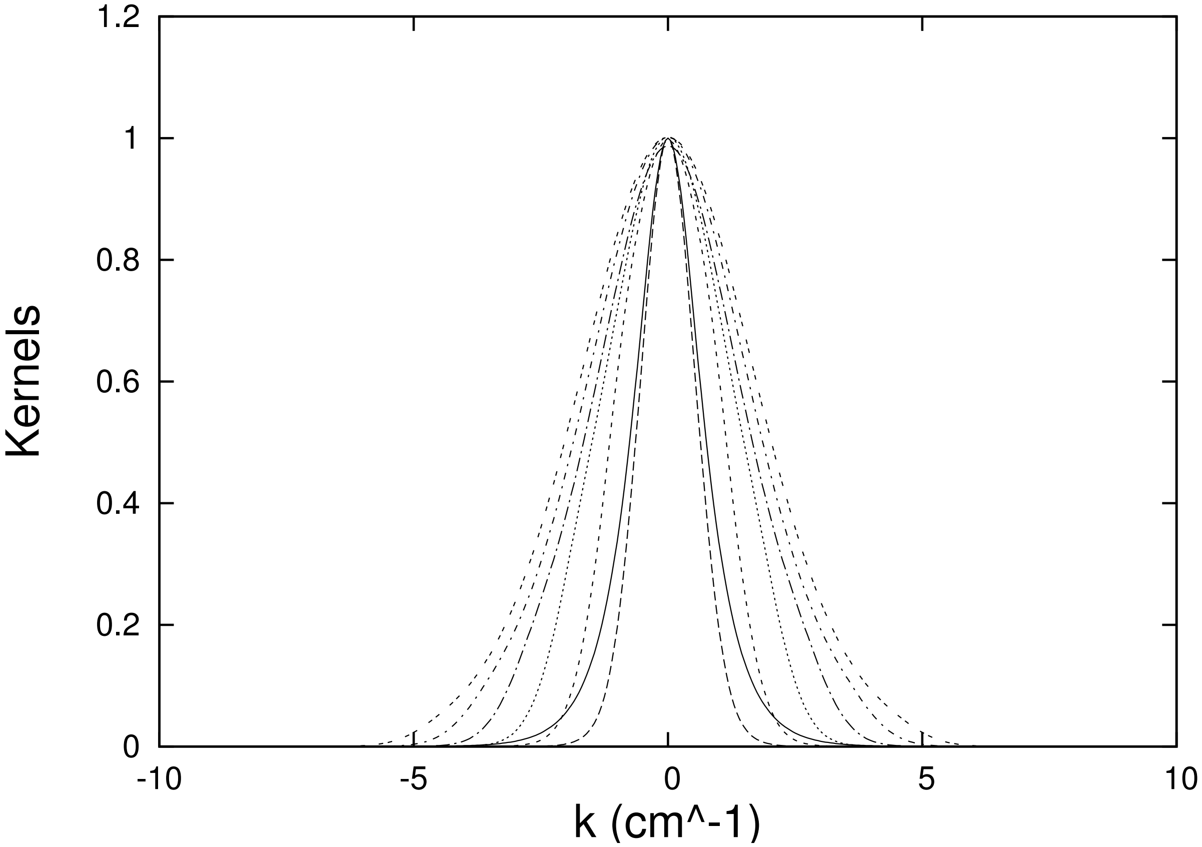

Figure 20.3.12: A comparison of the circular cylinder $m = 1$ kernel $[1/I_1'(kR)]$ and the first few elliptic cylinder $m = 1$ kernels $[k\beta_1^r(k)/Se_r'(U,q)]$, all normalized to 1 at $k = 0$.

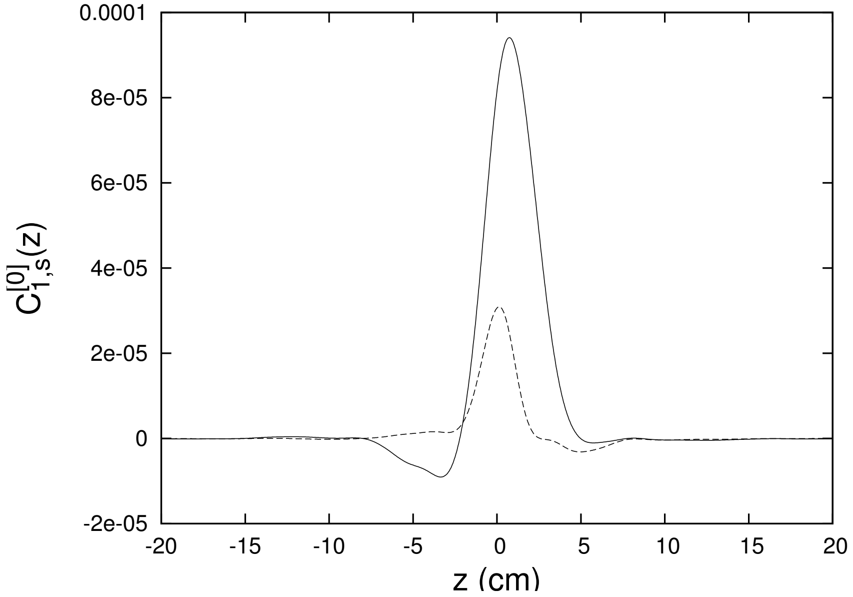

Figure 20.3.13: Dashed line: The function $C_{1,s}^{[0]}(z)$ produced by a pure noise field and using an elliptic cylinder. Solid line: The function $C_{1,s}^{[0]}(z)$ produced by a pure noise field and using a circular cylinder.

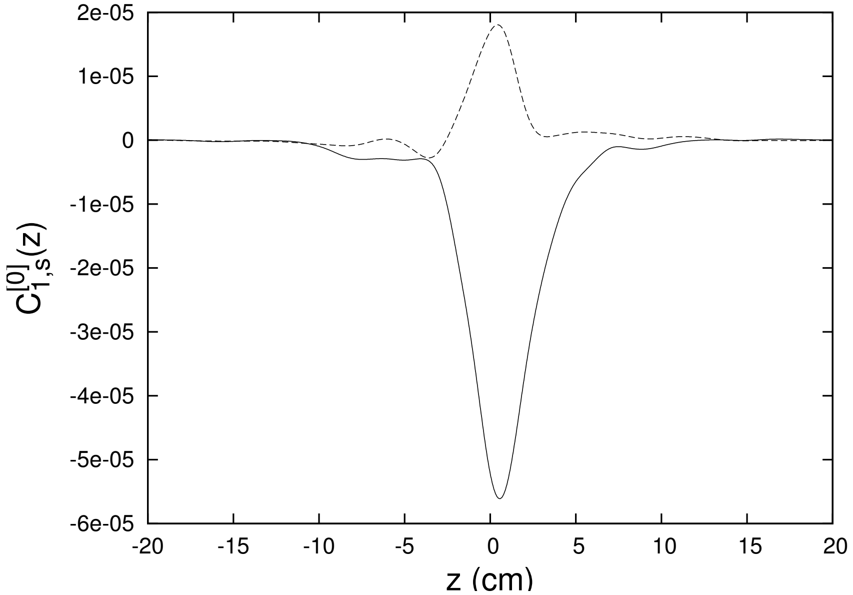

Figure 20.3.14: Results for the second random number seed. Dashed line: The function $C_{1,s}^{[0]}(z)$ produced by a pure noise field and using an elliptic cylinder. Solid line: The function $C_{1,s}^{[0]}(z)$ produced by a pure noise field and using a circular cylinder.

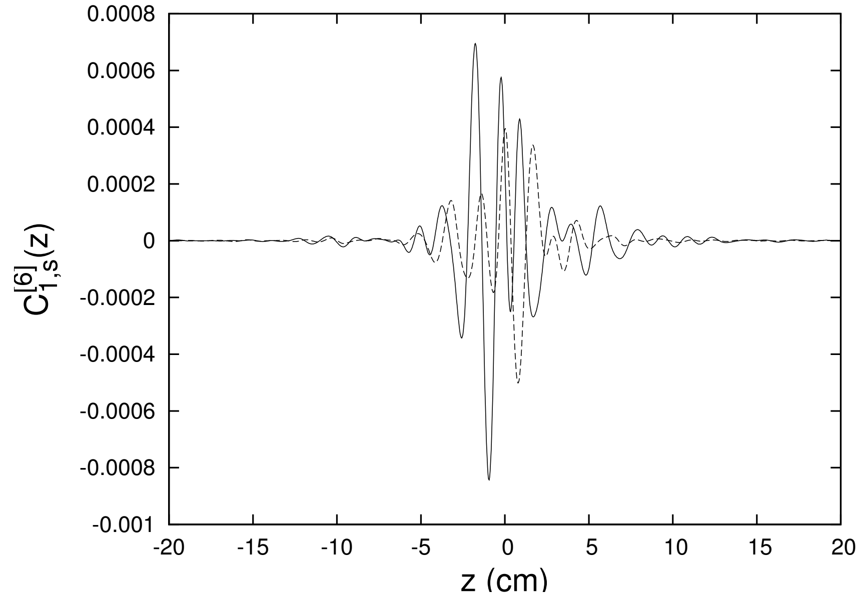

Figure 20.3.16: The function $C^{[6]}_{1,s}(z)$ produced by a pure noise field arising from a second different random number seed. Dashed line: Elliptic cylinder result. Solid line: Circular cylinder result.

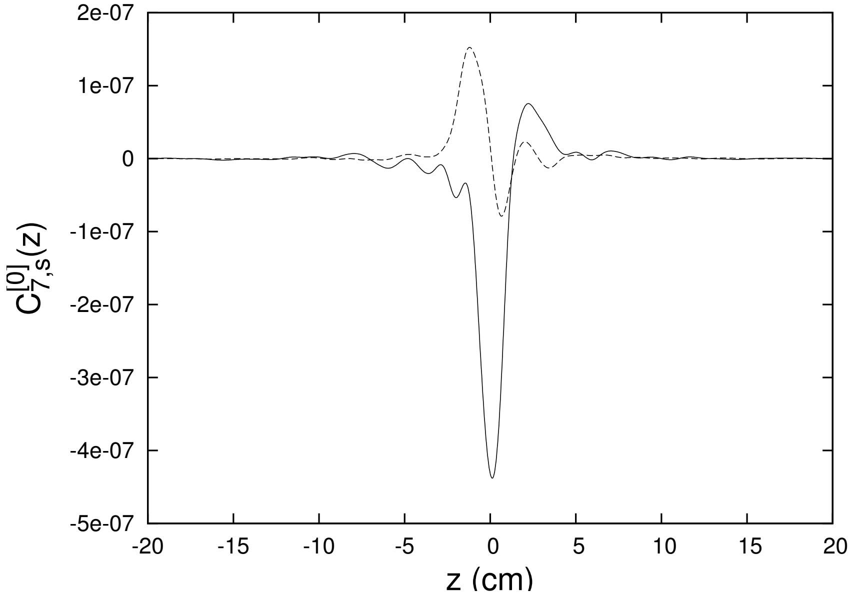

Figure 20.3.17: The function $C^{[0]}_{7,s}(z)$ produced by a pure noise field. Dashed line: Elliptic cylinder result. Solid line: Circular cylinder result.

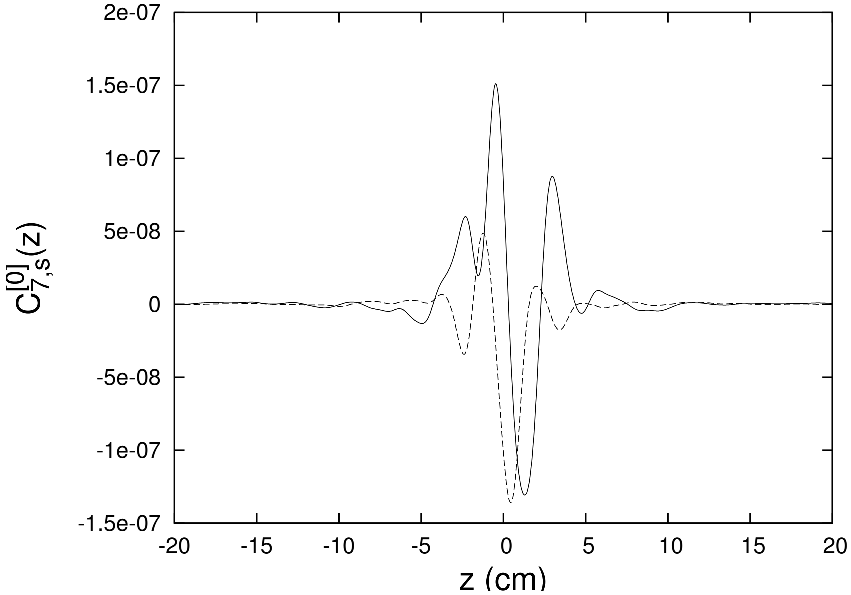

Figure 20.3.18: The function $C^{[0]}_{7,s}(z)$ produced by a pure noise field arising from a second different random number seed. Dashed line: Elliptic cylinder result. Solid line: Circular cylinder result.

eccentricity the larger the transition r. Moreover, we see from Figure 3.19 that the elliptic kernels for small r dominate.

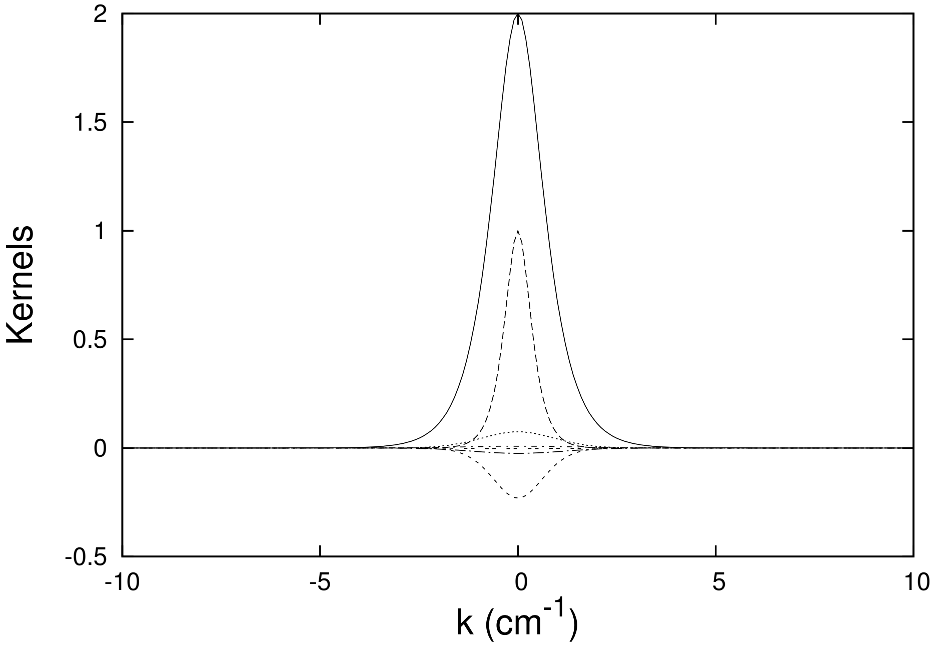

Figure 20.3.19: A comparison of the circular cylinder $m = 1$ kernel $[1/I_1'(kR)]$, shown as a solid line, and the first few relevant elliptical cylinder $m = 1$ kernels $[k\alpha_1^r(k)/Ce_r'(U,q)]$, namely those for $r = 1, 3, 5, 7, 9$, and 11, shown as a dashed lines. The elliptic kernels alternate in sign, and their magnitude at $k = 0$ decreases with increasing r.

Now we are prepared to examine the $C_{m,c}^{[n]}(z)$. Figures 3.21 and 3.22 show $C_{1,c}^{[0]}(z)$ for each noise realization. And Figures 3.23 through 3.26 show the associated quantities $C_{1,c}^{[6]}(z)$ and $C_{7,c}^{[0]}(z)$. Again there are statistical fluctuations, but the general trend is that the use of an elliptic cylinder yields on-axis gradients that have less sensitivity to errors in the grid data.

To study the problem more thoroughly, we should examine the results for a large number of seeds. We expect that when such results are examined, the effect of noise will average to zero (because the effect of noise can have either sign), but there will be a nonzero variance. What should be verified is that the variance is smaller for elliptic cylinders than for circular cylinders.

Figures 3.27 and 3.28 display circular and elliptical cylinder results for the $C_{1,c}^{[0]}(z)$ obtained for 12 seeds. They also show $< C_{1,c}^{[0]}(z) >$, the average of these results. Figures 3.29 through 3.32 do the same for $C_{1,c}^{[6]}(z)$ and $C_{7,c}^{[0]}(z)$. Evidently the averaged results are smaller than the individual results, thereby indicating that the average does indeed approach zero as the number of seeds is increased.

Figures 3.33 through 3.35 show the quantities $\{< [C_{1,c}^{[0]}(z)]^2 >\}^{1/2}$, $\{< [C_{1,c}^{[6]}(z)]^2 >\}^{1/2}$, and $\{< [C_{7,c}^{[0]}(z)]^2 >\}^{1/2}$, the root-mean-square values based on these 12 seeds. Results are shown for both the circular and elliptic cylinder. We see that, for the two cases of

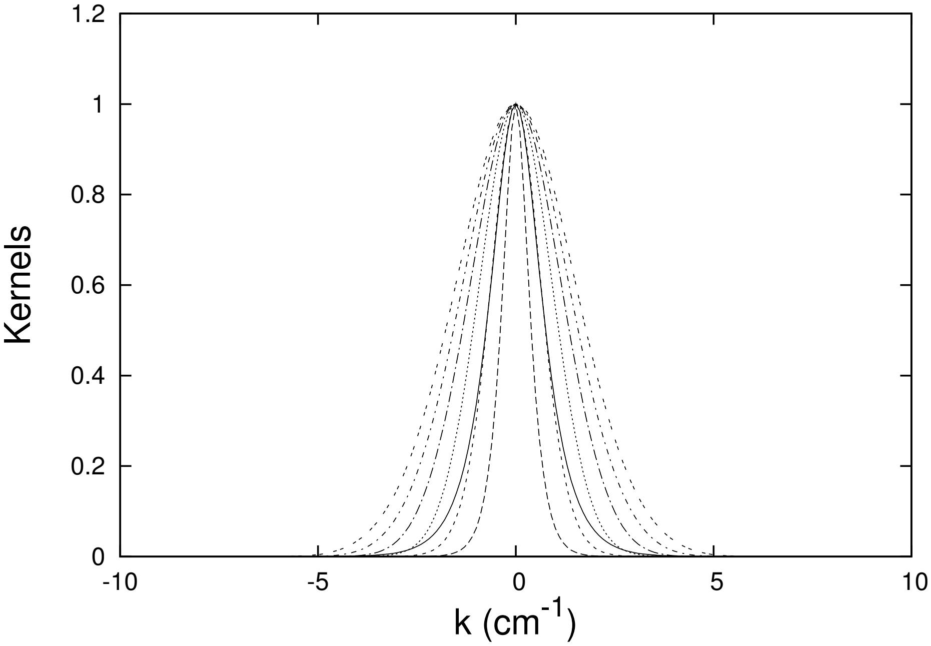

Figure 20.3.20: A comparison of the circular cylinder $m = 1$ kernel $[1/I_1'(kR)]$ and the first few elliptic cylinder $m = 1$ kernels $[k\alpha_1^r(k)/Ce_r'(U, q)]$, all normalized to 1 at $k = 0$.

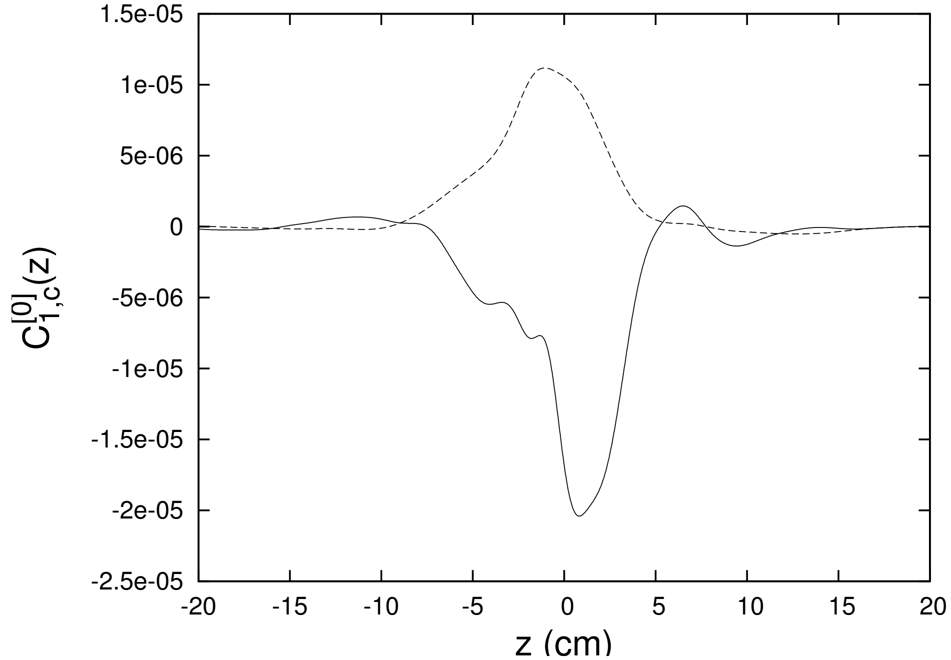

Figure 20.3.21: Dashed line: The function $C^{[0]}_{1,c}(z)$ produced by a pure noise field and using an elliptic cylinder. Solid line: The function $C^{[0]}_{1,c}(z)$ produced by a pure noise field and using a circular cylinder.

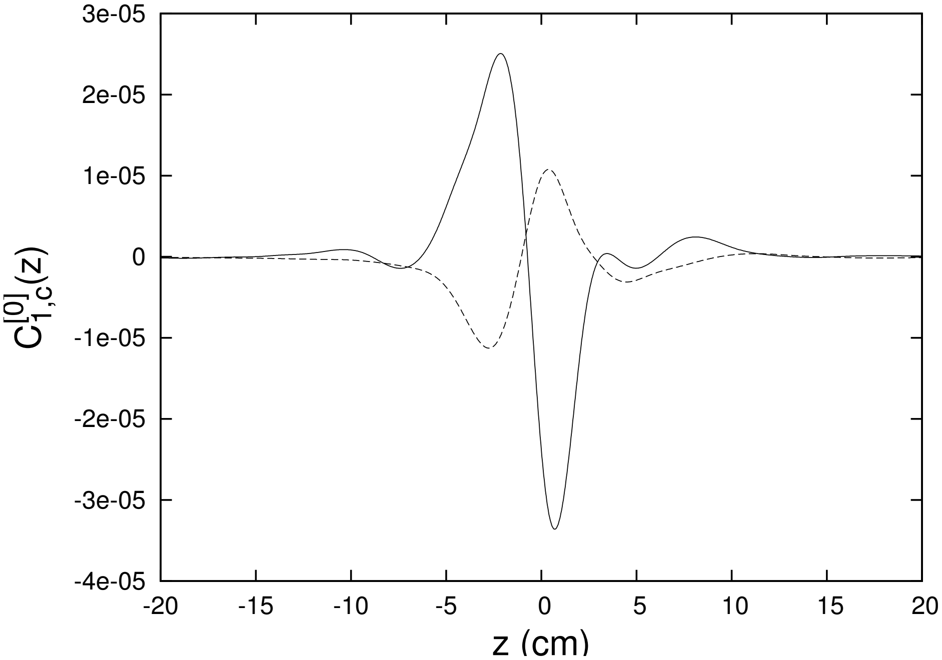

Figure 20.3.22: Results for the second random number seed. Dashed line: The function $C^{[0]}_{1,c}(z)$ produced by a pure noise field and using an elliptic cylinder. Solid line: The function $C^{[0]}_{1,c}(z)$ produced by a pure noise field and using a circular cylinder.

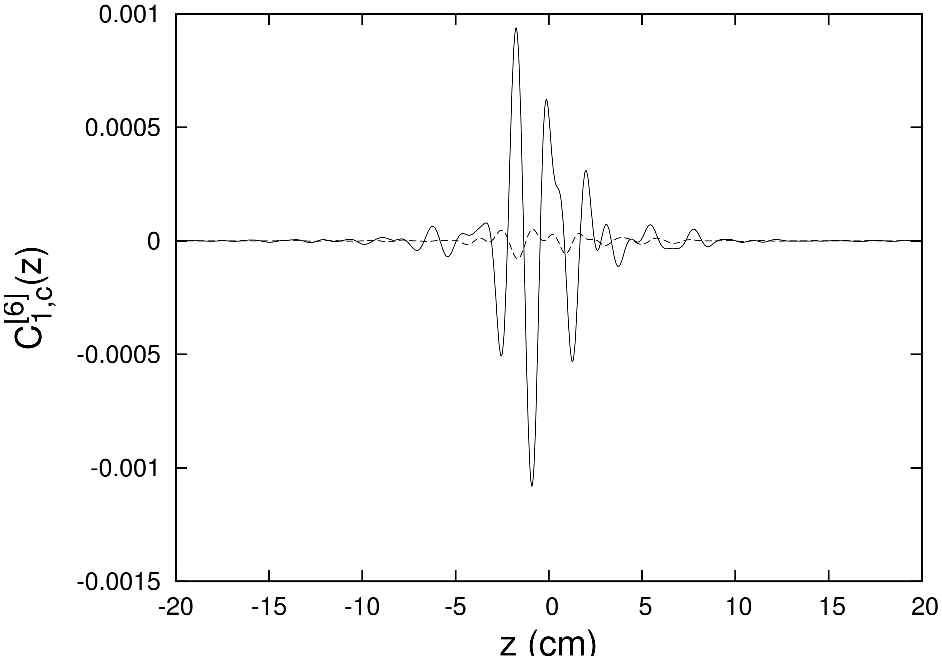

Figure 20.3.23: The function $C^{[6]}_{1,c}(z)$ produced by a pure noise field. Dashed line: Elliptic cylinder result. Solid line: Circular cylinder result.

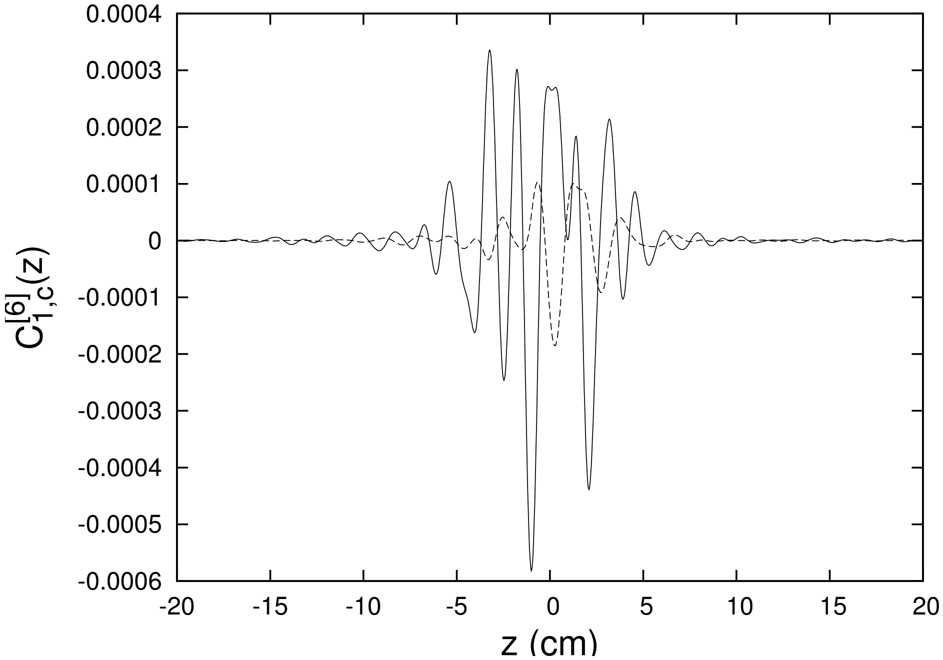

Figure 20.3.24: The function $C^{[6]}_{1,c}(z)$ produced by a pure noise field arising from a second different random number seed. Dashed line: Elliptic cylinder result. Solid line: Circular cylinder result.

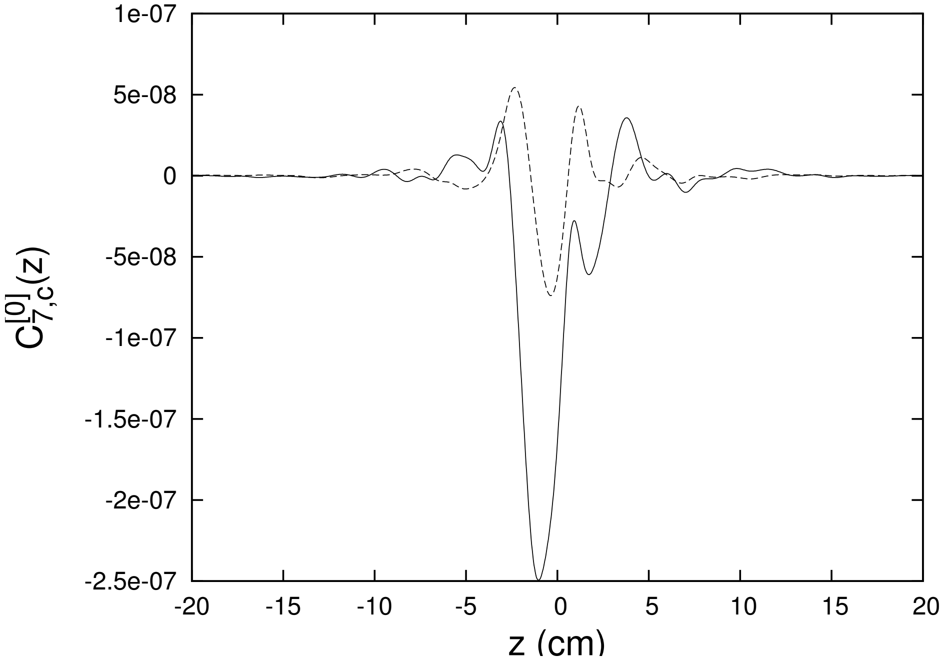

Figure 20.3.25: The function $C^{[0]}_{7,c}(z)$ produced by a pure noise field. Dashed line: Elliptic cylinder result. Solid line: Circular cylinder result.

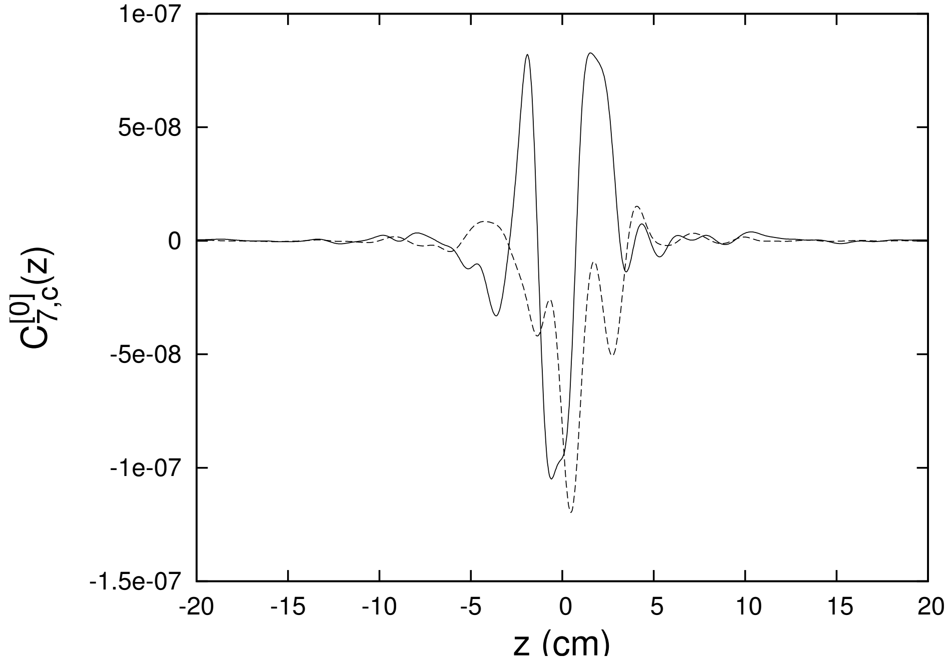

Figure 20.3.26: The function $C^{[0]}_{7,c}(z)$ produced by a pure noise field arising from a second different random number seed. Dashed line: Elliptic cylinder result. Solid line: Circular cylinder result.

$\{< [C^{[6]}_{1,c}(z)]^2 >\}^{1/2}$ and $\{< [C^{[0]}_{7,c}(z)]^2 >\}^{1/2}$, the root-mean-square values are indeed smaller for the elliptic cylinder compared to the circular cylinder.

The case for $\{< [C^{[0]}_{1,c}(z)]^2 >\}^{1/2}$ is inconclusive. It appears that the number of samples is still too small so that statistical fluctuations still overwhelm the expected effect. This hypothesis is validated by Figure 3.36. It shows the functions $C^{[0]}_{1,c}(z)$ produced by assigning a nonzero field value to only a *single* grid point. Consider the field value

$$(B_x, B_y, B_z) = (.01\,\mathrm{T}, 0, 0). \tag{20.3.1}$$

For the elliptic cylinder case we assign this field value to the grid point

$$(x, y, z) = (4\,\mathrm{cm}, 0, 0). \tag{20.3.2}$$

And for the circular cylinder case we assign this field value to the grid point

$$(x, y, z) = (2\,\mathrm{cm}, 0, 0). \tag{20.3.3}$$

All other grid points are assigned vanishing field values. As the figure shows, the elliptic cylinder result for $C^{[0]}_{1,c}(z)$ is indeed smaller than the circular cylinder result.

Chapter 21

Realistic Transfer Maps for General Straight Beam-Line Elements

Chapter 15 described cylindrical harmonic expansions for straight elements. This chapter utilizes these expansions and applies surface methods to several common magnetic beam-line elements.[1] It also summarizes various cases in which fields can be computed analytically. Particular attention is devoted to the way in which fringe fields fall off with increasing distance.

21.1 Solenoids

21.1.1 Preliminaries

A solenoid is a beam-line element whose field is described by a cylindrical harmonic expansion that contains (ideally) only an $m = 0$ term. We recall from Section 15.2.3 that in this case the magnetic scalar potential ψ has the expansion

$$\psi(x, y, z) = \psi_0(x, y, z) = C_0^{[0]}(z) - (1/4)(x^2 + y^2)C_0^{[2]}(z) + \cdots . \tag{21.1.1}$$

See (15.2.57). Correspondingly, the associated magnetic field has the expansion

$$B_x = \partial_x\psi_0 = -(1/2)xC_0^{[2]}(z) + \cdots , \tag{21.1.2}$$

$$B_y = \partial_y\psi_0 = -(1/2)yC_0^{[2]}(z) + \cdots , \tag{21.1.3}$$

$$B_z = \partial_z\psi_0 = C_0^{[1]}(z) - (1/4)(x^2 + y^2)C_0^{[3]}(z) + \cdots . \tag{21.1.4}$$

Finally, according to Section (15.4.1), there is a suitable associated vector potential $\hat{\boldsymbol{A}}^0$ given by the relation

$$\hat{A}_x^0 = -yU, \tag{21.1.5}$$

$$\hat{A}_y^0 = xU, \tag{21.1.6}$$

$$\hat{A}_z^0 = 0, \tag{21.1.7}$$

[1] Electrostatic beam-line elements can be treated in an analogous way.

where U is defined to be

$$U(\rho, z) = (1/2) \sum_{\ell=0}^{\infty} (-1)^{\ell} \frac{1}{2^{2\ell} \ell! (\ell+1)!} C_0^{[2\ell+1]}(z) \rho^{2\ell} \tag{21.1.8}$$

with

$$\rho^2 = x^2 + y^2. \tag{21.1.9}$$

From (1.2) through (1.9) we see that both $\boldsymbol{B}$ and $\hat{\boldsymbol{A}}^0$ are completely specified in terms of a single "master" function $C_0^{[1]}(z)$ and its derivatives. Moreover, according to (1.4), the on-axis field is given by the relation

$$B_z(0, 0, z) = C_0^{[1]}(z). \tag{21.1.10}$$

We will next see what can be said about the master function $C_0^{[1]}(z)$ in various cases.

21.1.2 Qualitatively Correct Iron-Dominated Solenoid Model

We next consider the case of an iron-dominated solenoid. Suppose an approximating signum function is defined by the rule

$$\mathrm{sgn}(z, a) = \tanh(z/a) \tag{21.1.11}$$

instead of the rule (1.21), and this approximating signum function is employed to define a soft-edge bump function with the use of (1.20). Then the relation (1.14) continues to hold, but with the soft-edge bump function defined in terms of (1.29) and (1.20).

In this case it can be verified that (1.15) through (1.18) remain true. See Exercise 1.2. However (1.26) and (1.27) are replaced by the asymptotic relations

$$\mathrm{sgn}(z, a) = 1 - 2\exp(-2z/a) + O[\exp(-4z/a)] \text{ as } z \to \infty, \tag{21.1.12}$$

$$\mathrm{bump}(z, a, L) = [\exp(2L/a) - 1] \exp(-2|z|/a) + O[\exp(-4|z|/a)] \text{ as } |z| \to \infty. \tag{21.1.13}$$

Consequently in this model (1.28) is replaced by the *exponential* fall off relation

$$C_0^{[1]}(z) = B(0, 0, z) = B[\exp(2L/a) - 1] \exp(-2|z|/a) + O[\exp(-4|z|/a)] \text{ as } |z| \to \infty. \tag{21.1.14}$$

The characteristic fall-off length is again governed by a.

This model does not correspond to any easily-described iron and current distribution. But it does have the property of exponential fall off, which is characteristic of iron-dominated solenoids when the coils are buried deep within the iron. See the next section. It therefore may be of some use in preliminary modeling studies of transfer maps for iron-dominated solenoids.

Exercises

21.1.1. Verify that $B_z(0, 0, z)$ as given by (1.11) describes the on-axis field of a simple air-core solenoid.

21.1.2. The purpose of this exercise is to verify the relations (1.15) through (1.18). Show that the approximating signum function (1.21) has the properties

$$\operatorname{sgn}(-z,a) = -\operatorname{sgn}(z,a), \tag{21.1.15}$$

$$\lim_{z\to\pm\infty} \operatorname{sgn}(z,a) = \pm 1. \tag{21.1.16}$$

Sketch $\operatorname{sgn}(z,a)$, $-\operatorname{sgn}(z-L,a)$, and $\operatorname{bump}(z,a,L)$ as given by (1.20) to verify the relations (1.15) through (1.17).

What remains is to prove the relation (1.18). Begin by writing

$$\int_{-\infty}^{\infty} \operatorname{bump}(z,a,L)dz = \lim_{w\to\infty} \int_{-w}^{w} \operatorname{bump}(z,a,L)dz. \tag{21.1.17}$$

Next verify from the representation (1.20) that

$$\int_{-w}^{w} \operatorname{bump}(z,a,L)dz = (1/2)\int_{-w}^{w} \operatorname{sgn}(z,a)dz - (1/2)\int_{-w}^{w} \operatorname{sgn}(z-L,a)dz. \tag{21.1.18}$$

Show that the first integral on the right side of (1.36) vanishes because of (1.33). Show that by making the change of variables $x = z - L$ the second integral on the right side of (1.36) becomes

$$\begin{aligned} -(1/2)\int_{-w}^{w} \operatorname{sgn}(z-L,a)dz &= -(1/2)\int_{-w-L}^{w-L} \operatorname{sgn}(x,a)dx \\ = -(1/2)\int_{-w-L}^{w+L} \operatorname{sgn}(x,a)dx &+ (1/2)\int_{w-L}^{w+L} \operatorname{sgn}(x,a)dx. \end{aligned} \tag{21.1.19}$$

Verify that the first integral in the second line of (1.37) vanishes, again because of (1.33). It follows that there is the result

$$\int_{-w}^{w} \operatorname{bump}(z,a,L)dz = (1/2)\int_{w-L}^{w+L} \operatorname{sgn}(x,a)dx. \tag{21.1.20}$$

Show from (1.34) that there is the result

$$\lim_{w\to\infty}(1/2)\int_{w-L}^{w+L} \operatorname{sgn}(x,a)dx = (1/2)2L = L. \tag{21.1.21}$$

Put all your intermediate results together to obtain the final result

$$\int_{-\infty}^{\infty} \operatorname{bump}(z,a,L)dz = L, \tag{21.1.22}$$

as desired. Note that the proof of this result has depended only on the representation (1.20) and properties (1.33) and (1.34), which are required properties of any approximating signum function.

21.1.3. Verify the limiting behavior (1.22). Verify the fall-off relations (1.26) through (1.28).

21.1.4. Verify for a long simple air-core solenoid that the on-axis field at either end ($z = 0$ or $z = L$) is $B/2$. Verify that the same is true for a long solenoid described by the tanh model (1.29), and for any bump function model that is constructed from approximating signum functions.

21.1.5. Verify the fall-off relations (1.30) through (1.32).

21.1.3 Improved Model for Iron-Dominated Solenoid

Chapter 16 described the computation of transfer maps for straight magnetic beam-line elements based on the *normal* component of the field on the surface of a cylinder. In this subsection we will use instead the *tangential* B_z component of the field on the surface of a cylinder. For simplicity, we will use the surface of a circular cylinder. This approach of employing the B_z component is particularly useful in the case of a solenoid.

From (15.2.13) we find the result

$$\begin{aligned} B_z(x,y,z) &= B_z(\rho,\phi,z) = \partial\psi(x,y,z)/\partial z \\ &= \sum_{m=-\infty}^{\infty} \int_{-\infty}^{\infty} dk G_m(k)(ik)\exp(ikz)\exp(im\phi)I_m(k\rho). \end{aligned} \tag{21.1.23}$$

Now integrate both sides of (2.1) over $\phi \in [0, 2\pi]$ to find the relation

$$\tilde{B}_z(\rho,0,z) = \int_{-\infty}^{\infty} dk G_0(k)(ik)\exp(ikz)I_0(k\rho) \tag{21.1.24}$$

where

$$\tilde{B}_z(\rho,0,z) = [1/(2\pi)] \int_0^{2\pi} d\phi B_z(\rho,\phi,z). \tag{21.1.25}$$

Next, from the uniqueness of the Fourier transform, it follows that

$$G_0(k)(ik)I_0(kR) = \tilde{\tilde{B}}_z(R,0,k) \tag{21.1.26}$$

where

$$\tilde{\tilde{B}}_z(R,0,k) = [1/(2\pi)] \int_{-\infty}^{\infty} dz \exp(-ikz)\tilde{B}_z(R,0,z). \tag{21.1.27}$$

Inserting (2.4) into (2.2) gives the result

$$\tilde{B}_z(\rho,0,z) = \int_{-\infty}^{\infty} dk \exp(ikz)\tilde{\tilde{B}}_z(R,0,k)I_0(k\rho)/I_0(kR). \tag{21.1.28}$$

Finally, use of (15.2.71) or (15.4.36) gives the relation

$$C_0^{[1]}(z) = \int_{-\infty}^{\infty} dk \exp(ikz)\tilde{\tilde{B}}_z(R,0,k)/I_0(kR) \tag{21.1.29}$$

from which it follows that

$$C_0^{[n]}(z) = \int_{-\infty}^{\infty} dk \exp(ikz)\tilde{\tilde{B}}_z(R,0,k)[(ik)^{n-1}/I_0(kR)]. \tag{21.1.30}$$

We have found expressions for the $m = 0$ on-axis gradients in terms of the B_z component of the magnetic field on the surface of a circular cylinder. If desired, we could also find expressions for the $m \neq 0$ on-axis gradients in terms of B_z on the surface.[2]

As a simple application, the representation (2.7) can be used to find an *approximation* to the on-axis gradients (and hence the magnetic field) in the case that the field is produced by an iron-dominated magnetic solenoid of bore radius R with a small pole gap of length L centered at $z = 0$. Solenoids for use in electron microscopes are often of this type. See Figure 1.1. In this case we may make the approximation

$$\begin{aligned} &B_z(R,\phi,z) = B_{\text{gap}} \text{ for } z \in (-L/2, L/2), \\ &B_z(R,\phi,z) = 0 \text{ elsewhere.} \end{aligned} \tag{21.1.31}$$

That is, the tangential surface field exists only in the gap, and is constant there both in ϕ and in z.[3] With the assumption (2.9), the relations (2.3) and (2.5) become

$$\tilde{\tilde{B}}_z(R,0,k) = [B_{\text{gap}}/(2\pi)]\int_{-L/2}^{L/2} dz \exp(-ikz) = [B_{\text{gap}}/(\pi k)]\sin(kL/2). \tag{21.1.32}$$

Correspondingly, we find for the on-axis gradient the result

$$C_0^{[1]}(z) = [B_{\text{gap}}/(\pi)]\int_{-\infty}^{\infty} dk \exp(ikz)\sin(kL/2)/[kI_0(kR)]. \tag{21.1.33}$$

Examination of the integral representation (2.11) for $C_0^{[1]}(z)$ reveals that it depends on the dimensionless quantities z/R and L/R. Indeed, upon making the change of integration variable given by

$$\lambda = kR, \tag{21.1.34}$$

(2.11) takes the form

$$C_0^{[1]}(z) = B_{\text{gap}}(L/R)F(z/R, L/R) \tag{21.1.35}$$

where F is a *profile function* given by

$$\begin{aligned} F(z/R, L/R) &= (1/\pi)(R/L)\int_{-\infty}^{\infty} d\lambda \exp(i\lambda z/R)\sin[(\lambda/2)(L/R)]/[\lambda I_0(\lambda)] \\ &= [1/(2\pi)]\int_{-\infty}^{\infty} d\lambda \exp(i\lambda z/R)\frac{\sin[(\lambda/2)(L/R)]}{[(\lambda/2)(L/R)]}[1/I_0(\lambda)] \\ &= [1/(2\pi)]\int_{-\infty}^{\infty} d\lambda \exp(i\lambda z/R)\{\text{sinc}[(\lambda/2)(L/R)]\}[1/I_0(\lambda)]. \end{aligned} \tag{21.1.36}$$

[2] There might also be occasions in which one might want to use the azimuthal component B_ϕ on the surface.

[3] That the tangential magnetic field should be zero outside the gap follows from the idealized boundary condition for the interface between vacuum and a medium with infinite magnetic permeability. That the field should be constant in the gap is a further idealization.

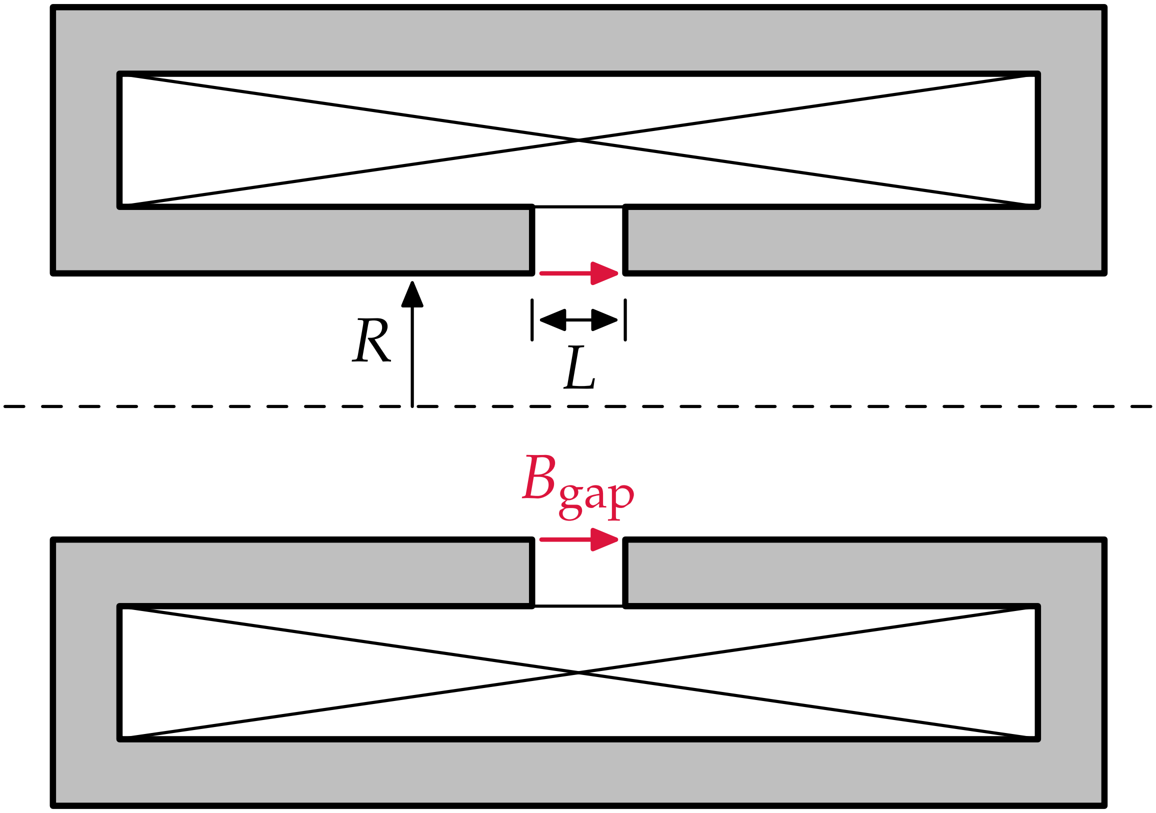

Figure 21.1.1: Schematic of an iron-dominated solenoid with an inter-pole gap L substantially smaller than the bore radius R.

Suppose that L is small compared to R so that L/R is small. Then, when the argument of the sine or sinc function in (2.14) differs significantly from zero, $[I_0(\lambda)]^{-1}$ will be essentially zero. Therefore, we can expand the sine or sinc function in a Taylor series and integrate term by term. We also note that the surface field model (2.9) is only reasonable in the limit of small L/R. Upon making the Taylor expansion just described, one finds that $F(z/R, L/R)$ differs from $F(z/R, 0)$ only by terms of order $(L/R)^2$ and

$$F(z/R, 0) = [1/(2\pi)] \int_{-\infty}^{\infty} d\lambda \exp(i\lambda z/R)/I_0(\lambda). \tag{21.1.37}$$

Therefore, for small L/R, it is useful to make the approximation

$$C_0^{[1]}(z) \simeq B_{\rm gap}(L/R)F(z/R, 0). \tag{21.1.38}$$

For example, Figure 1.2 displays $F(z/R, L/R)$ as a function of z/R for the two values $L/R = 0$ and $L/R = 1/2$. Evidently the two profiles nearly agree when $z = 0$, and are essentially identical away from $z = 0$.

Let us make the further and more drastic approximation of replacing $I_0(\lambda)$, the denominator in (2.15), by $\cosh(\lambda)$. In this approximation the integral (2.11) can be evaluated analytically to give the result

$$F(z/R, 0) \approx G(z/R) = [1/(2\pi)] \int_{-\infty}^{\infty} d\lambda \exp(i\lambda z/R)/\cosh(\lambda) = 1/\{2\cosh[\pi z/(2R)]\}. \tag{21.1.39}$$

Figure 1.2 also displays the approximate profile function $G(z/R)$.

There are three things that we can learn/observe from this approximation. First, although it is not a particularly good approximation, G becomes singular when $z = \pm iR$, which agrees with the discussion of analytic properties given in Subsection 19.1.2. [Note also that (1.12) is singular when $z = \pm ia$.] Second, G falls off *exponentially* as $\exp[-\pi|z|/(2R)]$ for large $|z|$. Third, as Figure 1.2 illustrates, $F(z/R, L/R)$ and correspondingly $C_0^{[1]}(z)$ essentially fall off for large $|z|$ in the same way as G. Thus, for example, at a distance of one bore diameter away from the center of the solenoid, when $|z| = 2R$, the on-axis field will have fallen from its maximum value by approximately a factor of $\exp(-\pi) \simeq .04$.

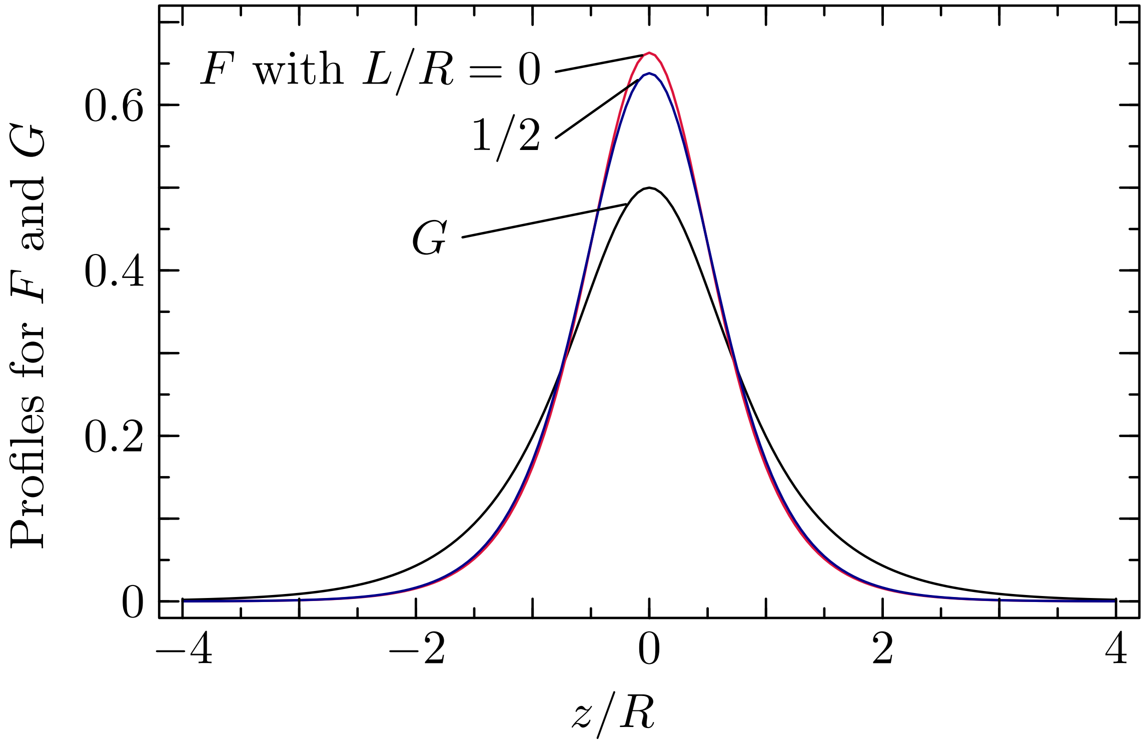

Figure 21.1.2: The profile function $F(z/R, L/R)$ as given by (2.14) in the cases $L/R = 0$ and $L/R = 1/2$, and the approximate profile function $G(z/R)$. The two curves that nearly agree are those for F, with the highest curve being that for F when $L/R = 0$. The third curve is that for G.

21.1.4 Quantitatively Correct Iron-dominated Solenoid

21.2 Realistic Wigglers/Undulators

21.2.1 An Iron-Dominated Superconducting Wiggler/Undulator

21.3 Quadrupoles

21.3.1 Validation of Circular Cylinder Surface Method

This subsection describes numerical tests performed for the case of a Lambertson type quadrupole. In this case the on-axis gradients and their derivatives can be determined analytically. The surface data $B_\rho(\rho = R, \phi, z)$ can also be found directly using the Biot-Savart law. We will first show that the gradients computed from the surface data following the method of Section 4 agree with the gradients determined analytically. Next we will add noise to the surface data, and again apply the method of Section 4 to this noisy data. We will find that this noise has no undue effect on the computed gradients. Finally, we will show that the noise also has no undue effect on the transfer map $\mathcal{M}$.

The method described in Section 4 has been implemented in the code MARYLIE 5.0 [**?**] as a user-defined routine. The routine reads from an external file the functions $a_m(R,z)$ and $b_m(R,z)$, see (4.1), evaluated on a discrete set of points z_i. It then generates the corresponding transfer map by using the built-in routine GENMAP to integrate the map equations (1.2). Since MARYLIE 5.0 is a 5^{th} order code, only the multipoles through $m=6$ need be considered.

The Fourier transforms (4.4) and (4.5) are calculated from the read-in values of $a_m(R,z)$ and $b_m(R,z)$ using Filon's method [3] for various values of k in the interval $[-k_{max}, k_{max}]$ where k_{max} is a suitable k cut-off for the integrals (4.2) and (4.3). For the cases described below, we have used the value $Rk_{max} = 20$. Filon's method requires interpolation of the functions $a_m(R,z)$ and $b_m(R,z)$; and for this purpose we use local parabolic fits.

The integration algorithm of GENMAP is based on a 11^{th} order multistep (Adams) method. Because the algorithm uses a fixed step size, one needs to provide values of the generalized gradients and their derivatives only at the predetermined locations in z required by GENMAP. The integrals (4.2) and (4.3) that provide the generalized on-axis gradients and their derivations are evaluated at the values of z needed by GENMAP, again using Filon's method. We emphasize that no interpolation of the generalized gradients is required by GENMAP.

We have tested the routine by treating the case of a Lambertson quadrupole [8, 9]. For this case only $b_2(R,z)$ and $b_6(R,z)$ are nonzero. Correspondingly only the functions $C^{[0]}_{2,s}$, $C^{[1]}_{2,s}$, $C^{[2]}_{2,s}$, $C^{[3]}_{2,s}$, $C^{[4]}_{2,s}$, and $C^{[0]}_{6,s}$ are required. The use of this case as an example has the virtue that the various C functions can be found exactly [10].

Also, the surface data $B_\rho(\rho = R, \phi, z)$ can be found directly using the Biot-Savart law, and this data can be integrated over ϕ to yield $b_2(R,z)$ and $b_6(R,z)$. In our test we evaluted $B_\rho(\rho = R, \phi, z)$ for 279 equally spaced z values within the interval

$$z \in [z_{min}, z_{max}] = [-7r, 7r] \tag{21.3.1}$$

according to the rule

$$z_i = z_{min} + \Delta(i-1) \text{ for } i = 1, 2, \cdots 279. \tag{21.3.2}$$

The cylinder on which we evaluated B_ρ had the radius

$$R = .75r. \tag{21.3.3}$$

Here $r = .128$ m is the radius of the quadrupole itself, and the length of the quadrupole is $2r$. Corresponding, $\Delta = 14r/278 = 6.44$ mm. The relatively large values of z_{min} and z_{max} were necessary because the large radius-to-length ratio of the quadrupole makes the fringe fields very extended.

For each z value the quantity $B_\rho(\rho = R, \phi, z)$ was evaluated for 256 equally spaced angles over the interval $[0, 2\pi]$, and these B_ρ values were used to compute the integrals

$$a_m(R,z) = \frac{1}{\pi}\int_0^{2\pi} d\phi \cos(m\phi) B_\rho(\rho = R, \phi, z), \tag{21.3.4}$$

$$b_m(R,z) = \frac{1}{\pi}\int_0^{2\pi} d\phi \sin(m\phi) B_\rho(\rho = R, \phi, z). \tag{21.3.5}$$

Because of the symmetries of a (normal) quadrupole only the functions b_2 and b_6 are non vanishing for $m \leq 6$. The net results of the steps just described are the values of these functions at the points (8.2). These functions are shown in Figures 8.1 and 8.2.

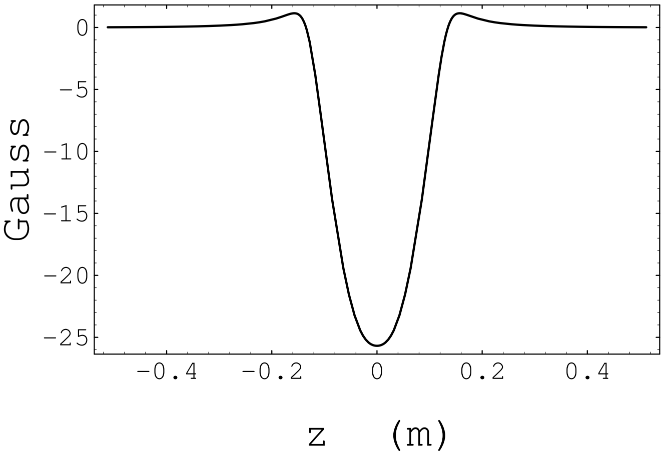

Figure 21.3.1: The angle integrated surface data $b_2(R,z)$. The magnet occupies the interval $z \in [-0.128\,\text{m}, 0.128\,\text{m}]$.

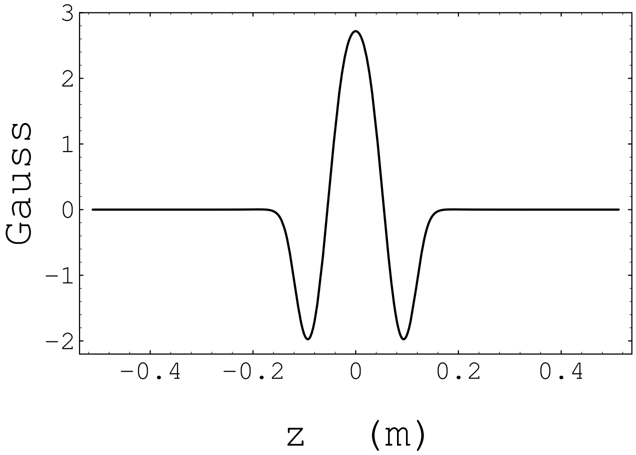

Figure 21.3.2: The angle integrated surface data $b_6(R,z)$.

Figure 8.3 shows $C_{2,s}^{[0]}$ determined both analytically and computed numerically from $b_2(R,z)$ using the method of Section 4 as described above. Evidently the agreement is excellent. Figure 8.4 shows analytic values of $C_{6,s}^{[0]}$ and values computed numerically from $b_6(R,z)$. Again the agreement is excellent. The most stringent test is a comparison of analytic values of $C_{2,s}^{[4]}$ with values computed numerically from $b_2(R,z)$. This comparison is given in Figure 8.5. Again the agreement is excellent.

As a final test of our routines, we compared the transfer maps for our Lambertson quadrupole obtained using either the analytically known on-axis gradients or on-axis gradients computed numerically from surface data. Table 8.1 shows that the (relative) difference

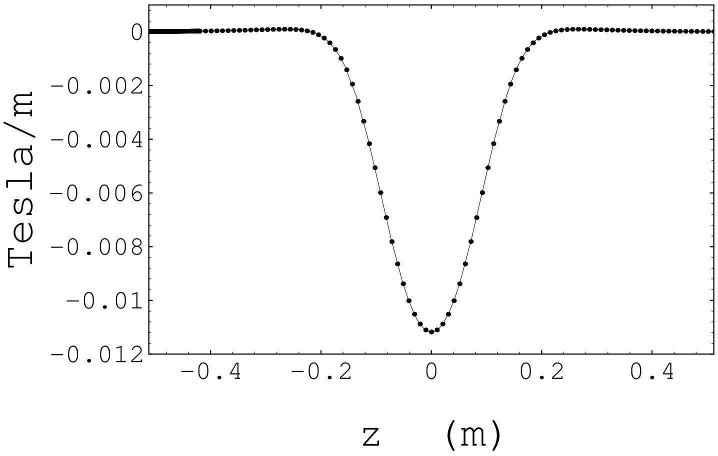

Figure 21.3.3: The function $C_{2,s}^{[0]}(z)$ as calculated numerically from surface data (dots) and analytically (solid line).

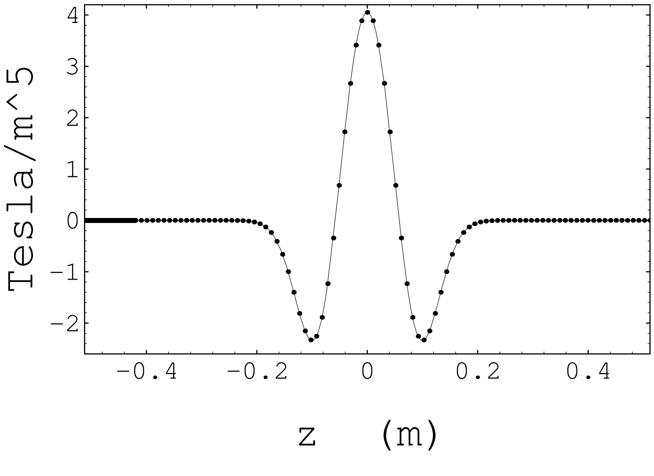

Figure 21.3.4: The function $C_{6,s}^{[0]}(z)$ as calculated numerically from surface data (dots) and analytically (solid line).

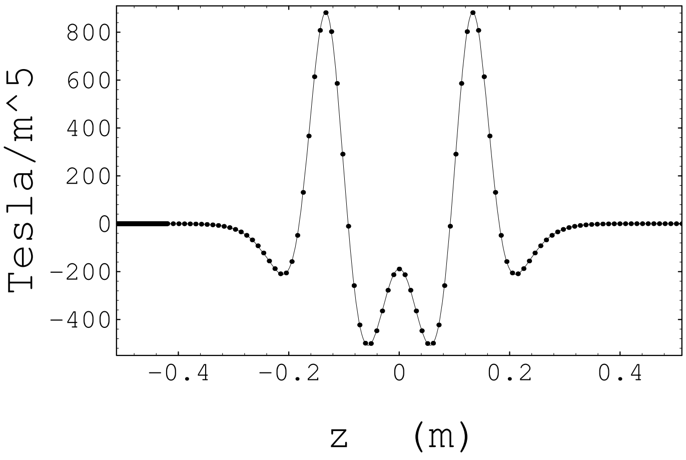

Figure 21.3.5: The function $C_{2,s}^{[4]}(z)$ as calculated numerically from surface data (dots) and analytically (solid line).

in the surface-data-based map, as compared to the exact map, is very small. Of course, apart from roundoff problems, we expect this difference will vanish as the number of sampling points in z and ϕ is made arbitrarily large.

Table 21.3.1: Relative difference between the surface-data-based map and the exact map.

map generators	relative difference
$\mathcal{R}_2$	$< 10^{-6}$
$f_3,\, f_4$	$< 10^{-5}$
$f_5,\, f_6$	$< 10^{-4}$

Now that the method of Section 4 has been verified to work, we will study the sensitivity of transfer map calculations to the presence of random errors (noise) in the surface data. As a simple model, consider the perturbed functions

$$b_2^{rnd}(R, z_i) = b_2(R, z_i)[1 + \epsilon_2(z_i)], \tag{21.3.6}$$

$$b_6^{rnd}(R, z_i) = b_6(R, z_i)[1 + \epsilon_6(z_i)], \tag{21.3.7}$$

where the $\epsilon_2(z_i)$, $\epsilon_6(z_i)$ are random variables uniformly distributed in the interval $[-\epsilon/2, \epsilon/2]$, and $b_2(R, z_i)$, $b_6(R, z_i)$ are the same as before. What effect do these errors have on the on-axis gradients computed from the (noisy) surface data?

Figure 8.6 shows $C_{2,s}^{[4]}$ for a particular realization of the error distribution (seed #2) and $\epsilon = 10^{-2}$. The solid line shows analytic results (the same as those of Figure 8.5) and the dots show results computed numerically from the noisy surface data. Close inspection of the figure shows that the points no longer fall exactly on the curve, as is to be expected in the case of noise. However, the size of the deviations from the curve is comparable to the size of the noise, and not unduly larger. To facilitate closer comparison, Figure 8.7 shows the difference between the analytic results and results computed numerically from the noisy surface data. Evidently the deviation is generally on the order of 1% or less, which is comparable with $\epsilon = 10^{-2}$.

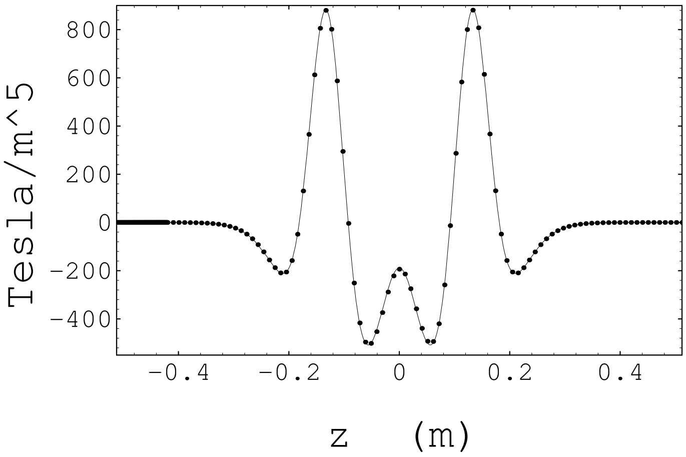

Figure 21.3.6: The function $C_{2,s}^{[4]}(z)$ as calculated numerically from noisy (seed #2) surface data (dots), and analytically (solid line).

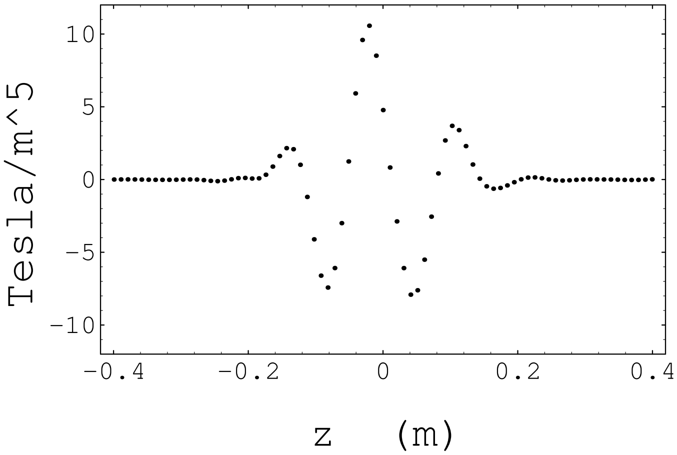

Figure 21.3.7: Difference between the solid line and dots of Figure 8.6.

Since, as we have seen, the computation of the on-axis gradients and their derivatives is not unduly affected by noise in the surface data, we expect the same will be true for the transfer map. This is indeed the case. Table 8.2 shows that the (relative) error in the noisy surface data based map (as compared to the exact map) is, at worst, on the order of the noise.

Table 21.3.2: Relative error of the noisy surface data based map compared to the exact map.

map generators	seed #1	seed#2	seed#3
$\mathcal{R}_2$	$< 3 \times 10^{-4}$	$< 8 \times 10^{-4}$	$< 5 \times 10^{-4}$
f_3, f_4	$< 10^{-3}$	$< 1.6 \times 10^{-3}$	$< 1.6 \times 10^{-3}$
f_5, f_6	$< 10^{-2}$	$< 1.5 \times 10^{-2}$	$< 1.3 \times 10^{-2}$

One might imagine that the introduction of noise would damage the differentiability (with respect to z) of the surface data $a_m(R, z)$ and $b_m(R, z)$. This is indeed true. Consider, for example, the function $b_2(R, z)$ of the previous section. Figure 9.1 shows its Fourier transform $\tilde{b}_2(R, k)$. Evidently the spectrum of b_2 cuts off beyond a wave number $k_{max} \simeq 150$ m^{-1}. For comparison, Figure 9.2 shows the Fourier transform of $\epsilon_2(z)$ for the case of seed #2. Note that the noise spectrum extends to $k'_{max} \simeq 600$ m^{-1}. This is to be expected since $\pi/\Delta \simeq 490$ m^{-1}. Finally, Figure 9.3 shows the Fourier transform of $b_2\epsilon_2$. Its spectrum extends to $k''_{max} \simeq 750$ m^{-1}. We see that $k''_{max} \simeq (k_{max} + k'_{max})$, as is also to be expected.

Although noise does damage the differentiability of surface data, it has considerably less effect on the on-axis gradients derived from the (noisy) surface data. Mathematically, this pleasant result arises from the spectral "cutoff" provided by the kernel $[k^{m+n-1}/I'_m(kR)]$ that occurs in (4.2) and (4.3). For example, Figure 9.4 shows the factor $[k^5/I'_2(kR)]$ that is relevant to the computation of $C^{[4]}_{2,s}$ for the quadrupole example of the last section. We see that it peaks at $k \simeq 50$ m^{-1}, and falls off rapidly beyond $k_{max} \simeq 200$ m^{-1}. Finally, Figure 9.5 shows the product of the two functions presented in Figures 9.3 and 9.4. From Figures 9.4 and 9.5 we see that the high wave-number part of the spectrum in Figure 9.3 is effectively filtered out. Correspondingly, as already seen in the previous section, noise in the surface data has no undue effect on the function $C^{[4]}_{2,s}$. We remark, as is obvious from our considerations, that noise has even less effect on the functions $C^{[n]}_{2,s}$ with $n < 4$. It also has no undue effect on $C^{[0]}_{6,s}$. We also note that the condition $Rk_{max} = 20$ used in Section 8 corresponds to $k_{max} \simeq 208$.

In summary, we have found that noise introduces high wave-number contributions to the spectrum of b^{rnd}_m where they are absent in the spectrum of b_m. These potentially damaging contributions are filtered by the kernel $[k^{m+n-1}/I'_m(kR)]$. Evidently this filtering becomes less effective with increasing n, and is improved by making R as large as possible. For the example studied, we found that smoothing was satisfactory for the selected value of R and the n values required for 5th-order calculations.

Finally we remark that, by making more detailed numerical studies, it should be possible to find the partial derivatives

$$\partial\mathcal{M}/\partial b_m(R, z_i) = \partial[\text{any selected coefficient of any generator for } \mathcal{M}]/\partial b_m(R, z_i). \quad (21.3.8)$$

That is, we can evaluate numerically how the map changes when the value of the surface data at any point is varied. In this way, we can get precise and complete information about the effect of possible noise.

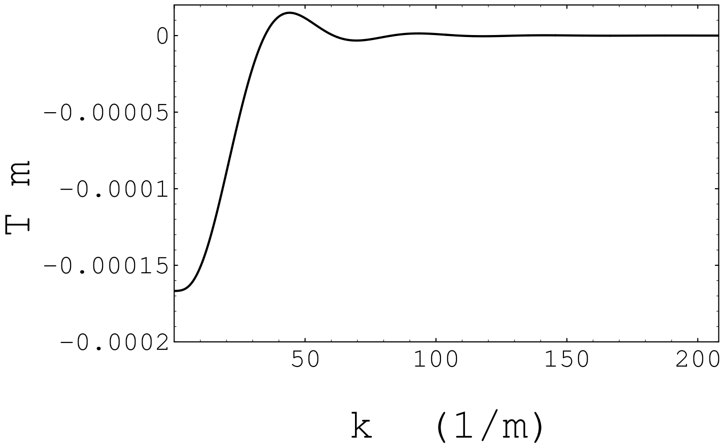

Figure 21.3.8: Real part of the function $\tilde{b}_2(R,k)$. The imaginary part vanishes.

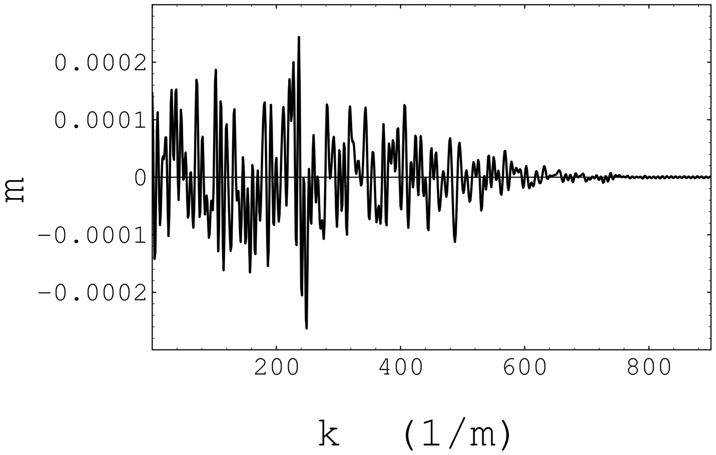

Figure 21.3.9: Real part of the function $\tilde{\epsilon}_2(k)$. The imaginary part has similar features.

Chapter 22

Realistic Transfer Maps for General Curved Beam-Line Elements: Theory

22.1 Introduction

Surface methods based on the use of cylinders are appropriate for straight beam-line elements or for bent elements with small sagitta. However, cylinders cannot be employed for elements with large sagitta, such as dipoles, where no straight cylinder would fit within the aperture. For such cases more complicated surfaces are required. For example, Figure 1.1 shows a bent box with straight end legs. Its surface could be used to treat a dipole with large sagitta. In this case, the bent part of the box would lie within the body of the dipole, and the straight legs would enclose the fringe-field regions.

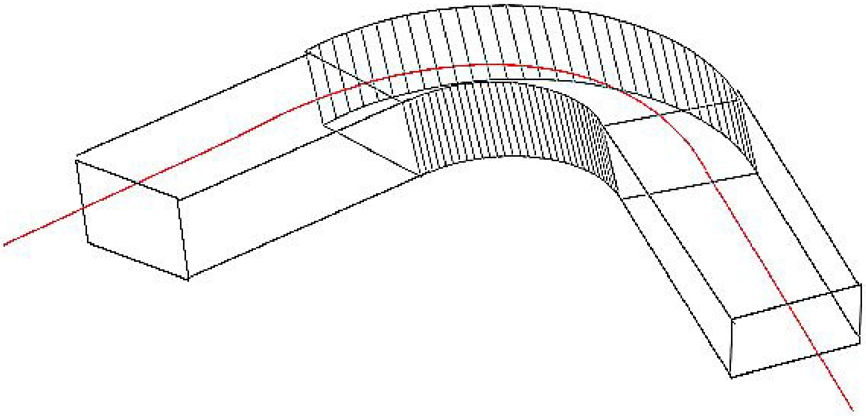

Figure 22.1.1: A bent box with straight end legs.

But now there is a complication: The *straight* cylinder methods succeeded because Laplace's equation is separable in circular, elliptical, and rectangular cylinder coordinates. Consequently, we were able to find a kernel that related the interior vector potential to the normal component of the surface magnetic field. However, there is no *bent* coordinate system with straight ends for which Laplace's equation is separable. The method of cylindrical multiples and on-axis gradients is only applicable to straight elements.

This problem can in principle be overcome if *both* the normal component of the magnetic field and the scalar potential for the magnetic field are known on the surface. (Note that a knowledge of the scalar potential on the surface is equivalent to a knowledge of the tangential component of the field on the surface.) Such data are in fact provided on a mesh by some 3-dimensional field solvers, and these data can be interpolated onto the surface.

Let V be some volume in three-dimensional space bounded by a surface S. Suppose that the magnetic field $\boldsymbol{B}(\boldsymbol{r})$ is source free when $\boldsymbol{r}$ is within V. That is, for $\boldsymbol{r}$ within V, $\boldsymbol{B}(\boldsymbol{r})$ satisfies the requirements

$$\nabla \cdot \boldsymbol{B}(\boldsymbol{r}) = 0, \tag{22.1.1}$$

$$\nabla \times \boldsymbol{B}(\boldsymbol{r}) = 0. \tag{22.1.2}$$

This will be the case for the magnetic field in an evacuated beam pipe. For a Hamiltonian treatment of trajectories, we need a vector potential $\boldsymbol{A}(\boldsymbol{r})$ such that

$$\boldsymbol{B}(\boldsymbol{r}) = \nabla \times \boldsymbol{A}(\boldsymbol{r}). \tag{22.1.3}$$

Let $\boldsymbol{n}'(\boldsymbol{r}')$ be the outward normal to S at the point $\boldsymbol{r}' \in S$. Then the normal component of $\boldsymbol{B}$ on S is given by the definition

$$B_n(\boldsymbol{r}') = \boldsymbol{n}'(\boldsymbol{r}') \cdot \boldsymbol{B}(\boldsymbol{r}'). \tag{22.1.4}$$

Also, let $\psi(\boldsymbol{r}')$ be the value of the magnetic scalar potential at the point $\boldsymbol{r}' \in S$. It satisfies the relation

$$\boldsymbol{B}(\boldsymbol{r}') = \nabla' \psi(\boldsymbol{r}'). \tag{22.1.5}$$

Then, with the aid of the vector potential for Dirac magnetic monopoles and Helmholtz's theorem, it can be shown that there are *kernels* $\boldsymbol{G}^n$ and $\boldsymbol{G}^t$ such that a suitable interior vector potential $\boldsymbol{A}(\boldsymbol{r})$ for $\boldsymbol{r}$ within V is given by the relation

$$\boldsymbol{A}(\boldsymbol{r}) = \boldsymbol{A}^n(\boldsymbol{r}) + \boldsymbol{A}^t(\boldsymbol{r}) \tag{22.1.6}$$

with

$$\boldsymbol{A}^n(\boldsymbol{r}) = \int_S dS' \; B_n(\boldsymbol{r}')\boldsymbol{G}^n(\boldsymbol{r}, \boldsymbol{r}') \tag{22.1.7}$$

and

$$\boldsymbol{A}^t(\boldsymbol{r}) = \int_S dS' \; \psi(\boldsymbol{r}')\boldsymbol{G}^t(\boldsymbol{r}, \boldsymbol{r}'). \tag{22.1.8}$$

(Here the superscripts n and t denote *normal* and *tangential*, respectively, and indicate the contributions to the vector potential made by the normal and tangential components of $\boldsymbol{B}$ on S.) Moreover, the constituents of $\boldsymbol{A}(\boldsymbol{r})$, and hence $\boldsymbol{A}(\boldsymbol{r})$ itself, satisfy the Coulomb gauge condition,

$$\nabla \cdot \boldsymbol{A}^n(\boldsymbol{r}) = \nabla \cdot \boldsymbol{A}^t(\boldsymbol{r}) = \nabla \cdot \boldsymbol{A}(\boldsymbol{r}) = 0. \tag{22.1.9}$$

A detailed exposition of this method, including expected accuracy and insensitivity to noise in the surface data, is the subject of this and the next few chapters. Thus, taken together, Chapters 15 through 21 and this chapter and Chapters 23 through 25 are intended to provide an extensive description of, and associated robust numerical algorithms for, the computation of transfer maps, including all fringe-field and higher-order multipole effects, for realistic beam-line elements having arbitrary geometry.[1]

Section 2 of this chapter describes the the mathematical tools required to treat general geometries. These tools are Dirac's magnetic monopole vector potential and Helmloltz's theorem. Sections 3 and 4 derive the relations (1.3) through (1.9), find the kernels $\boldsymbol{G}^n$ and $\boldsymbol{G}^t$, and describe their properties.

Before continuing on, we pause to advertise some of the virtues of what can be achieved with the use of general surface methods.

- The constituents $\boldsymbol{A}^n(\boldsymbol{r})$ and $\boldsymbol{A}^t(\boldsymbol{r})$ of $\boldsymbol{A}(\boldsymbol{r})$, and hence $\boldsymbol{A}(\boldsymbol{r})$ itself, are analytic functions of $\boldsymbol{r}$ for $\boldsymbol{r}$ within V, even when there are errors in the surface fields B_n and ψ, and no matter how poorly the integrals (1.7) and (1.8) are evaluated.

- The Maxwell equations for $\boldsymbol{B}(\boldsymbol{r})$, and the Coulomb gauge condition for $\boldsymbol{A}(\boldsymbol{r})$ and its constituents, are satisfied exactly even when there are errors in the surface fields B_n and ψ, and no matter how poorly the integrals (1.7) and (1.8) are evaluated.

- The kernels $\boldsymbol{G}^n$ and $\boldsymbol{G}^t$ are smoothing. Consequently, the $\boldsymbol{A}(\boldsymbol{r})$ given by (1.6) through (1.8) is relatively insensitive to noise in the surface fields B_n and ψ.

We hasten to add that the first two items above should not be taken to mean that there is no need to take care to evaluate integrals well. They just indicate that the worst disasters have been avoided. Subsequently we will learn that the kernels $\boldsymbol{G}^n$ and $\boldsymbol{G}^t$, and their $\boldsymbol{r}$ derivatives, can be strongly peaked in $\boldsymbol{r}'$ when $\boldsymbol{r}$ is near S. To obtain accurate results, this behavior of the kernels must be taken into account when integrating, with respect to $\boldsymbol{r}'$, over the surface S.

22.2 Mathematical Tools

22.2.1 Electric Dirac Strings

In this subsection we will motivate the subject of magnetic Dirac strings by treating the simpler electric case. Suppose $\boldsymbol{E}(\boldsymbol{r})$ is a vector field that obeys the equations

$$\nabla \times \boldsymbol{E} = 0, \tag{22.2.1}$$

$$\nabla \cdot \boldsymbol{E} = \rho. \tag{22.2.2}$$

From (2.1) we know there is a scalar potential ϕ such that

$$\boldsymbol{E} = -\nabla\phi, \tag{22.2.3}$$

[1] In this sentence we have used the term *multipole* loosely to refer, simply, to nonlinear terms arising from nonlinear magnetic field variations. As already emphasized earlier, the concept of cylindrical multipoles only applies to *straight* elements.

and from (2.2) it follows that

$$\nabla^2\phi = -\rho. \tag{22.2.4}$$

Introduce the notation

$$|\boldsymbol{r}-\boldsymbol{r}'| = ||\boldsymbol{r}-\boldsymbol{r}'|| = [(x-x')^2+(y-y')^2+(z-z')^2]^{1/2}. \tag{22.2.5}$$

Consider the function $1/|\boldsymbol{r}-\boldsymbol{r}'|$. It satisfies the relation

$$\nabla^2[1/|\boldsymbol{r}-\boldsymbol{r}'|] = -4\pi\delta_3(\boldsymbol{r}-\boldsymbol{r}') \tag{22.2.6}$$

where the indicated derivatives are to be taken with respect to the components of $\boldsymbol{r}$. Assuming that $\rho(\boldsymbol{r})$ falls off sufficiently rapidly at infinity, it follows that a solution to (2.4) is given by the relation

$$\phi(\boldsymbol{r}) = [1/(4\pi)]\int d^3\boldsymbol{r}'\rho(\boldsymbol{r}')/|\boldsymbol{r}-\boldsymbol{r}'|. \tag{22.2.7}$$

Moreover, (2.7) is the unique solution that vanishes at infinity.

For our discussion we will need some knowledge of low-order (spherical) multipole expansions, which we review briefly here. Suppose that the charge distribution ρ is nonzero only in some volume V surrounding the point $\boldsymbol{r}_d$. (Here the subscript d stands for *distribution*, and will later stand for *dipole*.) Then (2.7) becomes

$$\phi(\boldsymbol{r}) = [1/(4\pi)]\int_V d^3\boldsymbol{r}'\rho(\boldsymbol{r}')/|\boldsymbol{r}-\boldsymbol{r}'|. \tag{22.2.8}$$

Suppose also that $\boldsymbol{r}$ lies outside V so that the denominator in (2.8) never vanishes. Make the change of variables

$$\boldsymbol{r}' = \boldsymbol{r}_d + \boldsymbol{\xi} \tag{22.2.9}$$

so that (2.8) becomes

$$\phi(\boldsymbol{r}) = [1/(4\pi)]\int_{V_0} d^3\boldsymbol{\xi}\ \rho(\boldsymbol{r}_d+\boldsymbol{\xi})/|(\boldsymbol{r}-\boldsymbol{r}_d)-\boldsymbol{\xi}| \tag{22.2.10}$$

where V_0 is a volume surrounding the origin. Under the assumption that $\boldsymbol{r} \notin V$, the denominator factor in (2.10) can be expanded as a power series in the components of $\boldsymbol{\xi}$,

$$1/|(\boldsymbol{r}-\boldsymbol{r}_d)-\boldsymbol{\xi}| = [1/|\boldsymbol{r}-\boldsymbol{r}_d|][1+\boldsymbol{\xi}\cdot(\boldsymbol{r}-\boldsymbol{r}_d)/|\boldsymbol{r}-\boldsymbol{r}_d|^2 + O(\xi^2)]. \tag{22.2.11}$$

Put this expansion into the integral (2.10) to yield the result

$$\begin{aligned}\phi(\boldsymbol{r}) \;=\; & [1/(4\pi)][1/|\boldsymbol{r}-\boldsymbol{r}_d|]\int_{V_0} d^3\boldsymbol{\xi}\ \rho(\boldsymbol{r}_d+\boldsymbol{\xi}) \\ & +[1/(4\pi)][1/|\boldsymbol{r}-\boldsymbol{r}_d|^3](\boldsymbol{r}-\boldsymbol{r}_d)\cdot\int_{V_0} d^3\boldsymbol{\xi}\ \boldsymbol{\xi}\ \rho(\boldsymbol{r}_d+\boldsymbol{\xi}) + O(\xi^2).\end{aligned} \tag{22.2.12}$$

The integrals in (2.12) can be manipulated to bring them to the forms

$$\int_{V_0} d^3\boldsymbol{\xi}\ \rho(\boldsymbol{r}_d+\boldsymbol{\xi}) = \int_V d^3\boldsymbol{r}'\ \rho(\boldsymbol{r}') = Q, \tag{22.2.13}$$

$$\int_{V_0} d^3\boldsymbol{\xi}\ \boldsymbol{\xi}\ \rho(\boldsymbol{r}_d+\boldsymbol{\xi}) = \int_V d^3\boldsymbol{r}'\ (\boldsymbol{r}'-\boldsymbol{r}_d)\ \rho(\boldsymbol{r}') = \boldsymbol{p}_d. \tag{22.2.14}$$

Here Q, the total charge in V, is the monopole moment. And $\boldsymbol{p}_d$ is the dipole moment (with respect to the point $\boldsymbol{r}_d$) of the charge distribution in V. Thus, we find that

$$\phi(\boldsymbol{r}) = [Q/(4\pi)][1/|\boldsymbol{r}-\boldsymbol{r}_d|] + [1/(4\pi)][\boldsymbol{p}_d\cdot(\boldsymbol{r}-\boldsymbol{r}_d)]/|\boldsymbol{r}-\boldsymbol{r}_d|^3 + O(\xi^2). \tag{22.2.15}$$

That is, the potential arising from a charge distribution, at a point $\boldsymbol{r}$ outside the distribution, is a sum of monopole, dipole, and higher-order multipole contributions.

We recall that the prototypical example of a dipole consists of two opposite charges $\pm q$ separated by a distance 2ϵ in the limit that $\epsilon \to 0$ and $q \to \infty$ in such a way that the product $2q\epsilon$ remains constant. For example, suppose a charge $+q$ is placed at the location $\boldsymbol{r}_d + \boldsymbol{\epsilon}$ and a charge $-q$ is placed at the location $\boldsymbol{r}_d - \boldsymbol{\epsilon}$. Then we find that the potential due to this two-charge combination is given by the relation

$$\phi(\boldsymbol{r},\boldsymbol{r}_d) = [1/(4\pi)][q/|\boldsymbol{r}-(\boldsymbol{r}_d+\boldsymbol{\epsilon})| - q/|\boldsymbol{r}-(\boldsymbol{r}_d-\boldsymbol{\epsilon})|]. \tag{22.2.16}$$

Expansion of (2.16) in powers of $\boldsymbol{\epsilon}$ gives the result

$$\phi(\boldsymbol{r},\boldsymbol{r}_d) = [1/(4\pi)](2q\boldsymbol{\epsilon})\cdot(\boldsymbol{r}-\boldsymbol{r}_d)/|\boldsymbol{r}-\boldsymbol{r}_d|^3 + O(q\epsilon^2). \tag{22.2.17}$$

Now let $\boldsymbol{\epsilon} \to 0$ and $q \to \infty$ in such a way that

$$2q\boldsymbol{\epsilon} \to \boldsymbol{p}_d. \tag{22.2.18}$$

In this limit (2.17) becomes

$$\phi_d(\boldsymbol{r},\boldsymbol{r}_d) = [1/(4\pi)][\boldsymbol{p}_d\cdot(\boldsymbol{r}-\boldsymbol{r}_d)]/|\boldsymbol{r}-\boldsymbol{r}_d|^3, \tag{22.2.19}$$

in agreement with the second term in (2.15). We note, with the convention $q > 0$, that the dipole moment vector $\boldsymbol{p}_d$ points from the location of $-q$ to the location of $+q$.

We also note, for future use, that the field $\boldsymbol{E}_d(\boldsymbol{r},\boldsymbol{r}_d)$ at the point $\boldsymbol{r}$ arising from a dipole at the point $\boldsymbol{r}_d$ (with $\boldsymbol{r} \neq \boldsymbol{r}_d$) is given by the relation

$$\begin{aligned}\boldsymbol{E}_d(\boldsymbol{r},\boldsymbol{r}_d) &= -\nabla\phi_d(\boldsymbol{r},\boldsymbol{r}_d)\\ &= -[1/(4\pi)][\boldsymbol{p}_d/|\boldsymbol{r}-\boldsymbol{r}_d|^3] + [3/(4\pi)](\boldsymbol{r}-\boldsymbol{r}_d)[\boldsymbol{p}_d\cdot(\boldsymbol{r}-\boldsymbol{r}_d)]/|\boldsymbol{r}-\boldsymbol{r}_d|^5.\end{aligned} \tag{22.2.20}$$

We will now use the expression for the potential of a dipole, namely (2.19), to carry out an instructive construction and calculation. Suppose $\boldsymbol{r}_A$ and $\boldsymbol{r}_B$ are the locations of two points A and B. Imagine these two points to be joined by a line (path, *string*) L starting at $\boldsymbol{r}_A$ and ending at $\boldsymbol{r}_B$. See Figure 2.1. Divide the path into N segments, each of length Δs, and place a dipole of magnitude $g\Delta s$ at the center of each segment with the dipole moment vector pointing along the path at each point. Here g is some constant. Thus, the dipole moment $\Delta\boldsymbol{p}_d$ of each segment is given by the expression

$$\Delta\boldsymbol{p}_d = g\Delta s(\Delta\boldsymbol{r}/|\Delta\boldsymbol{r}|) = g\Delta\boldsymbol{r} \tag{22.2.21}$$

since $|\Delta \boldsymbol{r}| = \Delta s$. Let us compute the potential $\phi_s(\boldsymbol{r})$ produced by this *string* of dipoles. It will be the sum of the potentials of the individual dipoles. In the limit $\Delta s \to 0$ and $N \to \infty$ it is given by the integral

$$\begin{aligned}\phi_s(\boldsymbol{r}) &= [1/(4\pi)] \int_L d\boldsymbol{p}_d \cdot (\boldsymbol{r} - \boldsymbol{r}_d)/|\boldsymbol{r} - \boldsymbol{r}_d|^3 \\ &= [g/(4\pi)] \int_{\boldsymbol{r}_A}^{\boldsymbol{r}_B} d\boldsymbol{r}_d \cdot (\boldsymbol{r} - \boldsymbol{r}_d)/|\boldsymbol{r} - \boldsymbol{r}_d|^3. \qquad (22.2.22)\end{aligned}$$

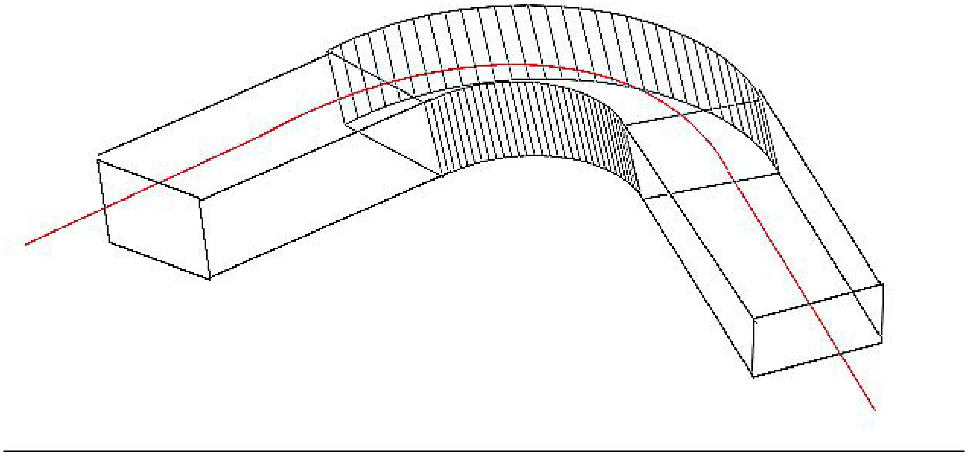

Figure 22.2.1: (Place Holder) A path L from the point A to the point B. Dipoles are laid out and aligned along the path to form a string.

Can the integral (2.22) be evaluated? Recall the identity

$$\nabla^d (1/|\boldsymbol{r} - \boldsymbol{r}_d|) = (\boldsymbol{r} - \boldsymbol{r}_d)/|\boldsymbol{r} - \boldsymbol{r}_d|^3 \qquad (22.2.23)$$

where ∇^d denotes differentiation with respect to the components of $\boldsymbol{r}_d$. This identity may be employed in (2.22) to yield the result

$$\begin{aligned}\phi_s(\boldsymbol{r}) &= [g/(4\pi)] \int_{\boldsymbol{r}_A}^{\boldsymbol{r}_B} d\boldsymbol{r}_d \cdot (\boldsymbol{r} - \boldsymbol{r}_d)/|\boldsymbol{r} - \boldsymbol{r}_d|^3 \\ &= [g/(4\pi)] \int_{\boldsymbol{r}_A}^{\boldsymbol{r}_B} d\boldsymbol{r}_d \cdot [\nabla^d (1/|\boldsymbol{r} - \boldsymbol{r}_d|)] \\ &= [g/(4\pi)]\{[(1/|\boldsymbol{r} - \boldsymbol{r}_B|)] - [(1/|\boldsymbol{r} - \boldsymbol{r}_A|)]\}. \qquad (22.2.24)\end{aligned}$$

We see that the potential $\phi_s(\boldsymbol{r})$ resulting from a string of dipoles is the same as the potential produced by a charge $-g$ located at $\boldsymbol{r}_A$ and a charge $+g$ located at $\boldsymbol{r}_B$. This mathematically derived result is also intuitive because we expect, for a string of dipoles arrayed head-to-tail, that adjacent head-tail pairs would cancel so all that would be left would be the initial negative tail and the final positive head.

Note that, as it stands, (2.22) is undefined for points $\boldsymbol{r} \in L$. However, since the integrand in (2.22) is a perfect differential, see (2.23), the path can be deformed at will to avoid any possible vanishings of the denominator in (2.22) without changing the value of the integral. Indeed, (2.24) shows that $\phi_s(\boldsymbol{r})$ depends only on the endpoints of the path, and is otherwise path independent.

22.2.2 Magnetic Dirac Strings

The General Case

In analogy to the work of the previous subsection, this subsection will describe calculations for the complementary case of a vector field $\boldsymbol{B}(\boldsymbol{r})$ that obeys the equations

$$\nabla \times \boldsymbol{B} = \boldsymbol{J}, \tag{22.2.25}$$

$$\nabla \cdot \boldsymbol{B} = 0. \tag{22.2.26}$$

Note, in order for (2.25) to make sense, we must require that

$$\nabla \cdot \boldsymbol{J} = \nabla \cdot (\nabla \times \boldsymbol{B}) = 0. \tag{22.2.27}$$

(Recall that the divergence of a curl vanishes.)

In the case of (2.25) and (2.26) it is often assumed that there is a vector potential $\boldsymbol{A}(\boldsymbol{r})$ such that

$$\boldsymbol{B} = \nabla \times \boldsymbol{A} \tag{22.2.28}$$

because (2.26) will then be satisfied automatically. Let us verify that this Ansatz is possible by construction. Substitution of (2.28) into (2.25) yields the hypothesis

$$\nabla \times (\nabla \times \boldsymbol{A}) = \boldsymbol{J}. \tag{22.2.29}$$

Recall the vector identity

$$\nabla \times (\nabla \times \boldsymbol{A}) = \nabla(\nabla \cdot \boldsymbol{A}) - \nabla^2 \boldsymbol{A} \tag{22.2.30}$$

where here it is essential that Cartesian components be employed. Let us make the further Coulomb gauge assumption

$$\nabla \cdot \boldsymbol{A} = 0. \tag{22.2.31}$$

In this circumstance (2.29) and (2.30) become

$$\nabla^2 \boldsymbol{A} = -\boldsymbol{J}. \tag{22.2.32}$$

Thanks to (2.6), equation (2.32) has the immediate solution

$$\boldsymbol{A}(\boldsymbol{r}) = [1/(4\pi)] \int d^3\boldsymbol{r}'\ \boldsymbol{J}(\boldsymbol{r}')/|\boldsymbol{r} - \boldsymbol{r}'|. \tag{22.2.33}$$

Moreover, (2.33) is the unique solution that vanishes at infinity. But wait, we must also verify that (2.33) also satisfies (2.31). It does, as you will have the pleasure of showing in Exercise 2.4.

Next suppose that the current distribution $\boldsymbol{J}$ is nonzero only in some volume V surrounding the point $\boldsymbol{r}_d$. Then (2.33) becomes

$$\boldsymbol{A}(\boldsymbol{r}) = [1/(4\pi)] \int_V d^3\boldsymbol{r}' \, \boldsymbol{J}(\boldsymbol{r}')/|\boldsymbol{r} - \boldsymbol{r}'|. \tag{22.2.34}$$

Suppose also that $\boldsymbol{r}$ lies outside V so that the denominator in (2.34) never vanishes. Make the change of variables (2.9) so that (2.34) can be rewritten in the form

$$\boldsymbol{A}(\boldsymbol{r}) = [1/(4\pi)] \int_{V_0} d^3\boldsymbol{\xi} \, \boldsymbol{J}(\boldsymbol{r}_d + \boldsymbol{\xi})/|(\boldsymbol{r} - \boldsymbol{r}_d) - \boldsymbol{\xi}| \tag{22.2.35}$$

where V_0 is a volume surrounding the origin. As before, make the expansion (2.11) so that (2.35) can be written in the form

$$\begin{aligned} \boldsymbol{A}(\boldsymbol{r}) \;\; = \;\; & [1/(4\pi)][1/|\boldsymbol{r} - \boldsymbol{r}_d|] \int_{V_0} d^3\boldsymbol{\xi} \, \boldsymbol{J}(\boldsymbol{r}_d + \boldsymbol{\xi}) \\ & +[1/(4\pi)][1/|\boldsymbol{r} - \boldsymbol{r}_d|^3] \int_{V_0} d^3\boldsymbol{\xi} \, [(\boldsymbol{r} - \boldsymbol{r}_d)\cdot\boldsymbol{\xi}] \, \boldsymbol{J}(\boldsymbol{r}_d + \boldsymbol{\xi}) + O(\xi^2). \end{aligned} \tag{22.2.36}$$

The integrals in (2.36) can again be manipulated to bring them to more convenient forms. For the first integral we find that

$$\int_{V_0} d^3\boldsymbol{\xi} \, \boldsymbol{J}(\boldsymbol{r}_d + \boldsymbol{\xi}) = \int_V d^3\boldsymbol{r}' \, \boldsymbol{J}(\boldsymbol{r}') = 0. \tag{22.2.37}$$

Here use has been made of (2.27). See Exercise 2.5. The second integral can be brought to the form

$$\begin{aligned} \int_{V_0} d^3\boldsymbol{\xi} \, [(\boldsymbol{r} - \boldsymbol{r}_d)\cdot\boldsymbol{\xi}] \, \boldsymbol{J}(\boldsymbol{r}_d + \boldsymbol{\xi}) \;\; &= \;\; \int_V d^3\boldsymbol{r}' \, [(\boldsymbol{r} - \boldsymbol{r}_d)\cdot(\boldsymbol{r}' - \boldsymbol{r}_d)] \, \boldsymbol{J}(\boldsymbol{r}') \\ &= \;\; \boldsymbol{m}_d \times (\boldsymbol{r} - \boldsymbol{r}_d). \end{aligned} \tag{22.2.38}$$

Here use has again been made of (2.27), and $\boldsymbol{m}_d$ is the magnetic dipole moment defined by the integral

$$\boldsymbol{m}_d = (1/2) \int_V d^3\boldsymbol{r}' \, [(\boldsymbol{r}' - \boldsymbol{r}_d) \times \boldsymbol{J}(\boldsymbol{r}')]. \tag{22.2.39}$$

See Exercise 2.6. Thus, we find that

$$\boldsymbol{A}(\boldsymbol{r}) = \boldsymbol{A}_d(\boldsymbol{r}, \boldsymbol{r}_d) + O(\xi^2) \tag{22.2.40}$$

where

$$\boldsymbol{A}_d(\boldsymbol{r}, \boldsymbol{r}_d) = [1/(4\pi)][\boldsymbol{m}_d \times (\boldsymbol{r} - \boldsymbol{r}_d)]/|\boldsymbol{r} - \boldsymbol{r}_d|^3. \tag{22.2.41}$$

We see that the vector potential arising from a current distribution, at a point $\boldsymbol{r}$ outside the distribution, is a sum of dipole and higher order multipole contributions. Unlike the electric case, there is no monopole contribution. We also remark that $\boldsymbol{A}(\boldsymbol{r}, \boldsymbol{r}_d)$ satisfies the Coulomb gauge condition (2.31),

$$\nabla \cdot \boldsymbol{A}(\boldsymbol{r}, \boldsymbol{r}_d) = 0. \tag{22.2.42}$$

See Exercise 2.7.

We recall that the prototypical example of a magnetic dipole consists of a small circular and planar ring of radius R, surrounding an area A and carrying a current I, in the limit that $A \to 0$ and $I \to \infty$ in such a way that the product AI remains constant. For example, suppose the ring is placed in the x, y plane and centered around the origin. Suppose also that the current I circulates in the counterclockwise direction when viewed from above (looking down from positive z toward the origin). Then we find that (2.39) takes the form

$$\boldsymbol{m}_d = (1/2) \int_V d^3\boldsymbol{r}' \; [\boldsymbol{r}' \times \boldsymbol{J}(\boldsymbol{r}')] = AI\boldsymbol{e}_z. \tag{22.2.43}$$

For the field $\boldsymbol{B}_d(\boldsymbol{r}, \boldsymbol{r}_d)$ at the point $\boldsymbol{r}$ arising from a magnetic dipole at the point $\boldsymbol{r}_d$ (with $\boldsymbol{r} \neq \boldsymbol{r}_d$) we find the result

$$\begin{aligned} \boldsymbol{B}_d(\boldsymbol{r}, \boldsymbol{r}_d) &= \nabla \times \boldsymbol{A}_d(\boldsymbol{r}, \boldsymbol{r}_d) \\ &= -[1/(4\pi)][\boldsymbol{m}_d/|\boldsymbol{r} - \boldsymbol{r}_d|^3] + [3/(4\pi)](\boldsymbol{r} - \boldsymbol{r}_d)[\boldsymbol{m}_d \cdot (\boldsymbol{r} - \boldsymbol{r}_d)]/|\boldsymbol{r} - \boldsymbol{r}_d|^5. \end{aligned} \tag{22.2.44}$$

Note that the right sides of (2.20) and (2.44) agree if $\boldsymbol{p}_d = \boldsymbol{m}_d$. Thus, we have the key mathematical relation

$$-\nabla\phi_d(\boldsymbol{r}, \boldsymbol{r}_d) = \nabla \times \boldsymbol{A}_d(\boldsymbol{r}, \boldsymbol{r}_d) \text{ when } \boldsymbol{p}_d = \boldsymbol{m}_d \text{ and } \boldsymbol{r} \neq \boldsymbol{r}_d. \tag{22.2.45}$$

In analogy to what was done in the previous subsection for a string of electric dipoles, let us compute the vector potential $\boldsymbol{A}_s(\boldsymbol{r})$ arising from a string of magnetic dipoles. Again we will initially divide the path into N equal segments, and the magnetic dipole moment of each segment will be given by the relation

$$\Delta\boldsymbol{m}_d = g\Delta s(\Delta\boldsymbol{r}/|\Delta\boldsymbol{r}|) = g\Delta\boldsymbol{r}. \tag{22.2.46}$$

In the limit $\Delta s \to 0$ and $N \to \infty$ the vector potential due to the string is given by the integral

$$\begin{aligned} \boldsymbol{A}_s(\boldsymbol{r}) &= [1/(4\pi)] \int_L d\boldsymbol{m}_d \times (\boldsymbol{r} - \boldsymbol{r}_d)/|\boldsymbol{r} - \boldsymbol{r}_d|^3 \\ &= [g/(4\pi)] \int_{\boldsymbol{r}_A}^{\boldsymbol{r}_B} d\boldsymbol{r}_d \times (\boldsymbol{r} - \boldsymbol{r}_d)/|\boldsymbol{r} - \boldsymbol{r}_d|^3. \end{aligned} \tag{22.2.47}$$

Recall (2.41). Note that, as it stands, (2.47) is undefined for points $\boldsymbol{r} \in L$. As before, the path can be deformed to avoid any possible vanishings of the denominator. However, unlike the electric case and as will soon be seen, so doing changes the value of $\boldsymbol{A}_s(\boldsymbol{r})$. We also note that the current distribution associated with a string of magnetic dipoles (all aligned along the string) is that of an infinitesimally thin solenoid bent into the shape of the string.

What is the nature of the magnetic field $\boldsymbol{B}_s(\boldsymbol{r})$ given by

$$\boldsymbol{B}_s(\boldsymbol{r}) = \nabla \times \boldsymbol{A}_s(\boldsymbol{r})? \tag{22.2.48}$$

We claim, for $\boldsymbol{r} \notin L$, that

$$\nabla \times \boldsymbol{A}_s(\boldsymbol{r}) = -\nabla \phi_s(\boldsymbol{r}). \tag{22.2.49}$$

We will prove this assertion shortly. Assuming it is true, the right side of (2.48) can be evaluated easily using (2.49). In view of (2.24), there is the relation

$$-\nabla \phi_s(\boldsymbol{r}) = [g/(4\pi)][(\boldsymbol{r}-\boldsymbol{r}_B)/|\boldsymbol{r}-\boldsymbol{r}_B|^3] - [g/(4\pi)][(\boldsymbol{r}-\boldsymbol{r}_A)/|\boldsymbol{r}-\boldsymbol{r}_A|^3]. \tag{22.2.50}$$

It follows that

$$\boldsymbol{B}_s(\boldsymbol{r}) = [g/(4\pi)][(\boldsymbol{r}-\boldsymbol{r}_B)/|\boldsymbol{r}-\boldsymbol{r}_B|^3] - [g/(4\pi)][(\boldsymbol{r}-\boldsymbol{r}_A)/|\boldsymbol{r}-\boldsymbol{r}_A|^3]. \tag{22.2.51}$$

We see that the field $\boldsymbol{B}_s(\boldsymbol{r})$ is that produced by two magnetic *monopoles*, one located at $\boldsymbol{r}_B$ with strength g, and a second located at $\boldsymbol{r}_A$ with strength $-g$.

At this juncture two comments are in order. First, the $\boldsymbol{B}_s(\boldsymbol{r})$ given by (2.51) evidently *is not* divergence free at the points $\boldsymbol{r}_A$ and $\boldsymbol{r}_B$. But the $\boldsymbol{B}_s(\boldsymbol{r})$ given by (2.48) is a curl, and we again recall the theorem that a curl *is* divergence free. The resolution to this apparent paradox is that $\boldsymbol{A}_s(\boldsymbol{r})$ is singular for $\boldsymbol{r} \in L$, and every neighborhood of the points $\boldsymbol{r}_A$ and $\boldsymbol{r}_B$ contains such singular points, and therefore the conditions for the theorem are not met. Correspondingly, (2.51) holds only for points $\boldsymbol{r} \notin L$.

The second comment is equally subtle. Suppose two different strings s and s' (but with the same endpoints) are used to compute $\boldsymbol{B}_s(\boldsymbol{r})$ and $\boldsymbol{B}_{s'}(\boldsymbol{r})$. Then, according to (2.51), these fields should agree except possibly at the points for which $\boldsymbol{r} \in L$ and/or $\boldsymbol{r} \in L'$. Thus, we have the relation

$$\nabla \times [\boldsymbol{A}_s(\boldsymbol{r}) - \boldsymbol{A}_{s'}(\boldsymbol{r})] = 0 \text{ for } \boldsymbol{r} \notin L \text{ and } \boldsymbol{r} \notin L'. \tag{22.2.52}$$

Let Σ be some surface spanning the two strings s and s'. See Figure 2.2. Three-dimensional Euclidean space with the surface Σ excluded is still simply connected. It follows that there is a function $\psi_{ss'}(\boldsymbol{r})$ such that

$$\boldsymbol{A}_s(\boldsymbol{r}) - \boldsymbol{A}_{s'}(\boldsymbol{r}) = \nabla \psi_{ss'}(\boldsymbol{r}) \text{ for } \boldsymbol{r} \notin \Sigma. \tag{22.2.53}$$

That is, the vector potentials associated with two different strings (but with the same endpoints) are related by a gauge transformation. From (2.53) we see that $\psi_{ss'}(\boldsymbol{r})$ will be singular for both $\boldsymbol{r} \in L$ and $\boldsymbol{r} \in L'$. It can be shown that $\psi_{ss'}(\boldsymbol{r})$ is also harmonic,

$$\nabla^2 \psi_{ss'}(\boldsymbol{r}) = 0 \text{ for } \boldsymbol{r} \notin L \text{ and } \boldsymbol{r} \notin L'. \tag{22.2.54}$$

See Exercise 2.13.

Finally, suppose we let $\boldsymbol{r}_B \to \infty$. In this limit, the first term on the right side of (2.51) vanishes, and we have the result

$$\boldsymbol{B}_s(\boldsymbol{r}) = -[g/(4\pi)][(\boldsymbol{r}-\boldsymbol{r}_A)/|\boldsymbol{r}-\boldsymbol{r}_A|^3], \tag{22.2.55}$$

which is the field of a monopole located at $\boldsymbol{r}_A$ and having strength $-g$. Correspondingly, the upper limit in the integral (2.47) is infinite, and the string s, which we will call a *half-infinite Dirac string*, extends from $\boldsymbol{r}_A$ to infinity. And the field (2.55) may be viewed as that of a *Dirac* magnetic monopole.

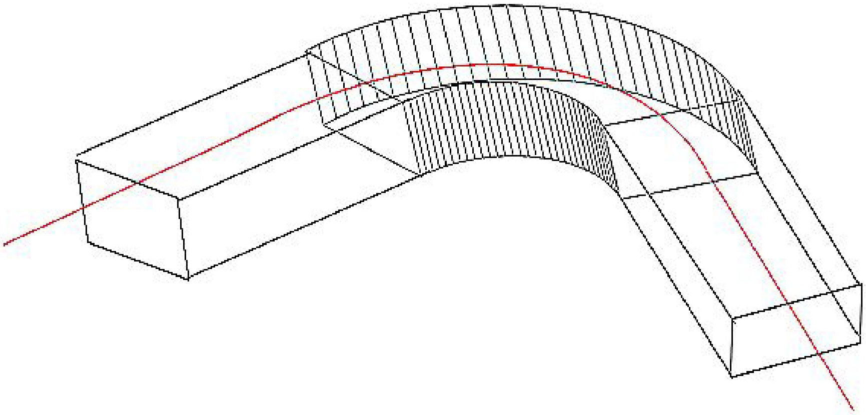

Figure 22.2.2: (Place holder.) A surface Σ spanning the two strings s and s'.

Straight Half-Infinite Strings

For future use, there is a special class of half-infinite strings that is particularly convenient. Let $\boldsymbol{m}$ be some unit vector. Consider the straight string (path) from $\boldsymbol{r}_A$ to infinity parameterized as

$$\boldsymbol{r}_d(\lambda) = \boldsymbol{r}_A + \lambda\boldsymbol{m} \text{ with } \lambda \in [0, \infty]. \tag{22.2.56}$$

See Figure 2.3. Then, on this path, $\boldsymbol{m}_d$ is in the direction of $\boldsymbol{m}$, and we also have the relation

$$d\boldsymbol{r}_d(\lambda) = \boldsymbol{m}d\lambda. \tag{22.2.57}$$

For this class of strings the integral (2.47) can be evaluated analytically. We begin by rewriting (2.47) in the form

$$\boldsymbol{A}_s(\boldsymbol{r}; \boldsymbol{r}_A, \boldsymbol{m}) = [g/(4\pi)] \int_0^\infty d\lambda\, \boldsymbol{m} \times [\boldsymbol{r} - \boldsymbol{r}_d(\lambda)]/|\boldsymbol{r} - \boldsymbol{r}_d(\lambda)|^3. \tag{22.2.58}$$

From (2.56) we see that

$$\boldsymbol{r} - \boldsymbol{r}_d(\lambda) = \boldsymbol{r} - \boldsymbol{r}_A - \lambda\boldsymbol{m} \tag{22.2.59}$$

and therefore

$$\boldsymbol{m} \times [\boldsymbol{r} - \boldsymbol{r}_d(\lambda)] = \boldsymbol{m} \times (\boldsymbol{r} - \boldsymbol{r}_A). \tag{22.2.60}$$

Consequently, the integral (2.58) simplifies to the form

$$\boldsymbol{A}_s(\boldsymbol{r}; \boldsymbol{r}_A, \boldsymbol{m}) = [g/(4\pi)][\boldsymbol{m} \times (\boldsymbol{r} - \boldsymbol{r}_A)] \int_0^\infty d\lambda/|\boldsymbol{r} - \boldsymbol{r}_d(\lambda)|^3. \tag{22.2.61}$$

As shown in Exercise 2.14, the integral appearing in (2.61) can be evaluated to yield the result

$$\begin{aligned}\int_0^\infty d\lambda/|\boldsymbol{r} - \boldsymbol{r}_d(\lambda)|^3 &= \int_0^\infty d\lambda/|\boldsymbol{r} - \boldsymbol{r}_A - \lambda\boldsymbol{m}|^3 \\ &= 1/\{|\boldsymbol{r} - \boldsymbol{r}_A|[|\boldsymbol{r} - \boldsymbol{r}_A| - \boldsymbol{m} \cdot (\boldsymbol{r} - \boldsymbol{r}_A)]\}. \end{aligned} \tag{22.2.62}$$

Therefore, $\boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m})$ takes the final explicit form

$$\boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m}) = [g/(4\pi)][\boldsymbol{m}\times(\boldsymbol{r}-\boldsymbol{r}_A)]/\{|\boldsymbol{r}-\boldsymbol{r}_A|[|\boldsymbol{r}-\boldsymbol{r}_A|-\boldsymbol{m}\cdot(\boldsymbol{r}-\boldsymbol{r}_A)]\}. \tag{22.2.63}$$

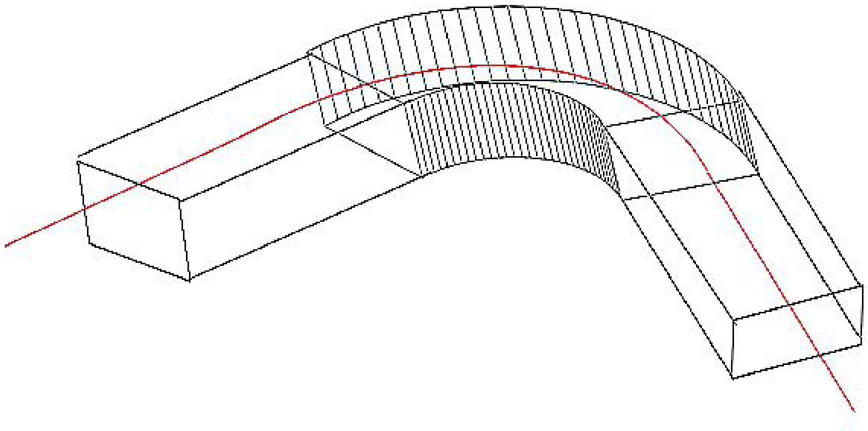

Figure 22.2.3: (Place holder.) A straight half-infinite string extending from $\boldsymbol{r}_A$ to infinity in the direction $\boldsymbol{m}$.

Remaining Verifications

It remains to be verified that (2.49) holds. Suppose that (2.19) is written in the form

$$\phi_d(\boldsymbol{r},\boldsymbol{r}_d;|\boldsymbol{p}_d|,\boldsymbol{n}_d) = [1/(4\pi)][|\boldsymbol{p}_d|\boldsymbol{n}_d\cdot(\boldsymbol{r}-\boldsymbol{r}_d)]/|\boldsymbol{r}-\boldsymbol{r}_d|^3 \tag{22.2.64}$$

where $\boldsymbol{n}_d$ is the unit vector in the direction of $\boldsymbol{p}_d$. Then (2.22) takes the form

$$\begin{aligned}\phi_s(\boldsymbol{r}) &= [1/(4\pi)]\int_L d\boldsymbol{p}_d\cdot(\boldsymbol{r}-\boldsymbol{r}_d)/|\boldsymbol{r}-\boldsymbol{r}_d|^3 \\ &= [g/(4\pi)]\int_{\boldsymbol{r}_A}^{\boldsymbol{r}_B} d\boldsymbol{r}_d\cdot(\boldsymbol{r}-\boldsymbol{r}_d)/|\boldsymbol{r}-\boldsymbol{r}_d|^3 \\ &= \int_L \phi_d(\boldsymbol{r},\boldsymbol{r}_d;gds,d\boldsymbol{r}_d/|d\boldsymbol{r}_d|),\end{aligned} \tag{22.2.65}$$

and therefore

$$-\nabla\phi_s(\boldsymbol{r}) = \int_L -\nabla\phi_d(\boldsymbol{r},\boldsymbol{r}_d;gds,d\boldsymbol{r}_d/|d\boldsymbol{r}_d|). \tag{22.2.66}$$

Suppose also that (2.41) is written in the form

$$\boldsymbol{A}_d(\boldsymbol{r},\boldsymbol{r}_d;|\boldsymbol{m}_d|,\boldsymbol{n}_d) = [1/(4\pi)][|\boldsymbol{m}_d|\boldsymbol{n}_d\times(\boldsymbol{r}-\boldsymbol{r}_d)]/|\boldsymbol{r}-\boldsymbol{r}_d|^3. \tag{22.2.67}$$

Then (2.47) takes the form

$$\begin{aligned}\boldsymbol{A}_s(\boldsymbol{r}) &= [1/(4\pi)]\int_L d\boldsymbol{m}_d \times (\boldsymbol{r}-\boldsymbol{r}_d)/|\boldsymbol{r}-\boldsymbol{r}_d|^3 \\ &= [g/(4\pi)]\int_{\boldsymbol{r}_A}^{\boldsymbol{r}_B} d\boldsymbol{r}_d \times (\boldsymbol{r}-\boldsymbol{r}_d)/|\boldsymbol{r}-\boldsymbol{r}_d|^3 \\ &= \int_L \boldsymbol{A}_d(\boldsymbol{r},\boldsymbol{r}_d; gds, d\boldsymbol{r}_d/|d\boldsymbol{r}_d|), \end{aligned} \tag{22.2.68}$$

and therefore

$$\nabla \times \boldsymbol{A}_s(\boldsymbol{r}) = \int_L \nabla \times \boldsymbol{A}_d(\boldsymbol{r},\boldsymbol{r}_d; gds, d\boldsymbol{r}_d/|d\boldsymbol{r}_d|). \tag{22.2.69}$$

Now compare the integrands on the right sides of (2.66) and (2.69). We see that they have identical arguments. Consequently, by (2.45), they are equal. It follows that the left sides of (2.66) and (2.69) are equal, and therefore (2.49) is correct.

There are still two final matters. First, (2.68) shows that $\boldsymbol{A}_s(\boldsymbol{r})$ is a superposition (integration over $\boldsymbol{r}_d$) of the $\boldsymbol{A}_d(\boldsymbol{r},\boldsymbol{r}_d)$ and, for each $\boldsymbol{A}_d(\boldsymbol{r},\boldsymbol{r}_d)$, we know that the relation (2.42) holds. It follows that $\boldsymbol{A}_s(\boldsymbol{r})$ also satisfies the Coulomb gauge condition,

$$\nabla \cdot \boldsymbol{A}_s(\boldsymbol{r}) = 0. \tag{22.2.70}$$

In particular, there is the relation

$$\nabla \cdot \boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m}) = 0. \tag{22.2.71}$$

Second, since $\boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m})$, is a magnetic monopole vector potential, there is the relation

$$\nabla \times \boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m}) = -[g/(4\pi)][(\boldsymbol{r}-\boldsymbol{r}_A)/|\boldsymbol{r}-\boldsymbol{r}_A|^3] = [g/(4\pi)]\nabla(1/|\boldsymbol{r}-\boldsymbol{r}_A|). \tag{22.2.72}$$

It follows that

$$\nabla \times [\nabla \times \boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m})] = 0. \tag{22.2.73}$$

The relations (2.71) and (2.73) will be of subsequent use.

Fully Infinite (Two) String Monopole Vector Potential

The previous discussion treated the half-infinite string vector potential for a magnetic monopole. In particular, (2.63) gives the vector potential $\boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m})$ for a magnetic monopole of strength $-g$, see (2.55), located at $\boldsymbol{r}_A$ with a straight string extending from $\boldsymbol{r}_A$ to ∞ in the direction $\boldsymbol{m}$. This vector potential is singular on the line

$$\boldsymbol{r} = \boldsymbol{r}_A + \lambda\boldsymbol{m} \text{ with } \lambda \in [0,\infty]. \tag{22.2.74}$$

For completeness we will now describe what we will call the *fully infinite* string monopole vector potential.[2] Suppose we form the average of $\boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m})$ and $\boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}_A,-\boldsymbol{m})$ by writing

$$\boldsymbol{A}_{2s}(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m}) = (1/2)[\boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m}) + \boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}_A,-\boldsymbol{m})]. \tag{22.2.75}$$

[2] The fully infinite string monopole vector potential is sometimes called the *Schwinger potential*.

This vector potential, which we will also call a *two*-string monopole vector potential, will (by superposition) also produce the monopole field (2.55), and will be singular along the full line

$$\boldsymbol{r} = \boldsymbol{r}_A + \lambda \boldsymbol{m} \text{ with } \lambda \in [-\infty, \infty]. \tag{22.2.76}$$

See Figure 2.4.

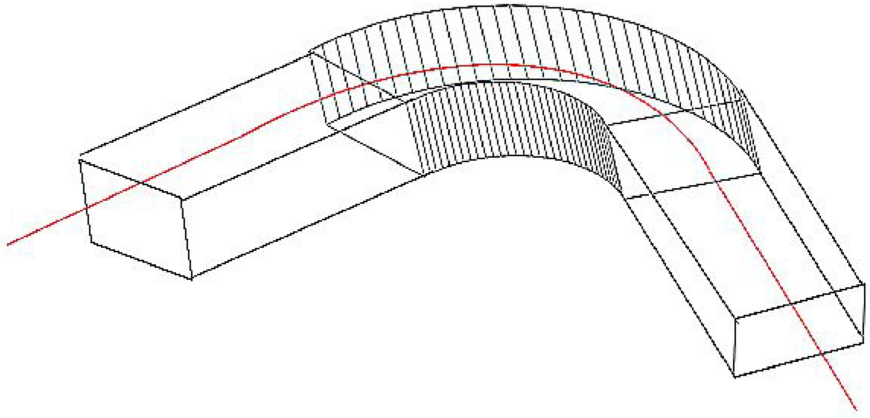

Figure 22.2.4: (Place holder.) A straight full infinite string extending from $\boldsymbol{r}_A$ to infinity in the directions ±$\boldsymbol{m}$.

By superposition, and the use of (2.71) and (2.73), the fully infinite string monopole vector potential satisfies the analogous relations

$$\nabla \cdot \boldsymbol{A}_{2s}(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m}) = 0 \tag{22.2.77}$$

and

$$\nabla \times [\nabla \times \boldsymbol{A}_{2s}(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m})] = 0, \tag{22.2.78}$$

provided $\boldsymbol{r}$ is not on the line (2.76). Finally, from (2.63) and the definition (2.75), we find that $\boldsymbol{A}_{2s}(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m})$ has the explicit form

$$\begin{aligned}
\boldsymbol{A}_{2s}(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m}) &= [g/(8\pi)][\boldsymbol{m}\times(\boldsymbol{r}-\boldsymbol{r}_A)]/\{|\boldsymbol{r}-\boldsymbol{r}_A|[|\boldsymbol{r}-\boldsymbol{r}_A| - \boldsymbol{m}\cdot(\boldsymbol{r}-\boldsymbol{r}_A)]\} \\
&\quad -[g/(8\pi)][\boldsymbol{m}\times(\boldsymbol{r}-\boldsymbol{r}_A)]/\{|\boldsymbol{r}-\boldsymbol{r}_A|[|\boldsymbol{r}-\boldsymbol{r}_A| + \boldsymbol{m}\cdot(\boldsymbol{r}-\boldsymbol{r}_A)]\} \\
&= \frac{[g/(4\pi)][\boldsymbol{m}\times(\boldsymbol{r}-\boldsymbol{r}_A)][\boldsymbol{m}\cdot(\boldsymbol{r}-\boldsymbol{r}_A)]}{|\boldsymbol{r}-\boldsymbol{r}_A|\{|\boldsymbol{r}-\boldsymbol{r}_A|^2 - [\boldsymbol{m}\cdot(\boldsymbol{r}-\boldsymbol{r}_A)]^2\}} \\
&= \frac{[g/(4\pi)][\boldsymbol{m}\times(\boldsymbol{r}-\boldsymbol{r}_A)][\boldsymbol{m}\cdot(\boldsymbol{r}-\boldsymbol{r}_A)]}{|\boldsymbol{r}-\boldsymbol{r}_A||\boldsymbol{m}\times(\boldsymbol{r}-\boldsymbol{r}_A)|^2}.
\end{aligned} \tag{22.2.79}$$

22.2.3 Helmholtz Decomposition

Suppose V is some simply connected volume in 3-dimensional space bounded by a surface S, and suppose $\boldsymbol{F}(\boldsymbol{r})$ is some 3-dimensional vector field defined in V. Then, according to a theorem of *Helmholtz*, there are scalar and vector potentials $\phi(\boldsymbol{r})$ and $\boldsymbol{A}(\boldsymbol{r})$ such that

$$\boldsymbol{F}(\boldsymbol{r}) = -\nabla\phi(\boldsymbol{r}) + \nabla \times \boldsymbol{A}(\boldsymbol{r}) \text{ for } \boldsymbol{r} \in \mathrm{V}. \tag{22.2.80}$$

Moreover, $\boldsymbol{A}(\boldsymbol{r})$ will have the property

$$\nabla \cdot \boldsymbol{A}(\boldsymbol{r}) = 0 \text{ for } \boldsymbol{r} \in \mathrm{V}. \tag{22.2.81}$$

Finally, let Let $G(\boldsymbol{r}, \boldsymbol{r}')$ be the function

$$G(\boldsymbol{r}, \boldsymbol{r}') = 1/|\boldsymbol{r} - \boldsymbol{r}'|. \tag{22.2.82}$$

Then, the scalar and vector potentials are given in terms of $\boldsymbol{F}(\boldsymbol{r})$, with $\boldsymbol{r} \in V$, by the relations

$$\phi(\boldsymbol{r}) = -[1/(4\pi)] \int_S dS'\, \boldsymbol{n}' \cdot \boldsymbol{F}(\boldsymbol{r}')G(\boldsymbol{r}, \boldsymbol{r}') + [1/(4\pi)] \int_V d^3\boldsymbol{r}'\, G(\boldsymbol{r}, \boldsymbol{r}')\nabla' \cdot \boldsymbol{F}(\boldsymbol{r}'), \tag{22.2.83}$$

$$\boldsymbol{A}(\boldsymbol{r}) = -[1/(4\pi)] \int_S dS'\, [\boldsymbol{n}' \times G(\boldsymbol{r}, \boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')] + [1/(4\pi)] \int_V d^3\boldsymbol{r}'\, G(\boldsymbol{r}, \boldsymbol{r}')\nabla' \times \boldsymbol{F}(\boldsymbol{r}'). \tag{22.2.84}$$

Here $\boldsymbol{n}'$ is the outward normal to S at the point $\boldsymbol{r}'$. We emphasize, as is evident from (2.80), (2.83), and (2.84), that for $\boldsymbol{r} \in V$ the vector field $\boldsymbol{F}(\boldsymbol{r})$ is completely specified in terms of the divergence and curl of $\boldsymbol{F}$ within V and the values of $\boldsymbol{F}$ on the bounding surface S. No information is required outside of V.

We will derive this result in stages. Before doing so, some remarks are in order. There two cases of special interest. If $\boldsymbol{F}(\boldsymbol{r})$ is globally defined and falls off at infinity at least as fast as $1/|\boldsymbol{r}|^2$, then we may take the surface S to infinity and find that the surface integrals vanish. This result shows that, with suitable boundary conditions (fall off) imposed at infinity, $\boldsymbol{F}(\boldsymbol{r})$ is completely specified in terms of its divergence and curl. That the operations of divergence and curl are necessary and sufficient to determine $\boldsymbol{F}(\boldsymbol{r})$ is a consequence of two things: the fact that we are working in *three* dimensions and certain properties of the Euclidean group in three dimensions. See Exercise 2.21.

The second case, of special interest for our purposes, is that for which $\boldsymbol{F}(\boldsymbol{r})$ is divergence and curl free (source free) in V,

$$\nabla \cdot \boldsymbol{F}(\boldsymbol{r}) = 0 \text{ for } \boldsymbol{r} \in \mathrm{V} \tag{22.2.85}$$

and

$$\nabla \times \boldsymbol{F}(\boldsymbol{r}) = 0 \text{ for } \boldsymbol{r} \in \mathrm{V}. \tag{22.2.86}$$

In this case, only the surface terms appear in (2.83) and (2.84), and we obtain the results

$$\phi(\boldsymbol{r}) = -[1/(4\pi)] \int_S dS'\, \boldsymbol{n}' \cdot \boldsymbol{F}(\boldsymbol{r}')G(\boldsymbol{r}, \boldsymbol{r}'), \tag{22.2.87}$$

$$\boldsymbol{A}(\boldsymbol{r}) = -[1/(4\pi)] \int_S dS' \, [\boldsymbol{n}' \times \boldsymbol{F}(\boldsymbol{r}')] G(\boldsymbol{r}, \boldsymbol{r}'). \tag{22.2.88}$$

We will eventually apply these results to the case of a magnetic field $\boldsymbol{B}(\boldsymbol{r})$ that is assumed to be source free within V, as in (1.1) and (1.2). We take the opportunity at this point to note that $G(\boldsymbol{r}, \boldsymbol{r}')$ as given by (2.82), and for fixed $\boldsymbol{r}'$, is an *analytic* function of the components of $\boldsymbol{r}$ for $\boldsymbol{r} \neq \boldsymbol{r}'$. It follows from the representations (2.87) and (2.88), under very mild assumptions on the surface behavior of $\boldsymbol{F}(\boldsymbol{r})$, boundedness and continuity will do, that $\phi(\boldsymbol{r})$ and $\boldsymbol{A}(\boldsymbol{r})$ are analytic functions of the components of $\boldsymbol{r}$ for $\boldsymbol{r}$ within V. Correspondingly, from (2.80), $\boldsymbol{F}(\boldsymbol{r})$ must then also be analytic for $\boldsymbol{r}$ within V.

We begin the proof of Helmholtz's theorem by noting that $G(\boldsymbol{r}, \boldsymbol{r}')$ has the properties

$$\nabla G(\boldsymbol{r}, \boldsymbol{r}') = -\nabla' G(\boldsymbol{r}, \boldsymbol{r}') = -(\boldsymbol{r} - \boldsymbol{r}')/|\boldsymbol{r} - \boldsymbol{r}'|^3, \tag{22.2.89}$$

$$\nabla^2 G(\boldsymbol{r}, \boldsymbol{r}') = (\nabla')^2 G(\boldsymbol{r}, \boldsymbol{r}') = -4\pi\delta_3(\boldsymbol{r} - \boldsymbol{r}'), \tag{22.2.90}$$

where ∇' denotes differentiation with respect to the components of $\boldsymbol{r}'$. As a result of (2.90) there is, for $\boldsymbol{r} \in V$, the identity

$$\begin{aligned}
\boldsymbol{F}(\boldsymbol{r}) &= \int_V d^3\boldsymbol{r}' \, \delta_3(\boldsymbol{r} - \boldsymbol{r}') \boldsymbol{F}(\boldsymbol{r}') \\
&= -[1/(4\pi)] \int_V d^3\boldsymbol{r}' \, \boldsymbol{F}(\boldsymbol{r}') \nabla^2 G(\boldsymbol{r}, \boldsymbol{r}') \\
&= -[1/(4\pi)] \nabla^2 \int_V d^3\boldsymbol{r}' \, \boldsymbol{F}(\boldsymbol{r}') G(\boldsymbol{r}, \boldsymbol{r}') \\
&= -\nabla^2 \boldsymbol{H}(\boldsymbol{r})
\end{aligned} \tag{22.2.91}$$

where

$$\boldsymbol{H}(\boldsymbol{r}) = [1/(4\pi)] \int_V d^3\boldsymbol{r}' \, \boldsymbol{F}(\boldsymbol{r}') G(\boldsymbol{r}, \boldsymbol{r}'). \tag{22.2.92}$$

Invoke again the vector identity

$$-\nabla^2 \boldsymbol{H}(\boldsymbol{r}) = \nabla \times [\nabla \times \boldsymbol{H}(\boldsymbol{r})] - \nabla[\nabla \cdot \boldsymbol{H}(\boldsymbol{r})]. \tag{22.2.93}$$

It follows that

$$\boldsymbol{F}(\boldsymbol{r}) = \nabla \times [\nabla \times \boldsymbol{H}(\boldsymbol{r})] - \nabla[\nabla \cdot \boldsymbol{H}(\boldsymbol{r})], \tag{22.2.94}$$

and therefore (2.80) holds with the definitions

$$\phi(\boldsymbol{r}) = \nabla \cdot \boldsymbol{H}(\boldsymbol{r}), \tag{22.2.95}$$

$$\boldsymbol{A}(\boldsymbol{r}) = \nabla \times \boldsymbol{H}(\boldsymbol{r}). \tag{22.2.96}$$

It remains to work out computationally useful expressions for $\phi(\boldsymbol{r})$ and $\boldsymbol{A}(\boldsymbol{r})$. Doing so requires a flurry of vector manipulations. Begin with $\phi(\boldsymbol{r})$. According to (2.92) and (2.95) it can be written as

$$\phi(\boldsymbol{r}) = [1/(4\pi)] \int_V d^3\boldsymbol{r}' \, \nabla \cdot [\boldsymbol{F}(\boldsymbol{r}') G(\boldsymbol{r}, \boldsymbol{r}')]. \tag{22.2.97}$$

Manipulate the integrand in (2.97) to find the result

$$\begin{aligned}\nabla\cdot[\boldsymbol{F}(\boldsymbol{r}')G(\boldsymbol{r},\boldsymbol{r}')] &= \boldsymbol{F}(\boldsymbol{r}')\cdot\nabla G(\boldsymbol{r},\boldsymbol{r}')] = -\boldsymbol{F}(\boldsymbol{r}')\cdot\nabla' G(\boldsymbol{r},\boldsymbol{r}')]\\ &= -\nabla'\cdot[\boldsymbol{F}(\boldsymbol{r}')G(\boldsymbol{r},\boldsymbol{r}')] + G(\boldsymbol{r},\boldsymbol{r}')\nabla'\cdot\boldsymbol{F}(\boldsymbol{r}'). \qquad (22.2.98)\end{aligned}$$

Employ this result in (2.97) to rewrite it in the form

$$\phi(\boldsymbol{r}) = [1/(4\pi)]\int_V d^3\boldsymbol{r}'\ \{-\nabla'\cdot[\boldsymbol{F}(\boldsymbol{r}')G(\boldsymbol{r},\boldsymbol{r}')] + G(\boldsymbol{r},\boldsymbol{r}')\nabla'\cdot\boldsymbol{F}(\boldsymbol{r}')\}. \qquad (22.2.99)$$

Finally, use the divergence theorem to transform the first term on the right side of (2.99) to yield the result

$$\phi(\boldsymbol{r}) = -[1/(4\pi)]\int_S dS'\ \boldsymbol{n}'\cdot\boldsymbol{F}(\boldsymbol{r}')G(\boldsymbol{r},\boldsymbol{r}') + [1/(4\pi)]\int_V d^3\boldsymbol{r}'\ G(\boldsymbol{r},\boldsymbol{r}')\nabla'\cdot\boldsymbol{F}(\boldsymbol{r}'), \quad (22.2.100)$$

in agreement with (2.83).

The case of $\boldsymbol{A}(\boldsymbol{r})$ requires somewhat more effort. Combining (2.92) and (2.96) gives the result

$$\boldsymbol{A}(\boldsymbol{r}) = [1/(4\pi)]\int_V d^3\boldsymbol{r}'\ \nabla\times[\boldsymbol{F}(\boldsymbol{r}')G(\boldsymbol{r},\boldsymbol{r}')]. \qquad (22.2.101)$$

Manipulate the integrand in (2.101) to find the result

$$\begin{aligned}\nabla\times[\boldsymbol{F}(\boldsymbol{r}')G(\boldsymbol{r},\boldsymbol{r}')] &= [\nabla G(\boldsymbol{r},\boldsymbol{r}')]\times\boldsymbol{F}(\boldsymbol{r}') = -\boldsymbol{F}(\boldsymbol{r}')\times\nabla G(\boldsymbol{r},\boldsymbol{r}')\\ &= \boldsymbol{F}(\boldsymbol{r}')\times\nabla' G(\boldsymbol{r},\boldsymbol{r}'). \qquad (22.2.102)\end{aligned}$$

There is also the vector identity

$$\nabla'\times[\boldsymbol{F}(\boldsymbol{r}')G(\boldsymbol{r},\boldsymbol{r}')] = G(\boldsymbol{r},\boldsymbol{r}')\nabla'\times\boldsymbol{F}(\boldsymbol{r}') - \boldsymbol{F}(\boldsymbol{r}')\times\nabla' G(\boldsymbol{r},\boldsymbol{r}'). \qquad (22.2.103)$$

Combining (2.102) and (2.103) gives the result

$$\nabla\times[\boldsymbol{F}(\boldsymbol{r}')G(\boldsymbol{r},\boldsymbol{r}')] = G(\boldsymbol{r},\boldsymbol{r}')\nabla'\times\boldsymbol{F}(\boldsymbol{r}') - \nabla'\times[\boldsymbol{F}(\boldsymbol{r}')G(\boldsymbol{r},\boldsymbol{r}')]. \qquad (22.2.104)$$

Employ this result in (2.101) to rewrite it in the form

$$\boldsymbol{A}(\boldsymbol{r}) = [1/(4\pi)]\int_V d^3\boldsymbol{r}'\ G(\boldsymbol{r},\boldsymbol{r}')\nabla'\times\boldsymbol{F}(\boldsymbol{r}') - [1/(4\pi)]\int_V d^3\boldsymbol{r}'\ \nabla'\times[\boldsymbol{F}(\boldsymbol{r}')G(\boldsymbol{r},\boldsymbol{r}')]. \qquad (22.2.105)$$

Now work on the second integral appearing on the right side of (2.105). Let $\boldsymbol{c}$ be any constant vector. By the divergence theorem there is the relation

$$\int_V d^3\boldsymbol{r}'\ \nabla'\cdot[\boldsymbol{c}\times G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')] = \int_S dS'\ \boldsymbol{n}'\cdot[\boldsymbol{c}\times G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')]. \qquad (22.2.106)$$

There is also the vector identity

$$\begin{aligned}\boldsymbol{n}'\cdot[\boldsymbol{c}\times G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')] &= -\boldsymbol{n}'\cdot[G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')\times\boldsymbol{c}]\\ &= -[\boldsymbol{n}'\times G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')]\cdot\boldsymbol{c}\\ &= -\boldsymbol{c}\cdot[\boldsymbol{n}'\times G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')]. \qquad (22.2.107)\end{aligned}$$

Consequently, (2.106) can be rewritten in the form

$$\int_V d^3\boldsymbol{r}'\ \nabla' \cdot [\boldsymbol{c} \times G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')] = -\boldsymbol{c} \cdot \int_S dS'\ [\boldsymbol{n}' \times G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')]. \tag{22.2.108}$$

Next manipulate the integrand on the left side of (2.108) to find the result

$$\begin{aligned} \nabla' \cdot [\boldsymbol{c} \times G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')] &= -\nabla' \cdot [G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}') \times \boldsymbol{c}] \\ &= -\{\nabla' \times [G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')]\} \cdot \boldsymbol{c} \\ &= -\boldsymbol{c} \cdot \{\nabla' \times [G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')]\}. \end{aligned} \tag{22.2.109}$$

Therefore (2.108) can be rewritten as

$$-\boldsymbol{c} \cdot \int_V d^3\boldsymbol{r}'\ \nabla' \times [G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')] = -\boldsymbol{c} \cdot \int_S dS'\ [\boldsymbol{n}' \times G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')], \tag{22.2.110}$$

from which it follows, because $\boldsymbol{c}$ is arbitrary, that

$$\int_V d^3\boldsymbol{r}'\ \nabla' \times [G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')] = \int_S dS'\ [\boldsymbol{n}' \times G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')]. \tag{22.2.111}$$

The last step is to employ (2.111) in (2.105) to obtain the final result

$$\boldsymbol{A}(\boldsymbol{r}) = [1/(4\pi)] \int_V d^3\boldsymbol{r}'\ G(\boldsymbol{r},\boldsymbol{r}')\nabla' \times \boldsymbol{F}(\boldsymbol{r}') - [1/(4\pi)] \int_S dS'\ [\boldsymbol{n}' \times G(\boldsymbol{r},\boldsymbol{r}')\boldsymbol{F}(\boldsymbol{r}')], \tag{22.2.112}$$

in agreement with (2.84).

It still remains to be shown that, for the definitions made, $\nabla \cdot \boldsymbol{A}(\boldsymbol{r}) = 0$. Look at (2.96). Since the divergence of a curl vanishes, when suitable smoothness conditions are met by the functions involved, it follows that under these conditions $\boldsymbol{A}(\boldsymbol{r})$ as given by (2.96), and therefore also by (2.112), is indeed divergence free. From (2.92) we see that the analytic properties of $\boldsymbol{H}(\boldsymbol{r})$ are determined by those of $\boldsymbol{F}(\boldsymbol{r})$. In general $\boldsymbol{H}(\boldsymbol{r})$ will be smoother than $\boldsymbol{F}(\boldsymbol{r})$. See Appendix F. Therefore, under mild conditions on $\boldsymbol{F}(\boldsymbol{r})$, the vector potential $\boldsymbol{A}(\boldsymbol{r})$ will be divergence free.

Exercises

22.2.1. Verify the expansions (2.11) and (2.17).

22.2.2. Verify (2.20).

22.2.3. Verify the identity (2.23) and its use to evaluate the integral (2.24).

22.2.4. Verify that $\boldsymbol{A}(\boldsymbol{r})$ as given by (2.33) satisfies (2.31).

22.2.5. The purpose of this exercise is to verify (2.37) using (2.27).

22.2.6. The purpose of this exercise is to verify (2.38) using the definition (2.39).

22.2.7. The purpose of this exercise is to verify (2.42) using the definition (2.41).

22.2.8. Verify (2.43).

22.2.9. Verify (2.44).

22.2.10. Show that the integral (2.47) can be written in the form

$$[g/(4\pi)]\int_{\boldsymbol{r}_A}^{\boldsymbol{r}_B} d\boldsymbol{r}_d \times (\boldsymbol{r}-\boldsymbol{r}_d)/|\boldsymbol{r}-\boldsymbol{r}_d|^3 = -[g/(4\pi)]\int_{\boldsymbol{r}_A}^{\boldsymbol{r}_B} d\boldsymbol{r}_d \times \nabla[1/|\boldsymbol{r}-\boldsymbol{r}_d|]. \quad (22.2.113)$$

22.2.11. Verify (2.50).

22.2.12. Nature of thin solenoid and nature of field at the end of a thin solenoid.

22.2.13. The purpose of this exercise is to verify (2.54).

22.2.14. The purpose of this exercise is to verify (2.62).

22.2.15. Evaluate $\boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m})$ as given by (2.63) for the case

$$\boldsymbol{r}_A = 0 \quad (22.2.114)$$

and

$$\boldsymbol{m} = \boldsymbol{e}_z. \quad (22.2.115)$$

Show, using spherical coordinates, that in this case $\boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m})$ has only a ϕ component A^s_ϕ given by

$$A^s_\phi(\boldsymbol{r};0,\boldsymbol{e}_z) = [g/(4\pi)](1+\cos\theta)/[r\sin\theta] = [g/(4\pi)](1/r)\cot(\theta/2) \quad (22.2.116)$$

Verify that A^s_ϕ is singular on the positive z axis, but not on the negative z axis. Show, by explicit calculation, that

$$\nabla \times \boldsymbol{A}_s(\boldsymbol{r};0,\boldsymbol{e}_z) = -[g/(4\pi)][\boldsymbol{r}/|\boldsymbol{r}|^3], \quad (22.2.117)$$

as expected.

Repeat the above calculations for the case $\boldsymbol{m} = -\boldsymbol{e}_z$. Show that again $\boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m})$ has only a ϕ component A^s_ϕ now given by

$$\begin{aligned} A^s_\phi(\boldsymbol{r};0,-\boldsymbol{e}_z) &= -[g/(4\pi)](1-\cos\theta)/[r\sin\theta] = -[g/(4\pi)](1/r)\sin\theta/(1+\cos\theta) \\ &= -[g/(4\pi)](1/r)\tan(\theta/2). \quad (22.2.118) \end{aligned}$$

Verify that this A^s_ϕ is singular on the negative z axis, but not on the posititve z axis. Show, by explicit calculation, that

$$\nabla \times \boldsymbol{A}_s(\boldsymbol{r};0,-\boldsymbol{e}_z) = -[g/(4\pi)][\boldsymbol{r}/|\boldsymbol{r}|^3], \quad (22.2.119)$$

again as expected.

Verify that $\boldsymbol{A}_s(\boldsymbol{r};0,-\boldsymbol{e}_z)$ and $\boldsymbol{A}_s(\boldsymbol{r};0,\boldsymbol{e}_z)$ are related by a gauge transformation,

$$\boldsymbol{A}_s(\boldsymbol{r};0,-\boldsymbol{e}_z)=\boldsymbol{A}_s(\boldsymbol{r};0,\boldsymbol{e}_z)+\nabla\chi \tag{22.2.120}$$

with

$$\chi=-[g/(2\pi)]\phi. \tag{22.2.121}$$

Form the fully infinite string vector potential $\boldsymbol{A}_{2s}(\boldsymbol{r};0,\boldsymbol{e}_z)$ using (2.75). Show that $\boldsymbol{A}_{2s}(\boldsymbol{r};0,\boldsymbol{e}_z)$ also has only a ϕ component given by

$$\begin{aligned}A_\phi^{2s}(\boldsymbol{r};0,\boldsymbol{e}_z) &= (1/2)A_\phi^{s}(\boldsymbol{r};0,\boldsymbol{e}_z)+(1/2)A_\phi^{s}(\boldsymbol{r};0,-\boldsymbol{e}_z)\\ &= [g/(4\pi)](1/r)(\cot\theta).\end{aligned} \tag{22.2.122}$$

Verify that $A_\phi^{2s}(\boldsymbol{r};0,\boldsymbol{e}_z)$ is singular everywhere on the z axis. Verify by explicit calculation that

$$\nabla\times\boldsymbol{A}_{2s}(\boldsymbol{r};0,\boldsymbol{e}_z)=-[g/(4\pi)][\boldsymbol{r}/|\boldsymbol{r}|^3], \tag{22.2.123}$$

also as expected.

According to Subsection 2.2, a magnetic Dirac string can be viewed as an infinitesimally thin solenoid. In the case that the string is straight, one can assign a definite vector to the string that points in the direction of current flow. Show that for a string directed along the z axis, as is the case for this exercise, the current is in the + (or perhaps −) $\boldsymbol{e}_\phi$ direction, which is the same direction as the associated vector potential $\boldsymbol{A}$.

22.2.16. Exercise on the singularity structure of the vector potential for a straight half-infinite Dirac string.

22.2.17. Let $\boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m})$ and $\boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m}')$ be equal strength monopole vector potentials produced by straight-line strings both originating at $\boldsymbol{r}_A$ but extending to infinity in the directions $\boldsymbol{m}$ and $\boldsymbol{m}'$. See (2.63). Show that both produce the same magnetic field (2.55) at points off the strings. Show that these vector potentials are related by a gauge transformation.

22.2.18. Verify (2.72) and (2.73).

22.2.19. Show from (2.79) that

$$|\boldsymbol{A}_{2s}(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m})|=\frac{|[g/(4\pi)][\boldsymbol{m}\cdot(\boldsymbol{r}-\boldsymbol{r}_A)]|}{|\boldsymbol{r}-\boldsymbol{r}_A||\boldsymbol{m}\times(\boldsymbol{r}-\boldsymbol{r}_A)|}. \tag{22.2.124}$$

Verify that $\boldsymbol{A}_{2s}(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m})$ is singular on, and only on, the line (2.76).

22.2.20. Suppose a vector field $\boldsymbol{F}(\boldsymbol{r})$ is specified in some volume V. Surround this volume by a *thin shell* Σ. Extend $\boldsymbol{F}(\boldsymbol{r})$ to all of space by requiring that it vanish outside Σ and go to zero smoothly within Σ. That is, on the boundary of V, which is the inner surface of Σ, $\boldsymbol{F}$ may have finite values; but within Σ it goes smoothly to zero so that it vanishes on the outer surface of Σ and beyond. It is a standard result in analysis that this can be done in such a way that $\boldsymbol{F}(\boldsymbol{r})$ will have as many derivatives as desired in Σ. Find formulas for $\phi(\boldsymbol{r})$ and $\boldsymbol{A}(\boldsymbol{r})$ in this case. Now let the shell shrink to zero thickness while keeping V unchanged so that Σ becomes the surface S. Show that the relations (2.80), (2.83), and (2.84) continue to give $\boldsymbol{F}(\boldsymbol{r})$ for $\boldsymbol{r}\in V$, and give $\boldsymbol{F}(\boldsymbol{r})=0$ for $\boldsymbol{r}\notin V$.

22.2.21. Suppose a vector field $\boldsymbol{F}(\boldsymbol{r})$ is globally defined and falls off at infinity at least as fast as $1/|\boldsymbol{r}|^2$. Show that, when the surface S in (2.83) and (2.84) is taken to infinity, the surface integrals then vanish. Consequently, (2.83) and (2.84) then take the form

$$\phi(\boldsymbol{r}) = [1/(4\pi)] \int d^3\boldsymbol{r}'\ G(\boldsymbol{r}, \boldsymbol{r}')\nabla' \cdot \boldsymbol{F}(\boldsymbol{r}'), \tag{22.2.125}$$

$$\boldsymbol{A}(\boldsymbol{r}) = [1/(4\pi)] \int d^3\boldsymbol{r}'\ G(\boldsymbol{r}, \boldsymbol{r}')\nabla' \times \boldsymbol{F}(\boldsymbol{r}'). \tag{22.2.126}$$

Thus, in view of (2.80), such a vector field is completely specified by a knowledge of its divergence and curl.

Why should this be the case? Suppose that $\boldsymbol{F}(\boldsymbol{r})$ has the Fourier representation

$$\boldsymbol{F}(\boldsymbol{r}) = \int d^3\boldsymbol{k}\ \exp(i\boldsymbol{k} \cdot \boldsymbol{r})\ \tilde{\boldsymbol{F}}(\boldsymbol{k}). \tag{22.2.127}$$

Such a representation is possible in any number of dimensions, and its existence is a consequence of the completeness of the unitary representations of the translation part of the Euclidean group. Show that there are the relations

$$\boldsymbol{\nabla} \cdot \boldsymbol{F}(\boldsymbol{r}) = i \int d^3\boldsymbol{k}\ \exp(i\boldsymbol{k} \cdot \boldsymbol{r})\ \boldsymbol{k} \cdot \tilde{\boldsymbol{F}}(\boldsymbol{k}), \tag{22.2.128}$$

$$\boldsymbol{\nabla} \times \boldsymbol{F}(\boldsymbol{r}) = i \int d^3\boldsymbol{k}\ \exp(i\boldsymbol{k} \cdot \boldsymbol{r})\ \boldsymbol{k} \times \tilde{\boldsymbol{F}}(\boldsymbol{k}). \tag{22.2.129}$$

Consequently, if the functions $\boldsymbol{\nabla} \cdot \boldsymbol{F}(\boldsymbol{r})$ and $\boldsymbol{\nabla} \times \boldsymbol{F}(\boldsymbol{r})$ are assumed known, then, by the Fourier inversion theorem, the functions $\boldsymbol{k} \cdot \tilde{\boldsymbol{F}}(\boldsymbol{k})$ and $\boldsymbol{k} \times \tilde{\boldsymbol{F}}(\boldsymbol{k})$ are also known. Recall the vector identity

$$\boldsymbol{a} \times (\boldsymbol{b} \times \boldsymbol{c}) = \boldsymbol{b}\ (\boldsymbol{a} \cdot \boldsymbol{c}) - \boldsymbol{c}\ (\boldsymbol{a} \cdot \boldsymbol{b}). \tag{22.2.130}$$

Use this identity to show that

$$\boldsymbol{k} \times (\boldsymbol{k} \times \tilde{\boldsymbol{F}}) = \boldsymbol{k}\ (\boldsymbol{k} \cdot \tilde{\boldsymbol{F}}) - \tilde{\boldsymbol{F}}\ (\boldsymbol{k} \cdot \boldsymbol{k}), \tag{22.2.131}$$

and therefore

$$\tilde{\boldsymbol{F}} = [1/(\boldsymbol{k} \cdot \boldsymbol{k})][\boldsymbol{k}(\boldsymbol{k} \cdot \tilde{\boldsymbol{F}})] - [1/(\boldsymbol{k} \cdot \boldsymbol{k})][\boldsymbol{k} \times (\boldsymbol{k} \times \tilde{\boldsymbol{F}})]. \tag{22.2.132}$$

Thus, the function $\tilde{\boldsymbol{F}}(\boldsymbol{k})$ is known if the functions $\boldsymbol{k} \cdot \tilde{\boldsymbol{F}}(\boldsymbol{k})$ and $\boldsymbol{k} \times \tilde{\boldsymbol{F}}(\boldsymbol{k})$ are known. Correspondingly, the function $\boldsymbol{F}(\boldsymbol{r})$ is determined if the functions $\boldsymbol{\nabla} \cdot \boldsymbol{F}(\boldsymbol{r})$ and $\boldsymbol{\nabla} \times \boldsymbol{F}(\boldsymbol{r})$ are assumed known. Finally, we note that the identity (2.130) may be viewed as a Lie algebraic relation for the cross-product Lie algebra. See Section 3.7.4. From Exercise 3.7.31 we know that the cross-product Lie algebra is equivalent to $so(3)$, and therefore (2.130) is also a property of $so(3)$. Finally, $so(3)$ is a subalgebra of the Lie algebra of the three-dimensional Euclidean group. Thus, the fact that a vector field in three dimensions is specified, if its divergence and curl are known, is a consequence of the properties of the three-dimensional Euclidean group.

22.3 Construction of Kernels G^n and G^t

22.3.1 Background

Let us apply the results of the previous section to the case of a magnetic field $\boldsymbol{B}(\boldsymbol{r})$ in a volume V under the assumption that there are no sources in V. See (1.1) and (1.2). As stated earlier, this would be the case of interest for charged particles propagating through an evacuated beam pipe. In this circumstance we may use (2.80), (2.87), and (2.88) to write

$$\boldsymbol{B}(\boldsymbol{r}) = -\nabla\phi^n(\boldsymbol{r}) + \nabla \times \boldsymbol{A}^t(\boldsymbol{r}) \text{ for } \boldsymbol{r} \in V \tag{22.3.1}$$

with

$$\phi^n(\boldsymbol{r}) = -[1/(4\pi)]\int_S dS'\, \boldsymbol{n}' \cdot \boldsymbol{B}(\boldsymbol{r}')G(\boldsymbol{r},\boldsymbol{r}'), \tag{22.3.2}$$

$$\boldsymbol{A}^t(\boldsymbol{r}) = -[1/(4\pi)]\int_S dS'\, [\boldsymbol{n}' \times \boldsymbol{B}(\boldsymbol{r}')]G(\boldsymbol{r},\boldsymbol{r}'). \tag{22.3.3}$$

Here, as before, the superscripts n and t denote *normal* and *tangential* since the quantities so denoted involve normal and tangential components of $\boldsymbol{B}$.

The relations (3.1) through (3.3) could be employed if one wished to integrate Newton's equations of motion, and also find Taylor maps based on these equations, for all that would then be required is the magnetic field $\boldsymbol{B}(\boldsymbol{r})$. See, for example, the equations of motion (1.6.68) and (1.6.69), or (1.6.135) through (1.6.138) and (1.6.145) through (1.6.147). However, if one wishes instead to employ a Hamiltonian formulation in order to reap the benefits of symplectic symmetry, then it is necessary to have the magnetic field specified *entirely* in terms of a vector potential rather than in terms of both a scalar and vector potential as in (3.1). What we need is a vector potential $\boldsymbol{A}^n(\boldsymbol{r})$ such that

$$\nabla \times \boldsymbol{A}^n(\boldsymbol{r}) = -\nabla\phi^n(\boldsymbol{r}). \tag{22.3.4}$$

Then, with the definition

$$\boldsymbol{A}(\boldsymbol{r}) = \boldsymbol{A}^n(\boldsymbol{r}) + \boldsymbol{A}^t(\boldsymbol{r}), \tag{22.3.5}$$

there would be the result

$$\boldsymbol{B}(\boldsymbol{r}) = \nabla \times \boldsymbol{A}(\boldsymbol{r}). \tag{22.3.6}$$

The construction of an $\boldsymbol{A}^n(\boldsymbol{r})$ that satisfies (3.4) can be accomplished with the aid of the Dirac monopole vector potential. Inspection of $\phi^n(\boldsymbol{r})$, as given by (3.2), shows that it appears to arise from a distribution of magnetic monopoles described by a magnetic charge surface density spread over the surface S. Therefore, it should be possible to find an equivalent vector potential based on the vector potential for a magnetic monopole.

22.3.2 Construction of G^n Using Half-Infinite String Monopoles

Let us make this idea precise. To do so, for simplicity, will use half-infinite string Dirac monopoles. (Fully infinite string Dirac monopoles can also be used. See Exercise 3.2.) Define $\boldsymbol{B}^n$ by the rule

$$\boldsymbol{B}^n = -\nabla\phi^n \tag{22.3.7}$$

so that the $\boldsymbol{A}^n$ that we seek satisfies

$$\nabla \times \boldsymbol{A}^n = \boldsymbol{B}^n. \tag{22.3.8}$$

Combining (3.2) and (3.7) gives the result

$$\boldsymbol{B}^n(\boldsymbol{r}) = [1/(4\pi)] \int_S dS' \; \boldsymbol{n}' \cdot \boldsymbol{B}(\boldsymbol{r}')\nabla G(\boldsymbol{r}, \boldsymbol{r}'). \tag{22.3.9}$$

From (2.89) we know that

$$\nabla G(\boldsymbol{r}, \boldsymbol{r}') = -(\boldsymbol{r} - \boldsymbol{r}')/|\boldsymbol{r} - \boldsymbol{r}'|^3. \tag{22.3.10}$$

But, from (2.72), we also have the relation

$$(4\pi/g)\nabla \times \boldsymbol{A}_s(\boldsymbol{r}; \boldsymbol{r}', \boldsymbol{m}') = -[(\boldsymbol{r} - \boldsymbol{r}')/|\boldsymbol{r} - \boldsymbol{r}'|^3]. \tag{22.3.11}$$

Define a quantity $\boldsymbol{K}(\boldsymbol{r}; \boldsymbol{r}', \boldsymbol{m}')$ by the rule

$$\begin{aligned} \boldsymbol{K}(\boldsymbol{r}; \boldsymbol{r}', \boldsymbol{m}') &= (4\pi/g)\boldsymbol{A}_s(\boldsymbol{r}; \boldsymbol{r}', \boldsymbol{m}') \\ &= [\boldsymbol{m}' \times (\boldsymbol{r} - \boldsymbol{r}')]/\{|\boldsymbol{r} - \boldsymbol{r}'|[|\boldsymbol{r} - \boldsymbol{r}'| - \boldsymbol{m}' \cdot (\boldsymbol{r} - \boldsymbol{r}')]\}. \end{aligned} \tag{22.3.12}$$

See (2.63). In view of (3.10) through (3.12), we have established the key relation

$$\nabla G(\boldsymbol{r}, \boldsymbol{r}') = \nabla \times \boldsymbol{K}(\boldsymbol{r}; \boldsymbol{r}', \boldsymbol{m}'). \tag{22.3.13}$$

See Exercise 2.15 for a specific instance of this relation.

We are almost done. Insertion of (3.13) into (3.9) gives the result

$$\begin{aligned} \boldsymbol{B}^n &= [1/(4\pi)] \int_S dS' \; \boldsymbol{n}' \cdot \boldsymbol{B}(\boldsymbol{r}')\nabla \times \boldsymbol{K}(\boldsymbol{r}; \boldsymbol{r}', \boldsymbol{m}') \\ &= [1/(4\pi)]\nabla \times \int_S dS' \; \boldsymbol{n}' \cdot \boldsymbol{B}(\boldsymbol{r}')\boldsymbol{K}(\boldsymbol{r}; \boldsymbol{r}', \boldsymbol{m}'). \end{aligned} \tag{22.3.14}$$

Comparison of (3.8) and (3.14) shows that we may make the definition

$$\boldsymbol{A}^n(\boldsymbol{r}) = \boldsymbol{A}^{n1s}(\boldsymbol{r}) \tag{22.3.15}$$

with

$$\boldsymbol{A}^{n1s}(\boldsymbol{r}) = [1/(4\pi)] \int_S dS' \; \boldsymbol{n}' \cdot \boldsymbol{B}(\boldsymbol{r}')\boldsymbol{K}(\boldsymbol{r}; \boldsymbol{r}', \boldsymbol{m}'). \tag{22.3.16}$$

Here we have used the superscript $n1s$ to indicate that the vector potential for *one* half-infinite Dirac *string* has been employed. Finally, we make the definitions

$$B_n(\boldsymbol{r}') = \boldsymbol{n}' \cdot \boldsymbol{B}(\boldsymbol{r}') \tag{22.3.17}$$

and

$$\begin{aligned} \boldsymbol{G}^{n1s}(\boldsymbol{r}; \boldsymbol{r}', \boldsymbol{m}') &= [1/(4\pi)]\boldsymbol{K}(\boldsymbol{r}; \boldsymbol{r}', \boldsymbol{m}') \\ &= \{\boldsymbol{m}'(\boldsymbol{r}') \times (\boldsymbol{r} - \boldsymbol{r}')\}/\{4\pi|\boldsymbol{r} - \boldsymbol{r}'|[|\boldsymbol{r} - \boldsymbol{r}'| - \boldsymbol{m}'(\boldsymbol{r}') \cdot (\boldsymbol{r} - \boldsymbol{r}')]\}. \end{aligned} \tag{22.3.18}$$

Here $\boldsymbol{n}'(\boldsymbol{r}')$ is the outward normal to S at the point $\boldsymbol{r}'$. With these definitions we have the result

$$\boldsymbol{A}^{n1s}(\boldsymbol{r}) = \int_S dS'\ B_n(\boldsymbol{r}')\boldsymbol{G}^{n1s}(\boldsymbol{r};\boldsymbol{r}',\boldsymbol{m}'). \tag{22.3.19}$$

Together (3.15) and (3.17) through (3.19) provide a realization of the relation (1.7).

In evaluating the integral (3.19) it necessary to specify $\boldsymbol{m}'(\boldsymbol{r}')$, the direction of the straight half-infinite Dirac string, as $\boldsymbol{r}'$ varies over S. There is considerable freedom in doing so, and different choices simply result in different gauges for $\boldsymbol{A}^{n1s}(\boldsymbol{r})$. There is only one major consideration. No string should intersect the volume V because it is desirable that $\boldsymbol{A}^{n1s}(\boldsymbol{r})$ be analytic for $\boldsymbol{r} \in V$. For many geometries a convenient choice is to require that $\boldsymbol{m}'(\boldsymbol{r}')$ be normal to and point outward from S,

$$\boldsymbol{m}'(\boldsymbol{r}') = \boldsymbol{n}'(\boldsymbol{r}'). \tag{22.3.20}$$

Other choices may also be convenient and useful.

22.3.3 Discussion

Let $\boldsymbol{A}^n(\boldsymbol{r})$ denote the $\boldsymbol{A}^{n1s}(\boldsymbol{r})$ given by (3.19) and let $\boldsymbol{G}^n(\boldsymbol{r},\boldsymbol{r}')$ denote the $\boldsymbol{G}^{n1s}(\boldsymbol{r};\boldsymbol{r}',\boldsymbol{m}')$ given by (3.18). At this point we can take pleasure in observing that $\boldsymbol{A}^n(\boldsymbol{r})$ and $\boldsymbol{G}^n(\boldsymbol{r},\boldsymbol{r}')$ have several desirable properties: First, as long as the Dirac strings for $\boldsymbol{r}' \in S$ do not intersect V, the functions $\boldsymbol{G}^n(\boldsymbol{r},\boldsymbol{r}')$, for every $\boldsymbol{r}' \in S$, are analytic in $\boldsymbol{r}$ for all $\boldsymbol{r} \in V$. It follows from (3.19), under mild conditions on $B_n(\boldsymbol{r}')$ for $\boldsymbol{r}' \in S$, that $\boldsymbol{A}^n(\boldsymbol{r})$ is analytic in V. Second, since the kernel $\boldsymbol{G}^n(\boldsymbol{r},\boldsymbol{r}')$ is essentially the vector potential for a Dirac magnetic monopole, see (3.12) and (3.18), it has, for $\boldsymbol{r} \in V$, the properties

$$\nabla \cdot [\boldsymbol{G}^n(\boldsymbol{r},\boldsymbol{r}')] = 0, \tag{22.3.21}$$

$$\nabla \times [\nabla \times \boldsymbol{G}^n(\boldsymbol{r},\boldsymbol{r}')] = 0. \tag{22.3.22}$$

See (2.71) and (2.73). It follows from (3.19), again under mild conditions on $B_n(\boldsymbol{r}')$, that $\boldsymbol{A}^n(\boldsymbol{r})$ has these same properties,

$$\nabla \cdot [\boldsymbol{A}^n(\boldsymbol{r})] = 0, \tag{22.3.23}$$

$$\nabla \times [\nabla \times \boldsymbol{A}^n(\boldsymbol{r})] = 0. \tag{22.3.24}$$

In practical applications, the surface values $B_n(\boldsymbol{r}')$ will only be known approximately, and the integrals (3.19) may be evaluated numerically with limited precision. It is comforting to know that, nevertheless, the resulting $\boldsymbol{A}^n(\boldsymbol{r})$ will be analytic in V and will satisfy the relations (3.23) and (3.24) exactly no matter what errors are present in the surface values $B_n(\boldsymbol{r}')$ and no matter how poorly the integrals (3.19) are evaluated. All that matters is that the kernel $\boldsymbol{G}^n$ be evaluated to high precision.

22.3.4 Construction of $\mathbf{G}^t$

What can be said about the properties of $\boldsymbol{A}^t(\boldsymbol{r})$ as given by (3.3)? Just as is the case for $\boldsymbol{A}^n(\boldsymbol{r})$, we would like $\boldsymbol{A}^t(\boldsymbol{r})$ to be analytic in V and to satisfy properties analogous to (3.23) and (3.24). That is, we desire the relations

$$\nabla \cdot [\boldsymbol{A}^t(\boldsymbol{r})] = 0, \tag{22.3.25}$$

$$\nabla \times [\nabla \times \boldsymbol{A}^t(\boldsymbol{r})] = 0, \tag{22.3.26}$$

and we would like to have them hold no matter how poorly the integral (3.3) is evaluated. As the expression (3.3) for $\boldsymbol{A}^t(\boldsymbol{r})$ stands, this is not the case. However, we can transform (3.3) into a form that meets all our hopes.

Since, by assumption, $\boldsymbol{B}(\boldsymbol{r}')$ is curl free for $\boldsymbol{r}' \in V$, there exists a scalar potential $\psi(\boldsymbol{r}')$ such that

$$\boldsymbol{B}(\boldsymbol{r}') = +\nabla'\psi(\boldsymbol{r}'). \tag{22.3.27}$$

[Note, by convention, we have used a minus sign in (2.3) and a plus sign in (3.27). See also (15.2.1) and (15.2.6).] Consequently, (3.3) can be rewritten in the form

$$\boldsymbol{A}^t(\boldsymbol{r}) = -[1/(4\pi)] \int_S dS' \, [\boldsymbol{n}' \times \nabla'\psi(\boldsymbol{r}')]G(\boldsymbol{r}, \boldsymbol{r}'). \tag{22.3.28}$$

[Also note, as observed earlier, that a knowledge of the tangential component of $\nabla'\psi(\boldsymbol{r}')$, which is what is involved in (3.28) and is equivalent to a knowledge of $\psi(\boldsymbol{r}')$ on S, is in turn equivalent to a knowledge of the tangential component of $\boldsymbol{B}(\boldsymbol{r}')$ on S under the assumption that $\boldsymbol{B}(\boldsymbol{r}')$ is curl free.] Next observe that there is the identity

$$[\nabla'\psi(\boldsymbol{r}')]G(\boldsymbol{r}, \boldsymbol{r}') = \nabla'[\psi(\boldsymbol{r}')G(\boldsymbol{r}, \boldsymbol{r}')] - \psi(\boldsymbol{r}')\nabla'G(\boldsymbol{r}, \boldsymbol{r}'). \tag{22.3.29}$$

Therefore (3.28) can also be written in the form

$$\begin{aligned} \boldsymbol{A}^t(\boldsymbol{r}) \;\; &= \;\; -[1/(4\pi)] \int_S dS' \, \{\boldsymbol{n}' \times \nabla'[\psi(\boldsymbol{r}')G(\boldsymbol{r}, \boldsymbol{r}')]\} \\ &\quad\; +[1/(4\pi)] \int_S dS' \, \{\boldsymbol{n}' \times [\psi(\boldsymbol{r}')\nabla'G(\boldsymbol{r}, \boldsymbol{r}')]\}. \end{aligned} \tag{22.3.30}$$

It can be shown that the first integral on the right side of (3.30) vanishes,

$$-[1/(4\pi)] \int_S dS' \, \{\boldsymbol{n}' \times \nabla'[\psi(\boldsymbol{r}')G(\boldsymbol{r}, \boldsymbol{r}')]\} = 0. \tag{22.3.31}$$

See Exercise 3.1. Moreover, the second integral can be rewritten in the form

$$[1/(4\pi)] \int_S dS' \, \{\boldsymbol{n}' \times [\psi(\boldsymbol{r}')\nabla'G(\boldsymbol{r}, \boldsymbol{r}')]\} = [1/(4\pi)] \int_S dS' \, \psi(\boldsymbol{r}')[\boldsymbol{n}' \times \nabla'G(\boldsymbol{r}, \boldsymbol{r}')]. \tag{22.3.32}$$

Consequently $\boldsymbol{A}^t(\boldsymbol{r})$ can also be written in the form

$$\boldsymbol{A}^t(\boldsymbol{r}) = [1/(4\pi)] \int_S dS' \, \psi(\boldsymbol{r}')[\boldsymbol{n}' \times \nabla'G(\boldsymbol{r}, \boldsymbol{r}')]. \tag{22.3.33}$$

Finally, let $\boldsymbol{G}^t(\boldsymbol{r},\boldsymbol{r'})$ be the kernel

$$\boldsymbol{G}^t(\boldsymbol{r},\boldsymbol{r'}) = [1/(4\pi)][\boldsymbol{n'}(\boldsymbol{r'}) \times \nabla' G(\boldsymbol{r},\boldsymbol{r'})]. \tag{22.3.34}$$

With this definition, $\boldsymbol{A}^t(\boldsymbol{r})$ takes the final form

$$\boldsymbol{A}^t(\boldsymbol{r}) = \int_S dS' \; \psi(\boldsymbol{r'})\boldsymbol{G}^t(\boldsymbol{r},\boldsymbol{r'}). \tag{22.3.35}$$

And working out (3.34) explicitly gives the result

$$\boldsymbol{G}^t(\boldsymbol{r},\boldsymbol{r'}) = [\boldsymbol{n'}(\boldsymbol{r'}) \times (\boldsymbol{r} - \boldsymbol{r'})]/[4\pi|\boldsymbol{r} - \boldsymbol{r'}|^3]. \tag{22.3.36}$$

We have derived the relation (1.8) with $\boldsymbol{G}^t$ given by (3.36).

At this point we should verify that we have achieved our desired goals. First, it is evident from (3.36) that $\boldsymbol{G}^t(\boldsymbol{r},\boldsymbol{r'})$ is analytic in the components of $\boldsymbol{r}$ for $\boldsymbol{r} \in V$ and $\boldsymbol{r'} \in S$. Therefore, from the representation (3.35), we see that, under mild conditions on $\psi(\boldsymbol{r'})$, $\boldsymbol{A}^t(\boldsymbol{r})$ will be analytic in V.

Next, let us compute $\nabla \cdot \boldsymbol{G}^t(\boldsymbol{r},\boldsymbol{r'})$ and $\nabla \times [\nabla \times \boldsymbol{G}^t(\boldsymbol{r},\boldsymbol{r'})]$. We will see that they both vanish for $\boldsymbol{r} \in V$. Recall the vector identity

$$\nabla \cdot (\boldsymbol{C} \times \boldsymbol{D}) = \boldsymbol{D} \cdot (\nabla \times \boldsymbol{C}) - \boldsymbol{C} \cdot (\nabla \times \boldsymbol{D}). \tag{22.3.37}$$

From this identity, (2.89), (3.34), and the fact that the curl of a gradient vanishes, it follows that

$$\begin{aligned}\nabla \cdot \boldsymbol{G}^t(\boldsymbol{r},\boldsymbol{r'}) &= -[1/(4\pi)]\boldsymbol{n'}(\boldsymbol{r'}) \cdot \{\nabla \times [\nabla' G(\boldsymbol{r},\boldsymbol{r'})]\} \\ &= [1/(4\pi)]\boldsymbol{n'}(\boldsymbol{r'}) \cdot \{\nabla \times [\nabla G(\boldsymbol{r},\boldsymbol{r'})]\} = 0. \end{aligned} \tag{22.3.38}$$

Also, it is evident from (2.90) and (3.34) that

$$\begin{aligned}\nabla^2 \boldsymbol{G}^t(\boldsymbol{r},\boldsymbol{r'}) &= [1/(4\pi)][\nabla^2][\boldsymbol{n'}(\boldsymbol{r'}) \times \nabla' G(\boldsymbol{r},\boldsymbol{r'})] \\ &= [1/(4\pi)]\{\boldsymbol{n'}(\boldsymbol{r'}) \times \nabla' [\nabla^2 G(\boldsymbol{r},\boldsymbol{r'})]\} \\ &= 0 \text{ for } \boldsymbol{r} \text{ within } V \text{ and } \boldsymbol{r'} \in S. \end{aligned} \tag{22.3.39}$$

Finally, again invoke the vector identity

$$\nabla \times (\nabla \times \boldsymbol{C}) = \nabla(\nabla \cdot \boldsymbol{C}) - \nabla^2 \boldsymbol{C}. \tag{22.3.40}$$

When applied to $\boldsymbol{G}^t(\boldsymbol{r},\boldsymbol{r'})$, in view of (3.38) and (3.39), it yields the relation

$$\nabla \times [\nabla \times \boldsymbol{G}^t(\boldsymbol{r},\boldsymbol{r'})] = 0 \text{ for } \boldsymbol{r} \text{ within } V \text{ and } \boldsymbol{r'} \in S. \tag{22.3.41}$$

We have seen that the kernel $\boldsymbol{G}^t(\boldsymbol{r},\boldsymbol{r'})$ satisfies the relations (3.38) and (3.41), and note that these relations are analogous to the relations (3.21) and (3.22) for $\boldsymbol{G}^n(\boldsymbol{r},\boldsymbol{r'})$. It follows, by the same reasoning used in the case of $\boldsymbol{G}^n(\boldsymbol{r},\boldsymbol{r'})$ and $\boldsymbol{A}^n(\boldsymbol{r})$, that $\boldsymbol{A}^t(\boldsymbol{r})$ satisfies the relations (3.25) and (3.26), and these relations hold exactly even in the presence of errors in the surface values $\psi(\boldsymbol{r'})$ and no matter how poorly the integrals (3.35) are evaluated. Similar to to the case of $\boldsymbol{G}^n$, all that matters is that the kernel $\boldsymbol{G}^t$ be evaluated to high precision.

22.3.5 Final Discussion

Let us put together what we have learned about analyticity and "exactness". Look at (3.5) and (3.6). Since $\boldsymbol{A}^n(\boldsymbol{r})$ and $\boldsymbol{A}^t(\boldsymbol{r})$ are both analytic in V, $\boldsymbol{A}(\boldsymbol{r})$ will be analytic in V. And since (3.23) through (3.26) hold, analogous results will hold for $\boldsymbol{A}(\boldsymbol{r})$,

$$\nabla \cdot [\boldsymbol{A}(\boldsymbol{r})] = 0, \tag{22.3.42}$$

$$\nabla \times [\nabla \times \boldsymbol{A}(\boldsymbol{r})] = 0. \tag{22.3.43}$$

Moreover, analyticity and the relations (3.42) and (3.43) will still hold exactly even in the presence of errors in the surface values B_n and ψ, and no matter how poorly the relevant integrals are evaluated. Finally, in view of (3.6), the Maxwell equation

$$\nabla \cdot \boldsymbol{B} = 0 \tag{22.3.44}$$

will be satisfied exactly. And, in view of (3.6) and (3.43), the second Maxwell equation

$$\nabla \times \boldsymbol{B} = 0 \tag{22.3.45}$$

will also be satisfied exactly.

Exercises

22.3.1. The purpose of this exercise is to verify the relation (3.31).

22.3.2. Subsection 3.2 described the construction of the kernel we called $\boldsymbol{G}^{\mathrm{n1s}}$ using the vector potential for a half-infinite string Dirac monopole. Another possibility is to use the vector potential for fully infinite string (two string) Dirac monopole to construct an analogous kernel we will call $\boldsymbol{G}^{\mathrm{n2s}}$. The purpose of this exercise is of explore that possibility.

The vector potential $\boldsymbol{A}_{2s}(\boldsymbol{r};\boldsymbol{r}_A,\boldsymbol{m})$ given by (2.75) also produces the monopole field (2.55) so that there is the relation

$$(4\pi/g)\nabla \times \boldsymbol{A}_{2s}(\boldsymbol{r};\boldsymbol{r}',\boldsymbol{m}') = -[(\boldsymbol{r}-\boldsymbol{r}')/|\boldsymbol{r}-\boldsymbol{r}'|^3]. \tag{22.3.46}$$

Now define a quantity $\boldsymbol{K}(\boldsymbol{r};\boldsymbol{r}',\boldsymbol{m}')$ by the rule

$$\begin{aligned}\boldsymbol{K}(\boldsymbol{r};\boldsymbol{r}',\boldsymbol{m}') &= (4\pi/g)\boldsymbol{A}_{2s}(\boldsymbol{r};\boldsymbol{r}',\boldsymbol{m}') \\ &= \frac{[\boldsymbol{m}\times(\boldsymbol{r}-\boldsymbol{r}_A)][\boldsymbol{m}\cdot(\boldsymbol{r}-\boldsymbol{r}_A)]}{|\boldsymbol{r}-\boldsymbol{r}_A||\boldsymbol{m}\times(\boldsymbol{r}-\boldsymbol{r}_A)|^2}.\end{aligned} \tag{22.3.47}$$

See (2.79). In view of (3.10), (3.21), and (3.22), we have also established the key relation

$$\nabla G(\boldsymbol{r},\boldsymbol{r}') = \nabla \times \boldsymbol{K}(\boldsymbol{r};\boldsymbol{r}',\boldsymbol{m}') \tag{22.3.48}$$

with $\boldsymbol{K}$ now given by (3.22). Also see Exercise 2.15 for a specific instance of this relation.

Next, insertion of (3.23) into (3.9) gives the result

$$\begin{aligned}\boldsymbol{B}^n &= [1/(4\pi)]\int_S dS'\ \boldsymbol{n}'\cdot\boldsymbol{B}(\boldsymbol{r}')\nabla\times\boldsymbol{K}(\boldsymbol{r};\boldsymbol{r}',\boldsymbol{m}')\\ &= [1/(4\pi)]\nabla\times\int_S dS'\ \boldsymbol{n}'\cdot\boldsymbol{B}(\boldsymbol{r}')\boldsymbol{K}(\boldsymbol{r};\boldsymbol{r}',\boldsymbol{m}').\end{aligned} \tag{22.3.49}$$

Comparison of (3.8) and (3.24) shows that we may also make the definition

$$\boldsymbol{A}^n(\boldsymbol{r}) = \boldsymbol{A}^{n2s}(\boldsymbol{r}) \tag{22.3.50}$$

with

$$\boldsymbol{A}^{n2s}(\boldsymbol{r}) = [1/(4\pi)]\int_S dS'\ \boldsymbol{n}'\cdot\boldsymbol{B}(\boldsymbol{r}')\boldsymbol{K}(\boldsymbol{r};\boldsymbol{r}',\boldsymbol{m}'). \tag{22.3.51}$$

Here we have used the superscript $n2s$ to indicate that the vector potential for a fully infinite (*2*-sided) Dirac *string* has been employed. Finally we may write (3.26) in the form

$$\boldsymbol{A}^{n2s}(\boldsymbol{r}) = \int_S dS'\ B_n(\boldsymbol{r}')\boldsymbol{G}^{n2s}(\boldsymbol{r};\boldsymbol{r}',\boldsymbol{m}') \tag{22.3.52}$$

where (3.17) is again employed and $\boldsymbol{G}^{n2s}(\boldsymbol{r};\boldsymbol{r}',\boldsymbol{m}')$ is the kernel

$$\begin{aligned}\boldsymbol{G}^{n2s}(\boldsymbol{r};\boldsymbol{r}',\boldsymbol{m}') &= [1/(4\pi)]\boldsymbol{K}(\boldsymbol{r};\boldsymbol{r}',\boldsymbol{m}')\\ &= \frac{[\boldsymbol{m}'\times(\boldsymbol{r}-\boldsymbol{r}_A)][\boldsymbol{m}'\cdot(\boldsymbol{r}-\boldsymbol{r}_A)]}{4\pi|\boldsymbol{r}-\boldsymbol{r}_A||\boldsymbol{m}'\times(\boldsymbol{r}-\boldsymbol{r}_A)|^2}.\end{aligned} \tag{22.3.53}$$

Together (3.25), (3.27), and (3.28) provide another realization of the relation (1.7). Show that this fully infinite Dirac string kernel obeys relations analogous to (3.21) and (3,22) and therefore the relations analogous to (3.23) and (3.24) are also satisfied.

In evaluating the integral (3.28) it again necessary to specify $\boldsymbol{m}'(\boldsymbol{r}')$, now the direction of the straight fully infinite Dirac string, as $\boldsymbol{r}'$ varies over S. As before, there is considerable freedom in doing so, and different choices simply result in different gauges for $\boldsymbol{A}^{n1s}(\boldsymbol{r})$. The major considerations are again that no string intersect the volume V and that the vector potential fall off rapidly in fringe-field regions. We also note that one may use $\boldsymbol{A}^{n1s}(\boldsymbol{r})$ for some parts of S and $\boldsymbol{A}^{n2s}(\boldsymbol{r})$ for other parts.

22.3.3. At the beginning of this section it was mentioned that (3.1) through (3.3) could be used to integrate Newton's equations of motion in terms of $\boldsymbol{B}(\boldsymbol{r})$. However the $\boldsymbol{B}(\boldsymbol{r})$ obtained using (3.1) is not guaranteed to satisfy the Maxwell equations if there are errors in surface values and/or the integrals are not evaluated accurately. Verify that, in this regard, there is no difficulty in the use of (3.2) by showing that it is guaranteed to satisfy

$$\nabla^2\phi^n(\boldsymbol{r}) = 0, \tag{22.3.54}$$

and therefore (3.43) is satisfied. Show that if (3.3) is replaced by (3.32), then (3.44) is also guaranteed.

22.3.4. Suppose $\boldsymbol{B}(\boldsymbol{r})$ is source free in a volume V bounded by a surface S, as in (1.1) and (1.2), and suppose $B_n(\boldsymbol{r}')$ and $\psi(\boldsymbol{r}')$ are known on S. The aim of this exercise is to compute $\boldsymbol{B}(\boldsymbol{r})$ in terms of $B_n(\boldsymbol{r}')$ and $\psi(\boldsymbol{r}')$ using the representation given by (1.3), (1.6) through (1.8), (1.10), and (1.11). Verify that

$$\nabla \times \boldsymbol{G}^n(\mathbf{r},\mathbf{r}') = [1/(4\pi)]\nabla G(\mathbf{r},\mathbf{r}') \tag{22.3.55}$$

from which it follows that

$$\begin{aligned}\boldsymbol{B}^n(\boldsymbol{r}) &= \nabla \times \boldsymbol{A}^n(\boldsymbol{r}) = \int_S dS'\ B_n(\boldsymbol{r}')\nabla \times \boldsymbol{G}^n(\boldsymbol{r},\boldsymbol{r}') \\ &= [1/(4\pi)]\int_S dS'\ B_n(\boldsymbol{r}')\nabla G(\mathbf{r},\mathbf{r}') \\ &= -[1/(4\pi)]\int_S dS'\ B_n(\boldsymbol{r}')(\mathbf{r}-\mathbf{r}')/|\mathbf{r}-\mathbf{r}'|^3,\end{aligned} \tag{22.3.56}$$

in accord with (3.9). Recall the vector identity

$$\nabla \times (\boldsymbol{C}\times\boldsymbol{D}) = (\boldsymbol{D}\cdot\nabla)\boldsymbol{C} + \boldsymbol{C}(\nabla\cdot\boldsymbol{D}) - (\boldsymbol{C}\cdot\nabla)\boldsymbol{D} - \boldsymbol{D}(\nabla\cdot\boldsymbol{C}). \tag{22.3.57}$$

Using (3.31) and (3.48), show that

$$\nabla \times \boldsymbol{G}^t(\boldsymbol{r},\boldsymbol{r}') = -[1/(4\pi)]\boldsymbol{n}'(\boldsymbol{r}')/|\boldsymbol{r}-\boldsymbol{r}'|^3 + [3/(4\pi)][\boldsymbol{n}'(\boldsymbol{r}')\cdot(\boldsymbol{r}-\boldsymbol{r}')](\boldsymbol{r}-\boldsymbol{r}')/|\boldsymbol{r}-\boldsymbol{r}'|^5, \tag{22.3.58}$$

from which it follows that

$$\begin{aligned}\boldsymbol{B}^t(\boldsymbol{r}) &= \nabla \times \boldsymbol{A}^t(\boldsymbol{r}) = \int_S dS'\ \psi(\boldsymbol{r}')\nabla \times \boldsymbol{G}^t(\boldsymbol{r},\boldsymbol{r}') \\ &= -[1/(4\pi)]\int_S dS'\ \psi(\boldsymbol{r}')\boldsymbol{n}'(\mathbf{r}')/|\mathbf{r}-\mathbf{r}'|^3 \\ &\quad + [3/(4\pi)]\int_S dS'\ \psi(\boldsymbol{r}')[\boldsymbol{n}'(\boldsymbol{r}')\cdot(\boldsymbol{r}-\boldsymbol{r}')](\boldsymbol{r}-\boldsymbol{r}')/|\boldsymbol{r}-\boldsymbol{r}'|^5.\end{aligned} \tag{22.3.59}$$

Observe that, if we wish, we may define kernels $\boldsymbol{K}^n(\boldsymbol{r},\boldsymbol{r}')$ and $\boldsymbol{K}^t(\boldsymbol{r},\boldsymbol{r}')$ by the rules

$$\begin{aligned}\boldsymbol{K}^n(\boldsymbol{r},\boldsymbol{r}') &= \nabla \times \boldsymbol{G}^n(\mathbf{r},\mathbf{r}') = [1/(4\pi)]\nabla G(\mathbf{r},\mathbf{r}') \\ &= -[1/(4\pi)](\mathbf{r}-\mathbf{r}')/|\mathbf{r}-\mathbf{r}'|^3\end{aligned} \tag{22.3.60}$$

and

$$\begin{aligned}\boldsymbol{K}^t(\boldsymbol{r},\boldsymbol{r}') &= \nabla \times \boldsymbol{G}^t(\boldsymbol{r},\boldsymbol{r}') \\ &= -[1/(4\pi)]\boldsymbol{n}'(\boldsymbol{r}')/|\boldsymbol{r}-\boldsymbol{r}'|^3 + [3/(4\pi)][\boldsymbol{n}'(\boldsymbol{r}')\cdot(\boldsymbol{r}-\boldsymbol{r}')](\boldsymbol{r}-\boldsymbol{r}')/|\boldsymbol{r}-\boldsymbol{r}'|^5.\end{aligned} \tag{22.3.61}$$

With the aid of these definitions, (3.47) and (3.50) take the form

$$\boldsymbol{B}^n(\boldsymbol{r}) = \int_S dS'\ B_n(\boldsymbol{r}')\boldsymbol{K}^n(\boldsymbol{r},\boldsymbol{r}') \tag{22.3.62}$$

and

$$\boldsymbol{B}^t(\boldsymbol{r}) = \int_S dS' \; \psi(\boldsymbol{r}')\boldsymbol{K}^t(\boldsymbol{r}, \boldsymbol{r}'). \tag{22.3.63}$$

Finally, write

$$\boldsymbol{B}(\boldsymbol{r}) = \boldsymbol{B}^n(\boldsymbol{r}) + \boldsymbol{B}^t(\boldsymbol{r}). \tag{22.3.64}$$

Show that, for fixed $\boldsymbol{r}'$, $\boldsymbol{K}^n(\boldsymbol{r}, \boldsymbol{r}')$ falls off as $1/r^2$ for large $r = |\boldsymbol{r}|$ and $\boldsymbol{K}^t(\boldsymbol{r}, \boldsymbol{r}')$ falls off as $1/r^3$.

22.3.5. Show that the Cartesian components of $\boldsymbol{A}(\boldsymbol{r})$, as given by (3.5), (3.17), and (3.32), are harmonic functions,

$$\nabla^2 \boldsymbol{A}(\boldsymbol{r}) = 0. \tag{22.3.65}$$

22.3.6. According to (3.12) and (3.18), $\boldsymbol{G}^{n1s}$ and $\boldsymbol{A}_s$ are proportional. Consequently, Exercise 2.15 provides a description of the direction of the vector $\boldsymbol{G}^n$ and, and hence the associated $\boldsymbol{A}^n$ produced using (1.7). The purpose of this exercise is to determine the direction of $\boldsymbol{G}^t$, and hence the associated $\boldsymbol{A}^t$ produced using (1.8). Consider, for purposes of calculation, a small patch of surface $\Delta S'$ located at the point

$$\boldsymbol{r}' = d\boldsymbol{e}_y \text{ with } d > 0 \tag{22.3.66}$$

and whose normal is given by the relation

$$\boldsymbol{n}'(\boldsymbol{r}') = \boldsymbol{e}_y. \tag{22.3.67}$$

Then, from (3.44), verify that there is the result

$$\boldsymbol{G}^t(\boldsymbol{r}, d\boldsymbol{e}_y) = [\boldsymbol{e}_y \times (\boldsymbol{r} - d\boldsymbol{e}_y)]/[4\pi|\boldsymbol{r} - d\boldsymbol{e}_y|^3]. \tag{22.3.68}$$

Also, verify the relation

$$\boldsymbol{e}_y \times (\boldsymbol{r} - d\boldsymbol{e}_y) = -x\boldsymbol{e}_z + z\boldsymbol{e}_x. \tag{22.3.69}$$

Show, therefore, that in this case, $\boldsymbol{G}^t$ is given by the relation

$$\boldsymbol{G}^t = [1/(4\pi)](-x\boldsymbol{e}_z + z\boldsymbol{e}_x)/[x^2 + (y-d)^2 + z^2]^{3/2}. \tag{22.3.70}$$

Recall that in cylindrical coordinates there is the relation

$$\boldsymbol{r} = x\boldsymbol{e}_x + y\boldsymbol{e}_y + z\boldsymbol{e}_z = \rho\cos\phi\boldsymbol{e}_x + \rho\sin\phi\boldsymbol{e}_y + z\boldsymbol{e}_z. \tag{22.3.71}$$

See (13.2.3) and (13.2.4). Consequently there is the relation

$$\partial\boldsymbol{r}/\partial\phi = -\rho\sin\phi\boldsymbol{e}_x + \rho\cos\phi\boldsymbol{e}_y = -y\boldsymbol{e}_x + x\boldsymbol{e}_y. \tag{22.3.72}$$

We also know that

$$\boldsymbol{e}_\phi = (\partial\boldsymbol{r}/\partial\phi)/|\partial\boldsymbol{r}/\partial\phi| = (-y\boldsymbol{e}_x + x\boldsymbol{e}_y)/\rho. \tag{22.3.73}$$

In the case of cylindrical coordinates the vector $\boldsymbol{e}_\phi$ circles around the z axis. Verify, by geometric analogy, that the vector $\boldsymbol{G}^t$ given by (3.70) circles about the y axis. And, according to (3.67), this axis is the $\boldsymbol{n}'(\boldsymbol{r}')$ axis.

22.4 Expansion of Kernels

22.4.1 Our Goal

22.4.2 Binomial Theorem

Since Newton's discovery we have known the binomial expansion

$$(1+x)^\alpha = \sum_{k=0}^{\infty} \left(\begin{array}{c} \alpha \\ k \end{array} \right) x^k. \tag{22.4.1}$$

Moreover, the binomial coefficients obey the recursion relations

$$\left(\begin{array}{c} \alpha \\ 0 \end{array} \right) = 1, \tag{22.4.2}$$

$$\left(\begin{array}{c} \alpha \\ k+1 \end{array} \right) = [(\alpha - k)/(k+1)] \left(\begin{array}{c} \alpha \\ k \end{array} \right), \tag{22.4.3}$$

and therefore can easily be computed sequentially.

22.4.3 Expansion of $\mathbf{G}^t(\mathbf{r}, \mathbf{r}')$

22.4.4 Expansion of $\mathbf{G}^n(\mathbf{r}, \mathbf{r}')$

Chapter 23

Realistic Transfer Maps for General Curved Beam-Line Elements: Exact Monopole Doublet Results

How do the surface methods for curved elements, described by relations (22.1.3) through (22.1.8) of Section 22.1 with the $\boldsymbol{G}^n$ and $\boldsymbol{G}^t$ found in Section 22.3, work in practice? The purpose of this chapter and the next two is to explore this question.

This chapter finds exact results for the case of a monopole doublet. Chapter 24 finds bent box monopole doublet results. Comparison of the results of these two chapters provides a benchmark for the accuracy of surface methods for curved beam-line elements. Chapter 25 applies surface methods to the case of a realistic storage-ring dipole.

23.1 Magnetic Monopole Doublet Vector Potential

Consider the monopole doublet magnetic field described by Equations (15.8.1) through (15.8.6) and Figures 15.8.1 through 15.8.5 of Section 15.8. In order to set up the Hamiltonian that will describe particle motion in this field, we need a vector potential $\boldsymbol{A}(\boldsymbol{r})$ such that

$$\nabla \times \boldsymbol{A}(\boldsymbol{r}) = \nabla\psi(\boldsymbol{r}) \tag{23.1.1}$$

with ψ given by (15.8.3). For this purpose we will employ the string vector potential given by (22.2.63). The desired vector potential will describe two Dirac magnetic monopoles of opposite sign. The upper, with strength $4\pi g$, will be situated at $\boldsymbol{r}^+ = a\boldsymbol{e}_y$, and will be taken to have a half-infinite string extending from $\boldsymbol{r}^+$ to infinity along the positive y axis. The lower, with strength $-4\pi g$, will be situated at $\boldsymbol{r}^- = -a\boldsymbol{e}_y$, and will be taken to have a half-infinite string extending from $\boldsymbol{r}^-$ to infinity along the negative y axis. See (22.2.63) and Figure 1.1. Thus, $\boldsymbol{A}(\boldsymbol{r})$ will be given by the relation

$$\boldsymbol{A}(\boldsymbol{r}) = \boldsymbol{A}^+(\boldsymbol{r}) + \boldsymbol{A}^-(\boldsymbol{r}) \tag{23.1.2}$$

with

$$\begin{aligned} \boldsymbol{A}^{+}(\boldsymbol{r}) &= -\boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}^{+}\rightarrow +\infty\boldsymbol{e}_y) \\ &= -g[\boldsymbol{e}_y\times(\boldsymbol{r}-a\boldsymbol{e}_y)]/\{|\boldsymbol{r}-a\boldsymbol{e}_y|[|\boldsymbol{r}-a\boldsymbol{e}_y|-\boldsymbol{e}_y\cdot(\boldsymbol{r}-a\boldsymbol{e}_y)]\} \\ &= -g(\boldsymbol{e}_y\times\boldsymbol{r})/\{|\boldsymbol{r}-a\boldsymbol{e}_y|[|\boldsymbol{r}-a\boldsymbol{e}_y|-y+a]\}, \end{aligned} \tag{23.1.3}$$

and

$$\begin{aligned} \boldsymbol{A}^{-}(\boldsymbol{r}) &= -(-1)\boldsymbol{A}_s(\boldsymbol{r};\boldsymbol{r}^{-}\rightarrow -\infty\boldsymbol{e}_y) \\ &= -(-g)[-\boldsymbol{e}_y\times(\boldsymbol{r}+a\boldsymbol{e}_y)]/\{|\boldsymbol{r}+a\boldsymbol{e}_y|[|\boldsymbol{r}+a\boldsymbol{e}_y|+\boldsymbol{e}_y\cdot(\boldsymbol{r}+a\boldsymbol{e}_y)]\} \\ &= -g(\boldsymbol{e}_y\times\boldsymbol{r})/\{|\boldsymbol{r}+a\boldsymbol{e}_y|[|\boldsymbol{r}+a\boldsymbol{e}_y|+y+a]\}. \end{aligned} \tag{23.1.4}$$

Here we have used the notation $\boldsymbol{r}^{+}\rightarrow +\infty\boldsymbol{e}_y$ to denote a string extending from $\boldsymbol{r}^{+}$ to infinity along the positive y axis, and have used the notation $\boldsymbol{r}^{-}\rightarrow -\infty\boldsymbol{e}_y$ to denote a string extending from $\boldsymbol{r}^{-}$ to infinity along the negative y axis. Also, as in Section 15.9.1, we have taken the monopoles to have strengths $\pm 4\pi g$ so as to avoid the appearance of 4π factors in subsequent formulas such as (1.3) and (1.4).

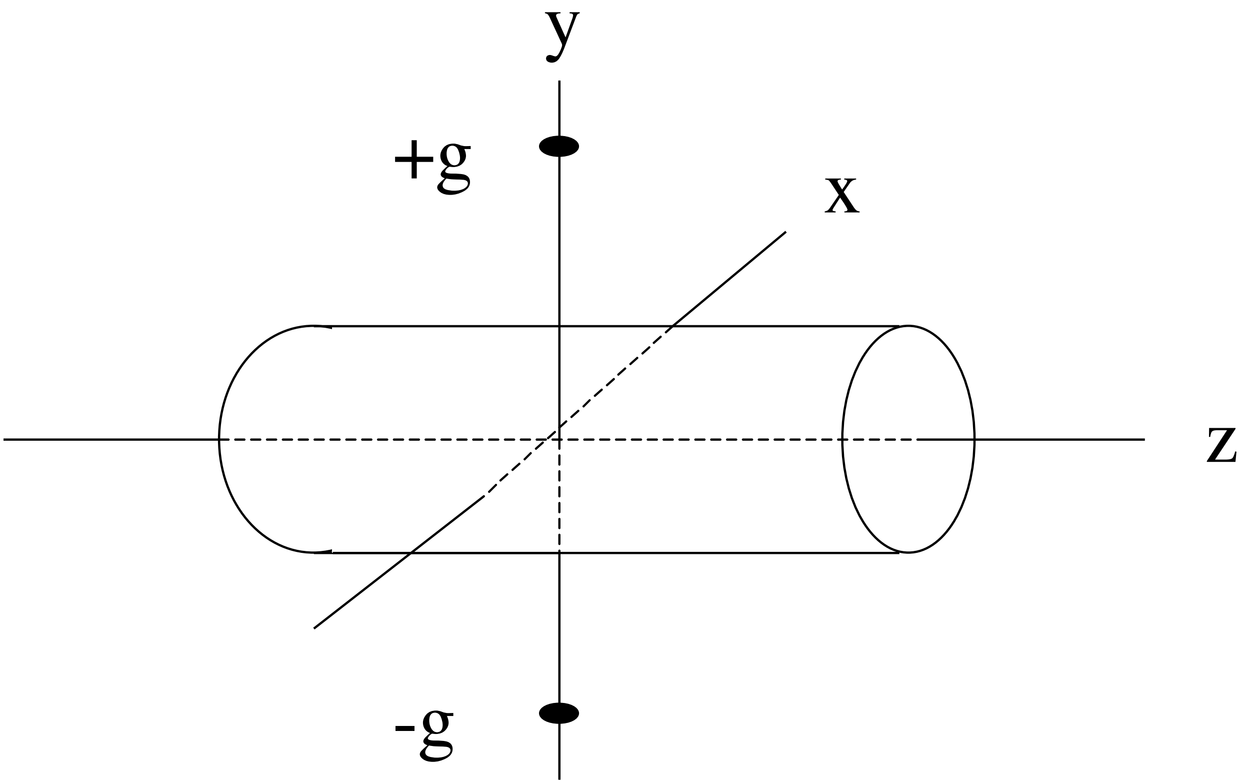

Figure 23.1.1: (Place holder) A monopole doublet consisting of two magnetic monopoles of equal and opposite sign placed on the y axis and centered on the origin. Also shown are half-infinite Dirac strings extending from the $+g$ monopole along the positive y axis and from the $-g$ monopole along the negative y axis.

Note that

$$\boldsymbol{e}_y\times\boldsymbol{r} = -x\boldsymbol{e}_z + z\boldsymbol{e}_x. \tag{23.1.5}$$

Therefore, in terms of components, the relation (1.2) takes the explicit form

$$\begin{aligned} A_x(x,y,z) &= -\frac{gz}{[x^2+(y-a)^2+z^2]^{1/2}\{[x^2+(y-a)^2+z^2]^{1/2}-y+a\}} \\ &\quad -\frac{gz}{[x^2+(y+a)^2+z^2]^{1/2}\{[x^2+(y+a)^2+z^2]^{1/2}+y+a\}}, \end{aligned} \tag{23.1.6}$$

$$A_y(x,y,z)=0, \tag{23.1.7}$$

$$\begin{aligned} A_z(x,y,z) &= +\frac{gx}{[x^2+(y-a)^2+z^2]^{1/2}\{[x^2+(y-a)^2+z^2]^{1/2}-y+a\}} \\ &\quad +\frac{gx}{[x^2+(y+a)^2+z^2]^{1/2}\{[x^2+(y+a)^2+z^2]^{1/2}+y+a\}}. \end{aligned} \tag{23.1.8}$$

Examination of (1.6) reveals that $A_x(x,y,z)$ is even in x and y, and odd in z; and examination of (1.8) shows that $A_z(x,y,z)$ is odd in x and even in y and z.

From (22.1.3) and (1.6) through (1.8), and with some algebraic effort, it can be checked that

$$\begin{aligned} B_x &= \partial_y A_z - \partial_z A_y = \partial_y A_z = \\ &= gx[x^2+(y-a)^2+z^2]^{-3/2} - gx[x^2+(y+a)^2+z^2]^{-3/2}, \end{aligned} \tag{23.1.9}$$

$$\begin{aligned} B_y &= \partial_z A_x - \partial_x A_z \\ &= g(y-a)\{[x^2+(y-a)^2+z^2]^{-3/2} - g(y+a)[x^2+(y+a)^2+z^2]^{-3/2}, \end{aligned} \tag{23.1.10}$$

$$\begin{aligned} B_z &= \partial_x A_y - \partial_y A_x = -\partial_y A_x = \\ &= gz[x^2+(y-a)^2+z^2]^{-3/2} - gz[x^2+(y+a)^2+z^2]^{-3/2}, \end{aligned} \tag{23.1.11}$$

in agreement with (15.9.4) through (15.9.6).

Figure 1.2 displays the quantity $A_x(x,y,z)$ as a function of z along the line $x=y=0$. Here, for convenience in plotting and as done before, we have used the values

$$a = 2.5 \text{ cm} = .025 \text{ m} \tag{23.1.12}$$

and

$$g = 1 \text{ Tesla (cm)}^2 = 1\times 10^{-4} \text{ Tesla m}^2. \tag{23.1.13}$$

Evidently A_x along this line falls off very slowly with increasing $|z|$. Indeed, for large $|z|$, we see from (1.6) that $A_x(x,y,z)$ has the asymptotic behavior

$$A_x(x,y,z) \simeq -2g/z. \tag{23.1.14}$$

Figure 1.3 displays A_z as a function of z along the line given by the conditions $x = -1/2$ cm and $y = 0$. It falls off somewhat more rapidly. From (1.8) we see that, for large $|z|$, it has the asymptotic behavior

$$A_z(x, y, z) \simeq 2gx/z^2. \tag{23.1.15}$$

Neither A_x nor A_z falls off as rapidly as $B_y(0, 0, z)$, which falls off as $1/|z|^3$ for large $|z|$. See Section 15.8.1 and Figure 15.8.3. We also note that if a cylindrical harmonic expansion is employed as in Section 16.3, which involves the use of on-axis gradients, then all components of the associated vector potential fall off as $1/|z|^3$ for large $|z|$. What we are observing is that the asymptotic behavior of the vector potential depends on the choice of gauge. Why not, then, employ a cylindrical harmonic expansion for which the asymptotic behavior of the associated vector potential is optimal? The reason is that we wish to treat cases for which the design orbit is significantly bent so that on-axis expansions are not applicable.

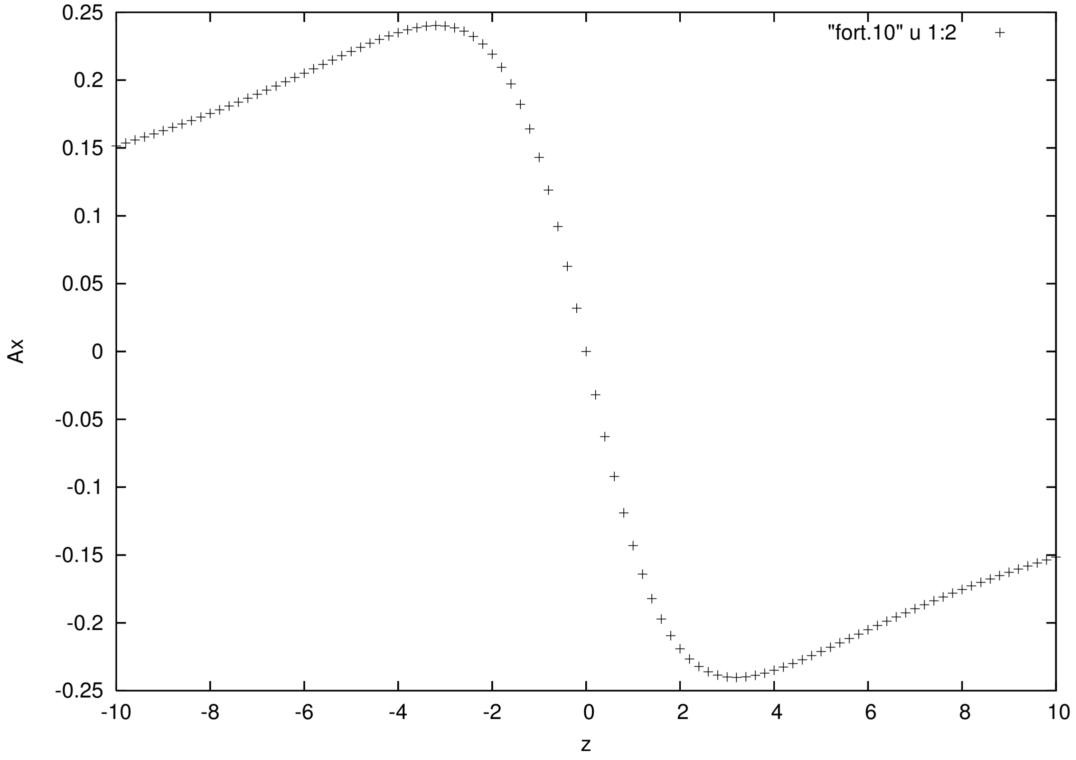

Figure 23.1.2: Behavior of A_x on the line $(0, 0, z)$. The quantity z is in cm.

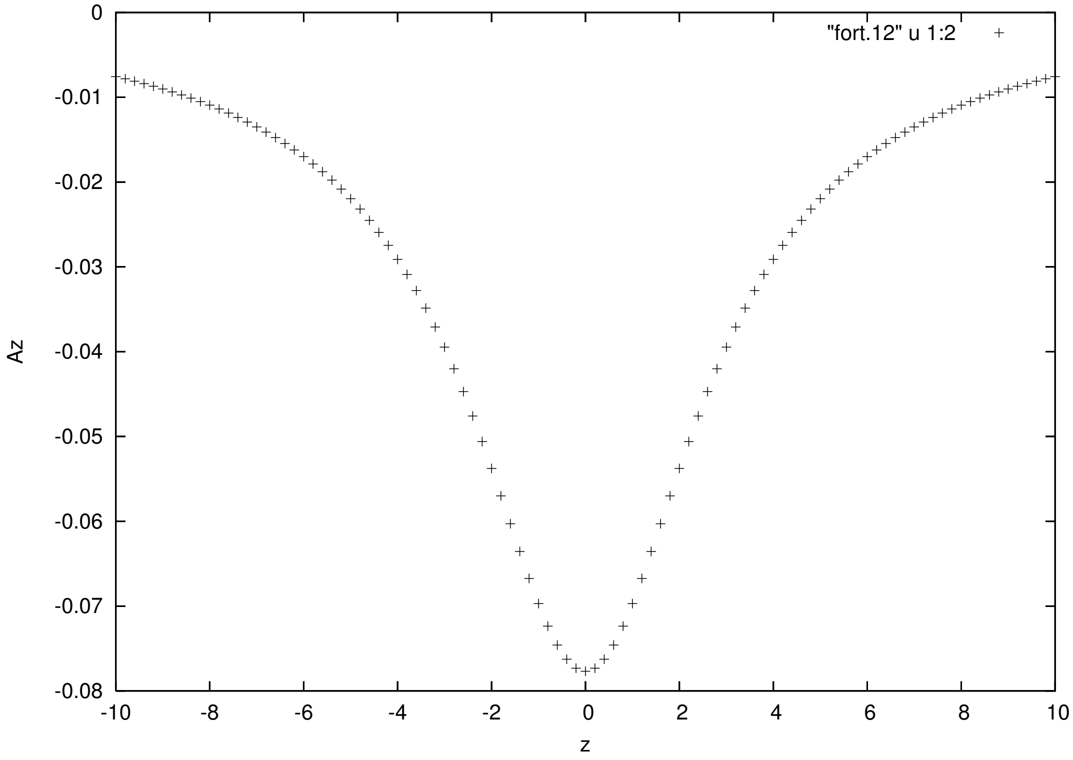

Figure 23.1.3: Behavior of A_z on the line $(-1/2, 0, z)$. The quantity z is in cm.

Exercises

23.1.1. Using (1.6) through (1.8), verify (1.9) through (1.11).

23.2 Selection of Hamiltonian and Scaled Variables

To compute orbits (and maps) it is convenient to use z as the independent variable. In this case, and for the vector potential given by (1.6) through (1.8), the Hamiltonian becomes

$$K = -[p_t^2/c^2 - m^2c^2 - (p_x - qA_x)^2 - p_y^2]^{1/2} - qA_z. \tag{23.2.1}$$

See (1.6.16). Let β and γ be the usual relativistic factors defined by

$$\beta = v/c, \tag{23.2.2}$$

$$\gamma = (1 - \beta^2)^{-1/2} \tag{23.2.3}$$

where v is the particle velocity. Then the magnitude of the mechanical momentum is given by the relation

$$p = \gamma m v = \gamma\beta m c \tag{23.2.4}$$

and the quantity p_t has the value

$$p_t = -(m^2c^4 + p^2c^2)^{1/2} = -\gamma m c^2. \tag{23.2.5}$$

Since K is independent of t, the quantities p_t and p will be constants of motion. Finally, let p^0 be the momentum for the design orbit.

At this point it is useful to introduce dimensionless/scaled variables by the rules

$$\hat{x} = x/\ell, \tag{23.2.6}$$

$$\hat{y} = y/\ell, \tag{23.2.7}$$

$$\tau = ct/\ell, \tag{23.2.8}$$

$$\hat{p}_x = p_x/p^0, \tag{23.2.9}$$

$$\hat{p}_y = p_y/p^0, \tag{23.2.10}$$

$$p_\tau = p_t/(p^0 c). \tag{23.2.11}$$

Here ℓ is a convenient scale length, and is not to be confused with the path length introduced in Exercise 1.7.8.

The dimensionless variables satisfy the Poisson bracket rules

$$[\hat{x}, \hat{p}_x] = [\hat{y}, \hat{p}_y] = [\tau, p_\tau] = 1/(\ell p^0). \tag{23.2.12}$$

From now on we will redefine their Poisson brackets so that conjugate variables again have unity Poisson brackets. This is permissible providing the Hamiltonian K is replaced by a properly scaled new Hamiltonian H given by the relation

$$\begin{aligned} H &= -[1/(\ell p^0)]\{[(p^0 c)^2 p_\tau^2/c^2 - m^2c^2 - (p^0\hat{p}_x - qA_x)^2 - (p^0)^2\hat{p}_y^2]^{1/2} + qA_z\} \\ &= -(1/\ell)\{p_\tau^2 - (mc/p^0)^2 - (\hat{p}_x - \mathcal{A}_x)^2 - \hat{p}_y^2]^{1/2} + \mathcal{A}_z\} \end{aligned} \tag{23.2.13}$$

where

$$\mathcal{A}_x(\hat{x}, \hat{y}, z) = (q/p^0)A_x(\ell\hat{x}, \ell\hat{y}, z), \tag{23.2.14}$$

$$\mathcal{A}_z(\hat{x}, \hat{y}, z) = (q/p^0)A_z(\ell\hat{x}, \ell\hat{y}, z). \tag{23.2.15}$$

(See Appendix D.)

23.3 Design Orbit and Fields

How should we choose a design orbit? We would like it to lie in the $y = 0$ plane, to pass through the origin, and to be symmetric about $z = 0$. How do we know that it is possible for there to be an orbit that lies in the $y = 0$ plane? Let us evaluate (1.9) through (1.11) to find $\boldsymbol{B}$ when $y = 0$. So doing gives the results

$$B_x(x, 0, z) = 0, \tag{23.3.1}$$

$$B_y(x, 0, z) = -2ga\{[x^2 + a^2 + z^2]^{-3/2}, \tag{23.3.2}$$

$$B_z(x, 0, z) = 0. \tag{23.3.3}$$

We see that if a particle is initially in the $y = 0$ plane and moving with a velocity in this plane, then the Lorentz force is also in this plane: thus there is no force acting to accelerate the particle out of this plane and it must remain in this plane. Next observe from (1.6) through (1.8) that $\boldsymbol{A}(\boldsymbol{r})$ vanishes at the origin,

$$\boldsymbol{A}(0, 0, 0) = 0. \tag{23.3.4}$$

Therefore the canonical and mechanical momenta agree at the origin. See (1.5.30). Consequently, and by symmetry, one way to achieve the desired design orbit is to select, for $z = 0$, the initial conditions

$$\hat{x} = \hat{y} = \tau = 0, \tag{23.3.5}$$

$$\hat{p}_x = \hat{p}_y = 0, \tag{23.3.6}$$

and then integrate both backward and forward in z to obtain the complete orbit. Note that for a orbit lying in the $y = 0$ plane the relations

$$\hat{y} = \hat{p}_y = 0 \tag{23.3.7}$$

hold for all z.

What remains is to select the values of p_τ and p^0. From (2.4) we see that for the design orbit there is the relation

$$p^0 = \gamma^0 \beta^0 mc. \tag{23.3.8}$$

From (2.5) we see that the energy on this orbit will be given by

$$p_t^0 = -\gamma^0 mc^2. \tag{23.3.9}$$

Therefore, on this orbit p_τ has the value

$$p_\tau = p_\tau^0 = p_t^0/(p^0 c) = -\gamma^0 mc^2/(\gamma^0 \beta^0 mcc) = -1/\beta^0. \tag{23.3.10}$$

And, with regard to the ingredients in (2.13), we see that

$$(p_\tau^0)^2 - (mc/p^0)^2 = (1/\beta^0)^2 - [1/(\gamma^0\beta^0)^2] = 1. \tag{23.3.11}$$

Therefore, on the design orbit, H becomes

$$H = -(1/\ell)\{[1 - (\hat{p}_x - \mathcal{A}_x)^2 - \hat{p}_y^2]^{1/2} + \mathcal{A}_z\}. \tag{23.3.12}$$

Finally, we should select (by trial and error) the quantity p^0, which now appears only in (2.14) and (2.15), in such a way that, for the specified values of a and g, the design orbit has some desired bend angle ϕ_{bend}. For purposes of illustration, we will require that ϕ_{bend} for an electron be approximately 30°.

Let us work out the spatial equations of motion associated with H as given by (3.12). For convenience we will take the scale length to have the value

$$\ell = 1 \text{ cm}. \tag{23.3.13}$$

We find the results

$$\hat{x}' = \partial H/\partial \hat{p}_x = (\hat{p}_x - \mathcal{A}_x)/[1 - (\hat{p}_x - \mathcal{A}_x)^2 - \hat{p}_y^2]^{1/2}, \tag{23.3.14}$$

$$\hat{y}' = \partial H/\partial \hat{p}_y = \hat{p}_y/[1 - (\hat{p}_x - \mathcal{A}_x)^2 - \hat{p}_y^2]^{1/2}, \tag{23.3.15}$$

$$\hat{p}_x' = -\partial H/\partial \hat{x} = (\partial \mathcal{A}_x/\partial \hat{x})(\hat{p}_x - \mathcal{A}_x)/[1 - (\hat{p}_x - \mathcal{A}_x)^2 - \hat{p}_y^2]^{1/2} + (\partial \mathcal{A}_z/\partial \hat{x}), \tag{23.3.16}$$

$$\hat{p}_y' = -\partial H/\partial \hat{y} = (\partial \mathcal{A}_x/\partial \hat{y})(\hat{p}_x - \mathcal{A}_x)/[1 - (\hat{p}_x - \mathcal{A}_x)^2 - \hat{p}_y^2]^{1/2} + (\partial \mathcal{A}_z/\partial \hat{y}). \tag{23.3.17}$$

Here a prime denotes d/dz.

We have already remarked that for this vector potential A_x and A_z are even in y, and therefore we may write

$$\mathcal{A}_x(\hat{x}, -\hat{y}, z) = \mathcal{A}_z(\hat{x}, \hat{y}, z), \tag{23.3.18}$$

$$\mathcal{A}_z(\hat{x}, -\hat{y}, z) = \mathcal{A}_z(\hat{x}, \hat{y}, z). \tag{23.3.19}$$

See (1.6) through (1.8). It follows that

$$[\partial \mathcal{A}_x(\hat{x}, \hat{y}, z)/\partial \hat{y}]|_{\hat{y}=0} = [\partial \mathcal{A}_z(\hat{x}, \hat{y}, z)/\partial \hat{y}]|_{\hat{y}=0} = 0. \tag{23.3.20}$$

Upon combining the information provided by (3.20) with the $(\hat{y}, \hat{p}_y)$ equations of motion (3.15) and (3.17) we see that there are orbits, one of which which will be the design orbit, that satisfy the conditions (3.7) for all z. Moreover, on these orbits, the $(\hat{x}, \hat{p}_x)$ equations of motion take the form

$$\hat{x}' = (\hat{p}_x - \mathcal{A}_x)/[1 - (\hat{p}_x - \mathcal{A}_x)^2]^{1/2}, \tag{23.3.21}$$

$$\hat{p}_x' = (\partial \mathcal{A}_x/\partial \hat{x})(\hat{p}_x - \mathcal{A}_x)/[1 - (\hat{p}_x - \mathcal{A}_x)^2]^{1/2} + (\partial \mathcal{A}_z/\partial \hat{x}), \tag{23.3.22}$$

and it is only this pair we need integrate. For the record we note that, on the design orbit so that (3.7) holds, there are the relations

$$\mathcal{A}_x|_{\hat{y}=0} = \mathcal{A}_x(\hat{x}, 0, z) = -\frac{(2gq/p^0)z}{(\hat{x}^2 + a^2 + z^2)^{1/2}[(\hat{x}^2 + a^2 + z^2)^{1/2} + a]}, \tag{23.3.23}$$

$$\mathcal{A}_z|_{\hat{y}=0} = \mathcal{A}_z(\hat{x}, 0, z) = +\frac{(2gq/p^0)\hat{x}}{(\hat{x}^2 + a^2 + z^2)^{1/2}[(\hat{x}^2 + a^2 + z^2)^{1/2} + a]}, \tag{23.3.24}$$

$$(\partial \mathcal{A}_x/\partial \hat{x})|_{\hat{y}=0} = +\frac{(2gq/p^0)(\hat{x}z)[2(\hat{x}^2 + a^2 + z^2)^{1/2} + a]}{(\hat{x}^2 + a^2 + z^2)^{3/2}[(\hat{x}^2 + a^2 + z^2)^{1/2} + a]^2}, \tag{23.3.25}$$

$$\begin{aligned}(\partial \mathcal{A}_z/\partial \hat{x})|_{\hat{y}=0} \;=\; & +\frac{(2gq/p^0)}{(\hat{x}^2 + a^2 + z^2)^{1/2}[(\hat{x}^2 + a^2 + z^2)^{1/2} + a]} \\ & -\frac{(2gq/p^0)(\hat{x}^2)[2(\hat{x}^2 + a^2 + z^2)^{1/2} + a]}{(\hat{x}^2 + a^2 + z^2)^{3/2}[(\hat{x}^2 + a^2 + z^2)^{1/2} + a]^2}.\end{aligned} \tag{23.3.26}$$

See (1.6) through (1.8), (2.14), and (2.15). Finally, imposing the initial conditions (3.5) and (3.6) and a suitable value for p^0 yield the design orbit.

Figures 3.1 and 3.2 display, in canonical coordinates, the design orbit that results from integrating the equations of motion (3.21) and (3.22), with the initial conditions (3.5) and (3.6), when the design momentum p^0 is selected to satisfy the relation

$$qg/p^0 = -.3291331 \text{ cm}. \tag{23.3.27}$$

(Recall that $q < 0$ for an electron.) Figure 3.1 shows the spatial part of the design orbit. Figure 3.2 displays the canonical momentum $\hat{p}_x$ on this orbit. Note that the canonical momentum depends on the choice of gauge.

To provide further insight, Figure 3.3 displays the *mechanical* scaled momentum $\hat{p}_x^{\text{mech}}$ related to the canonical momentum by the rule

$$\hat{p}_x^{\text{mech}} = \hat{p}_x - \mathcal{A}_x. \tag{23.3.28}$$

Note that the mechanical momentum does not depend on the choice of gauge. Finally observe that, with the aid of (3.28), the relation (3.21) can be rewritten in the form

$$\hat{x}' = \hat{p}_x^{\text{mech}}/[1 - (\hat{p}_x^{\text{mech}})^2]^{1/2}. \tag{23.3.29}$$

Figure 3.4 displays $\hat{x}'(z)$. We also reiterate that $\hat{y} = 0$ and $\hat{p}_y = 0$ on a design orbit.

On this design orbit there are, for $z = \mp 20$ cm, the end values

$$\hat{x}(\mp 20) = -4.75976218485406, \tag{23.3.30}$$

$$\hat{p}_x(\mp 20) = \pm.?, \tag{23.3.31}$$

$$\hat{p}_x^{\text{mech}}(\mp 20) = \pm.2588190579162489, \tag{23.3.32}$$

$$\hat{x}'(\mp 20) = \pm.2679492066493081. \tag{23.3.33}$$

Correspondingly, we find that over the interval $z \in [-20, 20]$ the bend angle has the value

$$\phi_{\text{bend}} = 30.000001520142693^\circ. \tag{23.3.34}$$

See Exercise 3.2.

For the design orbit the magnetic rigidity has the value

$$\begin{aligned} p^0/|q| &= g/(.3291331 \text{ cm}) = 1 \text{ Tesla (cm)}^2/(.3291331 \text{ cm}) \\ &= 3.0382845116458963 \text{ Tesla cm} \\ &= 3.0382845116458963 \times 10^{-2} \text{ Tesla m}. \end{aligned} \tag{23.3.35}$$

See (1.6.116). Correspondingly, we find the values

$$p^0 = 9.108547817 \text{ MeV/c}, \tag{23.3.36}$$

$$p_t^0 = -9.122870347 \text{ MeV}, \tag{23.3.37}$$

$$\begin{aligned} &\text{kinetic energy} = -p_t^0 - m_e c^2 \\ &= (\gamma^0 - 1) m_e c^2 \\ &= 8.611871287313742 \text{ MeV}, \end{aligned} \tag{23.3.38}$$

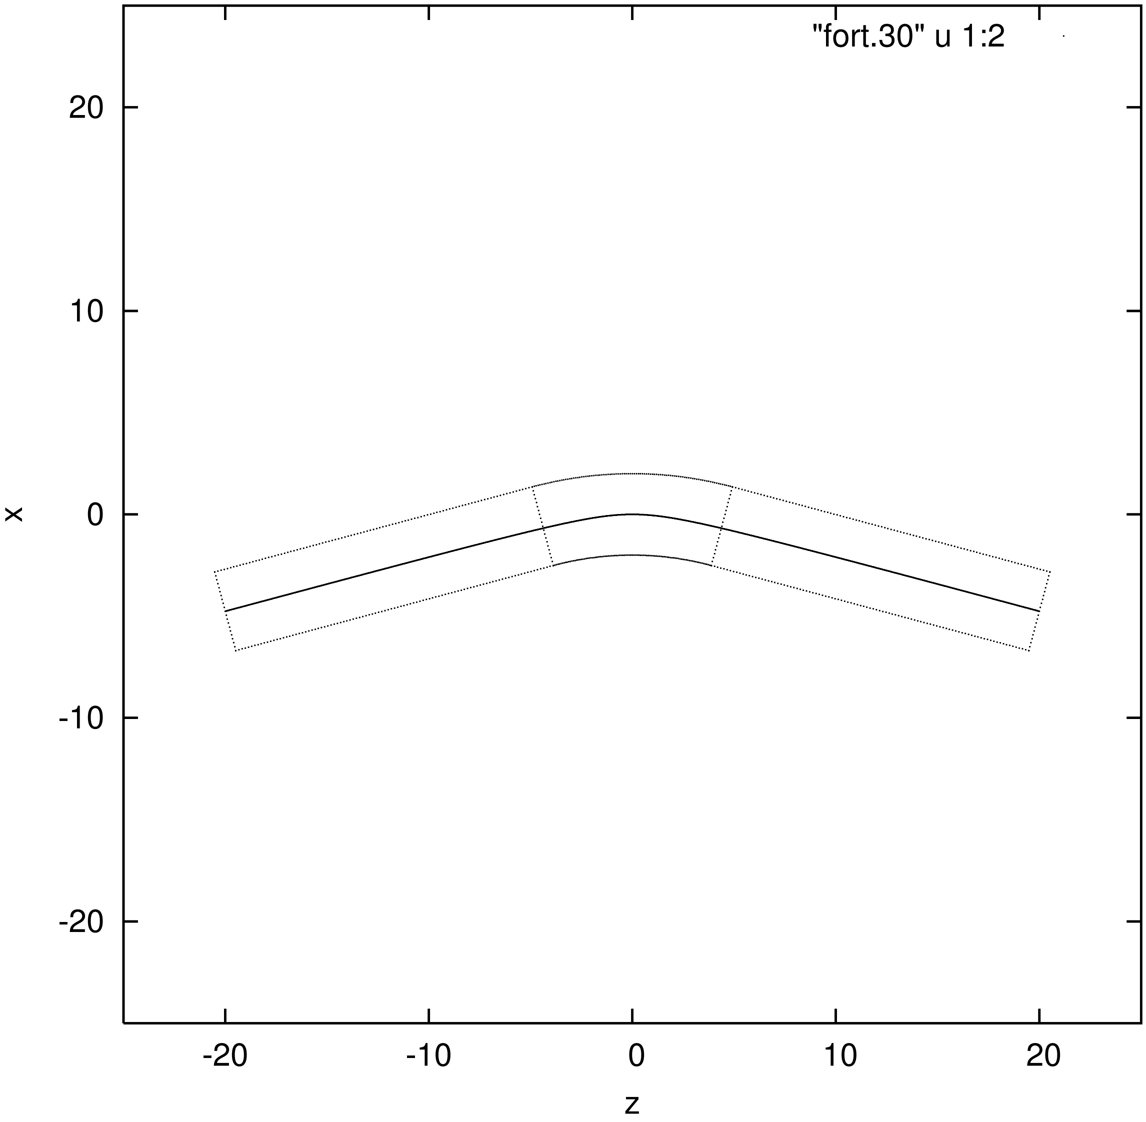

Figure 23.3.1: Design orbit $x(z) = \hat{x}(z)$. Also shown is a surrounding bent box with straight end legs. It will be employed in Chapter 24. The center curve is the design orbit. The outer curves are the boundary of the surrounding bent box with with straight end legs. For ease of visualization, the seams between the bent box and the straight end legs are also shown. The quantities x and z are in cm.

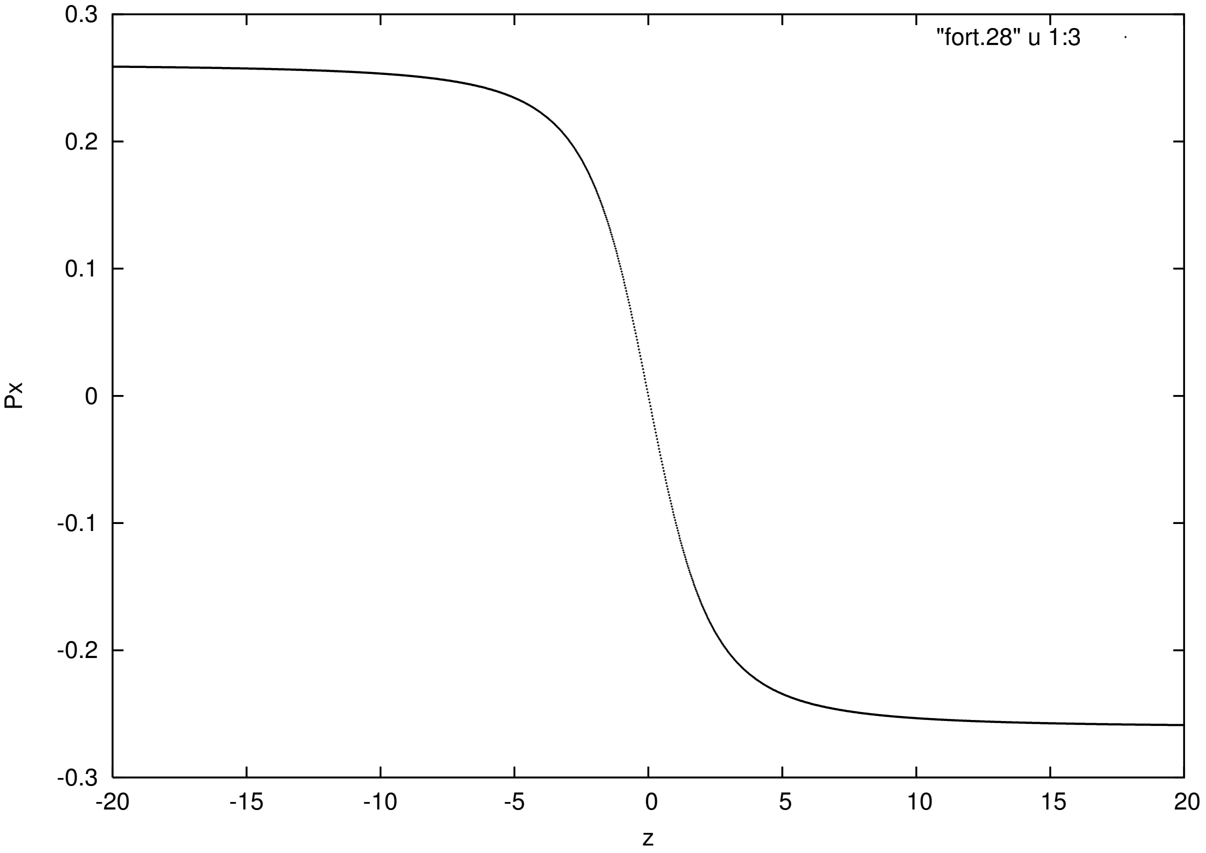

Figure 23.3.2: (Place holder) The canonical momentum $\hat{p}_x(z)$ on the design orbit. The quantity z is in cm.

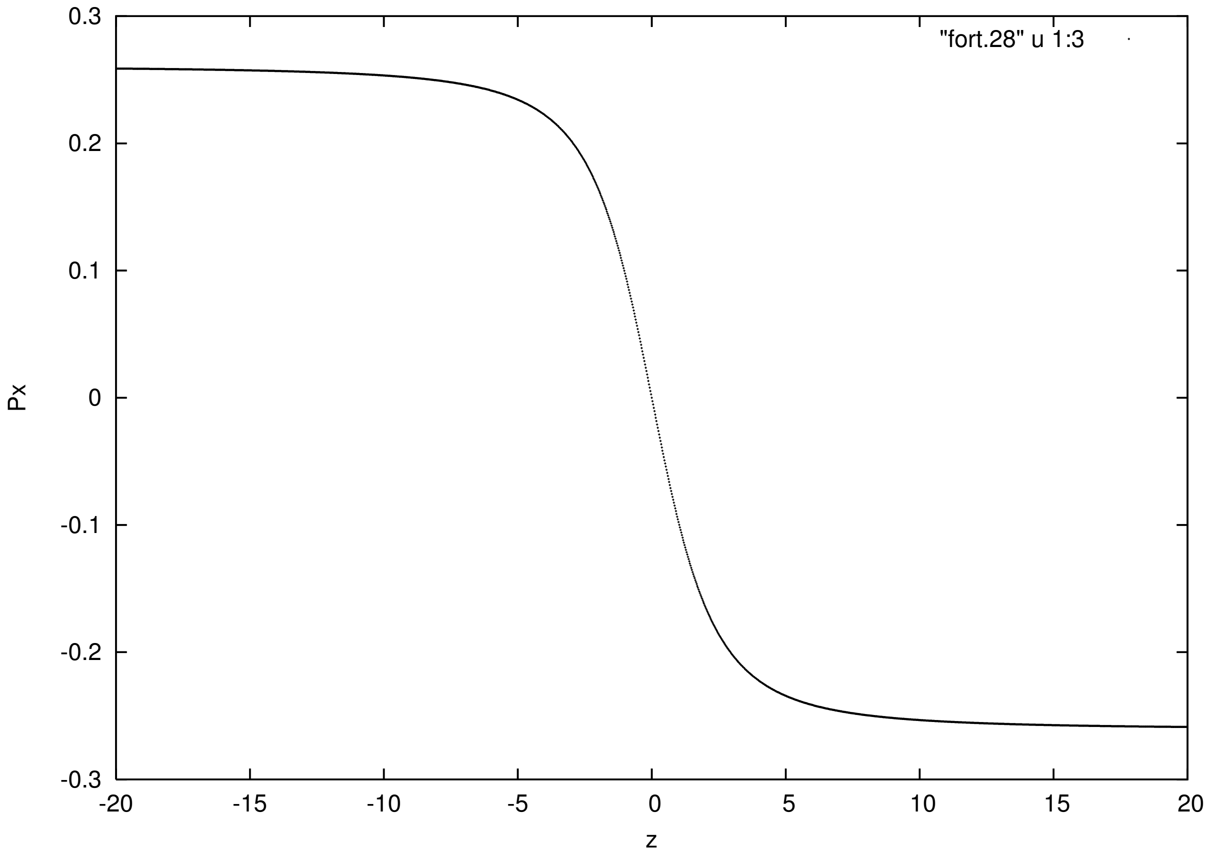

Figure 23.3.3: The scaled mechanical momentum $\hat{p}_x^{\text{mech}}(z)$ on the design orbit. The quantity z is in cm.

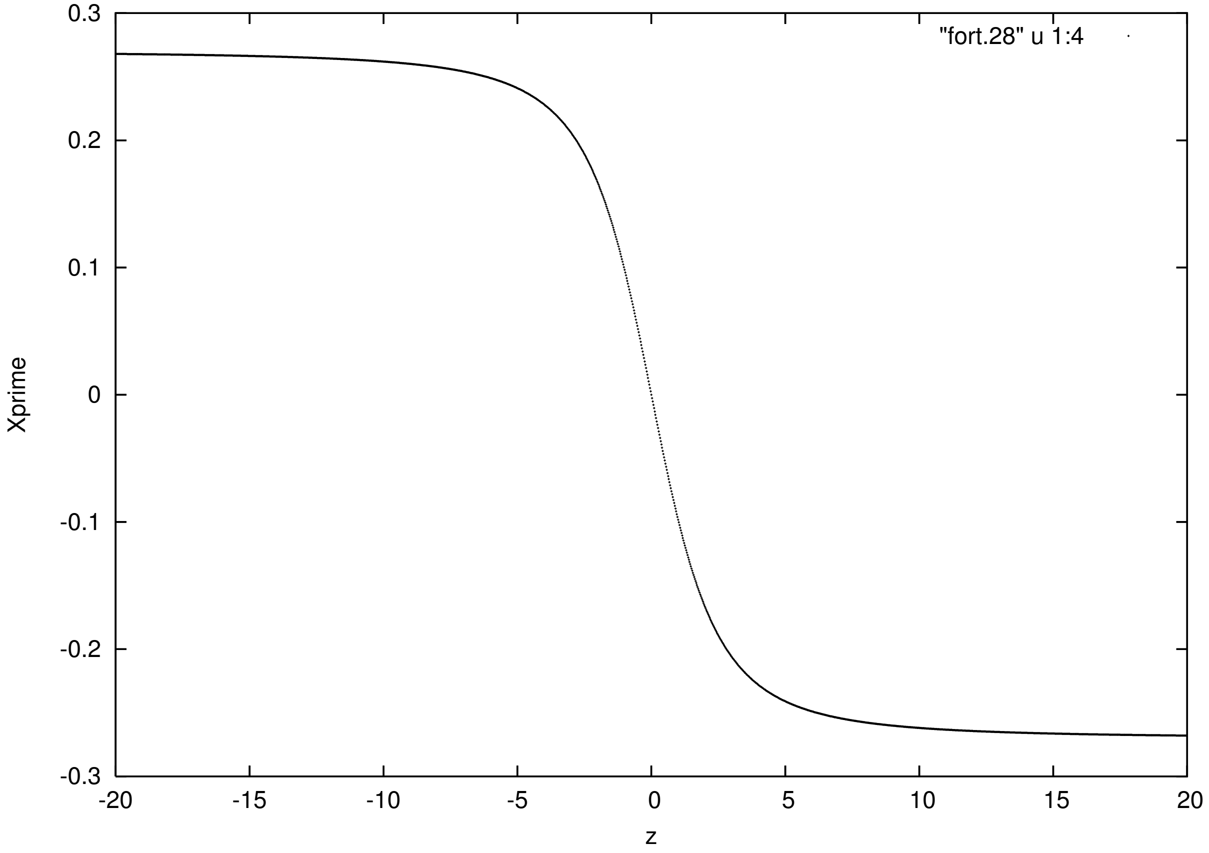

Figure 23.3.4: The quantity $\hat{x}'(z)$ on the design orbit. The quantity z is in cm.

$$\beta^0 = .9984300412295174, \tag{23.3.39}$$

$$\gamma^0 = 17.853008080511426. \tag{23.3.40}$$

Here we have used the values

$$m_e c^2 = .51099906 \text{ MeV}, \tag{23.3.41}$$

$$-q = e = 1.60217733 \times 10^{-19} \text{ coulomb}, \tag{23.3.42}$$

$$c = 2.99792458 \times 10^8 \text{ m/s}. \tag{23.3.43}$$

It is also useful to have graphics of the quantities B_y, $\mathcal{A}_x$, and $\mathcal{A}_z$ along the design orbit. They are displayed in Figures 3.5 through 3.7. Note that B_y falls off quite rapidly with increasing $|z|$, i.e. $\sim 1/|z|^3$, as expected for a monopole doublet. However, $\mathcal{A}_x$ and $\mathcal{A}_z$ fall off less rapidly on the design orbit. From (1.14) we expect for $\mathcal{A}_x$ a fall off $\sim 1/|z|$. And, from Figure 3.1 we see that on the design orbit $|x|$ grows linearly with $|z|$ for large $|z|$. Therefore, if (1.15) provides any indication, we expect that $\mathcal{A}_z$ will also fall off only as $1/|z|$ for large $|z|$.

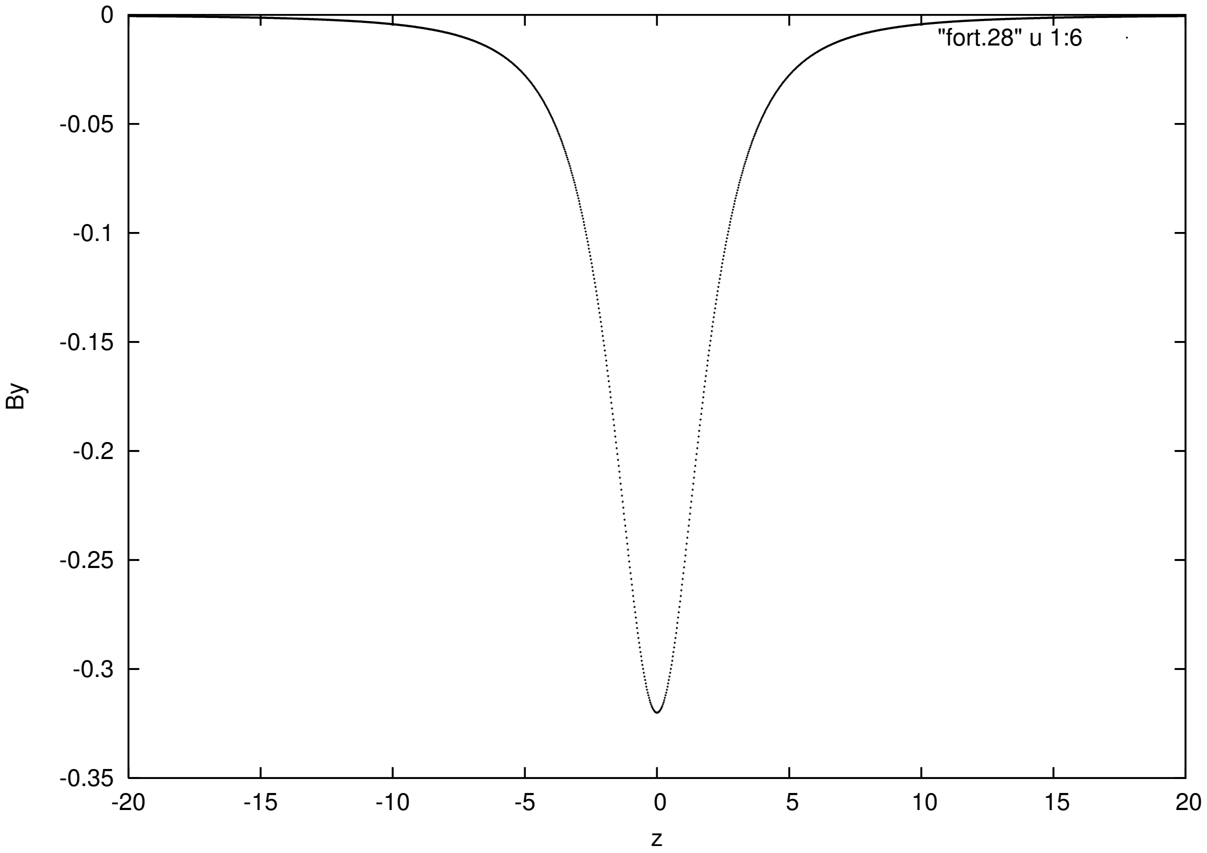

Figure 23.3.5: The quantity B_y on the design orbit. The quantity z is in cm.

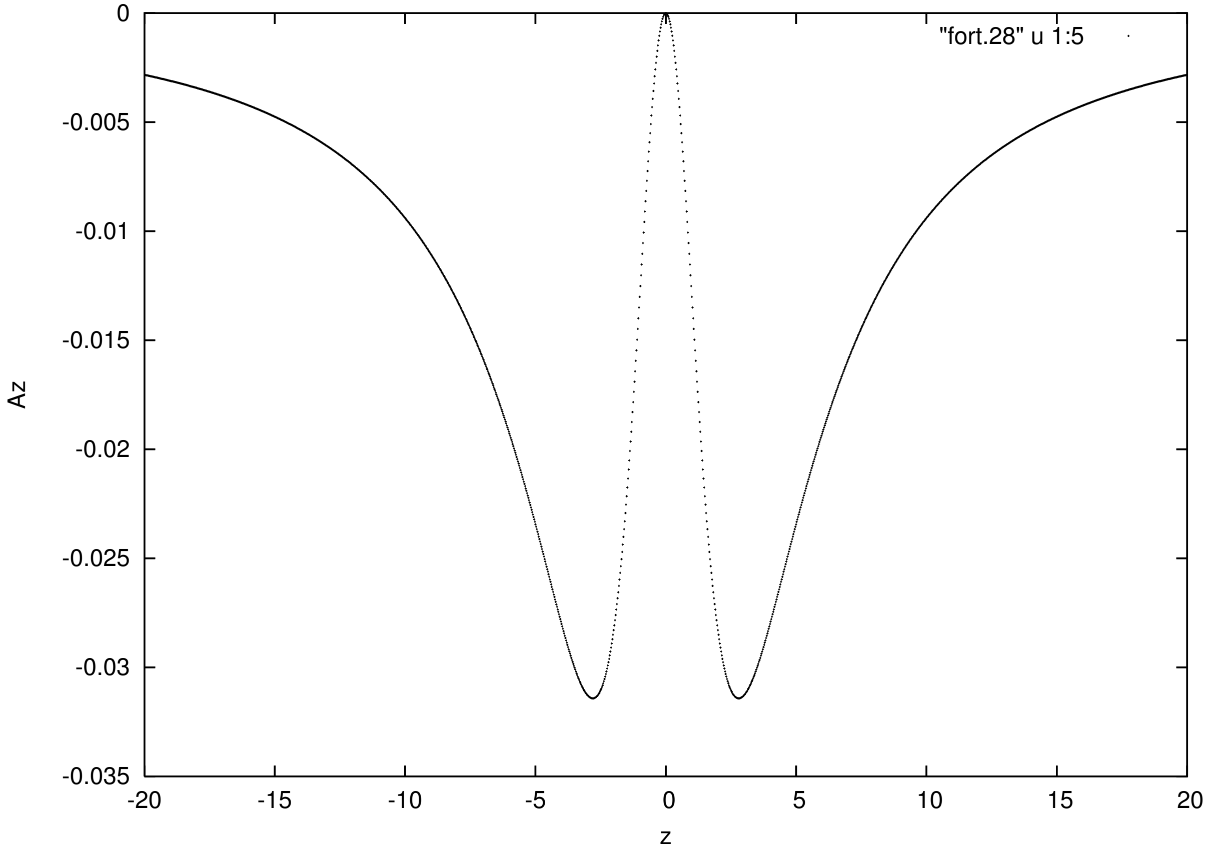

Figure 23.3.6: (Place holder) The quantity $\mathcal{A}_x$ on the design orbit. The quantity z is in cm.

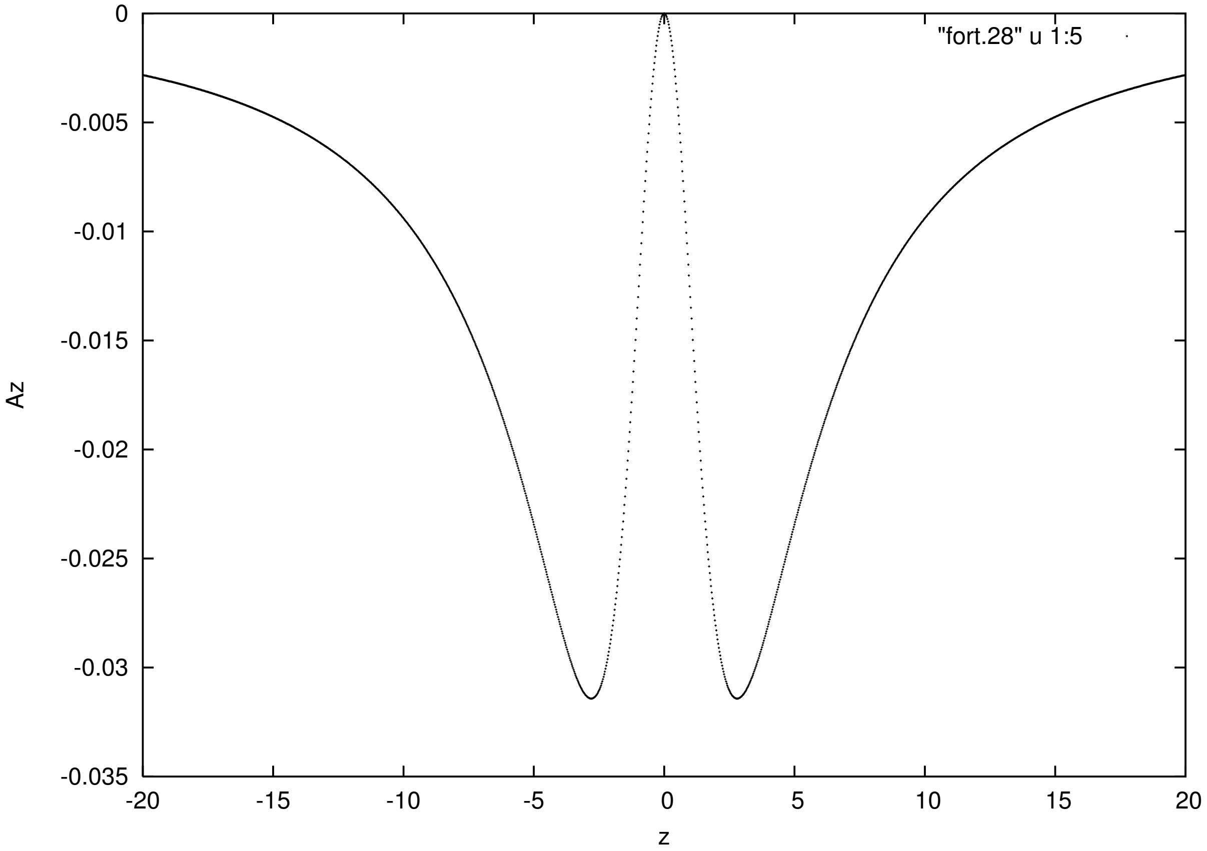

Figure 23.3.7: (Place Holder?) The quantity $\mathcal{A}_z$ on the design orbit. The quantity z is in cm.

Precise field values at some key points on the design orbit are given by the relations

$$B_y(-4.7597\cdots, 0, \mp 20) = -5.6290\cdots \times 10^{-4}, \tag{23.3.44}$$

$$B_y(0,0,0) = -.32, \tag{23.3.45}$$

$$B_y(-4.7597\cdots, 0, \mp 20)/B_y(0,0,0) \simeq 1.8 \times 10^{-3}, \tag{23.3.46}$$

$$\mathcal{A}_x(-4.7597\cdots, 0, \mp 20) = \pm 2.78\cdots \times 10^{-2}, \tag{23.3.47}$$

$$\mathcal{A}_z(-4.7597\cdots, 0, \mp 20) = -6.6\cdots \times 10^{-3}. \tag{23.3.48}$$

From (3.45) we see that B_y on the design orbit has fallen by a factor of $\simeq 1.8 \times 10^{-3}$ at the end points. By contrast, comparison of (3.31) and (3.36) shows that the vector potential for the half-infinite string choice of gauge still makes a significant contribution to the canonical momentum $\hat{p}_x$ at the end points. Compare also (3.30) and (3.31). Therefore it is important to use some other gauge for end-field termination.

Exercises

23.3.1. In Section 3 the design orbit was found by integrating the canonical pair (3.21) and (3.22). This exercise describes an alternate approach. It has the feature of illustrating that in mechanical variables the design orbit is manifestly gauge independent, as we know it should be.

Recall the relations (3.28) and (3.29). Suppose (3.28) is differentiated with respect to z and along the design orbit. Verify that doing so gives the result

$$(\hat{p}_x^{\rm mech})' = \hat{p}_x' - (\partial \mathcal{A}_x/\partial \hat{x})\hat{x}' - (\partial \mathcal{A}_x/\partial z). \tag{23.3.49}$$

Next employ (3.21) to rewrite the second term on the right of (3.49) in the form

$$-(\partial \mathcal{A}_x/\partial \hat{x})\hat{x}' = -(\partial \mathcal{A}_x/\partial \hat{x})(\hat{p}_x - \mathcal{A}_x)/[1-(\hat{p}_x - \mathcal{A}_x)^2]^{1/2}. \tag{23.3.50}$$

Observe that the right side of (3.50) agrees with the first term on the right side of (3.22) save for a sign. Show, therefore, that use of (3.22) in (3.49) yields, following a glorious cancellation, the simple result

$$(\hat{p}_x^{\rm mech})' = (\partial \mathcal{A}_z/\partial \hat{x}) - (\partial \mathcal{A}_x/\partial z). \tag{23.3.51}$$

Also, from (1.10), (2.14), and (2.15), we have the result
