$$[(\partial \mathcal{A}_z/\partial \hat{x}) - (\partial \mathcal{A}_x/\partial z)]|_{\hat{y}=0} = -(q/p^0)B_y(x,y,z)|_{y=0} \tag{23.3.52}$$

and, again from (1.10), we see that

$$B_y(x,y,z)|_{y=0} = -2ga/[x^2+a^2+z^2]^{3/2}. \tag{23.3.53}$$

It follows that (3.51) can be written in the final form

$$(\hat{p}_x^{\rm mech})' = -(q/p^0)B_y(x,y,z)|_{y=0} = (q/p^0)2ga/[\hat{x}^2+a^2+z^2]^{3/2}. \tag{23.3.54}$$

Together (3.29) and (3.54) form a convenient coupled set for numerical integration. Once the pair $\{\hat{x}(z), \hat{p}_x^{\rm mech}(z)\}$ has been found, the canonical momentum $\hat{p}_x(z)$ is given by the relation (3.28) rewritten in the form

$$\hat{p}_x = \hat{p}_x^{\rm mech} + \mathcal{A}_x|_{\hat{y}=0} \tag{23.3.55}$$

with $\mathcal{A}_x|_{\hat{y}=0}$ given by (3.23). Verify that $\mathcal{A}_x$ and $\mathcal{A}_z$ on the design orbit are given by the relations (3.23) and (3.24). Verify (3.25) and (3.26).

23.3.2. Verify (3.34) based on (3.33).

23.4 Terminating End Fields

23.4.1 Minimum Vector Potential for End Fields

The first few terms in the expansion [about the point $(X_0, 0, Y_0)$] of the minimum vector potential for a magnetic monopole doublet were found in Section 15.10. We recall the results

$$\boldsymbol{A}^{\min 1}(\boldsymbol{r}; X_0, Z_0) = [ga/(X_0^2 + Z_0^2 + a^2)^{3/2}](-z\boldsymbol{e}_x + x\boldsymbol{e}_z), \tag{23.4.1}$$

$$\begin{gathered}\boldsymbol{A}^{\min 2}(\boldsymbol{r}; X_0, Z_0) = [-2ga/(X_0^2 + Z_0^2 + a^2)^{5/2}] \times \\ [(Z_0y^2 - Z_0z^2 - X_0xz)\boldsymbol{e}_x + (X_0yz - Z_0xy)\boldsymbol{e}_y + (X_0x^2 + Z_0xz - X_0y^2)\boldsymbol{e}_z].\end{gathered} \tag{23.4.2}$$

See (15.10.7) and (15.10.8). The still higher-order terms (the terms for $n > 2$) can be found in an analogous way.

23.4.2 Associated Termination Error

Suppose we wish to initiate or terminate the magnetic field of a magnetic monopole doublet at the point $(X_0, 0, Y_0)$. Then we need to find the minimum vector potential expansion about this point in terms of variables appropriate to the relevant reference planes. As an example, supposed the field is initiated at the point $(X_0 = -4.7597\cdots, 0, Z_0 = -20)$ corresponding to the beginning of the left leg of the bent box in Figure 3.1. Then the relevant reference plane would be the incoming face of the left leg.

To be more precise, let $\boldsymbol{e}_\xi$ and $\boldsymbol{e}_\eta$ be unit vectors in this reference plane, and let $\boldsymbol{e}_\zeta$ be a unit vector perpendicular to this plane. These requirements can be met by making the definitions

$$\boldsymbol{e}_\xi = \cos\theta\boldsymbol{e}_x - \sin\theta\boldsymbol{e}_z, \tag{23.4.3}$$

$$\boldsymbol{e}_\eta = \boldsymbol{e}_y, \tag{23.4.4}$$

$$\boldsymbol{e}_\zeta = \sin\theta\boldsymbol{e}_x + \cos\theta e_z. \tag{23.4.5}$$

Here θ is the angle between the reference plane and the plane $Y_0 = 0$. See Figure 4.1. For the problem at hand, θ is given by the relation

$$\theta = (1/2)\phi_{\rm bend} \simeq 15°. \tag{23.4.6}$$

As the notation is intended to convey, the vectors $\boldsymbol{e}_\xi$, $\boldsymbol{e}_\eta$, $\boldsymbol{e}_\zeta$ comprise a right-handed orthonormal triad. Consequently, there are relations of the form

$$\boldsymbol{e}_\zeta \times \boldsymbol{e}_\xi = -\sin^2\theta(\boldsymbol{e}_x \times e_z) + \cos^2\theta(\boldsymbol{e}_z \times e_x) = \boldsymbol{e}_y = \boldsymbol{e}_\eta, \text{etc.} \tag{23.4.7}$$

Next we observe that, associated with the unit vectors $\boldsymbol{e}_\xi$, $\boldsymbol{e}_\eta$, $\boldsymbol{e}_\zeta$, we may define local expansion coordinates ξ, η, ζ by writing

$$\xi = x\cos\theta - z\sin\theta, \tag{23.4.8}$$

$$\eta = y, \tag{23.4.9}$$

$$\zeta = x\sin\theta + z\cos\theta. \tag{23.4.10}$$

Finally, the definitions (4.3) through (4.5) and (4.8) through (4.10) may be inverted to yield the relations

$$\boldsymbol{e}_x = \cos\theta\boldsymbol{e}_\xi + \sin\theta\boldsymbol{e}_\zeta, \tag{23.4.11}$$

$$\boldsymbol{e}_y = \boldsymbol{e}_\eta, \tag{23.4.12}$$

$$\boldsymbol{e}_z = -\sin\theta\boldsymbol{e}_\xi + \cos\theta\boldsymbol{e}_\zeta; \tag{23.4.13}$$

$$x = \xi\cos\theta + \zeta\sin\theta, \tag{23.4.14}$$

$$y = \eta, \tag{23.4.15}$$

$$z = -\xi\sin\theta + \zeta\cos\theta. \tag{23.4.16}$$

We also record that, as expected, there are the relations

$$\boldsymbol{r} = x\boldsymbol{e}_x + y\boldsymbol{e}_y + z\boldsymbol{e}_z = \xi\boldsymbol{e}_\xi + \eta\boldsymbol{e}_\eta + \zeta\boldsymbol{e}_\zeta. \tag{23.4.17}$$

With all these relations at hand, let us express the minimum vector potential for a magnetic monopole doublet in terms of the variables ξ, η, ζ and their associated unit vectors. From (4.1) and using (4.11) through (4.17) we find the result

$$\boldsymbol{A}^{\min 1}(\xi,\eta,\zeta;X_0,Z_0) = \boldsymbol{A}^{\min 1}(\boldsymbol{r};X_0,Z_0) = [ga/(X_0^2+Z_0^2+a^2)^{3/2}](-\zeta\boldsymbol{e}_\xi + \xi\boldsymbol{e}_\zeta). \tag{23.4.18}$$

And, from (4.2) and again using (4.11) through (4.17), we find the result

$$\begin{gathered}\boldsymbol{A}^{\min 2}(\xi,\eta,\zeta;X_0,Z_0) = \boldsymbol{A}^{\min 2}(\boldsymbol{r};X_0,Z_0) = -2ga/(X_0^2+Z_0^2+a^2)^{5/2}] \times \\ [(Z_0y^2 - Z_0z^2 - X_0xz)\boldsymbol{e}_\xi + (X_0yz - Z_0xy)\boldsymbol{e}_\eta + (X_0x^2 + Z_0xz - X_0y^2)\boldsymbol{e}_\zeta].\end{gathered} \tag{23.4.19}$$

Following the discussion of Section 16.1, what interests us with regard to the discontinuities in the transverse mechanical momenta associated with the field termination approximation are the ξ and η components of $\boldsymbol{A}^{\min}$ evaluated at $\zeta = 0$. From (4.18) and (4.19) we see that the lowest order contributions to these discontinuities are given by the relations

$$A_\xi^{\min 1}(\xi,\eta,0;X_0,Z_0) = A_\eta^{\min 1}(\xi,\eta,0;X_0,Z_0) = 0, \tag{23.4.20}$$

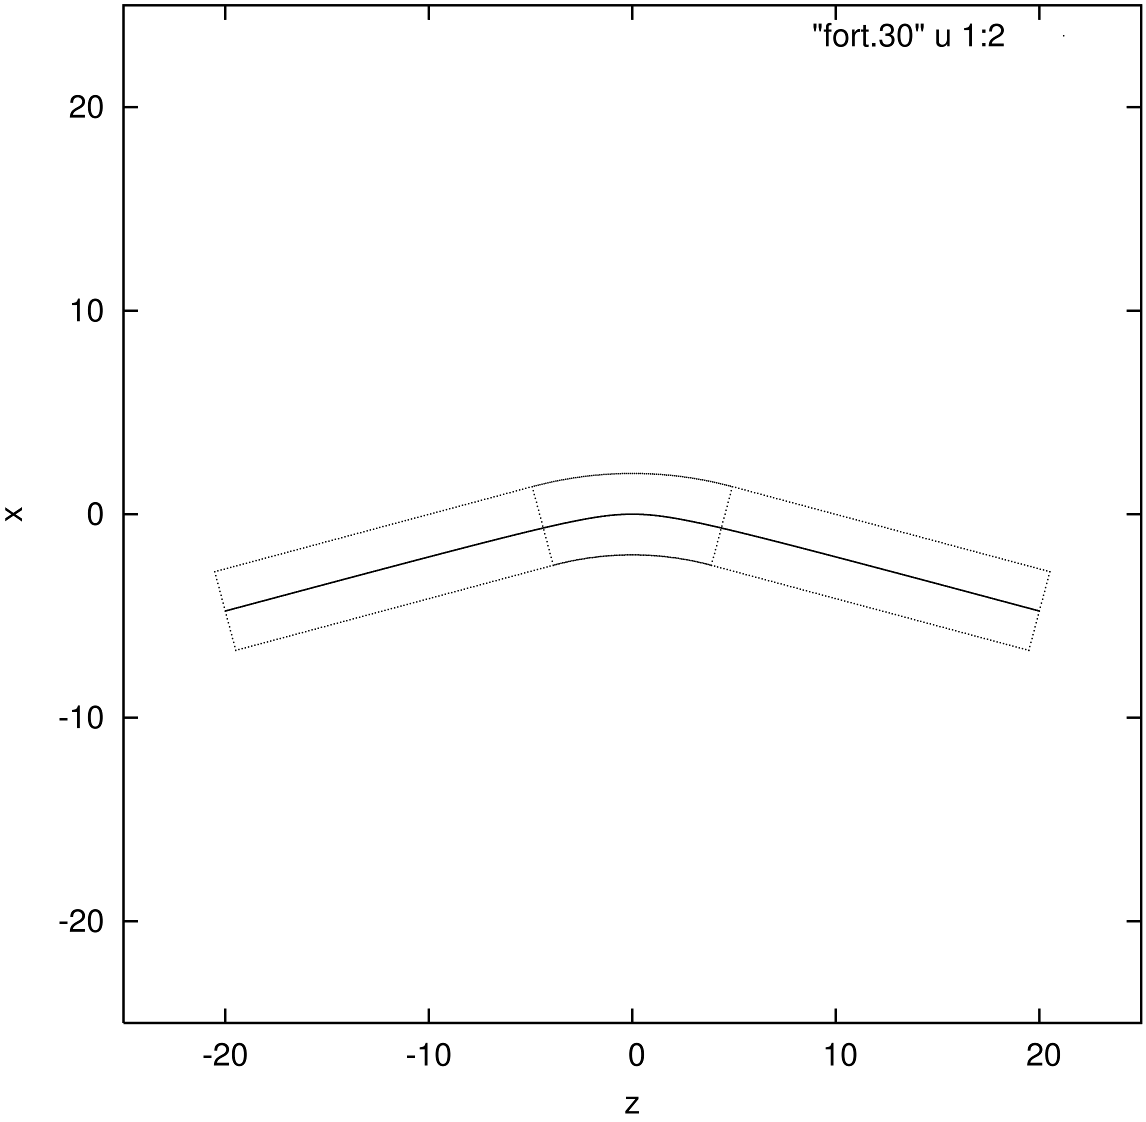

Figure 23.4.1: (Place Holder) The orthonormal triad $\boldsymbol{e}_\xi$, $\boldsymbol{e}_\eta$, $\boldsymbol{e}_\zeta$ and associated local deviation variables ξ, η, ζ for the entry of the left leg of the bent box with legs.

$$A_\xi^{\min 2}(\xi,\eta,0;X_0,Z_0) = [-2ga/(X_0^2+Z_0^2+a^2)^{5/2}](X_0\sin\theta+Z_0\cos\theta)\eta^2, \quad (23.4.21)$$

$$A_\eta^{\min 2}(\xi,\eta,0;X_0,Z_0) = [2ga/(X_0^2+Z_0^2+a^2)^{5/2}](X_0\sin\theta+Z_0\cos\theta)\xi\eta. \quad (23.4.22)$$

We conclude that $\boldsymbol{A}^{\min 1}$ makes no contributions to the discontinuities and that $\boldsymbol{A}^{\min 2}$ makes contributions that are quadratic in the deviation variables ξ and η.

Let us examine the (upon entry) discontinuities associated with $\boldsymbol{A}^{\min}$. As a measure of these, define the *dimensionless* quantities δ_ξ and δ_η by the relations

$$\delta_{\xi,\eta} = (1/p^0)\Delta_{\xi,\eta}^{\text{mech}}. \quad (23.4.23)$$

See (16.1.30) and (16.1.31). Upon employing (16.1.30) and (16.1.31) in (4.23), and with the use of (4.21) and (4.22), we find the results

$$\delta_\xi^2(\xi,\eta,0;X_0,Z_0) = (q/p^0)[-2ga/(X_0^2+Z_0^2+a^2)^{5/2}](X_0\sin\theta+Z_0\cos\theta)\eta^2, \quad (23.4.24)$$

$$\delta_\eta^2(\xi,\eta,0;X_0,Z_0) = (q/p^0)[2ga/(X_0^2+Z_0^2+a^2)^{5/2}](X_0\sin\theta+Z_0\cos\theta)\xi\eta. \quad (23.4.25)$$

Let us evaluate these discontinuities when the transverse deviations from the design orbit have the substantial values $\xi=\eta=1$ cm. So doing, and recalling (3.23) and (4.26), we find the results

$$\delta_\xi^2(\xi=1,\eta=1,0;X_0=-4.7597\cdots,Z_0=-20) = -8.8\cdots\times10^{-6}, \quad (23.4.26)$$

$$\delta_\eta^2(\xi=1,\eta=1,0;X_0=-4.7597\cdots,Z_0=-20) = 8.8\cdots\times10^{-6}. \quad (23.4.27)$$

These numbers are pleasantly small, and we conclude that there is relatively little discontinuity error associated with terminating the field of the monopole doublet to the left of $Z_0=-20$ providing the minimal vector potential is employed. The same is true for termination to the right of $Z_0=+20$.[1]

23.4.3 Taylor Expansion of String Vector Potential

$$\boldsymbol{A}^{\text{ex}}(\boldsymbol{r};\boldsymbol{R}_0) = \boldsymbol{A}^{\text{ex}}(x,y,z;X_0,Z_0) = \boldsymbol{A}(\boldsymbol{R}_0+\boldsymbol{r}) = \sum_{n=0}^{\infty}\boldsymbol{A}^{\text{ex}\,n}(x,y,z;X_0,Z_0) \quad (23.4.28)$$

where $\boldsymbol{A}^{\text{ex}\,n}(x,y,z;X_0,Z_0)$ is a homogeneous polynomial vector field of degree n in the components if $\boldsymbol{r}$.

$$A_x(\boldsymbol{R_0}+\boldsymbol{r}) = \\ -\frac{g(Z_0+z)}{[(X_0+x)^2+(y-a)^2+(Z_0+z)^2]^{1/2}\{[(X_0+x)^2+(y-a)^2+(Z_0+z)^2]^{1/2}-y+a\}} \\ -\frac{g(Z_0+z)}{[(X_0+x)^2+(y+a)^2+(Z_0+z)^2]^{1/2}\{[(X_0+x)^2+(y+a)^2+(Z_0+z)^2]^{1/2}+y+a\}}, \quad (23.4.29)$$

[1] However, one should not be overly sanguine. It turns out that the design orbit continues to bend by as much as a degree as one continues to the left of $Z_0=-20$ and the right of $Z_0=+20$. That is, true *asymptopia* has not been reached even when $Z_0=\pm20$ and (3.41) holds. The magnetic monopole doublet field, and the field of any iron-free dipole, are problematic to treat because of their slow fringe-field fall off.

$$A_y(\boldsymbol{R_0}+\boldsymbol{r}) = 0, \tag{23.4.30}$$

$$A_z(\boldsymbol{R_0}+\boldsymbol{r}) = \\ +\frac{g(X_0+x)}{[(X_0+x)^2+(y-a)^2+(Z_0+z)^2]^{1/2}\{[(X_0+x)^2+(y-a)^2+(Z_0+z)^2]^{1/2}-y+a\}} \\ +\frac{g(X_0+x)}{[(X_0+x)^2+(y+a)^2+(Z_0+z)^2]^{1/2}\{[(X_0+x)^2+(y+a)^2+(Z_0+z)^2]^{1/2}+y+a\}}. \tag{23.4.31}$$

$$A_x^{\text{ex}\,0}(x,y,z;X_0,Z_0) = -\frac{2gZ_0}{[X_0^2+a^2+Z_0^2]^{1/2}\{[X_0^2+a^2+Z_0^2]^{1/2}+a\}}, \tag{23.4.32}$$

$$A_y^{\text{ex}\,0}(x,y,z;X_0,Z_0) = 0, \tag{23.4.33}$$

$$A_z^{\text{ex}\,0}(x,y,z;X_0,Z_0) = \frac{2gX_0}{[X_0^2+a^2+Z_0^2]^{1/2}\{[X_0^2+a^2+Z_0^2]^{1/2}+a\}}. \tag{23.4.34}$$

Chapter 24

Realistic Transfer Maps for General Curved Beam-Line Elements: Bent Box Monopole Doublet Results

24.1 Choice of Surrounding Bent Box

Also shown in Figure 5.1 is the top view of a suitable bent box that surrounds this orbit. The top and bottom of the box are superposed in the figure, and lie in the planes $y = \pm 2$ cm. The circular arcs that comprise the bent portion of the box have the common center

$$(x_c, z_c) = (-17 \text{ cm}, 0) \tag{24.1.1}$$

and have radii

$$r_{\text{out}} = 19 \text{ cm}, \tag{24.1.2}$$

$$r_{\text{in}} = 15 \text{ cm}. \tag{24.1.3}$$

Both subtend an angle of 30°, and are extended by straight lines thereby forming the straight ends of the box.

How was this bent box determined? Again by trial and error. Note that the construction of the bent box is not critical. All that is required is that the bent box well surround the design orbit. Consider all circular arcs that pass through the origin and are symmetric about the x axis. Such arcs will have their centers on the x axis. Also require that each arc subtend an angle of 30°. With these restrictions the only remaining quantity to be selected is the radius of an arc. Finally, require that the optimal arc, when extended by straight lines at both ends, well fit the design orbit. Figure 6.1 below shows that, for the problem at hand, a good fit occurs when the arc radius has the value

$$r_{\text{fit}} = 17 \text{ cm}. \tag{24.1.4}$$

By construction, the center of this arc is given by (5.55).

Now determine the outer and inner boundaries of the box by requiring that they also be circular arcs with straight-line extensions. Further require that both arcs have a common

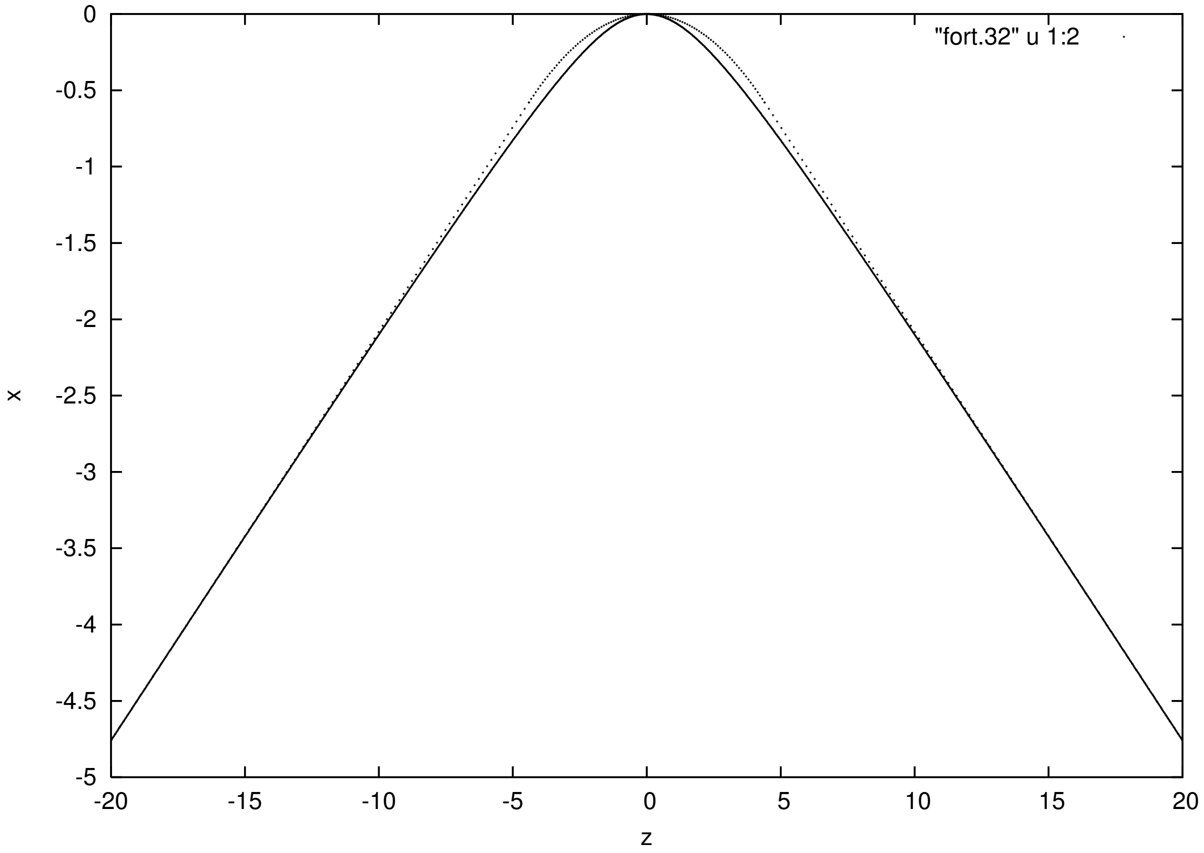

Figure 24.1.1: Design orbit $x(z)$ and best approximating circular arc with straight-line extensions. The solid line is the design orbit, and the dotted line is the best approximating circular arc with straight-line extensions. The quantities x and z are in cm.

center given by (5.55), and that both arcs subtend an angle of 30°. The last step is to specify the radius of each arc. This is conveniently done by the prescription

$$r_{\text{out}} = r_{\text{fit}} + w, \tag{24.1.5}$$

$$r_{\text{in}} = r_{\text{fit}} - w, \tag{24.1.6}$$

where $2w$ is the width of the box. For our illustration we have chosen the value

$$w = 2 \text{ cm}. \tag{24.1.7}$$

24.2 Comparison of Fields

How well do surface methods work for general geometries? In this subsection we will take magnetic field and scalar potential values for a monopole doublet, interpolate them onto the bent box surface found in the previous subsection, and then use surface methods to compute the interior field at various sample points. This computed interior field will then be compared with the actual monopole doublet field at these sample points, thereby providing a test of the accuracy of the method. Note that the bent box we have chosen has a square cross section with side 4 cm, and therefore is comparable in cross section to the 4 cm diameter cylinder used in Section 19.1.

24.2.1 Preliminaries

Since it is our intent to compute the interior field from surface values of B_n and ψ, it would be good to have some feel for how these quantities behave on the surface of the bent box with legs. Figure 5.7 displays B_n on the upper face, $y = 2$ cm, of the bent box with legs directly above the design orbit. Figure 5.8 does the same for ψ. Up to signs, similar results hold for the bottom face, $y = -2$ cm. The observation to be made is that B_n falls off fairly rapidly with increasing $|z|$, like $\sim 1/|z|^3$, and ψ falls off somewhat less rapidly, like $\sim 1/|z|^2$.

Something should also be said about the behavior of B_n and ψ on the sides of the box with legs. It is easily checked that, for a monopole doublet, B_x, B_z, and ψ are odd functions of y, and therefore must vanish in the midplane $y = 0$. From this fact, and from considerations of field-line geometry for the case of a monopole doublet field, we conclude that the values of B_n and ψ on the sides of the box with legs will be comparable to, and usually smaller than, their values on the top and bottom faces.

Taking into account the behavior of B_n and ψ on the entire surface of the box with legs, we conclude that it is only necessary to integrate over some bounded portion of the surface in order to compute the interior vector potential $\boldsymbol{A}$ accurately.

With this background in mind, we are prepared to make some numerical tests. We begin by imbedding the bent box with legs of Figure 5.1 (also see Figure 1.1) within a three-dimensional rectangular mesh,

$$x \in [x_{min}, x_{max}], \tag{24.2.1}$$

$$y \in [y_{min}, y_{max}], \tag{24.2.2}$$

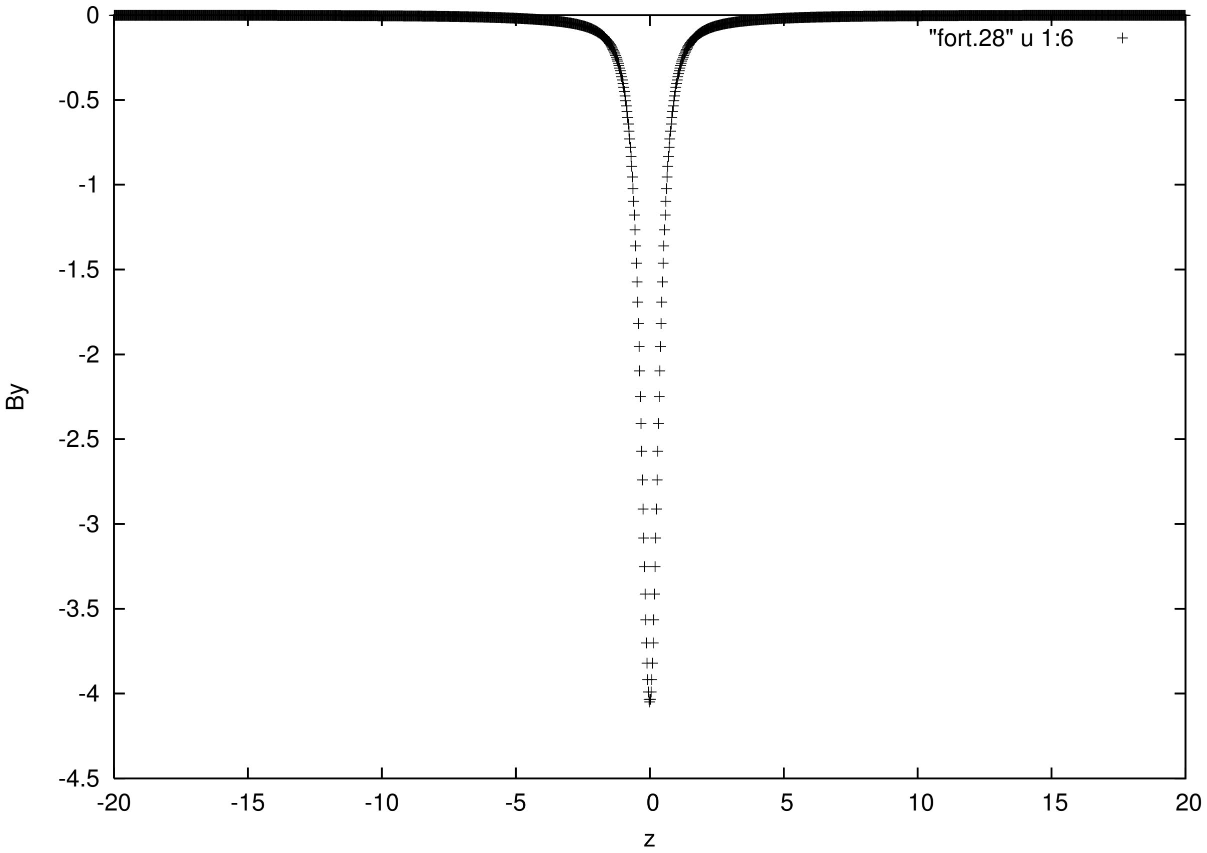

Figure 24.2.1: The quantity $B_n = B_y$ on the upper face, $y = 2$ cm, and directly above the design orbit. The quantity z is in cm.

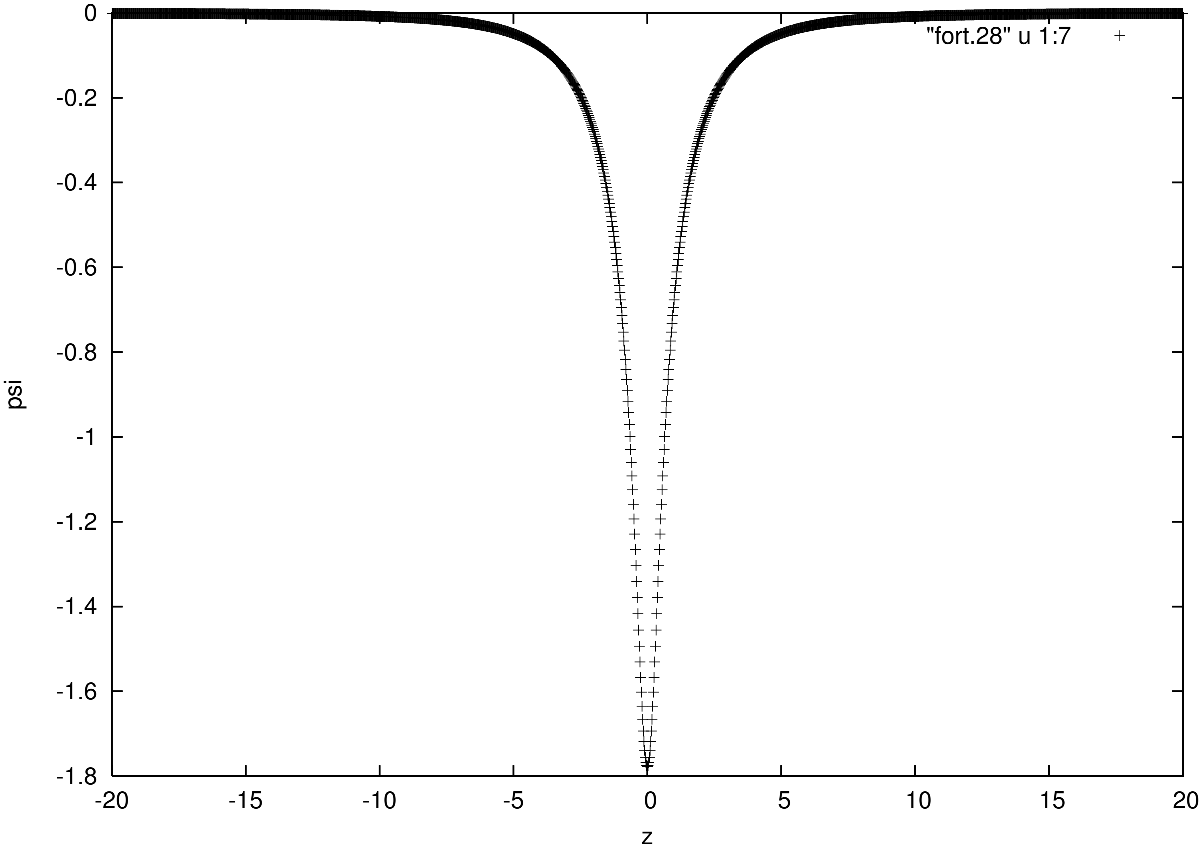

Figure 24.2.2: The quantity ψ on the upper face, $y = 2$ cm, and directly above the design orbit. The quantity z is in cm.

$$z \in [z_{min}, z_{max}], \tag{24.2.3}$$

with mesh-point spacings h_x, h_y, and h_z, respectively. By looking at Figure 5.1 we see that convenient end-point values are given by the relations

$$x_{min} = -7,\ x_{max} = 3, \tag{24.2.4}$$

$$y_{min} = -3,\ y_{max} = 3, \tag{24.2.5}$$

$$z_{min} = -25,\ z_{max} = 25. \tag{24.2.6}$$

See also the corner coordinates given in (5.76) through (5.79). For the mesh-point spacings we take the values

$$h_x = h_y = h_z = .05. \tag{24.2.7}$$

At each of these grid points we compute and store the quantities $\boldsymbol{B}$ and ψ for the monopole doublet field. It is data if this kind that could be expected for the output of some electromagnetic solver.

24.2.2 Evaluation of Surface Integrals

Our task now is to use this data to evaluate surface integrals of the kind (1.7) and (1.8). In this case the surface S, a bent box with legs, consists of a bent sector with straight end legs. When viewed from above, and as described earlier, the sector has inner and outer radii given by (5.59) and (5.60), and subtends an angle of 30°. It has corners at the locations

$$z^{\rm s}_{\ell\ell} = -3.882285676537811,\ x^{\rm s}_{\ell\ell} = -2.511112605663975, \tag{24.2.8}$$

$$z^{\rm s}_{{\rm u}\ell} = -4.917561856947894,\ x^{\rm s}_{{\rm u}\ell} = 1.352590699492298, \tag{24.2.9}$$

$$z^{\rm s}_{\rm ur} = 4.917561856947894,\ x^{\rm s}_{\rm ur} = 1.352590699492298, \tag{24.2.10}$$

$$z^{\rm s}_{\ell{\rm r}} = 3.882285676537811,\ x^{\rm s}_{\ell{\rm r}} = -2.511112605663975. \tag{24.2.11}$$

The left straight end leg, again when viewed form above, has leftmost corners at the locations

$$z^{\ell}_{\ell\ell} = -19.482361909794935,\ x^{\ell}_{\ell\ell} = -6.69114043422916, \tag{24.2.12}$$

$$z^{\ell}_{{\rm u}\ell} = -20.51763809020501,\ x^{\ell}_{{\rm u}\ell} = -2.8274371290729103. \tag{24.2.13}$$

The right straight end leg has rightmost corners at the locations

$$z^{\rm r}_{\rm ur} = 20.51763809020501,\ x^{\rm r}_{\rm ur} = -2.8274371290729103, \tag{24.2.14}$$

$$z^{\rm r}_{\ell{\rm r}} = 19.482361909794935,\ x^{\rm r}_{\ell{\rm r}} = -6.69114043422916. \tag{24.2.15}$$

Each straight end leg has a length of 16.150387336872548 cm.

We will decompose S into 12 pieces. The first 8 will be the top, bottom, inner, and outer faces of the two straight legs. The remaining 4 will be the top, bottom, inner, and outer faces of the bent sector. See Figures 1.1 and 5.1. The first 8 surfaces, those for the straight legs, are all rectangular, and can be conveniently integrated over using rectangular coordinates. Integrals over the remaining 4 surfaces, those for the bent sector, are most easily evaluated using polar/cylindrical coordinates. Our task is to parameterize these 12 pieces and find expressions for dS' for each. In particular, we will convert the integration over each of these pieces into a related integration over a unit square.

Consider the straight legs. We will present results for the left leg. Results for the right leg are analogous.

Note that the right end of the left leg abuts the left end of the bent sector. Again see Figure 5.1. Consequently, the top face of the left leg has corners at $(z^{\ell}_{\ell\ell}, x^{\ell}_{\ell\ell})$, $(z^{\ell}_{\mathrm{u}\ell}, x^{\ell}_{\mathrm{u}\ell})$, $(z^{\mathrm{s}}_{\mathrm{u}\ell}, x^{\mathrm{s}}_{\mathrm{u}\ell})$, and $(z^{\mathrm{s}}_{\ell\ell}, x^{\mathrm{s}}_{\ell\ell})$. It can be described in terms of parameters u and v by writing

$$z^{\ell\mathrm{t}}(u,v) = z^{\ell}_{\ell\ell} + (z^{\mathrm{s}}_{\ell\ell} - z^{\ell}_{\ell\ell})u + (z^{\ell}_{\mathrm{u}\ell} - z^{\ell}_{\ell\ell})v, \tag{24.2.16}$$

$$x^{\ell\mathrm{t}}(u,v) = x^{\ell}_{\ell\ell} + (x^{\mathrm{s}}_{\ell\ell} - x^{\ell}_{\ell\ell})u + (x^{\ell}_{\mathrm{u}\ell} - x^{\ell}_{\ell\ell})v, \tag{24.2.17}$$

$$y^{\ell\mathrm{t}} = 2, \tag{24.2.18}$$

with

$$u, v \in [0,1]. \tag{24.2.19}$$

In this case one finds for the surface element the relation

$$dS' = dz\,dx = [(z^{\mathrm{s}}_{\ell\ell} - z^{\ell}_{\ell\ell})(x^{\ell}_{\mathrm{u}\ell} - x^{\ell}_{\ell\ell}) - (z^{\ell}_{\mathrm{u}\ell} - z^{\ell}_{\ell\ell})(x^{\mathrm{s}}_{\ell\ell} - x^{\ell}_{\ell\ell})]du\,dv. \tag{24.2.20}$$

Similar results hold for the bottom face of the left leg.

The inner face of the left leg can be described in terms of parameters u and v by writing

$$z^{\ell\mathrm{i}}(u,v) = z^{\ell}_{\ell\ell} + (z^{\mathrm{s}}_{\ell\ell} - z^{\ell}_{\ell\ell})u, \tag{24.2.21}$$

$$x^{\ell\mathrm{i}}(u,v) = x^{\ell}_{\ell\ell} + (x^{\mathrm{s}}_{\ell\ell} - x^{\ell}_{\ell\ell})u, \tag{24.2.22}$$

$$y^{\ell\mathrm{i}}(u,v) = -2 + 4v, \tag{24.2.23}$$

again with

$$u, v \in [0,1]. \tag{24.2.24}$$

In this case one finds for the surface element the relation

$$dS' = [4/\cos(\pi/12)](z^{\mathrm{s}}_{\ell\ell} - z^{\ell}_{\ell\ell})du\,dv. \tag{24.2.25}$$

Similar results hold for the outer face of the left leg.

Consider the bent sector. The top face of the bent sector can be described in terms of cylindrical coordinates ρ, ϕ, and y by writing

$$z^{\mathrm{st}} = \rho\sin\phi, \tag{24.2.26}$$

$$x^{\mathrm{st}} = \rho\cos\phi - 17, \tag{24.2.27}$$

$$y^{\mathrm{st}} = 2. \tag{24.2.28}$$

Introduce parameters u and v by writing

$$\rho(u,v) = 15 + 4v, \tag{24.2.29}$$

$$\phi(u,v) = -\pi/12 + (\pi/6)u, \tag{24.2.30}$$

again with the understanding (5.83). Combining (5.90) through (5.94) gives the results

$$z^{\rm st}(u,v) = (15+4v)\sin(-\pi/12+\pi u/6), \tag{24.2.31}$$

$$x^{\rm st}(u,v) = (15+4v)\cos(-\pi/12+\pi u/6) - 17, \tag{24.2.32}$$

$$y^{\rm st}(u,v) = 2. \tag{24.2.33}$$

In this case one finds for the surface element of the top face of the bent sector the relation

$$dS' = \rho d\rho\, d\phi = (2\pi/3)(15+4v)du\, dv. \tag{24.2.34}$$

Similar results hold for the bottom face of the bent sector.

The inner face of the bent sector can be described in terms of relations analogous to (5.90) and (5.91) with $\rho = 15$,

$$z^{\rm si}(u,v) = 15\sin(-\pi/12+\pi u/6), \tag{24.2.35}$$

$$x^{\rm si}(u,v) = 15\cos(-\pi/12+\pi u/6) - 17. \tag{24.2.36}$$

Here we have again used (5.94). We also write

$$y^{\rm si}(u,v) = -2+4v. \tag{24.2.37}$$

In this case we find for the surface element the relation

$$dS' = \rho d\phi\, dy = 10\pi du\, dv. \tag{24.2.38}$$

Similar results hold for the outer face of the bent sector.

The result of the work so far is that the integrations over the 12 pieces of S have been converted into integrations over 12 unit squares of the form (5.83). For each piece, changes in u produce longitudinal displacements, and changes in v produce transverse displacements. We next select points within each unit square to be used in evaluating the various surface integrals numerically.

For the straight legs this is achieved as follows: Each unit square corresponding to a leg surface is decomposed into $100 \times 160 = 16,000$ small rectangles by the prescription

$$h_u = 1/100,\ h_v = 1/160. \tag{24.2.39}$$

Thus, there are 100 subdivisions in the longitudinal direction and 160 subdivisions in the transverse directions.

For the surfaces of the bent sector each corresponding unit square is decomposed into $160 \times 160 = 25,600$ small squares by the prescription

$$h_u = 1/160,\ h_v = 1/160. \tag{24.2.40}$$

Thus, for these surfaces there are 160 subdivisions for both the longitudinal and transverse directions.[1]

[1] More subdivisions are used for the bent sector surfaces because the fields are expected to vary more rapidly over these surfaces. See Figures 5.7 and 5.8.

The integral over each small rectangle or small square is approximated using a 7-point cubature formula. (For a discussion of cubature formulas, see Appendix T.) The values of the integrands at the cubature points are obtained from the values of $\boldsymbol{B}$ and ψ at the grid points using 3-dimensional cubic spline interpolation.[2] Finally, all the small rectangle and small square results are summed to obtain the required integrals over S.

24.2.3 Resulting Vector Potential

Figures 5.9 and 5.10 show the components A_x^{sd} and A_z^{sd} of the vector potential computed along the design trajectory based on bent-box *surface data*.[3] The A_y^{sd} component vanishes in the midplane, and therefore is not shown. For the contribution from the B_n the kernel $\boldsymbol{G}^{n2s}$ was used for the top and bottom faces, and the kernel $\boldsymbol{G}^{n1s}$ was used for the side faces. In all cases the strings were taken to lie on lines parallel to the x axis. For the contribution from ψ the kernel $\boldsymbol{G}^t$ was used.

Recall that the vector potential used in the previous subsection and given by (2.102) through (2.104) has no x component and only a z component on the design orbit. By contrast, A_x^{sd} as shown in Figure 5.9, although small, is not zero on the design orbit. Note also that A_z as displayed in Figure 5.4 and the A_z^{sd} displayed in Figure 5.10, while similar, are not the same. This apparent discrepancy arises from the fact that the vector potential given by (2.102) through (2.104) and the vector potential computed from surface data differ by a gauge transformation. We also remark that examination of the numerical results reveals that the nonzero contribution to A_x^{sd} arises from surface ψ values. See (3.43).

24.2.4 Comparison of Fields

If the interior vector potential $\boldsymbol{A}^{sd}$ has been computed successfully using surface methods, so that it differs from the vector potential given by (2.102) through (2.104) at most only by a gauge transformation, in the interior of the box it should also give rise to the monopole-doublet $\boldsymbol{B}$ field (2.105) through (2.107). Let $\boldsymbol{B}^{sd}$ be the magnetic field given by

$$\boldsymbol{B}^{sd} = \nabla \times \boldsymbol{A}^{sd} \tag{24.2.41}$$

and let $\boldsymbol{B}^e$ be the exact $\boldsymbol{B}$ field. Then, for example, use of (5.105) to compute B_y^{sd} on the design orbit should produce a graphic similar to Figure 5.5.[4] This is indeed the case. A plot of B_y^{sd} on the design orbit is indistinguishable to the eye from Figure 5.5.

To give a better indication of the error involved, define a relative error $\boldsymbol{\Delta}$ by the relation

$$\boldsymbol{\Delta} = (\boldsymbol{B}^{sd} - \boldsymbol{B}^e)/B_y^{maxmag}. \tag{24.2.42}$$

[2] Note that, like the case of cylindrical surfaces, the data at most of the data points on the grid are unused. For each cubature point on S there is an associated point in x,y,z space, and only data at the grid points near these points are actually used in interpolation.

[3] That is, as just described, grid data were manufactured and interpolated onto the 12 pieces of the surface S at the points required for the repeated use of a 7-point cubature formula. The results from these surface values were processed, by repeated application of this cubature formula, to find A_x^{sd} and A_z^{sd} along the design trajectory.

[4] Note that the use of (5.105) requires a knowledge of spatial derivatives of the components of $\boldsymbol{A}$. These derivatives are obtained by differentiating the kernels $\boldsymbol{G}$ under the integral sign prior to carrying out the required surface integrations. See Subsections 4.3 and 4.4.

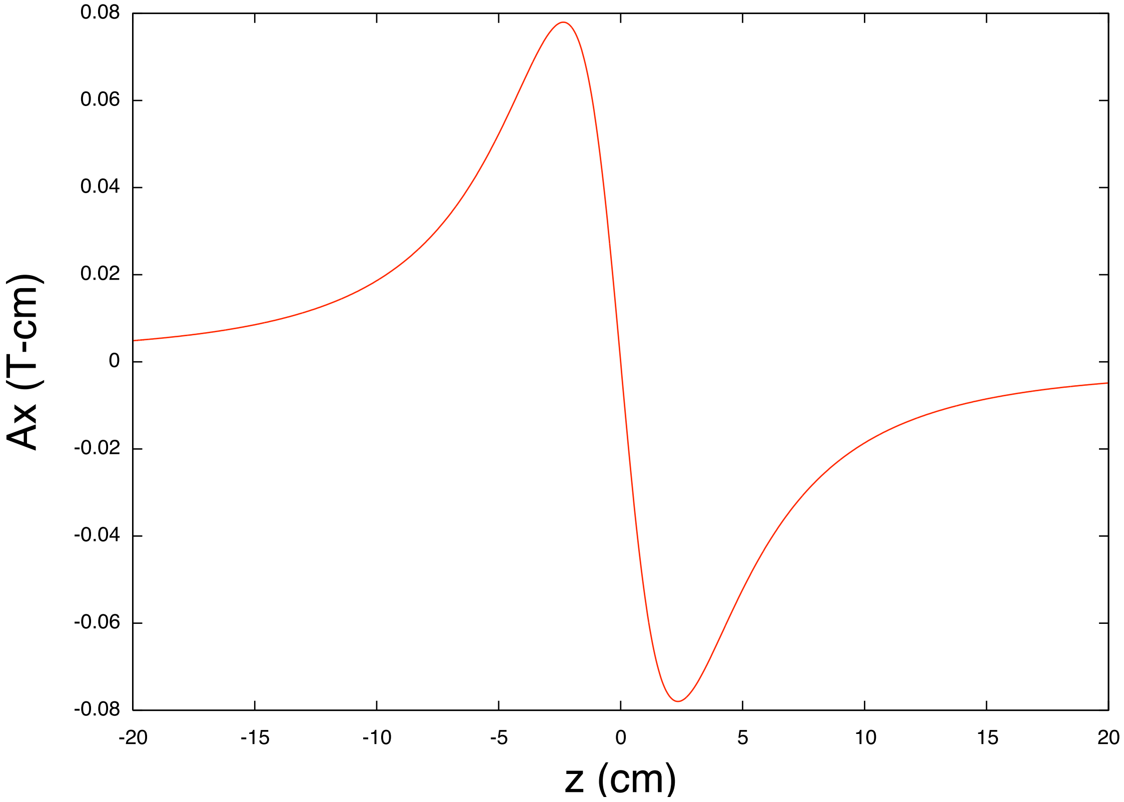

Figure 24.2.3: The quantity A_x^{sd} on the design orbit. The quantity z is in cm.

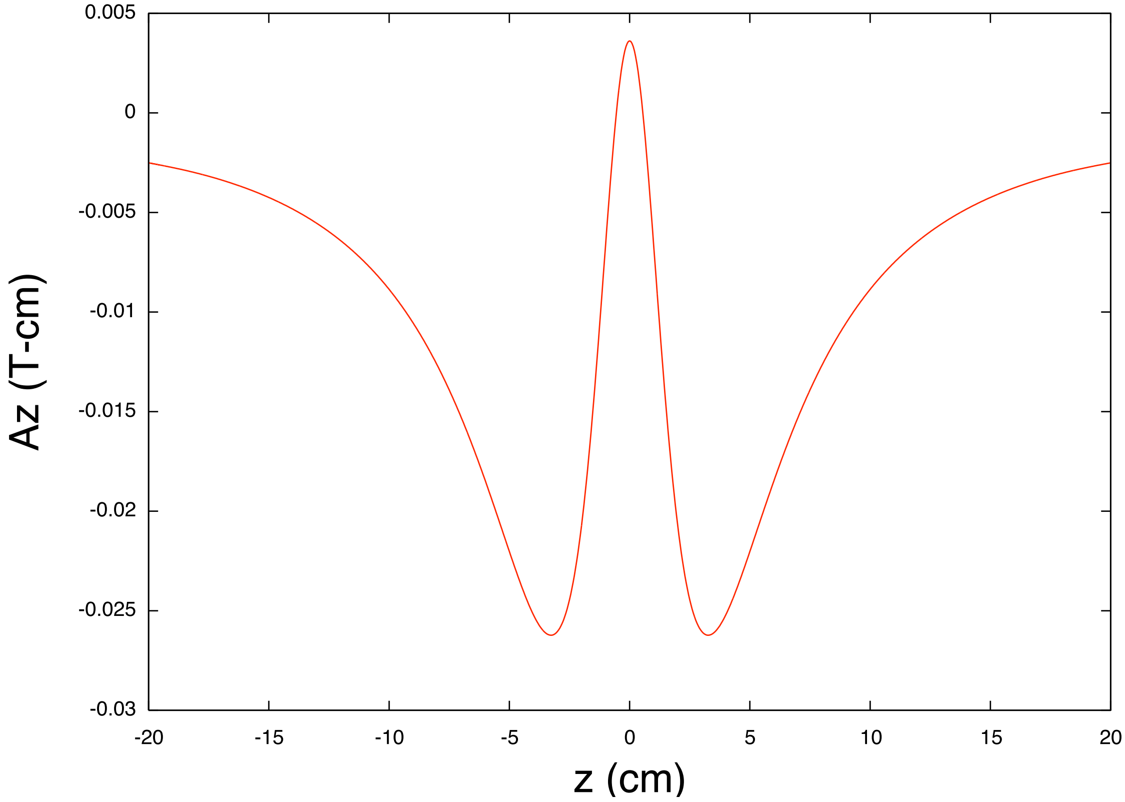

Figure 24.2.4: The quantity A_z^{sd} on the design orbit. The quantity z is in cm.

Here B_y^{maxmag} is the *maximum* value of the *magnitude* of B_y^e on the design orbit,

$$B_y^{maxmag} = |B_y(x = 0, y = 0, z = 0)| = 2g/a^2 = .32 \text{ Tesla}. \tag{24.2.43}$$

See (15.8.5) and Figure 15.8.3. Figure 5.11 displays the value of Δ_y on the design orbit as a function of z. We see that Δ_y is very small over most of the interval $z \in [-20, 20]$, but rises very rapidly to a value of $\simeq 5 \times 10^{-4}$ at the endpoints.

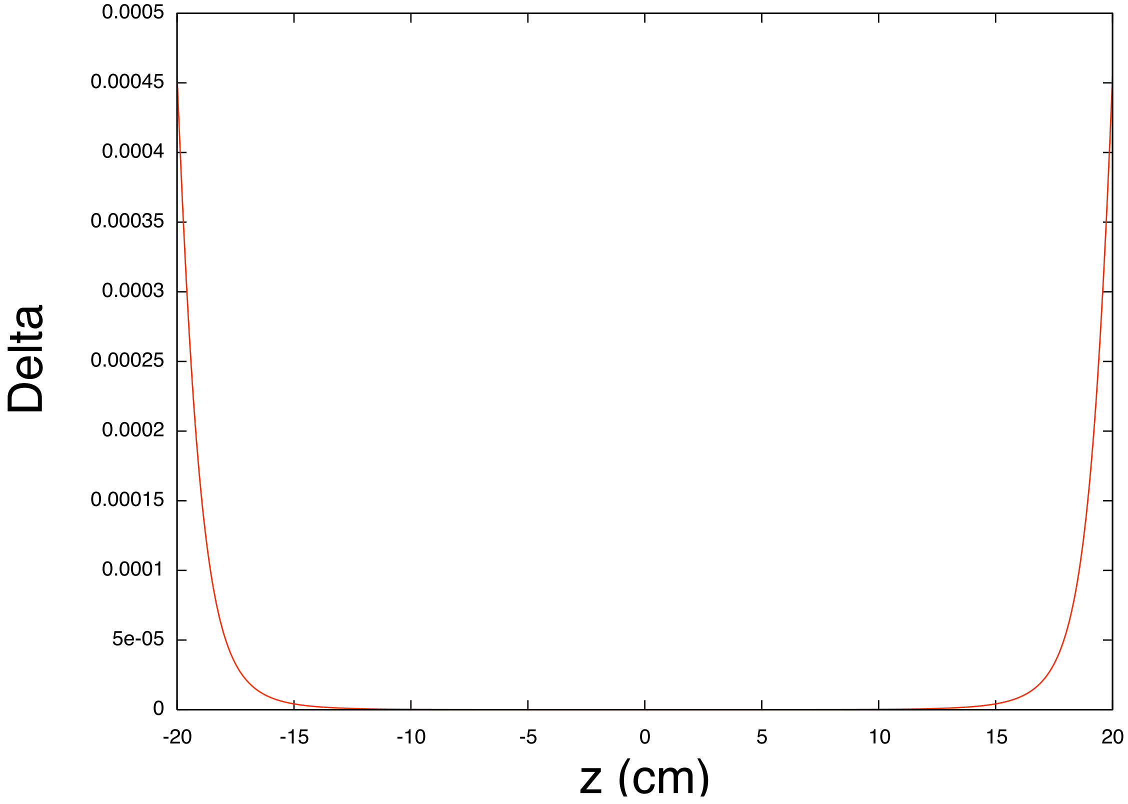

Figure 24.2.5: The relative error Δ_y on the design orbit. The quantity z is in cm.

While the very small error for most of the interval error is very satisfying, the rapid increase of the error at the endpoints might seem alarming. It is not. The relative error Δ_y remains bounded and eventually goes to zero as $|z|$ goes to infinity. Moreover, both B_y^{sd} and B_y^e are small for $|z| \geq 20$, and go to zero as $|z|$ goes to infinity.

To elaborate on these assertions, we begin by noting that both B_y^{sd} and B_y^e are negative. See Figure 5.5. But B_y^{sd} is slightly less negative than B_y^e because, by terminating the straight legs of the box at $z = \pm 20$, the surface fields that serve as a “source” for the interior field are effectively set to zero beyond $z \in [-20, 20]$. Correspondingly, Δ_y is positive. Observe that, because B_y^{sd} is negative, Δ_y always obeys the crude bound

$$\Delta_y < -B_y^e/B_y^{maxmag}. \tag{24.2.44}$$

At the end points the coordinates x, y, z have the values

$$x \simeq -4.76, y = 0, z = \pm 20. \tag{24.2.45}$$

See (5.45). Using these values in (15.8.5) we find that B_y^e has the value

$$B_y^e(x \simeq -4.76, y = 0, z = \pm 20) \simeq -5.63 \times 10^{-4} \text{ Tesla.} \tag{24.2.46}$$

Correspondingly, at worst and for $|z| \geq 20$, Δ_y can never exceed

$$5.63 \times 10^{-4}/.32 \simeq 1.8 \times 10^{-3}. \tag{24.2.47}$$

And since B_y^e for large $|z|$ falls off as $|z|^{-3}$, Δ_y must eventually go to zero for large $|z|$ as $|z|^{-3}$.

Figure 5.11 displays the relative error in the y component of $\boldsymbol{B}^{sd}$ on the design orbit. We are also interested in examining the relative error in all the components of $\boldsymbol{B}^{sd}$ in the vicinity of the design orbit. For this purpose it is convenient to introduce a deviation variable ξ by writing

$$x = x^d + \xi \tag{24.2.48}$$

where x^d is the design orbit shown in Figure 5.6. Figure 5.12 shows Δ, the magnitude of $\boldsymbol{\Delta}$, over the domain $\xi \in [-1, 1], z \in [0, 20]$ in the plane $y = 0$. Figure 5.13 shows Δ over the same domain in the plane $y = 1$. For ease of visualization, values are shown only for $y \geq 0$ and $z \geq 0$ since Δ is even in these variables.

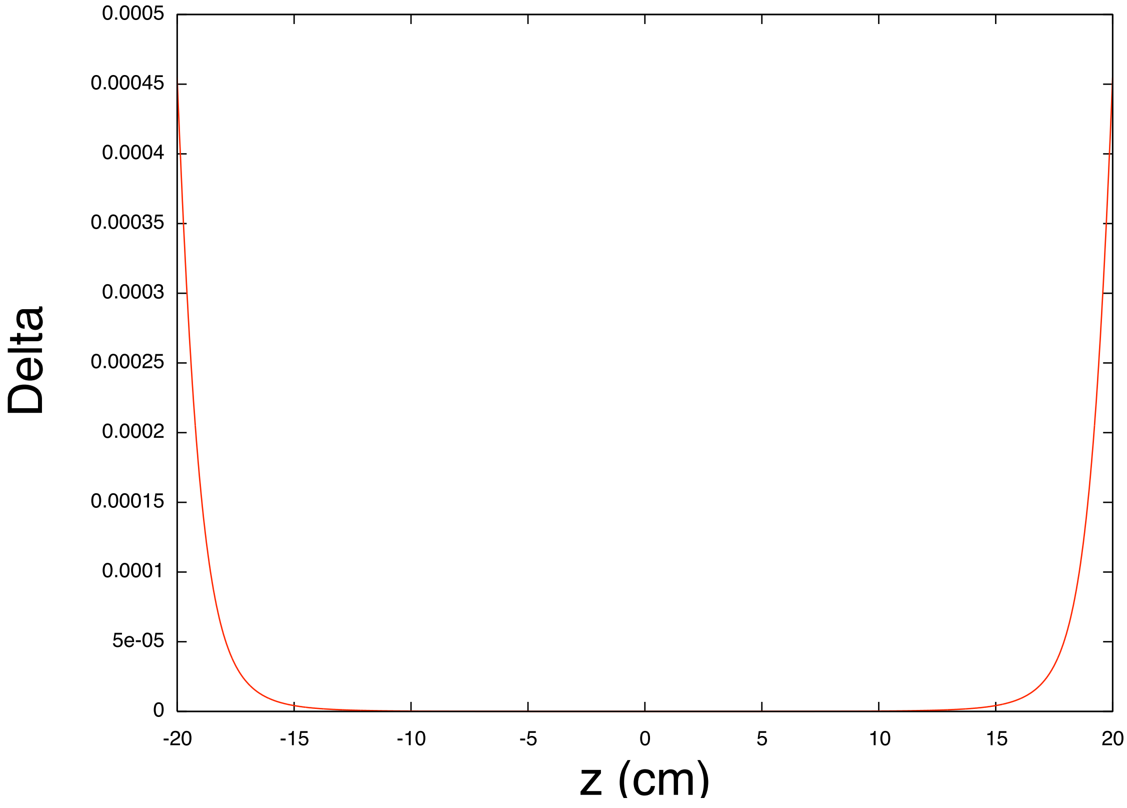

Figure 24.2.6: Place holder. The quantity $\Delta = |\boldsymbol{\Delta}|$ as a function of ξ and z in the vicinity of the design orbit and in the plane $y = 0$. The quantities ξ, y, and z are in cm.

Upon examining these figures we see that $\cdots$.

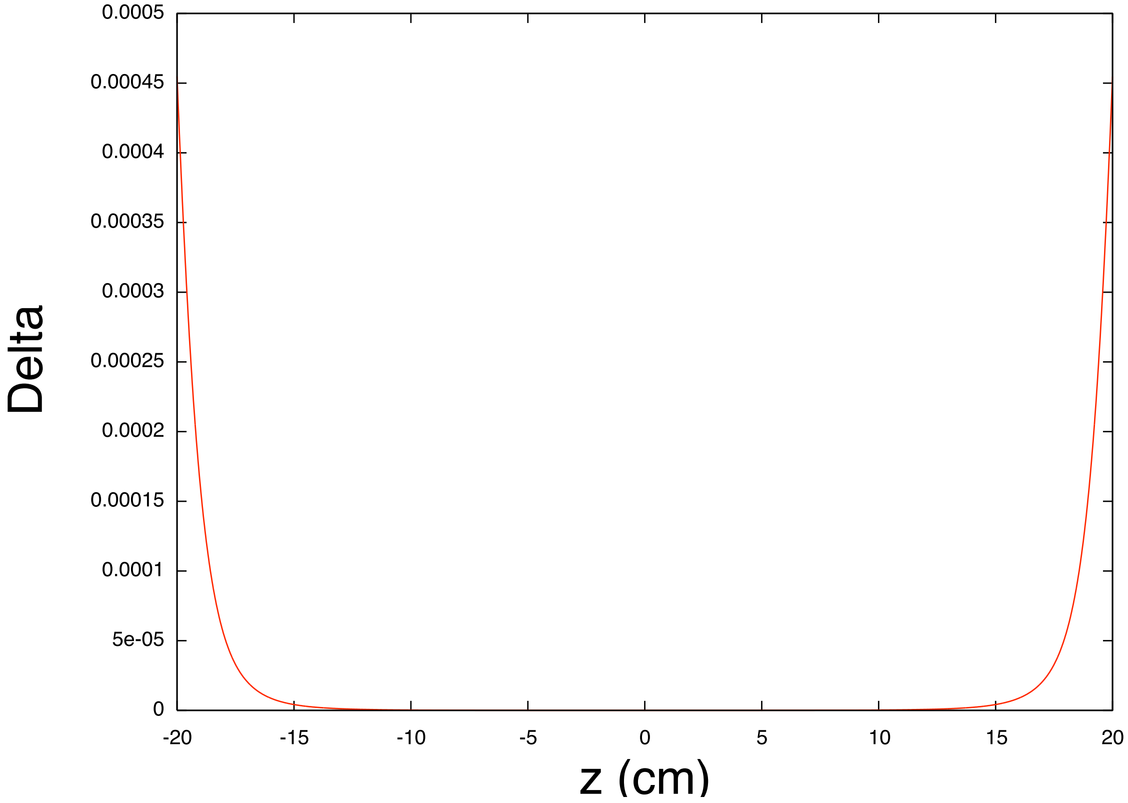

Figure 24.2.7: Place holder. The quantity $\Delta = |\boldsymbol{\Delta}|$ as a function of ξ and z in the vicinity of the design orbit and in the plane $y = 1$. The quantities ξ, y, and z are in cm

24.3 Comparison of Design Orbits

How accurate are design orbits computed using surface methods? In this subsection we will use surface methods to compute a design orbit for the case of a magnetic monopole doublet. Comparison of this design orbit with the design orbit selected in Subsection 5.1 will provide a further indication of the accuracy of surface methods.

24.4 Terminating End Fields

Let us compute the magnetic field $\boldsymbol{B}$ associated with the first two terms in (9.3). We find the result

$$\begin{aligned}\boldsymbol{B}(\boldsymbol{r};X_0,Z_0) &= -[2ga/(X_0^2+Z_0^2+a^2)^{3/2}]\boldsymbol{e}_y\\ &\quad +[6ga/(X_0^2+Z_0^2+a^2)^{5/2}](X_0x+Z_0z)\boldsymbol{e}_y\\ &\quad +[6ga/(X_0^2+Z_0^2+a^2)^{5/2}][y(X_0\boldsymbol{e}_x+Z_0\boldsymbol{e}_z)]. \qquad (24.4.1)\end{aligned}$$

Next let us find the minimum vector potential $\boldsymbol{A}^{\rm min}$ associated with the first two terms in (9.3). Begin by decomposing $\boldsymbol{B}$ into homogeneous polynomials by rewriting (9.4) in the form (2.109) with

$$\boldsymbol{B}^0(\boldsymbol{r};X_0,Z_0) = -[2ga/(X_0^2+Z_0^2+a^2)^{3/2}]\boldsymbol{e}_y \qquad (24.4.2)$$

and

$$\boldsymbol{B}^1(\boldsymbol{r};X_0,Z_0) = [6ga/(X_0^2+Z_0^2+a^2)^{5/2}][(X_0x+Z_0z)\boldsymbol{e}_y+y(X_0\boldsymbol{e}_x+Z_0\boldsymbol{e}_z)]. \qquad (24.4.3)$$

The minimum vector potential associated with this magnetic field is given by the relations (2.109) through (2.111). Working out the indicated cross products yields the results

$$\boldsymbol{A}^{\min 1}(\boldsymbol{r};X_0,Z_0) = [ga/(X_0^2+Z_0^2+a^2)^{3/2}](-z\boldsymbol{e}_x+x\boldsymbol{e}_z), \qquad (24.4.4)$$

$$\begin{gathered}\boldsymbol{A}^{\min 2}(\boldsymbol{r};X_0,Z_0) = [-2ga/(X_0^2+Z_0^2+a^2)^{5/2}]\times\\ [(Z_0y^2-Z_0z^2-X_0xz)\boldsymbol{e}_x+(X_0yz-Z_0xy)\boldsymbol{e}_y+(X_0x^2+Z_0xz-X_0y^2)\boldsymbol{e}_z].\end{gathered} \qquad (24.4.5)$$

Simple calculation verifies that there are the relations

$$\nabla\times\boldsymbol{A}^{\min 1}(\boldsymbol{r};X_0,Z_0) = \boldsymbol{B}^0(\boldsymbol{r};X_0,Z_0), \qquad (24.4.6)$$

$$\nabla\times\boldsymbol{A}^{\min 2}(\boldsymbol{r};X_0,Z_0) = \boldsymbol{B}^1(\boldsymbol{r};X_0,Z_0), \qquad (24.4.7)$$

as desired. We note that $\boldsymbol{A}^{\min 1}$ falls off as $(1/|X_0|)^3$ or $(1/|Z_0|)^3$ for large $|X_0|$ or $|Z_0|$, and $\boldsymbol{A}^{\min 2}$ falls off as $(1/|X_0|)^4$ or $(1/|Z_0|)^4$. In general, successive $\boldsymbol{A}^{\min n}$ fall off with ever increasing powers of $(1/|X_0|)$ or $(1/|Z_0|)$.

$$\boldsymbol{e}_\xi = \cos\theta\boldsymbol{e}_x - \sin\theta\boldsymbol{e}_z, \qquad (24.4.8)$$

$$\boldsymbol{e}_\eta = \boldsymbol{e}_y, \tag{24.4.9}$$

$$\boldsymbol{e}_\zeta = \sin\theta \boldsymbol{e}_x + \cos\theta e_z. \tag{24.4.10}$$

$$\boldsymbol{e}_\zeta \times \boldsymbol{e}_\xi = -\sin^2\theta(\boldsymbol{e}_x \times e_z) + \cos^2\theta(\boldsymbol{e}_z \times e_x) = \boldsymbol{e}_y = \boldsymbol{e}_\eta; \tag{24.4.11}$$

$$\boldsymbol{e}_x = \cos\theta \boldsymbol{e}_\xi + \sin\theta \boldsymbol{e}_\zeta, \tag{24.4.12}$$

$$\boldsymbol{e}_y = \boldsymbol{e}_\eta \tag{24.4.13}$$

$$\boldsymbol{e}_z = -\sin\theta \boldsymbol{e}_\xi + \cos\theta \boldsymbol{e}_\zeta. \tag{24.4.14}$$

$$\boldsymbol{r} = x\boldsymbol{e}_x + y\boldsymbol{e}_y + z\boldsymbol{e}_z = \xi\boldsymbol{e}_\xi + \eta\boldsymbol{e}_\eta + \zeta\boldsymbol{e}_\zeta. \tag{24.4.15}$$

$$\begin{aligned} x &= \boldsymbol{r} \cdot e_x = (\xi\boldsymbol{e}_\xi + \eta\boldsymbol{e}_\eta + \zeta\boldsymbol{e}_\zeta) \cdot \boldsymbol{e}_x \\ &= \xi\boldsymbol{e}_\xi \cdot \boldsymbol{e}_x + \eta\boldsymbol{e}_\eta \cdot e_x + \zeta\boldsymbol{e}_\zeta \cdot e_x \\ &= \xi\cos\theta + \zeta\sin\theta. \end{aligned} \tag{24.4.16}$$

$$\begin{aligned} y &= \boldsymbol{r} \cdot e_y = (\xi\boldsymbol{e}_\xi + \eta\boldsymbol{e}_\eta + \zeta\boldsymbol{e}_\zeta) \cdot \boldsymbol{e}_y \\ &= \xi\boldsymbol{e}_\xi \cdot \boldsymbol{e}_y + \eta\boldsymbol{e}_\eta \cdot e_y + \zeta\boldsymbol{e}_\zeta \cdot e_y \\ &= \eta. \end{aligned} \tag{24.4.17}$$

$$\begin{aligned} z &= \boldsymbol{r} \cdot e_z = (\xi\boldsymbol{e}_\xi + \eta\boldsymbol{e}_\eta + \zeta\boldsymbol{e}_\zeta) \cdot \boldsymbol{e}_z \\ &= \xi\boldsymbol{e}_\xi \cdot \boldsymbol{e}_z + \eta\boldsymbol{e}_\eta \cdot e_z + \zeta\boldsymbol{e}_\zeta \cdot e_z \\ &= -\xi\sin\theta + \zeta\cos\theta. \end{aligned} \tag{24.4.18}$$

$$\boldsymbol{B}^0(\boldsymbol{r}; X_0, Z_0) \;=\; -[2ga/(X_0^2 + Z_0^2 + a^2)^{3/2}]\boldsymbol{e}_\eta. \tag{24.4.19}$$

$$\begin{aligned} \boldsymbol{A}^{\min 1}(\xi,\eta,\zeta; X_0, Z_0) &= -(1/2)\boldsymbol{r} \times \boldsymbol{B}^0(\boldsymbol{r}; X_0, Z_0) \\ &= [ga/(X_0^2 + Z_0^2 + a^2)^{3/2}](-\zeta\boldsymbol{e}_\xi + \xi\boldsymbol{e}_\zeta), \end{aligned} \tag{24.4.20}$$

$$\boldsymbol{A}^{\min 1}(\xi,\eta,0; X_0, Z_0) \;=\; [ga/(X_0^2 + Z_0^2 + a^2)^{3/2}](\xi\boldsymbol{e}_\zeta), \tag{24.4.21}$$

$$A_\xi^{\min 1}(\xi,\eta,0; X_0, Z_0) = A_\eta^{\min 1}(\xi,\eta,0; X_0, Z_0) = 0. \tag{24.4.22}$$

$$\begin{aligned} \boldsymbol{B}^1(\boldsymbol{r}; X_0, Z_0) &= [6ga/(X_0^2 + Z_0^2 + a^2)^{5/2}] \times \\ &\quad [(X_0x + Z_0z)\boldsymbol{e}_y + y(X_0\boldsymbol{e}_x + Z_0\boldsymbol{e}_z)]. \end{aligned} \tag{24.4.23}$$

$$(X_0x + Z_0z)\boldsymbol{e}_y = [x_0(\xi\cos\theta + \zeta\sin\theta) + Z_0(-\xi\sin\theta + \zeta\cos\theta)]\boldsymbol{e}_\eta, \tag{24.4.24}$$

$$\begin{aligned} y(X_0\boldsymbol{e}_x + Z_0\boldsymbol{e}_z) &= \eta[X_0(\cos\theta\boldsymbol{e}_\xi + \sin\theta\boldsymbol{e}_\zeta) + Z_0(-\sin\theta\boldsymbol{e}_\xi + \cos\theta\boldsymbol{e}_\zeta)] \\ &= \eta[(X_0\cos\theta - Z_0\sin\theta)\boldsymbol{e}_\xi + (X_0\sin\theta + Z_0\cos\theta)\boldsymbol{e}_\zeta]. \end{aligned} \tag{24.4.25}$$

$$\begin{aligned} \boldsymbol{B}^1(\xi,\eta,\zeta;X_0,Z_0) &= [6ga/(X_0^2+Z_0^2+a^2)^{5/2}] \times \\ &\quad \{[X_0(\xi\cos\theta + \zeta\sin\theta) + Z_0(-\xi\sin\theta + \zeta\cos\theta)]\boldsymbol{e}_\eta \\ &\qquad + \eta[(X_0\cos\theta - Z_0\sin\theta)\boldsymbol{e}_\xi + (X_0\sin\theta + Z_0\cos\theta)\boldsymbol{e}_\zeta]\}. \end{aligned} \tag{24.4.26}$$

$$\begin{aligned} \boldsymbol{B}^1(\xi,\eta,0;X_0,Z_0) &= [6ga/(X_0^2+Z_0^2+a^2)^{5/2}] \times \\ &\quad \{[X_0(\xi\cos\theta) + Z_0(-\xi\sin\theta)]\boldsymbol{e}_\eta \\ &\qquad + \eta[(X_0\cos\theta - Z_0\sin\theta)\boldsymbol{e}_\xi + (X_0\sin\theta + Z_0\cos\theta)\boldsymbol{e}_\zeta]\}. \end{aligned} \tag{24.4.27}$$

$$\boldsymbol{r}(\xi,\eta,\zeta) = \xi\boldsymbol{e}_\xi + \eta\boldsymbol{e}_\eta + \zeta\boldsymbol{e}_\zeta. \tag{24.4.28}$$

$$\boldsymbol{r}(\xi,\eta,0) = \xi\boldsymbol{e}_\xi + \eta\boldsymbol{e}_\eta. \tag{24.4.29}$$

$$\begin{aligned} \boldsymbol{e}_\eta \times \boldsymbol{B}^1(\xi,\eta,0;X_0,Z_0) &= [6ga/(X_0^2+Z_0^2+a^2)^{5/2}] \times \\ &\quad \{\eta[(-X_0\cos\theta + Z_0\sin\theta)\boldsymbol{e}_\zeta + (X_0\sin\theta + Z_0\cos\theta)\boldsymbol{e}_\xi]\}. \end{aligned} \tag{24.4.30}$$

$$\begin{aligned} [\eta\boldsymbol{e}_\eta \times \boldsymbol{B}^1(\xi,\eta,0;X_0,Z_0)]_\xi &= [6ga/(X_0^2+Z_0^2+a^2)^{5/2}] \times \\ &\quad \{\eta^2[(X_0\sin\theta + Z_0\cos\theta)]\}. \end{aligned} \tag{24.4.31}$$

$$\begin{aligned} \boldsymbol{e}_\xi \times \boldsymbol{B}^1(\xi,\eta,0;X_0,Z_0) &= [6ga/(X_0^2+Z_0^2+a^2)^{5/2}] \times \\ &\quad \{[X_0(\xi\cos\theta) + Z_0(-\xi\sin\theta)]\boldsymbol{e}_\zeta \\ &\qquad - \eta[(X_0\sin\theta + Z_0\cos\theta)\boldsymbol{e}_\eta]\}. \end{aligned} \tag{24.4.32}$$

$$\begin{aligned} [\xi\boldsymbol{e}_\xi \times \boldsymbol{B}^1(\xi,\eta,0;X_0,Z_0)]_\eta &= [6ga/(X_0^2+Z_0^2+a^2)^{5/2}] \times \\ &\quad \{-\xi\eta[(X_0\sin\theta + Z_0\cos\theta)]\}. \end{aligned} \tag{24.4.33}$$

$$\boldsymbol{A}^{\min 2}(\xi,\eta,0;X_0,Z_0) \;=\; -(1/3)\boldsymbol{r}(\xi,\eta,0)\times\boldsymbol{B}^1(\xi,\eta,0;X_0,Z_0). \tag{24.4.34}$$

$$A_\xi^{\min 2}(\xi,\eta,0;X_0,Z_0) = [-2ga/(X_0^2+Z_0^2+a^2)^{5/2}](X_0\sin\theta+Z_0\cos\theta)\eta^2, \tag{24.4.35}$$

$$A_\eta^{\min 2}(\xi,\eta,0;X_0,Z_0) = [2ga/(X_0^2+Z_0^2+a^2)^{5/2}](X_0\sin\theta+Z_0\cos\theta)\xi\eta. \tag{24.4.36}$$

24.6 Pole Face Rotation

24.7 Comparison of Maps

How accurate are maps computed using surface methods? In this subsection we will use surface methods to compute the transfer map about the design orbit found in Subsection 5.3. We will also compute the exact transfer map for the case of a magnetic monopole doublet. Comparison of these maps will provide a final indication of the accuracy of surface methods.

24.8 Smoothing and Insensitivity to Errors

Exercises

24.8.1. Show that any orbit having the initial conditions $Y=0$ and $P_y=0$ when $z=0$ must lie in the $y=0$ plane.

24.8.2. Show that, in the case of a 30° bend produced by a magnetic monopole doublet, one expects the asymptotic behavior

$$\lim_{z\to\mp\infty} X'(z) = \pm\tan(15^\circ) = \pm.267949\cdots. \tag{24.8.1}$$

Actually, in the numerical computations for Section 20.5.1, p^0 was chosen so that

$$X'(z=\mp 20) = \pm\tan(15^\circ) = \pm.267949\cdots. \tag{24.8.2}$$

See (5.47) and (5.48). From Figure 5.3 we observe that "asymptopia" has essentially been achieved when $|z|\geq 20$ so that the requirements (5.113) and (5.114) are nearly equivalent.

24.8.3. Consider $A_z(x,y,z)$ as given by (2.104). Under the assumption that $|x|$ increases linearly with $|z|$, as it does for large $|z|$ on the design orbit shown in Figure 5.1, find the midplane, $y=0$, asymptotic behavior of $A_z(x,y,z)$ for large $|z|$. Do the same for $B_y(x,y,z)$. Verify that the results you obtain are consistent with Figures 5.4 and 5.5.

24.8.4. Verify the parameterizations (5.80) through (5.83), (5.85) through (5.88), (5.95) through (5.97), and (5.99) through (5.101). Verify the surface elements (5.84), (5.89), (5.98), and (5.102).

Chapter 27

Representations of $sp(2n)$ and Related Matters

Historically there are several mathematical groups that have been studied in detail because of their relevance to our understanding of the physical world. A detailed knowledge of the 3-dimensional rotation group is of great use in many areas including rigid body dynamics, condensed matter physics, chemistry, atomic physics, nuclear physics, and elementary particle physics. Knowledge of the rotation-translation group leads to a classification of crystals and quasicrystals. Knowledge of the Lorentz group leads to the construction of spinors, 4-vectors, general tensors, and classical fields. Knowledge of the Poincaré group (the Lorentz group plus translations in space and time) leads to a classification of elementary particles and the construction of quantum fields. An understanding of the invariants of the full group of space-time diffeomorphisms plays a role in general relativity. Knowledge of various other groups, including E_8, facilitates many-body theory calculations. Finally, there are the various "internal" and/or gauge symmetry groups that play an important role in our current understanding of elementary particles and the fundamental forces.

We have seen that the symplectic group is the underlying group for Hamiltonian systems. Yet, in contrast to most of the groups just mentioned, almost nothing is commonly known or readily available about the symplectic group. For example, many readers will be familiar with some aspects of the rotation group including spin (irreducible representations and how they are labeled) and how spins couple and combine (the Clebsch-Gordan series and coefficients for the rotation group). Yet few have heard or read about representations of the symplectic group, knowledge of its Clebsch-Gordan series is not widespread, and little is known in detail about its Clebsch-Gordan coefficients.

The purpose of this chapter is to describe some aspects of the finite-dimensional representations of the first few symplectic groups with the hope that this knowledge, like that for the well-studied groups, will also ultimately prove useful. [What we will actually be finding are the finite dimensional irreducible unitary representations of $usp(2n)$, which is equivalent to $sp(2n, \mathbb{R})$ over the complex field. See Sections 5.10 and 7.3.] Indeed, as a first consequence of this effort, we will find a symplectic classification of all analytic vector fields. Additional applications will be made in Chapters 29, 32, and 33.

27.1 Structure of $sp(2,\mathbb{R})$

The Lie algebra $sp(2,\mathbb{R})$ is generated by the Lie operators associated with the quadratic polynomials q^2, qp, and p^2. See Section 5.6. For present purposes it is convenient to introduce the basis polynomials

$$J_3 = -(i/4)(p^2+q^2) \tag{27.1.1}$$

$$J_\pm = (1/4)(q \pm ip)^2. \tag{27.1.2}$$

They obey the Poisson bracket rules

$$[J_3, J_\pm] = \pm J_\pm, \tag{27.1.3}$$

$$[J_+, J_-] = 2J_3. \tag{27.1.4}$$

These rules are the familiar ones for angular momentum, and indicate that the Lie algebras $so(3,\mathbb{R})$, $su(2)$, $sp(2,\mathbb{R})$, and $usp(2)$ are equivalent when one works over the complex field as in (1.1) and (1.2).

As a result of (7.3.14) through (7.3.16) we have the relations

$$: J_3 :^\dagger =: J_3 :, \tag{27.1.5}$$

$$: J_\pm :^\dagger =: J_\mp : . \tag{27.1.6}$$

Thus, $: J_3 :$ is Hermitian. Finally, consider Lie transformations of the form

$$\mathcal{M}(\theta) = \exp(-i\theta : J_3 :) = \exp[-(\theta/4) : p^2 + q^2 :]. \tag{27.1.7}$$

These transformations are both real symplectic and unitary. Indeed, they have the periodicity property

$$\mathcal{M}(\theta + 4\pi) = \mathcal{M}(\theta), \tag{27.1.8}$$

and therefore form a *maximal torus* in $Sp(2,\mathbb{R})$. See Sections 3.9 and 7.2.

We next bring the rules (1.3) and (1.4) to Cartan form. For a review of the Cartan form for a Lie algebra, see Section 5.8. Let $\boldsymbol{e}^1$ be a unit vector. For the case of $sp(2)$ it is convenient to introduce root vectors $\pm\boldsymbol{\alpha}$ by the relations

$$\pm\,\boldsymbol{\alpha} = \pm 2\boldsymbol{e}^1. \tag{27.1.9}$$

(Observe that they have length 2.) Then we have the normalization relation

$$\sum_{\boldsymbol{\mu}} (\boldsymbol{e}^1 \cdot \boldsymbol{\mu})(\boldsymbol{\mu} \cdot \boldsymbol{e}^1) = 8. \tag{27.1.10}$$

Compare with (5.8.21). Next introduce quantities c^1 and $r(\pm\boldsymbol{\alpha})$ by the relations

$$c^1 = 2J_3 = -(i/2)(p^2+q^2), \tag{27.1.11}$$

$$r(\pm\boldsymbol{\alpha}) = \sqrt{2}J_\pm = (\sqrt{2}/4)(q \pm ip)^2. \tag{27.1.12}$$

They evidently obey the Poisson bracket rules

$$[c^1, r(\boldsymbol{\mu})] = (\boldsymbol{e}^1 \cdot \boldsymbol{\mu}) r(\boldsymbol{\mu}), \tag{27.1.13}$$

$$[r(\boldsymbol{\mu}), r(-\boldsymbol{\mu})] = (\boldsymbol{e}^1 \cdot \boldsymbol{\mu}) c^1. \tag{27.1.14}$$

These are the Cartan rules for $sp(2)$. Note that there are the conjugacy relations

$$: c^1 :^\dagger =: c^1 :, \tag{27.1.15}$$

$$: r(\boldsymbol{\mu}) :^\dagger =: r(-\boldsymbol{\mu}) :, \tag{27.1.16}$$

and $: c^1 :$ is Hermitian as desired. The root vectors $\pm\boldsymbol{\alpha}$ are shown in Figure 1.1. Finally, we note the pleasing fact that for the scalar product (7.3.12) the basis elements c^1 and $r(\boldsymbol{\mu})$ all have unit norm and, indeed, are orthonormal:

$$\langle c^1, c^1 \rangle = \langle r(\boldsymbol{\mu}), r(\boldsymbol{\mu}) \rangle = 1, \tag{27.1.17}$$

$$\langle c^1, r(\boldsymbol{\mu}) \rangle = 0, \tag{27.1.18}$$

$$\langle r(\boldsymbol{\mu}), r(-\boldsymbol{\mu}) \rangle = 0. \tag{27.1.19}$$

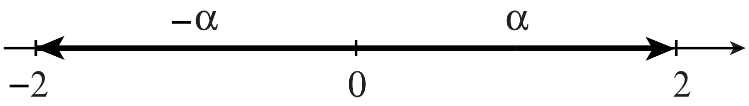

Figure 27.1.1: Root vectors for $sp(2)$.

Exercises

27.1.1. Verify (1.3) through (1.8).

27.1.2. Define J_1 and J_2 by the rules

$$J_\pm = J_1 \pm i J_2. \tag{27.1.20}$$

Verify the $su(2)$ Poisson bracket rules

$$[J_1, J_2] = i J_3, \text{ etc.} \tag{27.1.21}$$

27.1.3. Verify (1.10) and (1.13) through (1.19).

27.2 Representations of $sp(2,\mathbb{R})$

It is well known that irreducible representations of $su(2)$ are labeled by a non-negative integer or half-integer j, and vectors within a representation are labeled by an integer or half-integer m that ranges between $-j$ and j by integer steps. Let $\hat{J}_3$, $\hat{J}_\pm$ be a set of irreducible matrices (with $\hat{J}_3$ Hermitian) whose commutation rules are the same as the Poisson bracket rules (1.3) and (1.4). Then, in a representation labeled by j, there is a "highest" vector $|j\rangle$ with $m = j$ having the property

$$\hat{J}_3|j\rangle = j|j\rangle, \text{ or}$$
$$(2\hat{J}_3)|j\rangle = (2j)|j\rangle. \tag{27.2.1}$$

In the terminology of Cartan, the vector $|j\rangle$ is an eigenvector of highest weight with weight $(2j)$. [See (1.11).] It follows that the fundamental weight $\boldsymbol{\phi}^1$ for $sp(2)$ is given by the relation

$$\boldsymbol{\phi}^1 = \boldsymbol{e}^1 = \boldsymbol{\alpha}/2. \tag{27.2.2}$$

Correspondingly, the highest weight for a representation characterized by the non-negative integer n, with $n = 2j$, is given by the relation

$$\boldsymbol{w}^h = n\boldsymbol{\phi}^1\ ,\ n = 2j. \tag{27.2.3}$$

Call this representation $\Gamma(n)$.

Figure 2.1 shows the fundamental weight $\boldsymbol{\phi}^1$ along with the root vectors $\pm\boldsymbol{\alpha}$. Figure 2.2 shows the weight diagrams for the first few representations. For $su(2)$, and hence $sp(2,\mathbb{R})$, each weight (vector within a representation) has unit multiplicity. It follows that the dimension of the representation $\Gamma(n)$ is given by the relation

$$\dim\Gamma(n) = n + 1. \tag{27.2.4}$$

Sometimes we will label a representation by its dimension.

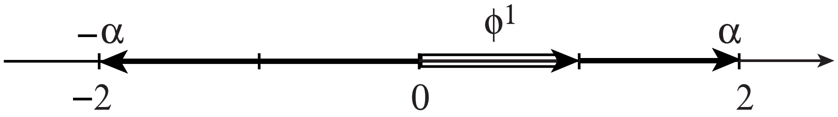

Figure 27.2.1: The fundamental weight $\boldsymbol{\phi}^1$ and the root vectors $\pm\boldsymbol{\alpha}$ for $sp(2)$.

Let $\mathcal{P}_n$ denote the set of polynomials homogeneous of degree n in the variables q, p; and let f_2 be a quadratic polynomial in q, p. Then, in view of (7.6.14), we have the relation

$$: f_2 : \mathcal{P}_n \subseteq \mathcal{P}_n. \tag{27.2.5}$$

It follows that the set of homogeneous polynomials of degree n forms a representation of $sp(2,\mathbb{R})$.

What representations occur? The study of this question is facilitated by using the map $\mathcal{A}(\theta)$ defined by the equation

$$\mathcal{A}(\theta) = \exp(-i\theta : p^2 - q^2 :). \tag{27.2.6}$$

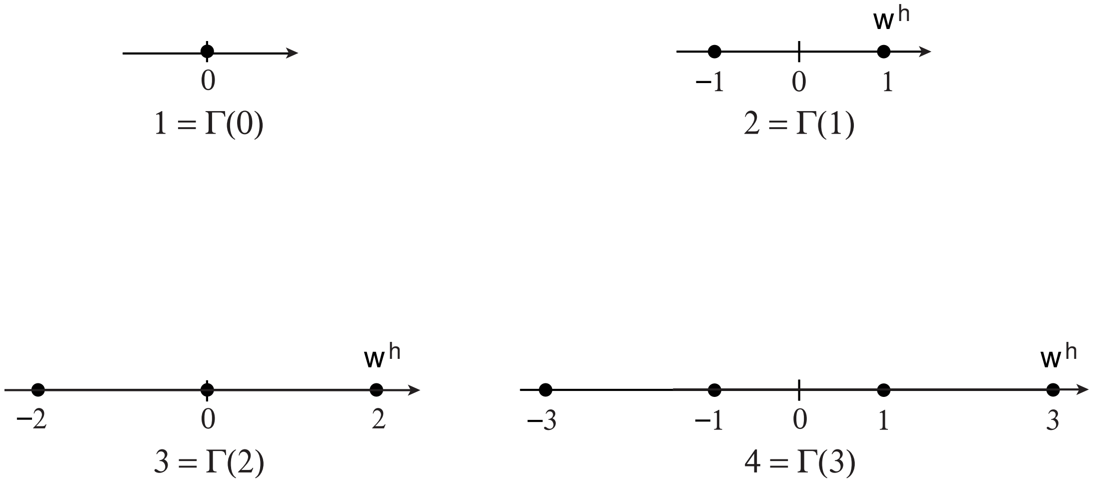

Figure 27.2.2: Weight diagrams for the $sp(2)$ repesentations $\Gamma(0)$, $\Gamma(1)$, $\Gamma(2)$, and $\Gamma(3)$.

Evidently $\mathcal{A}$ is *complex* symplectic and, in view of (7.3.14) through (7.3.16), it is also unitary. Calculation gives the results

$$\mathcal{A}(\theta)q = q\cos(2\theta) + ip\sin(2\theta), \tag{27.2.7}$$

$$\mathcal{A}(\theta)p = iq\sin(2\theta) + p\cos(2\theta). \tag{27.2.8}$$

In particular, there is the relation

$$\mathcal{A}(\pi/8)q = (1/\sqrt{2})(q + ip), \tag{27.2.9}$$

$$\mathcal{A}(\pi/8)p = i(1/\sqrt{2})(q - ip). \tag{27.2.10}$$

The map $\mathcal{A}(\pi/8)$ is the operator analog of the matrix W given by (3.9.9). See Exercise 2.2. Also, since $\mathcal{A}$ is a Lie transformation, there is the relation

$$\mathcal{A}(\pi/8)(q^r p^s) = [\mathcal{A}(\pi/8)q]^r[\mathcal{A}(\pi/8)p]^s = (1/\sqrt{2})^{r+s}(i)^s(q + ip)^r(q - ip)^s. \tag{27.2.11}$$

With the aid of $\mathcal{A}$, we define transformed Lie basis polynomials $\tilde{c}^1$, $\tilde{r}(\pm\boldsymbol{\alpha})$, by the rule

$$\tilde{c}^1 = \mathcal{A}(-\pi/8)c^1 = -qp, \tag{27.2.12}$$

$$\tilde{r}(\boldsymbol{\alpha}) = \mathcal{A}(-\pi/8)r(\boldsymbol{\alpha}) = (1/\sqrt{2})q^2, \tag{27.2.13}$$

$$\tilde{r}(-\boldsymbol{\alpha}) = \mathcal{A}(-\pi/8)r(-\boldsymbol{\alpha}) = -(1/\sqrt{2})p^2. \tag{27.2.14}$$

Since $\mathcal{A}$ is symplectic, the transformed basis polynomials obey the same Poisson bracket rules (1.13) and (1.14). See (5.4.14) and Section 6.3. Since $\mathcal{A}$ is also unitary, as is easily verified, the transformed basis polynomials also satisfy the orthonormality relations (1.17) through (1.19) and the conjugacy relations (1.15) and (1.16).

Now consider the action of the Lie operators $:\tilde{c}^1:$ and $:\tilde{r}(\pm\boldsymbol{\alpha}):$ on the general monomial $q^r p^s$. Calculation gives the results

$$:\tilde{c}^1: q^r p^s = (r - s)q^r p^s, \tag{27.2.15}$$

$$:\tilde{r}(\boldsymbol{\alpha}): q^r p^s = (\sqrt{2}) s q^{r+1} p^{s-1}, \tag{27.2.16}$$

$$:\tilde{r}(-\boldsymbol{\alpha}): q^r p^s = (\sqrt{2}) r q^{r-1} p^{s+1}. \tag{27.2.17}$$

Evidently any monomial of a given degree can be transformed into any other monomial of the same degree with the aid of $\tilde{r}(\pm\boldsymbol{\alpha})$. Therefore $sp(2)$ acts *irreducibly* on $\mathcal{P}_n$. Also q^n is the vector of highest weight in $\mathcal{P}_n$, and has the weight $n\boldsymbol{\phi}^1$,

$$:\tilde{c}^1: q^n = nq^n = (\boldsymbol{e}^1 \cdot n\boldsymbol{\phi}^1) q^n. \tag{27.2.18}$$

We conclude that $\mathcal{P}_n$ carries the representation $\Gamma(n)$. From (7.3.36) and (2.4) we find the result

$$\dim \mathcal{P}_n = N(n,2) = n+1 = \dim \Gamma(n). \tag{27.2.19}$$

The equality of $\dim \mathcal{P}_n$ and $\dim \Gamma(n)$ is to be expected from the fact that $sp(2)$ acts irreducibly on $\mathcal{P}_n$. It can be shown that $\Gamma(n)$ is self conjugate,

$$\overline{\Gamma}(n) = \Gamma(n). \tag{27.2.20}$$

See Exercise 3.7.36.

Let $\mathcal{A}(\pi/8)$ act on both sides of (2.15) through (2.17). Then, for the left side of (2.15), we find the result

$$\begin{aligned} \mathcal{A}(\pi/8): \tilde{c}^1 : q^r p^s &= \mathcal{A}(\pi/8)[\tilde{c}^1, q^r p^s] = [\mathcal{A}(\pi/8)\tilde{c}^1, \mathcal{A}(\pi/8) q^r p^s] \\ &= [c^1, \mathcal{A}(\pi/8) q^r p^s] =: c^1 : (1/\sqrt{2})^{r+s} (i)^s (q+ip)^r (q-ip)^s. \end{aligned} \tag{27.2.21}$$

For the right side we find

$$\mathcal{A}(\pi/8)(r-s) q^r p^s = (r-s)(1/\sqrt{2})^{r+s} (i)^s (q+ip)^r (q-ip)^s. \tag{27.2.22}$$

Therefore, after cancellation of common terms, (2.15) is transformed under the action of $\mathcal{A}(\pi/8)$ to the relation

$$:(p^2+q^2)/2: (q+ip)^r (q-ip)^s = i(r-s)(q+ip)^r (q-ip)^s. \tag{27.2.23}$$

Similary, (2.16) and (2.17) are transformed to the relations

$$:(q+ip)^2: (q+ip)^r (q-ip)^s = -4is(q+ip)^{r+1}(q-ip)^{s-1}, \tag{27.2.24}$$

$$:(q-ip)^2: (q+ip)^r (q-ip)^s = 4ir(q+ip)^{r-1}(q-ip)^{s+1}. \tag{27.2.25}$$

The monomials $q^r p^s$ (with $r+s=n$) obviously form a basis for $\mathcal{P}_n$. The relations (2.9) through (2.11) show that the complex polynomials $(q+ip)^r(q-ip)^s$ also form a basis for $\mathcal{P}_n$ and, with the factors $(1/\sqrt{2})^n(i^s)$, the two bases are related by the symplectic and unitary transformations $\mathcal{A}(\pm\pi/8)$. According to (2.23) the polynomials $(q+ip)^r(q-ip)^s$ are eigenfunctions of the harmonic oscillator Lie operator $:(p^2+q^2)/2:$. For this reason, they will be referred to as the *resonance* basis. The utility of the resonance basis will become clear in Chapter 23. Since it is made from Cartesian components, the monomial basis $q^r p^s$ will be referred to as the *Cartesian* basis.

Exercises

27.2.1. The Lie algebras for $su(2)$ and $sp(2)$ are equivalent over the complex field. Yet, for purposes of observing how $u(n)$ is embedded within $sp(2n)$, it is convenient to give $su(2)$ and $sp(2)$ different root vector structures. Specifically, for $su(2)$ we define two root vectors $\pm\boldsymbol{\alpha}$ by the rules

$$\pm\,\boldsymbol{\alpha} = \pm\sqrt{2}\boldsymbol{e}^1. \tag{27.2.26}$$

(Observe they have length $\sqrt{2}$). Then the $su(2)$ Lie algebra is spanned by the elements c^1, $r(\boldsymbol{\alpha})$, and $r(-\boldsymbol{\alpha})$; and the Cartan rules (1.13) and (1.14) give the results

$$[c^1, r(\pm\boldsymbol{\alpha})] = \{\boldsymbol{e}^1\cdot(\pm\boldsymbol{\alpha})\}r(\pm\boldsymbol{\alpha}) = \pm\sqrt{2}r(\pm\boldsymbol{\alpha}), \tag{27.2.27}$$

$$[r(\boldsymbol{\alpha}), r(-\boldsymbol{\alpha})] = (\boldsymbol{e}^1\cdot\boldsymbol{\alpha})c^1 = \sqrt{2}c^1. \tag{27.2.28}$$

Consider the $su(2)$ within $sp(4)$ as described in Section 5.7. Upon making the identifications $c \leftrightarrow c^1$ and $r(\pm) \leftrightarrow r(\pm\boldsymbol{\alpha})$, verify that the rules (5.7.10) and (5.7.11) are identical to (2.27) and (2.28). Show that C^1 and $R(\pm\boldsymbol{\alpha})$ as given by (5.8.8) and (5.8.11) satisfy analogous commutation rules, and therefore describe one of the $su(2)$ subgroups within $su(3)$. Show that there are two other $su(2)$ subgroups within $su(3)$ corresponding to the use of $R(\pm\boldsymbol{\beta})$ and $R(\pm\boldsymbol{\gamma})$ and suitable linear combinations of the C^j. Note that all the $su(3)$ root vectors in Figure 5.8.1 have length $\sqrt{2}$. With regard to representations of $su(2)$, call them $\Gamma(n)$, show that there is one such for each n value with $n = 0, 1, 2, \cdots$. Show that the highest weight for $\Gamma(n)$ is given by

$$\boldsymbol{w}^h = n\boldsymbol{\phi}^1 \tag{27.2.29}$$

with

$$\boldsymbol{\phi}^1 = (1/\sqrt{2})\boldsymbol{e}^1. \tag{27.2.30}$$

Draw $su(2)$ weight diagrams for the first few representations. Verify that they are similar to those for $sp(2)$, see Figure 2.2, except that the spacing between dots is $\sqrt{2}$ rather than 2. Examine the weight diagrams for $su(3)$ as shown in Figures 5.8.3 through 5.8.8. Show that the spacing between the dots in the directions of the $su(3)$ root vectors is $\sqrt{2}$. These dots describe $su(2)$ representations within $su(3)$.

27.2.2. For a $2n$-dimensional phase space, let $\mathcal{A}(\pi/8)$ be the map defined by the equation

$$\mathcal{A}(\pi/8) = \exp[-i(\pi/8) : (p_1^2 - q_1^2) + (p_2^2 - q_2^2) + \cdots + (p_n^2 - q_n^2) :]. \tag{27.2.31}$$

Show that $\mathcal{A}(\pi/8)$ has the property

$$\mathcal{A}(\pi/8)z_a = \sum_b W_{ab}z_b \tag{27.2.32}$$

where W is the matrix given by (3.9.9).

27.2.3. For first-order polynomials, and in analogy with (2.9) and (2.10), introduce the basis elements $a^\pm$ defined by the relations

$$a^+ = (1/\sqrt{2})(p + iq) = \mathcal{A}(\pi/8)p, \tag{27.2.33}$$

$$a^- = (1/\sqrt{2})(p - iq) = -i\mathcal{A}(\pi/8)q. \tag{27.2.34}$$

Show that these elements satisfy the Poisson bracket relations

$$[a^+, a^-] = \mathcal{A}(\pi/8)[p, -iq] = i. \tag{27.2.35}$$

Let H be the harmonic oscillator Hamiltonian

$$H = (\omega/2)(p^2 + q^2). \tag{27.2.36}$$

Show that H can be written in the form

$$H = \omega a^+ a^-. \tag{27.2.37}$$

Use (2.35) to verify the equations of motion

$$\dot{a}^\pm = [a^\pm, H] = \omega[a^\pm, a^+ a^-] = \pm i\omega a^\pm. \tag{27.2.38}$$

Show that they have the solution

$$a^\pm(t) = a^\pm(0)\exp(\pm i\omega t). \tag{27.2.39}$$

From this result, find $q(t)$ and $p(t)$.

27.3 Symplectic Classification of Analytic Vector Fields in Two Variables

Let $\mathcal{L}_{\boldsymbol{f}}$ be a general vector field in two variables z_1 and z_2 where $\boldsymbol{f}$ denotes the collection of 2 functions (f_1, f_2) as in Section 5.3. (The functions f_1 and f_2 may also depend on the time t, but for simplicity we will suppress this possible dependence in our notation because t only plays the role of a parameter.) Assume that f_1 and f_2 are analytic at some common point z_1^0, z_2^0. Without loss of generality we may take this point to be the origin. (If not, make a linear change of variables that sends z_1^0, z_2^0 to the origin.) Then we may decompose the Taylor expansions of the components of $\boldsymbol{f}$ into sums of homogeneous polynomials and, in so doing, decompose $\mathcal{L}_{\boldsymbol{f}}$ into a sum of vector fields of the form $\mathcal{L}_{\boldsymbol{f}^n}$ where the components of $\boldsymbol{f}^n$ are homogeneous polynomials of degree n:

$$\mathcal{L}_{\boldsymbol{f}} = \sum_{n=0}^{\infty} \mathcal{L}_{\boldsymbol{f}^n}. \tag{27.3.1}$$

The homogeneous vector fields $\mathcal{L}_{\boldsymbol{f}^n}$ can now be considered individually.

Let Σ denote the vector field

$$\Sigma = \sum_a z_a(\partial/\partial z_a) = z_1(\partial/\partial z_1) + z_2(\partial/\partial z_2) = q(\partial/\partial q) + p(\partial/\partial p). \tag{27.3.2}$$

Then, by Euler's relation, we have the result

$$\#\Sigma\#\mathcal{L}_{\boldsymbol{f}^n} = \{\Sigma, \mathcal{L}_{\boldsymbol{f}^n}\} = (n-1)\mathcal{L}_{\boldsymbol{f}^n}. \tag{27.3.3}$$

See Exercises 1.5.1 and 7.6.7. (Remark: Sometimes Σ is called the *Euler* field because of its connection with the Euler relation.) We will say that $\mathcal{L}_{\boldsymbol{f}^n}$ is homogeneous of degree $(n-1)$. In view of (5.3.3) and (5.3.17), in the special case of a Hamiltonian vector field $: f_n :$ there is the result

$$\#\Sigma\# : f_n := \{\Sigma, : f_n :\} = (n-2) : f_n : . \tag{27.3.4}$$

Thus, the vector field $: f_n :$ is homogeneous of degree $(n-2)$. Finally it is easily verified that there is a grading relation of the form

$$\{\mathcal{L}_{\boldsymbol{f}^\ell}, \mathcal{L}_{\boldsymbol{g}^m}\} = \mathcal{L}_{\boldsymbol{h}^n} \text{ with } n = \ell + m - 1. \tag{27.3.5}$$

Let f_2 be a quadratic polynomial in q, p. Then, using (3.5), we have the relation

$$\#f_2\#\mathcal{L}_{\boldsymbol{g}^m} = \{: f_2 :, \mathcal{L}_{\boldsymbol{g}^m}\} = \mathcal{L}_{\boldsymbol{h}^m}. \tag{27.3.6}$$

We draw the important conclusion that the set of homogeneous vector fields $\mathcal{L}_{\boldsymbol{g}^m}$ transforms under and forms a representation of $sp(2, \mathbb{R})$.

What irreducible representations occur? Consider first the case of Hamiltonian vector fields. In this case

$$\#f_2\# : g_m := \{: f_2 :, : g_m :\} =: [f_2, g_m] :=: (: f_2 : g_m) : . \tag{27.3.7}$$

It follows from the previous section that the Hamiltonian vector fields $: g_m :$ are transformed into each other under the action of $sp(2, \mathbb{R})$ and carry the irreducible representation $\Gamma(m)$.

What about general vector fields? Note that

$$: q := \partial/\partial p \;\text{ and }\; : p := -\partial/\partial q. \tag{27.3.8}$$

It follows that any $\mathcal{L}_{\boldsymbol{g}^0}$ is a Hamiltonian vector field, and these fields carry the representation $\Gamma(1)$. Next consider the vector fields $\mathcal{L}_{\boldsymbol{g}^1}$. They evidently form a 4-dimensional space spanned by the vector fields $z_a(\partial/\partial z_b)$ with $a = 1, 2$ and $b = 1, 2$.[1] We know that any $: h_2 :$ is such a vector field, and that these vector fields carry the representation $\Gamma(2)$, which is 3 dimensional. Also, Σ is of the form $\mathcal{L}_{\boldsymbol{g}^1}$. From (3.4) we conclude that

$$\#f_2\#\Sigma = \{: f_2 :, \Sigma\} = -\{\Sigma, : f_2 :\} = -\#\Sigma\# : f_2 := 0. \tag{27.3.9}$$

Consequently, Σ carries the representation $\Gamma(0)$. It follows that any $\mathcal{L}_{\boldsymbol{g}^1}$ can be written *uniquely* in the form

$$\begin{aligned} \mathcal{L}_{\boldsymbol{g}^1} &= \lambda_1 : q^2 : +\lambda_2 : qp : +\lambda_3 : p^2 : +\lambda_4\Sigma =: \lambda_1 q^2 + \lambda_2 qp + \lambda_3 p^2 : +\lambda_4\Sigma \\ &= : h_2 : +\lambda_4\Sigma. \end{aligned} \tag{27.3.10}$$

[1] Let $z_1, z_2, \cdots z_m$ be m variables. Consider the m^2 vector fields $z_a(\partial/\partial z_b)$. They can be shown to form a basis for the Lie algebra $g\ell(m)$. See Exercise 10.8.

The term $: h_2 :$ is a member of the representation $\Gamma(2)$, and the term $\lambda_4\Sigma$ belongs to $\Gamma(0)$. That is, the vector fields $\mathcal{L}_{\boldsymbol{g}^1}$ carry as a direct sum the representations $\Gamma(2)$ and $\Gamma(0)$. Note that

$$\dim \mathcal{L}_{\boldsymbol{g}^1} = 4 = 3 + 1 = \dim \Gamma(2) + \dim \Gamma(0), \tag{27.3.11}$$

as required.

With this background in mind, let us consider the general case $\mathcal{L}_{\boldsymbol{g}^m}$ with $m \geq 1$. Any such vector field can be written in the form

$$\mathcal{L}_{\boldsymbol{g}^m} = \sum_{a=1}^{2} g_a^m (\partial/\partial z_a) \tag{27.3.12}$$

where g_1^m and g_2^m denote two homogeneous polynomials of degree m. We have just learned that the $(\partial/\partial z_a)$ carry the representation $\Gamma(1)$, and we know from the previous section that the g_a^m carry the representation $\Gamma(m)$. It follows from the derivation property of $\#f_2\#$ that $\mathcal{L}_{\boldsymbol{g}^m}$ must carry the direct product representation $\Gamma(m) \otimes \Gamma(1)$. See Exercise 3.2. Also, in the case of $sp(2)$, we have the Clebsch-Gordan series result

$$\Gamma(m) \otimes \Gamma(1) = \Gamma(m+1) \oplus \Gamma(m-1). \tag{27.3.13}$$

This is just the $sp(2)$ analog of the familiar statement that spin $m/2$ and spin $1/2$ combine to make spin $(m+1)/2$ and spin $(m-1)/2$. Recall (5.8.33) and remember that for the purposes of the present section and previous section we have made the definition $n = 2j$.

It follows that any $\mathcal{L}_{\boldsymbol{g}^m}$ with $m \geq 1$ has the unique decomposition

$$\mathcal{L}_{\boldsymbol{g}^m} =: h_{m+1} : + \mathcal{G}^{m-1}. \tag{27.3.14}$$

Here h_{m+1} is a unique homogeneous polynomial of degree $m+1$ that is a member of the representation $\Gamma(m+1)$ and $\mathcal{G}^{m-1}$ is a unique vector field homogeneous of degree $(m-1)$ that is a member of the representation $\Gamma(m-1)$. Let us introduce the notation

$$\mathcal{H}^{m+1} =: h_{m+1} : \tag{27.3.15}$$

to denote a Hamiltonian vector field that carries the representation $\Gamma(m+1)$. Then (3.13) can be written in the form

$$\mathcal{L}_{\boldsymbol{g}^m} = \mathcal{H}^{m+1} + \ \mathcal{G}^{m-1}. \tag{27.3.16}$$

We *define* $\mathcal{G}^{m-1}$ to be the *non-Hamiltonian* part of $\mathcal{L}_{\boldsymbol{g}^m}$. What we have learned is that any homogeneous polynomial vector field in two variables can be uniquely decomposed into a Hamiltonian and a non-Hamiltonian part. We will learn subsequently that this result holds in any (even) number of variables.

In the case of two variables there is an additional step that can be made. Consider any vector field of the form $f_{m-1}\Sigma$. In view of (3.9) this vector field is a member of the representation $\Gamma(m-1)$. Thus, in the case of two variables we may write

$$\mathcal{L}_{\boldsymbol{g}^m} = : h_{m+1} : + f_{m-1}\Sigma \tag{27.3.17}$$

where both h_{m+1} and f_{m-1} are uniquely determined.

As a simple, but instructive, example of the decomposition just described, consider the case of the damped harmonic oscillator described by the equation of motion

$$\ddot{q} + 2\beta\dot{q} + q = 0. \tag{27.3.18}$$

This equation can be rewritten in the first-order form

$$\dot{q} = p, \tag{27.3.19}$$

$$\dot{p} = -(q + 2\beta p). \tag{27.3.20}$$

These equations can next be expressed in the Lie form

$$\dot{q} = \mathcal{L}q,\ \dot{p} = \mathcal{L}p \tag{27.3.21}$$

where $\mathcal{L}$ is the vector field

$$\mathcal{L} = p(\partial/\partial q) - (q + 2\beta p)(\partial/\partial p). \tag{27.3.22}$$

Evidently $\mathcal{L}$ is of the form (3.10). By comparing coefficients we find the decomposition

$$\mathcal{L} = : -(p^2 + 2\beta pq + q^2)/2 : -\beta\Sigma. \tag{27.3.23}$$

It is easily verified that the Hamiltonian $(p^2+2\beta pq+q^2)/2$ produces simple harmonic motion with a frequency ω_1 given by the relation

$$\omega_1^2 = 1 - \beta^2. \tag{27.3.24}$$

Also, in this case, the vector fields $\mathcal{H}^2$ and $\mathcal{G}^0$ commute. Since the vector field $-\beta\Sigma$ produces exponential decay, it follows that the general solution to (3.18) is of the form

$$q = Ae^{-\beta t}\sin(\omega_1 t + \phi). \tag{27.3.25}$$

What we have learned is that damping contributes both a non-Hamiltonian and a Hamiltonian part to the vector field. The non-Hamiltonian part produces exponential decay, and the Hamiltonian part shifts the frequency. For further detail, see Exercises 3.7 through 3.10.

Exercises

27.3.1. A Lie algebra is called *simple* if it has no invariant subalgebras (ideals). See Section 8.9. Show that the Lie algebra $su(2)$, and hence also $sp(2)$ and $so(3)$, is simple. Show that $su(3)$ is simple. What are the ranks of $sp(2)$, $so(3)$, $su(2)$, and $su(3)$? See Section 5.8.

27.3.2. Show that $\#f_2\#$ has the derivation property

$$\#f_2\# \sum_a g_a(\partial/\partial z_a) = \sum_a (: f_2 : g_a)(\partial/\partial z_a) + \sum_a g_a\#f_2\#(\partial/\partial z_a). \tag{27.3.26}$$

27.3.3. Compare the dimensions of both sides of (3.13).

27.3.4. Use (5.3.26), and the discussion surrounding it, as well as (3.16) and (3.17) to show that $\mathcal{G}^{m-1}$ is non-Hamiltonian.

27.3.5. Show that Σ can be written in the form

$$\Sigma = -\sum_{a,b} z_a J_{ab} : z_b : . \tag{27.3.27}$$

We know that both the z_a and the $: z_b :$ transform according to $\Gamma(1)$. But Σ carries the representation $\Gamma(0)$. It follows that the numbers J_{ab} are the Clebsch-Gordan *coefficients* that couple $\Gamma(1) \otimes \Gamma(1)'$ down to $\Gamma(0)$.

27.3.6. Consider the vector $\mathcal{L}_{\boldsymbol{g}^2}$ given by

$$\mathcal{L}_{\boldsymbol{g}^2} = q^2(\partial/\partial q). \tag{27.3.28}$$

Find h_3 and f_1 as in (3.15) for this vector field.

27.3.7. Verify (3.18) through (3.23). Verify that the vector field $-\beta\Sigma$ produces exponential decay,

$$e^{-t\beta\Sigma} q = e^{-\beta t} q, \tag{27.3.29}$$

$$e^{-t\beta\Sigma} p = e^{-\beta t} p. \tag{27.3.30}$$

For the Hamiltonian

$$H = (p^2 + 2\beta pq + q^2)/2 \tag{27.3.31}$$

make the transformation of variables

$$q = \frac{1}{\sqrt{2}}(Q - P), \tag{27.3.32}$$

$$p = \frac{1}{\sqrt{2}}(Q + P). \tag{27.3.33}$$

Verify that this transformation is symplectic, and hence H is transformed to H' with

$$H' = (1/2)[(1-\beta)P^2 + (1+\beta)Q^2]. \tag{27.3.34}$$

Also, show that Σ is unchanged by this transformation,

$$q(\partial/\partial q) + p(\partial/\partial p) = Q(\partial/\partial Q) + P(\partial/\partial P). \tag{27.3.35}$$

Next make a second transformation of variables,

$$Q = [(1-\beta)/(1+\beta)]^{1/4}\overline{q}. \tag{27.3.36}$$

$$P = [(1+\beta)/(1-\beta)]^{1/4}\overline{p}. \tag{27.3.37}$$

Verify that this transformation is also symplectic, and hence H' is transformed to H'' with

$$H'' = (1/2)(1-\beta^2)^{1/2}(\overline{p}^2 + \overline{q}^2) = (\omega_1/2)(\overline{p}^2 + \overline{q}^2). \tag{27.3.38}$$

Again show that Σ is unchanged,

$$Q(\partial/\partial Q) + P(\partial/\partial P) = \overline{q}(\partial/\partial\overline{q}) + \overline{p}(\partial/\partial\overline{p}). \tag{27.3.39}$$

(This is the *second* time that Σ is unchanged. Why must this be? See Exercise 9.4.) Evidently, in accord with previous claims, H'' produces simple harmonic motion with frequency ω_1. And, since Σ is unchanged, the new variables still exhibit the same exponential decay as that in (3.29) and (3.30).

27.3.8. The oscillator described by (3.18) is underdamped when $\beta < 1$, critically damped when $\beta = 1$, and overdamped when $\beta > 1$. Exercise 3.6 deals with the underdamped case. Carry out a smiliar analysis for the critically and overdamped cases. Hint: For the overdamped case, H' as given by (3.34) produces *hyperbolic* motion. In this case, make the transformation of variables

$$Q = [(\beta - 1)/(\beta + 1)]^{1/4}\overline{q}, \tag{27.3.40}$$

$$P = [(\beta + 1)/(\beta - 1)]^{1/4}\overline{p}. \tag{27.3.41}$$

Verify that this transformation is symplectic and hence H' is transformed to H'' with

$$H'' = (1/2)(\beta^2 - 1)^{1/2}(-\overline{p}^2 + \overline{q}^2). \tag{27.3.42}$$

Show that H'' produces growth that goes like $\exp[t(\beta^2 - 1)^{1/2}]$ as well as decay that goes as $\exp[-t(\beta^2 - 1)^{1/2}]$. For large β the growth rate of the growing term is almost as large as the decay rate in (3.29) and (3.30). They therefore nearly cancel. The net and well know result is that it takes a very long time for a highly overdamped oscillator to come to rest.

27.3.9. Find a pair of differential equations of the form

$$\dot{\overline{q}} = \cdots ,$$

$$\dot{\overline{p}} = \cdots ,$$

by expressing q, p in terms of $\overline{q}, \overline{p}$ with the aid of (3.32) through (3.37) and using (3.19) and (3.20). Find the vector field for these differential equations and decompose it into Hamiltonian and non-Hamiltonian parts. Solve the differential equations.

27.3.10. Show that H as given by (3.31) and $\mathcal{L}$ as given by (3.23) have the property

$$\mathcal{L}H = -\beta\Sigma H = -2\beta H. \tag{27.3.43}$$

Therefore, H must evolve according to the *nonoscillatory* rule

$$H = \text{ (constant) } \times e^{-2\beta t}. \tag{27.3.44}$$

Verify directly from (3.19) and (3.25) that (3.44) is, in fact, correct.

27.3.11. Let G be the function

$$G = az_1^2 + bz_1z_2 + cz_2^2 = aq^2 + bqp + cp^2. \tag{27.3.45}$$

Find the associated gradient vector field $\mathcal{L}_G$. See Exercise 5.3.7. Decompose $\mathcal{L}_G$ into Hamiltonian and non-Hamiltonian parts. Find G such that

$$\mathcal{L}_G = \Sigma. \tag{27.3.46}$$

Can a gradient vector field ever also be a Hamiltonian vector field?

27.3.12. The Van der Pol oscillator is described by the differential equation

$$\ddot{q} - 2\lambda(1 - q^2)\dot{q} + q = 0 \tag{27.3.47}$$

with $\lambda > 0$. Upon making the definition $p = \dot{q}$, show that (3.47) is produced by the vector field

$$\mathcal{L} = p(\partial/\partial q) - (q - 2\lambda p)(\partial/\partial p) - 2\lambda q^2 p(\partial/\partial p). \tag{27.3.48}$$

Evidently $\mathcal{L}$ has the homogeneous decomposition

$$\mathcal{L} = \mathcal{L}_{\boldsymbol{g}^1} + \mathcal{L}_{\boldsymbol{g}^3} \tag{27.3.49}$$

where

$$\mathcal{L}_{\boldsymbol{g}^1} = p(\partial/\partial q) - (q - 2\lambda p)(\partial/\partial p), \tag{27.3.50}$$

$$\mathcal{L}_{\boldsymbol{g}^3} = -2\lambda q^2 p(\partial/\partial p). \tag{27.3.51}$$

Verify that these homogeneous vector fields in turn have the decompositions

$$\mathcal{L}_{\boldsymbol{g}^1} =: h_2 : + \mathcal{G}^0 \tag{27.3.52}$$

with

$$h_2 = -(p^2 - 2\lambda pq + q^2)/2, \tag{27.3.53}$$

$$\mathcal{G}^0 = \lambda[q(\partial/\partial q) + p(\partial/\partial p)] = \lambda\Sigma; \tag{27.3.54}$$

$$\mathcal{L}_{\boldsymbol{g}^3} =: h_4 : + \mathcal{G}^2, \tag{27.3.55}$$

with

$$h_4 = -(\lambda/2)q^3 p, \tag{27.3.56}$$

$$\mathcal{G}^2 = -(\lambda/2)q^2\Sigma. \tag{27.3.57}$$

Show from (3.54) that the solution $q = 0$ is unstable for $\lambda > 0$. Argue that for small λ the solutions to (3.47) should be nearly those for a simple harmonic oscillator, i.e., any circle in q, p phase space. Show from energy considerations that for small λ the Van der Pol oscillator should have a limit cycle that is nearly a circle in phase space (about the origin) of radius 2, which is indeed the case. Observe that

$$\mathcal{G}^0 + \mathcal{G}^2 = \lambda(1 - q^2/2)\Sigma. \tag{27.3.58}$$

Show that for a solution of the form $q = A\sin(t + \phi)$ there is the relation

$$\langle(1 - q^2/2)\rangle = 1 - A^2/4 \tag{27.3.59}$$

where $\langle\ \rangle$ denotes time averaging. Show that there is the general operator relation

$$\{: f_2 :, (\mathcal{G}^0 + \mathcal{G}^2)\} = \lambda[: f_2 : (1 - q^2/2)]\Sigma. \tag{27.3.60}$$

By considering an operator of the form

$$\exp(-t : f_2 :)(\mathcal{G}^0 + \mathcal{G}^2)\exp(t : f_2 :), \tag{27.3.61}$$

use (3.60) to find the relation

$$\langle\mathcal{G}^0 + \mathcal{G}^2\rangle = \lambda\langle(1 - q^2/2)\rangle\Sigma. \tag{27.3.62}$$

Thus, on the limit cycle, the growth/damping due to $(\mathcal{G}^0 + \mathcal{G}^2)$ averages to zero. Consider what appears to be a generalization of the Van der Pol oscillator described by the equation

$$\ddot{q} - 2\lambda\dot{q} + 2\tau q^2\dot{q} + q = 0 \tag{27.3.63}$$

where λ and τ are positive. Verify that (3.63) can be brought to the form (3.47) by a suitable scaling of q. Verify, for small λ and τ, that (3.63) has a nearly circular limit cycle in phase space whose radius is given by the relation

$$A = 2\sqrt{(\lambda/\tau)}. \tag{27.3.64}$$

27.3.13. Suppose that f is an analytic function of the complex variable $z = x + iy$, and write the relations

$$w = f(z) \tag{27.3.65}$$

and

$$w = u(x, y) + iv(x, y). \tag{27.3.66}$$

Then, because f is assumed analytic, u and v satisfy the Cauchy-Riemann equations

$$\partial u/\partial x = \partial v/\partial y, \tag{27.3.67}$$

$$\partial u/\partial y = -\partial v/\partial x. \tag{27.3.68}$$

In terms of the phase-space variables $\{q, p\}$, consider the differential form

$$v(q, p)dq + u(q, p)dp. \tag{27.3.69}$$

According to Exercise 6.4.6, this form will be exact if there is the relation

$$\partial v/\partial p = \partial u/\partial q. \tag{27.3.70}$$

From the Cauchy-Riemann equation (3.67) we see that the relation (3.70) is in fact true, and therefore there is a function H such that

$$u(q, p) = \partial H/\partial p, \tag{27.3.71}$$

$$v(q,p) = \partial H/\partial q. \tag{27.3.72}$$

We know that any Hamiltonian gives rise to the Hamiltonian vector field $: -H :$ given by the rule

$$: -H := (\partial H/\partial p)(\partial/\partial q) - (\partial H/\partial q)(\partial/\partial p). \tag{27.3.73}$$

In view of (3.71) and (3.72), we also have the relation

$$: -H := u(q,p)(\partial/\partial q) - v(q,p)(\partial/\partial p). \tag{27.3.74}$$

Thus, any analytic function f gives rise to a Hamiltonian vector field.

Consider the differential form

$$u(q,p)dq - v(q,p)dp. \tag{27.3.75}$$

Show, using the second Cauchy-Riemann equation (3.68), that this form is also exact so that there is a function K such that

$$u(q,p) = \partial K/\partial q, \tag{27.3.76}$$

$$v(q,p) = -\partial K/\partial p. \tag{27.3.77}$$

Show that the Hamiltonian vector field $: -K :$ is given in terms of u and v by the relation

$$: -K := -v(q,p)(\partial/\partial q) - u(q,p)(\partial/\partial p). \tag{27.3.78}$$

Thus, any analytic function f also gives rise to a second Hamiltonian vector field. Show that (3.78) arises from (3.74) upon replacing f by if.

For the analytic function f given by

$$f(z) = z^2, \tag{27.3.79}$$

find the Hamiltonians H and K.

27.3.14. Review Exercise 3.13. For the analytic function f given by

$$f(z) = z^2, \tag{27.3.80}$$

consider the vector field $\mathcal{L}$ given by

$$\mathcal{L} = u(q,p)(\partial/\partial q) + v(q,p)(\partial/\partial p). \tag{27.3.81}$$

Verify that this vector field is not Hamiltonian, and decompose it into Hamiltonian and non-Hamiltonian parts. Make analogous calculations for the vector field $\mathcal{L}'$ given by

$$\mathcal{L}' = -v(q,p)(\partial/\partial q) + u(q,p)(\partial/\partial p). \tag{27.3.82}$$

27.3.15. Show that Duffing's equation (1.4.31) arises from the vector field $\mathcal{L} = \mathcal{L}_0 + \mathcal{L}_1 + \mathcal{L}_3$ where

$$\mathcal{L}_0 = (\epsilon \cos \omega\tau)(\partial/\partial p), \tag{27.3.83}$$

$$\mathcal{L}_1 = p(\partial/\partial q) - (q + 2\beta p)(\partial/\partial p), \tag{27.3.84}$$

$$\mathcal{L}_3 = -(q^3)(\partial/\partial p). \tag{27.3.85}$$

Verify that $\mathcal{L}_0$ and $\mathcal{L}_3$ are Hamiltonian,

$$\mathcal{L}_0 =: (\epsilon \cos \omega\tau) q :, \tag{27.3.86}$$

$$\mathcal{L}_3 = - : q^4/4 : . \tag{27.3.87}$$

Using (3.22) and (3.23), decompose $\mathcal{L}_1$ into Hamiltonian and non-Hamiltonian parts.

27.4 Structure of $sp(4,\mathbb{R})$

The Lie algebra $sp(4,\mathbb{R})$ is 10 dimensional, and its Cartan subalgebra is 2 dimensional. Therefore, in the Cartan basis, there should be 8 ladder operators. They are labelled by 8 two-component root vectors consisting of 4 vectors and their negatives. We will call these 4 vectors $\boldsymbol{\alpha}$, $\boldsymbol{\beta}$, $\boldsymbol{\gamma}$, and $\boldsymbol{\delta}$. They are given in terms of two orthogonal unit vectors $\boldsymbol{e}^1$ and $\boldsymbol{e}^2$ by the relations

$$\boldsymbol{\alpha} = 2\boldsymbol{e}^1, \tag{27.4.1}$$

$$\boldsymbol{\beta} = \boldsymbol{e}^1 + \boldsymbol{e}^2, \tag{27.4.2}$$

$$\boldsymbol{\gamma} = 2\boldsymbol{e}^2, \tag{27.4.3}$$

$$\boldsymbol{\delta} = -\boldsymbol{e}^1 + \boldsymbol{e}^2. \tag{27.4.4}$$

The eight $sp(4)$ root vectors (the vectors $\boldsymbol{\alpha}$, $\boldsymbol{\beta}$, $\boldsymbol{\gamma}$, $\boldsymbol{\delta}$ and their negatives) are shown in Figure 4.1. Note that all root vectors are of the form $(\pm\boldsymbol{e}^i \pm \boldsymbol{e}^j)$ with i, j and the signs taken independently and the zero vector omitted. Thus, there are basically two kinds of root vectors: *short* root vectors with length $\sqrt{2}$ and *long* root vectors with length 2. (And the angle between any two successive root vectors as one goes around the root diagram is 45 degrees.) They satisfy the normalization relations

$$\sum_{\boldsymbol{\mu}} (\boldsymbol{e}^i \cdot \boldsymbol{\mu})(\boldsymbol{\mu} \cdot \boldsymbol{e}^j) = 12\delta_{ij}. \tag{27.4.5}$$

Again see Section 5.8 for an analogous treatment of $su(3)$.

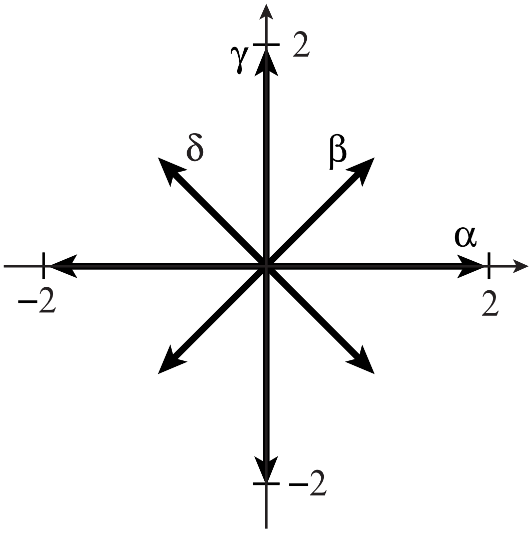

Figure 27.4.1: Root diagram showing the root vectors for $sp(4)$.

The Lie algebra $sp(4,\mathbb{R})$ is generated by the monomials $z_a z_b$ with a, b ranging from 1 to 4. See Section 5.7. For present purposes it is convenient to use as the basis for the Cartan subalgebra the polynomials

$$c^1 = -(i/2)(p_1^2 + q_1^2), \tag{27.4.6}$$

$$c^2 = -(i/2)(p_2^2 + q_2^2). \tag{27.4.7}$$

The Lie operators associated with c^1 and c^2 obviously commute. They are also Hermitian,

$$: c^j :^\dagger =: c^j : . \tag{27.4.8}$$

Finally, Lie transformations of the form

$$\begin{aligned}\mathcal{M}(\theta_1, \theta_2) &= \exp(-i\theta_1 : c^1 : -i\theta_2 : c^2 :) \\ &= \exp[-(\theta_1/2) : p_1^2 + q_1^2 : -(\theta_2/2) : p_2^2 + q_2^2 :]\end{aligned} \tag{27.4.9}$$

are real symplectic, unitary, and lie on a 2-torus which is a maximal torus in $Sp(4, \mathbb{R})$. See Sections 3.9, 5.9, and 7.2.

For the ladder operators in $sp(4)$ we use the polynomials

$$r(\pm\boldsymbol{\alpha}) = (\sqrt{2}/4)(q_1 \pm ip_1)^2, \tag{27.4.10}$$

$$r(\pm\boldsymbol{\beta}) = (1/2)(q_1 \pm ip_1)(q_2 \pm ip_2), \tag{27.4.11}$$

$$r(\pm\boldsymbol{\gamma}) = (\sqrt{2}/4)(q_2 \pm ip_2)^2, \tag{27.4.12}$$

$$r(\pm\boldsymbol{\delta}) = (i/2)(q_1 \mp ip_1)(q_2 \pm ip_2). \tag{27.4.13}$$

Their associated Lie operators obey the conjugation relations

$$: r(\boldsymbol{\mu}) :^\dagger =: r(-\boldsymbol{\mu}) : . \tag{27.4.14}$$

It is easily verified that the Cartan subalgebra and ladder operators satisfy the Poisson bracket rules

$$[c^j, c^k] = 0, \tag{27.4.15}$$

$$[c^j, r(\boldsymbol{\mu})] = (\boldsymbol{e}^j \cdot \boldsymbol{\mu}) r(\boldsymbol{\mu}), \tag{27.4.16}$$

$$[r(\boldsymbol{\mu}), r(-\boldsymbol{\mu})] = \sum_j (\boldsymbol{e}^j \cdot \boldsymbol{\mu}) c^j, \tag{27.4.17}$$

as desired. There are also the relations

$$[r(\boldsymbol{\mu}), r(\boldsymbol{\nu})] = N(\boldsymbol{\mu}, \boldsymbol{\nu}) r(\boldsymbol{\mu} + \boldsymbol{\nu}) \tag{27.4.18}$$

provided the sum $(\boldsymbol{\mu} + \boldsymbol{\nu})$ is again a root vector. All other brackets vanish. For the case of $sp(4)$, the $N(\boldsymbol{\mu}, \boldsymbol{\nu})$ have the values $\pm\sqrt{2}$. The positive N's are $N(\boldsymbol{\alpha}, \boldsymbol{\delta})$, $N(\boldsymbol{\beta}, \boldsymbol{\delta})$, $N(\boldsymbol{\beta}, -\boldsymbol{\delta})$, $N(\boldsymbol{\gamma}, -\boldsymbol{\delta})$, $N(\boldsymbol{\delta}, -\boldsymbol{\beta})$, $N(\boldsymbol{\delta}, -\boldsymbol{\gamma})$, $N(-\boldsymbol{\alpha}, \boldsymbol{\beta})$, $N(-\boldsymbol{\beta}, \boldsymbol{*})$, $N(-\boldsymbol{\beta}, *)$, $N(-\boldsymbol{\gamma}, *)$, $N(-\boldsymbol{\delta}, *)$, $N(-\boldsymbol{\delta}, *)$. We also note, as was true for sp(2), that for the scalar product (7.3.12) the basis elements c^j and $r(\boldsymbol{\mu})$ are orthonormal,

$$\langle c^j, c^j \rangle = \langle r(\boldsymbol{\mu}), r(\boldsymbol{\mu}) \rangle = 1, \tag{27.4.19}$$

$$\langle c^j, c^k \rangle = 0 \text{ for } j \neq k, \tag{27.4.20}$$

$$\langle c^j, r(\boldsymbol{\mu}) \rangle = 0, \tag{27.4.21}$$

$$\langle r(\boldsymbol{\mu}), r(\boldsymbol{\nu}) \rangle = 0 \text{ for } \boldsymbol{\mu} \neq \boldsymbol{\nu}. \tag{27.4.22}$$

At this point, we remark that it is tempting to assume that the rank of a Lie algebra equals the maximum number of mutually commuting elements. (Some texts even make this claim!) This need not be the case. For $sp(4)$, which has rank 2, it is evident that the 3 elements $:p_1^2:$, $:p_1p_2:$, and $:p_2^2:$ are mutually commuting. However, they are not Hermitian and, when exponentiated, do not even produce a torus (not to mention a maximal torus). Nor can other elements be found in the Lie algebra such that relations of the form (4.16) hold with the $:p_kp_\ell:$ playing the role of the c's. Instead, as will be evident in Section 27.5 [see (5.12), (5.14), and (5.16)], they are related by a symplectic unitary transformation to ladder operators. Therefore they do not meet the requirements to form a Cartan subalgebra.

We close this section by examining how $sp(2)$, $u(2)$, $su(2)$, and $so(2)$ reside within $sp(4)$. The presence of $sp(2)$ is evident. Comparison of Figures 1.1 and 4.1, and comparison of (1.1) and (4.10), shows that if we identify the coordinate pair q,p with the pair q_1,p_1, then the $r(\pm\boldsymbol{\alpha})$ for $sp(2)$ and $sp(4)$ agree. Also, the c^1 for $sp(2)$ given by (1.11) agrees with the c^1 given for $sp(4)$ by (4.6). We also note that there is a second $sp(2)$ within $sp(4)$ generated by $r(\pm\boldsymbol{\gamma})$ and c^2. It is identical to the $sp(2)$ of Section 27.1 if we identify the pair q,p with q_2,p_2. Thus, there is an $sp(2)$ within $sp(4)$ for each equal and opposite pair of *long* root vectors. (See also Exercise 5.5.) These root vectors have length 2 as is requred for an $sp(2)$ root vector. See Section 27.1.

The presence of $u(2)$ and $su(2)$ within $sp(4)$ is less evident. Comparison of (5.7.8) and (4.13) shows that there are the relations

$$r(\pm) = r(\mp\boldsymbol{\delta}). \tag{27.4.23}$$

Also, comparison of (5.7.4), (5.7.9) and (4.6), (4.7) gives the relations

$$b^0 = i(c^1 + c^2), \tag{27.4.24}$$

$$c = (1/\sqrt{2})(c^1 - c^2). \tag{27.4.25}$$

Thus, the $su(2)$ of Section 5.7 is associated with c and the $r(\mp\boldsymbol{\delta})$ root vectors of $sp(4)$, and also including b^0 yields $u(2)$. We also note that the spin 1 objects $h^\pm$ and h^0 of Section 5.7 given by (5.7.21) through (5.7.23) are proportional to the $sp(4)$ generators $r(\boldsymbol{\alpha})$, $r(\boldsymbol{\beta})$, and $r(\boldsymbol{\gamma})$ given by (4.10) through (4.12). Reference to Figure 4.1 shows that they should indeed transform among each other under the action of $r(\mp\boldsymbol{\delta})$ as given by (5.7.26) and (5.7.27). Moreover, we note that there is a second $su(2)$ [and a corresponding $u(2)$] within $sp(4)$ associated with the root vectors $r(\pm\boldsymbol{\beta})$. Thus, there is an $su(2)$ and a $u(2)$ within $sp(4)$ for each equal and opposite pair of *short* root vectors. These root vectors have length $\sqrt{2}$ as required for $su(2)$ root vectors. See Exercise 2.1.

Finally, there is an $so(2)$ subalgebra within $sp(4)$ whose presence is not at all obvious from looking at the $sp(4)$ root diagram. Let J_z be the quadratic polynomial defined by the equation

$$J_z = q_1p_2 - q_2p_1. \tag{27.4.26}$$

It generates rotations in the q_1,q_2 and p_1,p_2 planes:

$$\exp:\theta J_z:q_1 = q_1\cos\theta + q_2\sin\theta, \tag{27.4.27}$$

$$\exp:\theta J_z:q_2 = -q_1\sin\theta + q_2\cos\theta; \tag{27.4.28}$$

$$\exp : \theta J_z p_1 = p_1 \cos\theta + p_2 \sin\theta, \tag{27.4.29}$$

$$\exp : \theta J_z : p_2 = -p_1 \sin\theta + p_2 \cos\theta. \tag{27.4.30}$$

From (4.13) we see that it is related to elements in the Cartan basis by the equation

$$J_z = -[r(\boldsymbol{\delta}) - r(-\boldsymbol{\delta})]. \tag{27.4.31}$$

Exercises

27.4.1. Verify the Lie product rules (4.15) through (4.18).

27.4.2. Verify the relations (4.26) through (4.31). Show that J_z obeys the eigen relations

$$: J_z (q_1 \pm i q_2)^n = \mp i n (q_1 \pm i q_2)^n, \tag{27.4.32}$$

$$: J_z : (p_1 \pm i p_2)^n = \mp i n (p_1 \pm i p_2)^n. \tag{27.4.33}$$

27.4.3. Explore the properties of J_z' that is defined in analogy to J_z by the equation

$$J_z' = -[r(\boldsymbol{\beta}) - r(-\boldsymbol{\beta})]. \tag{27.4.34}$$

See Figure 4.1.

27.5 Representations of $sp(4, \mathbb{R})$

The description of representations of $sp(4)$ follows the general Cartan procedure as described for $su(3)$ in Section 5.8. For $sp(4)$, since it has rank 2, there are two fundamental weights $\boldsymbol{\phi}^1$ and $\boldsymbol{\phi}^2$. They are given by the relations

$$\boldsymbol{\phi}^1 = \boldsymbol{e}^1 = \boldsymbol{\alpha}/2, \tag{27.5.1}$$

$$\boldsymbol{\phi}^2 = \boldsymbol{e}^1 + \boldsymbol{e}^2 = \boldsymbol{\beta}, \tag{27.5.2}$$

and are shown in Figure 5.1 along with the $sp(4)$ root vectors. Thus, for $sp(4)$, every highest weight $\boldsymbol{w}^h$ is of the form

$$\boldsymbol{w}^h = m\boldsymbol{\phi}^1 + n\boldsymbol{\phi}^2 = (m+n)\boldsymbol{e}^1 + n\boldsymbol{e}^2, \tag{27.5.3}$$

where m and n are arbitrary nonnegative integers. Correspondingly, for each m, n pair, there is an irreducible representation $\Gamma(m,n)$ with highest weight $\boldsymbol{w}^h$ given by (5.3). It can be shown that the dimension of $\Gamma(m,n)$ is given by the relation

$$\dim \Gamma(m,n) = (1/6)(m+2n+3)(m+n+2)(m+1)(n+1). \tag{27.5.4}$$

See Exercise 5.1. It can also be shown that these representations are self conjugate,

$$\overline{\Gamma}(m,n) = \Gamma(m,n). \tag{27.5.5}$$

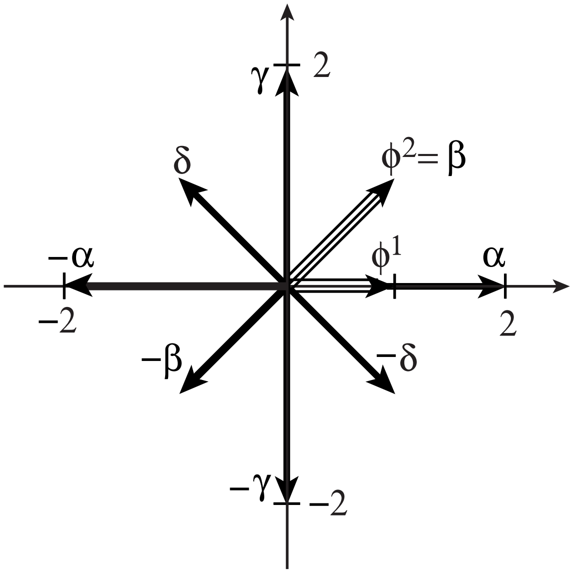

Figure 27.5.1: Fundamental weights $\boldsymbol{\phi}^1$ and $\boldsymbol{\phi}^2$ for $sp(4)$. The root vectors are also shown.

Table 27.5.1: Dimensions of Representations of $sp(4)$.

m	n	$\dim\Gamma(m,n)$	m	n	$\dim\Gamma(m,n)$
0	0	1	0	2	14
1	0	4	3	0	20
0	1	5	2	1	35
2	0	10	1	2	40
1	1	16	0	3	30

See Exercise 3.7.36. For quick reference the dimensions of the first few representations are listed in Table 5.1 above. Where there is no possibility of confusion, we will sometimes refer to a representation by its dimension.

From a knowledge of the root vectors and the highest weight it is a simple matter to construct weight diagrams for the low-dimensional representations. Figures 5.2 through 5.7 show weight diagrams for the first few representations. Inspection of these figures and reference to Table 5.1 shows that the weights must have unit multiplicities for the representations $\Gamma(0,0)$, $\Gamma(1,0)$, and $\Gamma(0,1)$. For $\Gamma(2,0)$, which is the adjoint or regular representation, the weight vector at the origin has multiplicity 2. The representation $\Gamma(1,0)$ corresponds to the representation of $sp(4)$ by 4×4 matrices of the form JS. See (5.7.27) of Section 5.7. It happens that the Lie algebras for $sp(4)$ and $so(5)$ are equivalent over the complex field. The $sp(4)$ representation $\Gamma(0,1)$, which is 5 dimensional, is related to the obvious 5×5 matrix representation of $so(5)$. See Exercise 5.4.

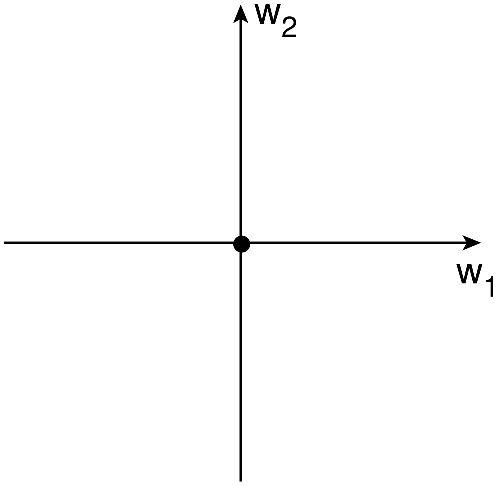

Figure 27.5.2: Weight diagram for the representation $1 = \Gamma(0,0)$.

Now, in mimicry of what was done before in Section 21.2, let $\mathcal{P}_m$ denote the set of polynomials homogeneous of degree m in the variables q_1, p_1, q_2, p_2; and let f_2 be a quadratic polynomial in these variables. Then we have the relation

$$: f_2 : \mathcal{P}_m \subseteq \mathcal{P}_m. \tag{27.5.6}$$

It follows that the set of homogeneous polynomials of degree m forms a representation of $sp(4,\mathbb{R})$.

What irreducible representations occur? The study of this question is again facilitated by a map $\mathcal{A}(\pi/8)$ defined this time by the equation

$$\mathcal{A}(\pi/8) = \exp[-i(\pi/8) : p_1^2 - q_1^2 + p_2^2 - q_2^2 :]. \tag{27.5.7}$$

As before, $\mathcal{A}$ is complex symplectic and unitary. Calculation gives the result

$$\begin{aligned}&\mathcal{A}(\pi/8)(q_1^{r_1}p_1^{s_1}q_2^{r_2}p_2^{s_2}) = \\ &(1/\sqrt{2})^{r_1+s_1+r_2+s_2}(i)^{s_1+s_2}(q_1+ip_1)^{r_1}(q_1-ip_1)^{s_1}(q_2+ip_2)^{r_2}(q_2-ip_2)^{s_2}.\end{aligned} \tag{27.5.8}$$

Evidently $\mathcal{A}(\pm\pi/8)$ again transforms between what we will again call the Cartesian and resonance bases.

With the aid of $\mathcal{A}$ we again define transformed Lie basis polynomials $\tilde{c}^j$ and $\tilde{r}(\boldsymbol{\mu})$ by the rule

$$\tilde{c}^1 = \mathcal{A}(-\pi/8)c^1 = -q_1p_1, \tag{27.5.9}$$

$$\tilde{c}^2 = \mathcal{A}(-\pi/8)c^2 = -q_2p_2, \tag{27.5.10}$$

$$\tilde{r}(\boldsymbol{\alpha}) = \mathcal{A}(-\pi/8)r(\boldsymbol{\alpha}) = (1/\sqrt{2})q_1^2, \tag{27.5.11}$$

$$\tilde{r}(-\boldsymbol{\alpha}) = \mathcal{A}(-\pi/8)r(-\boldsymbol{\alpha}) = -(1/\sqrt{2})p_1^2, \tag{27.5.12}$$

$$\tilde{r}(\boldsymbol{\beta}) = \mathcal{A}(-\pi/8)r(\boldsymbol{\beta}) = q_1q_2, \tag{27.5.13}$$

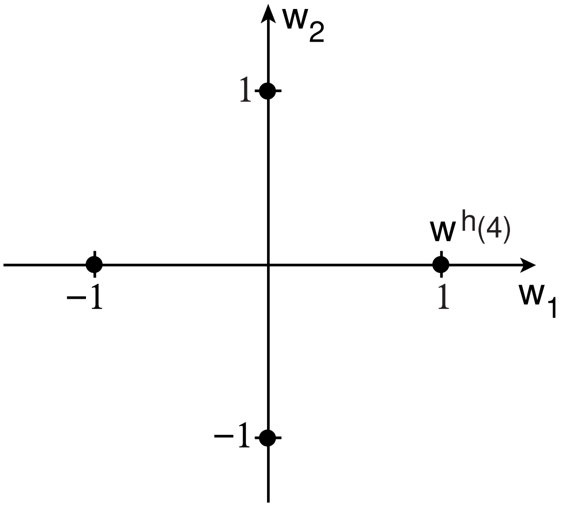

Figure 27.5.3: Weight diagram for the fundamental representation $4 = \Gamma(1,0)$.

$$\tilde{r}(-\boldsymbol{\beta}) = \mathcal{A}(-\pi/8)r(-\boldsymbol{\beta}) = -p_1p_2, \tag{27.5.14}$$

$$\tilde{r}(\boldsymbol{\gamma}) = \mathcal{A}(-\pi/8)r(\boldsymbol{\gamma}) = (1/\sqrt{2})q_2^2, \tag{27.5.15}$$

$$\tilde{r}(-\boldsymbol{\gamma}) = \mathcal{A}(-\pi/8)r(-\boldsymbol{\gamma}) = -(1/\sqrt{2})p_2^2, \tag{27.5.16}$$

$$\tilde{r}(\boldsymbol{\delta}) = \mathcal{A}(-\pi/8)r(\boldsymbol{\delta}) = p_1q_2, \tag{27.5.17}$$

$$\tilde{r}(-\boldsymbol{\delta}) = \mathcal{A}(-\pi/8)r(-\boldsymbol{\delta}) = p_2q_1. \tag{27.5.18}$$

Since $\mathcal{A}$ is symplectic, the transformed basis polynomials obey the same Poisson bracket rules (4.15) athrough (4.18). Since $\mathcal{A}$ is also unitary, the transformed basis polynomials also satisfy the orthonormality relations (4.19) through (4.22) and the conjugacy relations (4.8) and (4.14).

Now consider the actions of the Lie operators $:\tilde{c}^j:$ and $:\tilde{r}(\boldsymbol{\mu}):$ on the general monomials $q_1^{r_1}p_1^{s_1}q_2^{r_2}p_2^{s_2}$. Calculation gives the results

$$:\tilde{c}^1: q_1^{r_1}p_1^{s_1}q_2^{r_2}p_2^{s_2} = (r_1 - s_1)q_1^{r_1}p_1^{s_1}q_2^{r_2}p_2^{s_2}, \tag{27.5.19}$$

$$:\tilde{c}^2: q_1^{r_1}p_1^{s_1}q_2^{r_2}p_2^{s_2} = (r_2 - s_2)q_1^{r_1}p_1^{s_1}q_2^{r_2}p_2^{s_2}, \tag{27.5.20}$$

$$:\tilde{r}(\boldsymbol{\alpha}): q_1^{r_1}p_1^{s_1}q_2^{r_2}p_2^{s_2} = \sqrt{2}s_1q_1^{r_1+1}p_1^{s_1-1}q_2^{r_2}p_2^{s_2}, \tag{27.5.21}$$

$$:\tilde{r}(-\boldsymbol{\alpha}): q_1^{r_1}p_1^{s_1}q_2^{r_2}p_2^{s_2} = \sqrt{2}r_1q_1^{r_1-1}p_1^{s_1+1}q_2^{r_2}p_2^{s_2}, \tag{27.5.22}$$

$$:\tilde{r}(\boldsymbol{\beta}): q_1^{r_1}p_1^{s_1}q_2^{r_2}p_2^{s_2} = s_1q_1^{r_1}p_1^{s_1-1}q_2^{r_2+1}p_2^{s_2} + s_2q_1^{r_1+1}p_1^{s_1}q_2^{r_2}p_2^{s_2-1}, \tag{27.5.23}$$

$$:\tilde{r}(-\boldsymbol{\beta}): q_1^{r_1}p_1^{s_1}q_2^{r_2}p_2^{s_2} = r_1q_1^{r_1-1}p_1^{s_1}q_2^{s_2}p_2^{s_2+1} + r_2q_1^{r_1}p_1^{s_1+1}q_2^{r_2-1}p_2^{s_2}, \tag{27.5.24}$$

$$:\tilde{r}(\boldsymbol{\gamma}): q_1^{r_1}p_1^{s_1}q_2^{r_2}p_2^{s_2} = \sqrt{2}s_2q_1^{r_1}p_1^{s_1}q_2^{r_2+1}p_2^{s_2-1}, \tag{27.5.25}$$

$$:\tilde{r}(-\boldsymbol{\gamma}): q_1^{r_1}p_1^{s_1}q_2^{r_2}p_2^{s_2} = \sqrt{2}r_2q_1^{r_1}p_1^{s_1}q_2^{r_2-1}p_2^{s_2+1}, \tag{27.5.26}$$

$$:\tilde{r}(\boldsymbol{\delta}): q_1^{r_1}p_1^{s_1}q_2^{r_2}p_2^{s_2} = -r_1q_1^{r_1-1}p_1^{s_1}q_2^{r_2+1}p_2^{s_2} + s_2q_1^{r_1}p_1^{s_1+1}q_2^{r_2}p_2^{s_2-1}, \tag{27.5.27}$$

$$:\tilde{r}(-\boldsymbol{\delta}): q_1^{r_1}p_1^{s_1}q_2^{r_2}p_2^{s_2} = s_1q_1^{r_1}p_1^{s_1-1}q_2^{r_2}p_2^{s_2+1} - r_2q_1^{r_1+1}p_1^{s_1}q_2^{r_2-1}p_2^{s_2}. \tag{27.5.28}$$

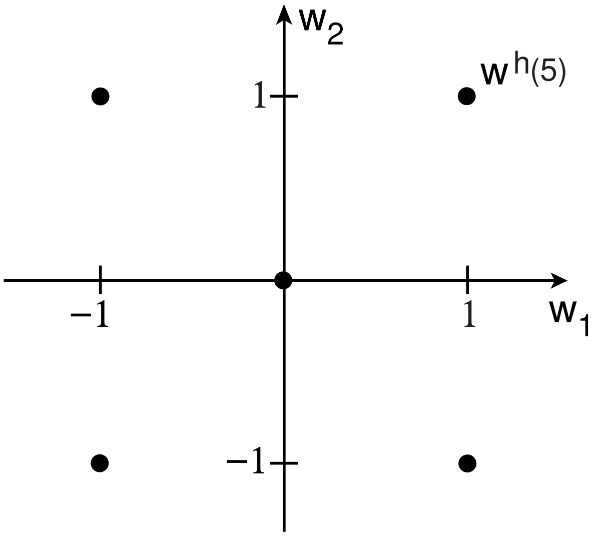

Figure 27.5.4: Weight diagram for the representation $5 = \Gamma(0, 1)$.

Evidently any monomial of a given degree can be transformed into any other monomial of the same degree with the aid of the $\tilde{r}(\boldsymbol{\mu})$. Therefore $sp(4)$ acts irreducibly on $\mathcal{P}_m$. Also, q_1^m is the vector of highest weight in $\mathcal{P}_m$, and has the weight $\boldsymbol{\omega}^h = m\boldsymbol{\phi}^1$,

$$: \tilde{c}^1 : q_1^m = mq_1^m = (\boldsymbol{e}^1 \cdot m\boldsymbol{\phi}^1)q_1^m, \tag{27.5.29}$$

$$: \tilde{c}^2 : q_1^m = 0 = (\boldsymbol{e}^2 \cdot m\boldsymbol{\phi}^1)q_1^m.$$

Upon examination of (5.3) we conclude that, in the case of 4 variables, $\mathcal{P}_m$ carries the representation $\Gamma(m, 0)$ of $sp(4)$. From (7.3.36) and (5.4) we find, as expected, the result

$$\dim \mathcal{P}_m = N(m, 4) = (1/6)(m + 3)(m + 2)(m + 1) = \dim \Gamma(m, 0). \tag{27.5.30}$$

Note that, unlike the case of 2 variables, the $\mathcal{P}_m$ for various m do not carry *all* the representations of $sp(4)$, but only the representations $\Gamma(m, 0)$.

As before, we can let $\mathcal{A}(\pi/8)$ act on both sides of (5.19) through (5.28). Doing so gives results analogous to those in (2.23) through (2.25). Consequently, as before, the $: c^j :$ and $: r(\boldsymbol{\mu}) :$ act on the resonance basis in the same way that the $: \tilde{c}^j :$ and $: \tilde{r}(\boldsymbol{\mu}) :$ act on the monomial basis.

Exercises

27.5.1. Weyl discovered that for the simple Lie algebras the dimension of a representation $\Gamma(\boldsymbol{w}^h)$ labeled by the highest weight $\boldsymbol{w}^h$ is given the formula

$$\dim \Gamma(\boldsymbol{w}^h) = \prod_{\boldsymbol{\mu}>0} [\boldsymbol{\mu} \cdot (\boldsymbol{w}^h + \boldsymbol{\mu}^+/2)]/[\boldsymbol{\mu} \cdot (\boldsymbol{\mu}^+/2)]. \tag{27.5.31}$$

Here the product is to be taken over all *positive* root vectors and $\boldsymbol{\mu}^+$ is the sum of all positive roots as in (12.49). [As was the case for weights (see Section 5.8), we define a root $\boldsymbol{\mu}$ to be

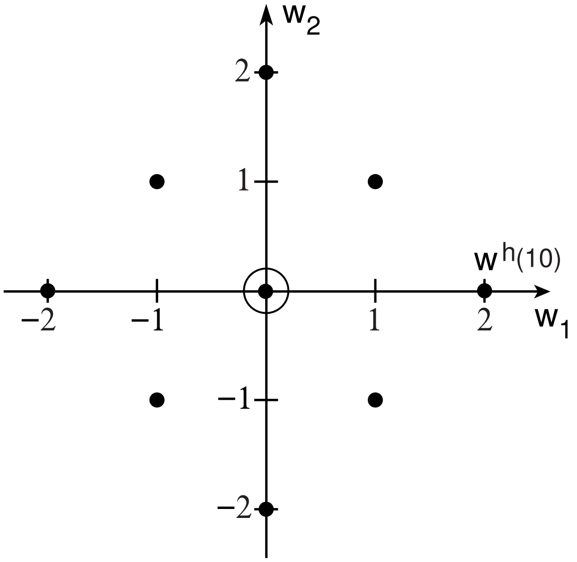

Figure 27.5.5: Weight diagram for the adjoint representation $10 = \Gamma(2,0)$. The circled weight at the origin has multiplicity 2. The other eight weights are located at the tips of the $sp(4)$ root vectors.

positive (and write $\boldsymbol{\mu} > 0$) if its first nonvanishing component is positive.] Show that the results (2.4), (5.4), and (5.8.21) for $sp(2)$, $sp(4)$, and $su(3)$ follow from Weyl's formula. If you are feeling algebraically rambunctious, verify (8.5) for $sp(6)$.

27.5.2. Verify (5.30).

27.5.3. Look at the $sp(4)$ weight diagrams shown in Figures 5.2 through 5.7. Verify that the spacing between the dots in the directions of the long $sp(4)$ root vectors is 2. These dots describe $sp(2)$ representations within $sp(4)$. See Section 21.2. Verify that the spacing between the dots in the directions of the short $sp(4)$ root vectors is $\sqrt{2}$. These dots describe $su(2)$ representations within $sp(4)$. See Exercise 2.1.

27.5.4. The goal of this exercise is to relate the Lie algebras $sp(4)$ and $so(5)$, and the Lie groups $Sp(4)$ and $SO(5)$. You already know from Exercise 3.7.31 that they have the same dimension. You also know from Section 5.10.1 that $sp(2n,\mathbb{R})$ and $usp(2n)$ are equivalent over the complex field, but not over the real field. In this exercise you will show that $usp(4)$ and $so(5,\mathbb{R})$ are isomorphic. Therefore, in so doing, you will show that that $sp(4,\mathbb{R})$ and $so(5,\mathbb{R})$ are equivalent over the complex field, but not over the real field.

Review Exercise 8.2.12. There it is shown that if $K \in su(4)$, then L given by

$$L_{\alpha\beta}(K) = -(1/2)\mathrm{tr}[K(A^{\alpha})^{\dagger}A^{\beta}] \tag{27.5.32}$$

will have the property $L \in so(6,\mathbb{R})$. Correspondingly, from the relation

$$R_{\alpha\beta}(v) = (1/4)\mathrm{tr}[v^{T}A^{\alpha}v(A^{\beta})^{\dagger}], \tag{27.5.33}$$

there will be an $R \in SO(6,\mathbb{R})$ for every $v \in SU(4)$. Now suppose that $K \in sp(4,\mathbb{C})$ as well so that $K \in usp(4)$. Then we will also have $v \in Sp(4,\mathbb{C})$ so that $v \in USp(4)$.

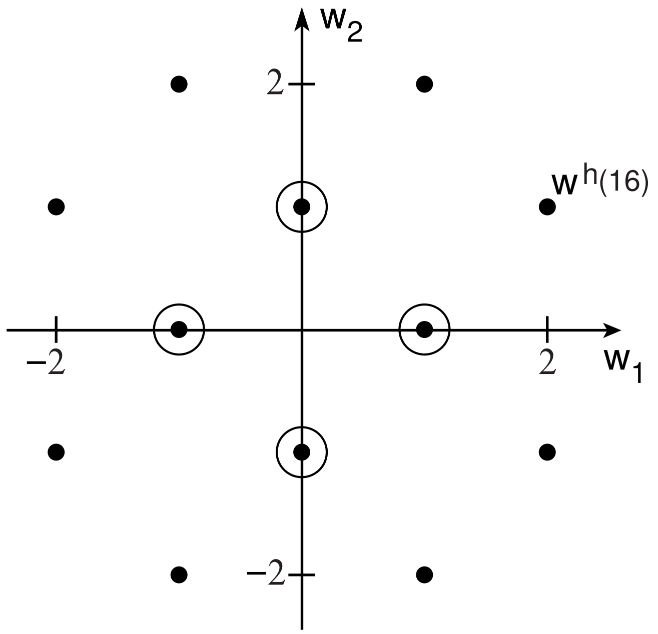

Figure 27.5.6: Weight diagram for the representation $16 = \Gamma(1,1)$. The circled weights on the inner diamond have multiplicity 2.

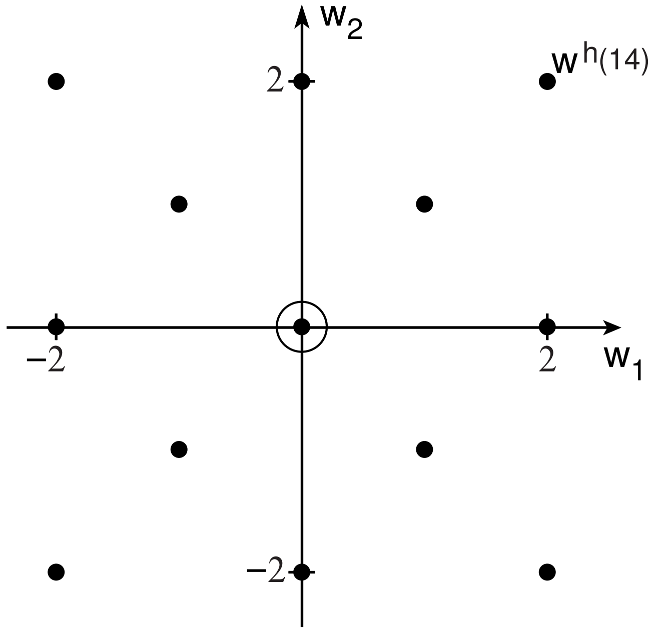

Figure 27.5.7: Weight diagram for the representation $14 = \Gamma(0,2)$. The circled weight at the origin has multiplicity 2.

Suppose we set $\alpha = 6$ in (5.33). From (8.2.98) we see that

$$A^6 = J, \tag{27.5.34}$$

and therefore, if v is symplectic, there is the relation

$$v^T A^6 v = v^T J v = J = A^6. \tag{27.5.35}$$

Consequently, show that there is the result

$$\begin{aligned} R_{6\beta}(v) &= (1/4)\text{tr}[v^T A^6 v (A^\beta)^\dagger] = (1/4)\text{tr}[v^T J v (A^\beta)^\dagger] \\ &= (1/4)\text{tr}[J(A^\beta)^\dagger] = (1/4)\text{tr}[A^6(A^\beta)^\dagger] = \delta_{6\beta}. \end{aligned} \tag{27.5.36}$$

Next set $\beta = 6$ in (5.33). Show that

$$\begin{aligned} R_{\alpha 6}(v) &= (1/4)\text{tr}[v^T A^\alpha v (A^6)^\dagger] = (1/4)\text{tr}[v^T A^\alpha v (J)^\dagger] \\ &= (1/4)\text{tr}[A^\alpha v (J)^\dagger v^T] = (1/4)\text{tr}[A^\alpha J^\dagger] \\ &= (1/4)\text{tr}[A^\alpha (A^6)^\dagger] = \delta_{\alpha 6}. \end{aligned} \tag{27.5.37}$$

Consequently show that, when $v \in USp(4)$, R has the block form

$$R(v) = \begin{pmatrix} R_{11} & R_{12} & R_{13} & R_{14} & R_{15} & 0 \\ R_{21} & R_{22} & R_{23} & R_{24} & R_{25} & 0 \\ R_{31} & R_{32} & R_{33} & R_{34} & R_{35} & 0 \\ R_{41} & R_{42} & R_{43} & R_{44} & R_{45} & 0 \\ R_{51} & R_{52} & R_{53} & R_{54} & R_{55} & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{27.5.38}$$

Let $\hat{R}$ be the 5×5 matrix

$$\hat{R} = \begin{pmatrix} R_{11} & R_{12} & R_{13} & R_{14} & R_{15} \\ R_{21} & R_{22} & R_{23} & R_{24} & R_{25} \\ R_{31} & R_{32} & R_{33} & R_{34} & R_{35} \\ R_{41} & R_{42} & R_{43} & R_{44} & R_{45} \\ R_{51} & R_{52} & R_{53} & R_{54} & R_{55} \end{pmatrix}. \tag{27.5.39}$$

We know that $R \in SO(6,\mathbb{R})$ when $v \in USp(4)$, and we have seen that R must then also have the form (5.38). Consequently, there is the result that $\hat{R} \in SO(5,\mathbb{R})$ when $v \in USp(4)$. Therefore (5.33) provides a map of $USp(4)$ into $SO(5,\mathbb{R})$ when α, β are restricted to range from 1 to 5. Verify that this map is a homomorphism,

$$\hat{R}(v_1 v_2) = \hat{R}(v_1)\hat{R}(v_2), \tag{27.5.40}$$

and that

$$\hat{R}(-v) = \hat{R}(v) \tag{27.5.41}$$

so that the homomorphism is two to one.

Finally, we should study the relation between $usp(4)$ and $so(5,\mathbb{R})$. Show from (5.32) that

$$L_{6\beta}(K) = L_{\alpha 6}(K) = 0 \text{ when } K \in usp(4). \tag{27.5.42}$$

We already know that L is real and antisymmetric when $K \in su(4)$ and hence it will be real and antisymmetric when $K \in usp(4)$ since $usp(4)$ is a subalgebra of $su(4)$. It follows that (5.32) provides a map of $usp(4)$ into $so(5,\mathbb{R})$ when α, β are restricted to range from 1 to 5. Your last task is to show that this map is an isomorphism.

As a first step, verify that $J \in usp(4)$. Consider computing $L(J)$. From (5.32) we know that

$$L_{\alpha\beta}(J) = -(1/2)\text{tr}[J(A^\alpha)^\dagger A^\beta]. \tag{27.5.43}$$

Examine the products $(A^\alpha)^\dagger A^\beta$. See (8.2.112) through (8.2.116). Observe that the products are either symmetric matrices S or antisymmetric matrices A. Recall that matrices of the form JS are traceless. Therefore we only need be concerned with those products that are antisymmetric. But in this case we only need consider those products whose results are proportional to $J = A^6$ because of the orthogonality condition (8.2.121). From (8.2.108) we see that the only products that contribute are of the form A^2A^4. Verify that

$$\begin{aligned} L_{24}(J) &= -(1/2)\text{tr}[J(A^2)^\dagger A^4] = (1/2)\text{tr}[JA^2A^4] \\ &= (1/2)\text{tr}[JA^6] = -(1/2)\text{tr}[A^6(A^6)^\dagger] = -2. \end{aligned} \tag{27.5.44}$$

Thus, show that

$$L(J) = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -2 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}. \tag{27.5.45}$$

Next verify that (5.32) provides a homomorphism of $usp(4)$ into $so(5,\mathbb{R})$ when α, β are restricted to range from 1 to 5. Finally, make an argument analogous to that of Exercise 8.9.19 to show that (5.32) provides an isomorphism of $usp(4)$ into $so(5,\mathbb{R})$ when α, β are restricted to range from 1 to 5.

27.5.5. In this exercise we will see that there is a particularly interesting $sp(2)$ subalgebra residing within $sp(4)$. This subalgebra is of use in the Lie algebraic treatment of (light) optical systems having axial symmetry. See Appendix X.

Consider the monomials

$$\tilde{r}(\boldsymbol{\alpha}) = (1/\sqrt{2})q_1^2, \tag{27.5.46}$$

$$\tilde{c}^1 = -q_1p_1, \tag{27.5.47}$$

$$\tilde{r}(-\boldsymbol{\alpha}) = -(1/\sqrt{2})p_1^2; \tag{27.5.48}$$

$$\tilde{r}(\boldsymbol{\gamma}) = (1/\sqrt{2})q_2^2, \tag{27.5.49}$$

$$\tilde{c}^2 = -q_2p_2, \tag{27.5.50}$$

$$\tilde{r}(-\boldsymbol{\gamma}) = -(1/\sqrt{2})p_2^2. \tag{27.5.51}$$

Note that, consistent with the symmetry of the $sp(4)$ root vector diagram shown in Figure 4.1, the the ingredients of (5.46) through (5.48) are analogous to those of (5.49) through (5.51).

Verify that there are the Poisson bracket relations

$$[\tilde{c}^1, \tilde{r}(\pm\boldsymbol{\alpha})] = \pm 2\tilde{r}(\pm\boldsymbol{\alpha})], \tag{27.5.52}$$

$$[\tilde{r}(\boldsymbol{\alpha}), \tilde{r}(-\boldsymbol{\alpha})] = 2\tilde{c}^1. \tag{27.5.53}$$

As expected, reference to (1.13) and (1.14) reveals that these are the Cartan rules for $sp(2)$. Also, evidently the ingredients of (5.49) through (5.51) obey the same rules. Finally, the ingredients of (5.46) through (5.48) are evidently in involution (commute) with the ingredients of (5.49) through (5.51).

View q_1,q_2 and p_1,p_2 as components of vectors $\boldsymbol{q}$ and $\boldsymbol{p}$ by writing

$$\boldsymbol{q} = (q_1, q_2) \text{ and } \boldsymbol{p} = (p_1, p_2). \tag{27.5.54}$$

Also, make the definitions

$$q^2 = \boldsymbol{q} \cdot \boldsymbol{q} = (q_1)^2 + (q_2)^2, \tag{27.5.55}$$

$$\boldsymbol{q} \cdot \boldsymbol{p} = q_1 p_1 + q_2 p_2, \tag{27.5.56}$$

$$p^2 = \boldsymbol{p} \cdot \boldsymbol{p} = (p_1)^2 + (p_2)^2, \tag{27.5.57}$$

$$L_+ = (1/\sqrt{2})q^2, \tag{27.5.58}$$

$$L_0 = -\boldsymbol{q} \cdot \boldsymbol{p}, \tag{27.5.59}$$

$$L_- = -(1/\sqrt{2})p^2. \tag{27.5.60}$$

Verify that there are the Poisson bracket relations

$$[L_0, L_\pm] = \pm 2L_\pm, \tag{27.5.61}$$

$$[L_+, L_{]} = 2L_0. \tag{27.5.62}$$

Evidently these relations are the Cartan rules for $sp(2)$. Is this surprising? We see from the work leading up to this point that this result is to be expected.

Finally, observe that the quantities in (5.55) through (5.57) are invariant under rotations in the $1, 2$ plane: Define the Lie operator $\mathcal{J}_z$ by the rule

$$\mathcal{J}_z =: J_z : \tag{27.5.63}$$

where J_z is defined by (4.26). See also Subsection 16.2.5.2 and (16.2.218) through (16.2.222) of Exercise 16.2.16. Verify that there are the relations

$$\mathcal{J}_z q^2 = \mathcal{J}_z(\boldsymbol{q} \cdot \boldsymbol{p}) = \mathcal{J}_z p^2 = 0. \tag{27.5.64}$$

27.6 Symplectic Classification of Analytic Vector Fields in Four Variables

For the case of analytic vector fields, and in the spirit of Section 17.3, we need to consider in this section vector fields of the form $\mathcal{L}_{\boldsymbol{g}^m}$ where the components of $\boldsymbol{g}^m$ are homogeneous polynomials of degree m in the 4 variables z_1 through z_4. Mutatis mutandis, many of the same results follow as before. With Σ defined by

$$\Sigma = \sum_a z_a(\partial/\partial z_a), \tag{27.6.1}$$

the relations (3.2) and (3.3) are still true. Also, (3.4) remains true, and (3.5) and (3.6) hold when f_2 is quadratic in z_1 through z_4. It follows that in the 4-variable case the Hamiltonian vector fields $: h_m :$ are transformed into each other under the action of $sp(4,\mathbb{R})$ and carry the irreducible representation $\Gamma(m,0)$. Also, any $\mathcal{L}_{\boldsymbol{g}^0}$ is a Hamiltonian vector field, and these fields carry the representation $\Gamma(1,0)$.

Next consider the vector fields $\mathcal{L}_{\boldsymbol{g}^1}$. They form a 16-dimensional space spanned by the vector fields $z_a(\partial/\partial z_b)$ with $a,b = 1,2,3,4$. We know that any $: h_2 :$ is such a vector field, and that these vector fields carry the representation $\Gamma(2,0)$, which is 10 dimensional. Also, Σ is of the form $\mathcal{L}_{\boldsymbol{g}^1}$ and, by (3.8), carries the 1-dimensional representation $\Gamma(0,0)$. We will see that any $\mathcal{L}_{\boldsymbol{g}^1}$ can be written uniquely in the form

$$\mathcal{L}_{\boldsymbol{g}^1} = \mathcal{H}^{2,0} + \mathcal{G}^{0,1} + \mathcal{G}^{0,0}. \tag{27.6.2}$$

Here $\mathcal{H}^{2,0}$ denotes a Hamiltonian vector field of the form

$$\mathcal{H}^{2,0} =: h_2 :, \tag{27.6.3}$$

which therefore carries the representation $\Gamma(2,0)$. $\mathcal{G}^{0,0}$ is a non-Hamiltonian vector field that is a (constant) multiple of Σ, and therefore carries the representation $\Gamma(0,0)$. Finally, $\mathcal{G}^{0,1}$ is a non-Hamiltonian vector field that carries the representation $\Gamma(0,1)$. Note from Table 5.1 that $\Gamma(0,1)$ has dimension 5 so that we have the completeness count $16 = 10 + 5 + 1$.

According to (6.3) finding a suitable basis for the vector fields in $\mathcal{H}^{2,0}$ is equivalent to finding a suitable basis for the quadratic polynomials in 4-dimensional phase space. But this has already been done: we may use the basis provided by the $sp(4)$ generators given in the Cartesian Cartan basis by (5.9) through (5.18).

For the non-Hamiltonian parts we will prove the claims just made by exhibiting suitable bases for $\mathcal{G}^{0,0}$ and $\mathcal{G}^{0,1}$. For our purposes, it is convenient to work in the Cartesian (monomial) basis and use the transformed generators defined in (5.9) through (5.18). Consider the 4 vector fields $z_a(\partial/\partial z_a)$ with $a = 1$ through 4. Evidently, they are mutually commuting. We also observe that the 3 vector fields $: \tilde{c}^1 :$, $: \tilde{c}^2 :$, and $\tilde{\mathcal{G}}^{0,0}_{0,0} = \Sigma$ are made from the $z_a(\partial/\partial z_a)$,

$$: \tilde{c}^1 := - : q_1p_1 := -p_1(\partial/\partial p_1) + q_1(\partial/\partial q_1) = z_1(\partial/\partial z_1) - z_3(\partial/\partial z_3), \tag{27.6.4}$$

$$: \tilde{c}^2 := - : q_2p_2 := -p_2(\partial/\partial p_2) + q_2(\partial/\partial q_2) = z_2(\partial/\partial z_2) - z_4(\partial/\partial z_4), \tag{27.6.5}$$

$$\tilde{\mathcal{G}}^{0,0}_{0,0} = \Sigma = z_1(\partial/\partial z_1) + z_2(\partial/\partial z_2) + z_3(\partial/\partial z_3) + z_4(\partial/\partial z_4). \tag{27.6.6}$$

As a fourth such linearly independent vector field we take the element $\tilde{\mathcal{G}}_{0,0}^{0,1}$ defined by the equation

$$\tilde{\mathcal{G}}_{0,0}^{0,1} = z_1(\partial/\partial z_1) + z_3(\partial/\partial z_3) - z_2(\partial/\partial z_2) - z_4(\partial/\partial z_4). \tag{27.6.7}$$

See Exercise 6.1. In addition we define other elements $\tilde{\mathcal{G}}_{k,\ell}^{0,1}$ by the equations

$$\begin{aligned}\tilde{\mathcal{G}}_{1,1}^{0,1} &= (1/2)\#\tilde{r}(\boldsymbol{\beta})\#\tilde{\mathcal{G}}_{0,0}^{0,1} = (1/2)\{:\tilde{r}(\boldsymbol{\beta}):,\tilde{\mathcal{G}}_{0,0}^{0,1}\}\\ &= -z_1(\partial/\partial z_4) + z_2(\partial/\partial z_3),\end{aligned} \tag{27.6.8}$$

$$\begin{aligned}\tilde{\mathcal{G}}_{-1,-1}^{0,1} &= (1/2)\#\tilde{r}(-\boldsymbol{\beta})\#\tilde{\mathcal{G}}_{0,0}^{0,1} = (1/2)\{:\tilde{r}(-\boldsymbol{\beta}):,\tilde{\mathcal{G}}_{0,0}^{0,1}\}\\ &= z_4(\partial/\partial z_1) - z_3(\partial/\partial z_2),\end{aligned} \tag{27.6.9}$$

$$\begin{aligned}\tilde{\mathcal{G}}_{-1,1}^{0,1} &= (1/2)\#\tilde{r}(\boldsymbol{\delta})\#\tilde{\mathcal{G}}_{0,0}^{0,1} = (1/2)\{:\tilde{r}(\boldsymbol{\delta}):,\tilde{\mathcal{G}}_{0,0}^{0,1}\}\\ &= -z_3(\partial/\partial z_4) - z_2(\partial/\partial z_1),\end{aligned} \tag{27.6.10}$$

$$\begin{aligned}\tilde{\mathcal{G}}_{1,-1}^{0,1} &= (1/2)\#\tilde{r}(-\boldsymbol{\delta})\#\tilde{\mathcal{G}}_{0,0}^{0,1} = (1/2)\{:\tilde{r}(-\boldsymbol{\delta}):,\tilde{\mathcal{G}}_{0,0}^{0,1}\}\\ &= z_4(\partial/\partial z_3) + z_1(\partial/\partial z_2).\end{aligned} \tag{27.6.11}$$

Since Σ commutes with all the $sp(4)$ generators, we immediately have the results

$$\#\tilde{c}^j\#\tilde{\mathcal{G}}_{0,0}^{0,0} = \{:\tilde{c}^j:,\Sigma\} = -\{\Sigma,:\tilde{c}^j:\} = 0, \tag{27.6.12}$$

$$\#r(\boldsymbol{\mu})\#\tilde{\mathcal{G}}_{0,0}^{0,0} = \{:r(\boldsymbol{\mu}):,\Sigma\} = -\{\Sigma,:r(\boldsymbol{\mu}):\} = 0. \tag{27.6.13}$$

Thus, in keeping with its labels, $\tilde{\mathcal{G}}_{0,0}^{0,0}$ carries the representation $\Gamma(0,0)$.

Direct computation shows that the five elements $\tilde{\mathcal{G}}_{k,\ell}^{0,1}$ obey the rules

$$\#\tilde{c}^j\#\tilde{\mathcal{G}}_{k,\ell}^{0,1} = \{:\tilde{c}^j:,\tilde{\mathcal{G}}_{k,\ell}^{0,1}\} = \boldsymbol{e}^j\cdot(k\boldsymbol{e}^1+\ell\boldsymbol{e}^2)\tilde{\mathcal{G}}_{k,\ell}^{0,1}. \tag{27.6.14}$$

That is why the subscripts are taken to have the k,ℓ values shown. Reference to Figure 5.4 shows that the right sides of (6.14) are the components of the weights for the representation $\Gamma(0,1)$. In particular, we see that $\tilde{\mathcal{G}}_{1,1}^{0,1}$ occupies the highest weight site $\boldsymbol{w}^h$ given by (5.3) for the representation $\Gamma(0,1)$. Therefore there should be the ladder relations

$$\#\tilde{r}(\boldsymbol{\alpha})\#\tilde{\mathcal{G}}_{1,1}^{0,1} = \#\tilde{r}(\boldsymbol{\beta})\#\tilde{\mathcal{G}}_{1,1}^{0,1} = \#\tilde{r}(-\boldsymbol{\delta})\#\tilde{\mathcal{G}}_{1,1}^{0,1} = 0. \tag{27.6.15}$$

Direct calculation shows that these relations are true. Similarly, there are the ladder relations

$$\#\tilde{r}(\pm\boldsymbol{\alpha})\#\tilde{\mathcal{G}}_{0,0}^{0,1} = 0, \tag{27.6.16}$$

$$\#\tilde{r}(\pm\boldsymbol{\gamma})\#\tilde{\mathcal{G}}_{0,0}^{0,1} = 0, \tag{27.6.17}$$

because there are no weights in $\Gamma(0,1)$, see Figure 5.4, at the sites $\pm\boldsymbol{\alpha}$, $\pm\boldsymbol{\gamma}$. Further calculation gives the relation

$$\#\tilde{r}(-\boldsymbol{\beta})\#\tilde{\mathcal{G}}_{1,1}^{0,1} = \tilde{\mathcal{G}}_{0,0}^{0,1}, \tag{27.6.18}$$

and all the other ladder relations one expects for the representation $\Gamma(0,1)$.

For the sake of comparison, consider the Hamiltonian vector fields $:\tilde{r}(\pm\boldsymbol{\beta}):$ and $:\tilde{r}(\pm\boldsymbol{\delta}):$. They belong to $\mathcal{H}^{2,0}$ and occupy the same sites as $\tilde{\mathcal{G}}^{0,1}_{\pm1,\pm1}$ and $\tilde{\mathcal{G}}^{0,1}_{\mp1,\pm1}$, respectively, in Figure 5.5. They have the form

$$:\tilde{r}(\boldsymbol{\beta}):=:q_1q_2:=z_1(\partial/\partial z_4)+z_2(\partial/\partial z_3), \tag{27.6.19}$$

$$:\tilde{r}(-\boldsymbol{\beta}):=-:p_1p_2:=z_4(\partial/\partial z_1)+z_3(\partial/\partial z_2), \tag{27.6.20}$$

$$:\tilde{r}(\boldsymbol{\delta}):=:p_1q_2:=z_3(\partial/\partial z_4)-z_2(\partial/\partial z_1), \tag{27.6.21}$$

$$:\tilde{r}(-\boldsymbol{\delta}):=:p_2q_1:=z_4(\partial/\partial z_3)-z_1(\partial/\partial z_2). \tag{27.6.22}$$

Evidently the vector fields (6.7) through (6.11) and (6.19) through (6.22) are linearly independent. However, in contrast to (6.15), we have the nonzero result

$$\#\tilde{r}(-\boldsymbol{\delta})\#:\tilde{r}(\boldsymbol{\beta}):=-(\sqrt{2}):\tilde{r}(\boldsymbol{\alpha}):. \tag{27.6.23}$$

Our proof is complete, and in the process of proof we have exhibited explicit expressions for the 5 vector fields $\tilde{\mathcal{G}}^{0,1}_{0,0}$, $\tilde{\mathcal{G}}^{0,1}_{\pm1,\pm1}$, and $\tilde{\mathcal{G}}^{0,1}_{\mp1,\pm1}$ that span $\tilde{\mathcal{G}}^{0,1}$ in the monomial basis. If desired, these vector fields can be transformed to the resonance basis with the aid of the operator

$$\hat{\mathcal{A}}(\pi/8)=\exp[-i(\pi/8)\#p_1^2-q_1^2+p_2^2-q_2^2\#]. \tag{27.6.24}$$

Of course, the results of such a transformation will again be linear combinations of $\tilde{\mathcal{G}}^{0,1}_{0,0}$, $\tilde{\mathcal{G}}^{0,1}_{\pm1,\pm1}$, and $\tilde{\mathcal{G}}^{0,1}_{\mp1,\pm1}$ because $\hat{\mathcal{A}}(\pi/8)$ is generated by an $\#f_2\#$ and we know that the set of $\mathcal{G}^{0,1}$ is transformed into itself under such transformations. For example, we have the result

$$\mathcal{G}^{0,1}_{0,0}=\hat{\mathcal{A}}(\pi/8)\tilde{\mathcal{G}}^{0,1}_{0,0}= \tag{27.6.25}$$

At this juncture we point out that there is a one-to-one correspondence between the elements $\tilde{\mathcal{G}}^{0,0}_{0,0}$ and $\tilde{\mathcal{G}}^{0,1}_{k,\ell}$ and the matrices JA of Section 4.3. We first note that, according to (4.3.3), the matrices JA are transformed into themselves under the (commutator) action of $sp(2n)$, and therefore must form a representation of $sp(2n)$. Also, taken together, the matrices JS [which generate $sp(2n)$] and the matrices JA generate $g\ell(2n)$. Similarly, the vector fields $\mathcal{H}^{2,0}$ [which generate $sp(2n)$] and the vector fields $\mathcal{G}^{0,1}$ and $\mathcal{G}^{0,0}$ span $\mathcal{L}_{\boldsymbol{g}^1}$, and it is easily verified that $\mathcal{L}_{\boldsymbol{g}^1}$ in turn generates $g\ell(2n)$. In analogy to (7.2.4), write the relations

$$\tilde{\mathcal{G}}^{0,0}_{0,0}z_c=[J\tilde{A}(0,0;0,0)z]_c=\sum_d[J\tilde{A}(0,0;0,0)]_{cd}z_d, \tag{27.6.26}$$

$$\tilde{\mathcal{G}}^{0,1}_{k,\ell}z_c=[J\tilde{A}(0,1;k,\ell)z]_c=\sum_d[J\tilde{A}(0,1;k,\ell)]_{cd}z_d. \tag{27.6.27}$$

Then, from the definitions (6.6) through (6.11), we find the results

$$\tilde{A}(0,0;0,0)=-J=\begin{pmatrix}0&0&-1&0\\0&0&0&-1\\1&0&0&0\\0&1&0&0\end{pmatrix}, \tag{27.6.28}$$

$$\tilde{A}(0,1;0,0) = \begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix}, \tag{27.6.29}$$

$$\tilde{A}(0,1;1,1) = \begin{pmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \tag{27.6.30}$$

$$\tilde{A}(0,1;-1,-1) = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix}, \tag{27.6.31}$$

$$\tilde{A}(0,1;-1,1) = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \tag{27.6.32}$$

$$\tilde{A}(0,1;1,-1) = \begin{pmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}. \tag{27.6.33}$$

Note that, as expected, the matrices $\tilde{A}$ are antisymmetric and span the space of 4×4 antisymmetric matrices. Also, the matrix JA, when exponentiated and with A given by any multiple of the $\tilde{A}$ in (6.28), produces a positive multiple of the identity matrix. The remaining JA, with A any linear combination of the five $\tilde{A}$ given by (6.29) through (6.33), are traceless and therefore are in $s\ell(4,\mathbb{R})$.

We now turn to the general case $\mathcal{L}_{\boldsymbol{g}^m}$ with $m \geq 1$. Any such vector field can be written in the form

$$\mathcal{L}_{\boldsymbol{g}^m} = \sum_{a=1}^{4} g_a^m(\partial/\partial z_a). \tag{27.6.34}$$

We know that the g_a^m carry the representation $\Gamma(m,0)$ and the $(\partial/\partial z_a)$ carry the representation $\Gamma(1,0)$. It follows as before from the derivation property of $\#f_2\#$ that $\mathcal{L}_{\boldsymbol{g}^m}$ must carry the direct product representation $\Gamma(m,0) \otimes \Gamma(1,0)$. In the case of $sp(4)$ there is the Clebsch-Gordan series result

$$\Gamma(m,0) \otimes \Gamma(1,0) = \Gamma(m+1,0) \oplus \Gamma(m-1,1) \oplus \Gamma(m-1,0). \tag{27.6.35}$$

Consequently, any $\mathcal{L}_{\boldsymbol{g}^m}$ with $m \geq 1$ has the unique decomposition

$$\mathcal{L}_{\boldsymbol{g}^m} = \mathcal{H}^{m+1,0} + \mathcal{G}^{m-1,1} + \mathcal{G}^{m-1,0}. \tag{27.6.36}$$

Here $\mathcal{H}^{m+1,0}$ is a Hamiltonian vector field that carries the representation $\Gamma(m+1,0)$, and $\mathcal{G}^{m-1,1}$ and $\mathcal{G}^{m-1,0}$ are non-Hamiltonian vector fields that carry the representations $\Gamma(m-1,1)$ and $\Gamma(m-1,0)$, respectively.

The vector field $\mathcal{H}^{m+1,0}$ is of the form $: h_{m+1} :$. Finding a basis for $\mathcal{G}^{m-1,0}$ is also easy. Since Σ carries the representation $\Gamma(0,0)$, we have the result that $\mathcal{G}^{m-1,0}$ is of the form

$$\mathcal{G}^{m-1,0} = f_{m-1}\Sigma, \tag{27.6.37}$$

where f_{m-1} is any homogeneous polynomial of degree $(m-1)$. Finding the basis elements for $\mathcal{G}^{m-1,1}$ in general requires some work. One may, for example, follow a procedure similar to that used to find the basis for $\mathcal{G}^{0,1}$. A more systematic procedure would be to compute and tabulate the complete set of Clebsch-Gordan coefficients for the first several representations of $sp(4)$. These coefficients could then be used for modest m to find a basis for $\Gamma(m-1,1)$ in terms of the basis elements for $\Gamma(m,0) \times \Gamma(1,0)$.

As a specific example, let us consider vector fields of the form $\mathcal{L}_{\boldsymbol{g}^2}$. This set of fields has dimension $4N(2,4) = 40$. The set of Hamiltonian vector fields $\mathcal{H}^{3,0}$ has dimension $N(3,4) = 20$. The set of non-Hamiltonian vector fields $\mathcal{G}^{1,0}$ has dimension $\dim\Gamma(1,0) = 4$. See Figure 5.3. They are spanned by the basis elements $z_a\Sigma$. The set of non-Hamiltonian vector fields $\mathcal{G}^{1,1}$ has dimension $\dim\Gamma(1,1) = 16$. See Figure 5.6. Finding a basis for them would require more work. Some further tools for this task are described in Sections 21.10 and 21.11.2.

Exercises

27.6.1. The choice of $\tilde{\mathcal{G}}^{0,1}_{0,0}$ as given in (6.7) must be made with care to assure that it is "pure" $\Gamma(0,1)$ and contains no $\Gamma(0,0)$ or $\Gamma(2,0)$ "contamination". For example, one could add any amount of Σ and $: \tilde{c}^j :$ to the selected $\tilde{\mathcal{G}}^{0,1}_{0,0}$ and still satisfy (6.14) with $k, \ell = 0$. Show that the truth of (6.18) ensures that $\tilde{\mathcal{G}}^{0,0}_{0,1}$ as defined by (6.7) has no $\Gamma(0,0)$ contamination. Show that the truth of (6.16) and (6.17) ensures that $\tilde{\mathcal{G}}^{0,1}_{0,0}$ as defined by (6.7) has no $\Gamma(2,0)$ contamination. Verify the relations (6.8) through (6.23). The basis elements given by (6.7) through (6.11) have the weights displayed in Figure 5.4. Verify that any attempt to raise or lower an element to produce one with a weight different from those shown in Figure 5.4 leads to a null result as in (6.15) through (6.18).

27.6.2. Verify (6.28) through (6.33).

27.6.3. The relation (6.35) implies the relation

$$\begin{aligned}&[\dim\Gamma(m,0)][\dim\Gamma(1,0)] = \\ &\dim\Gamma(m+1,0) + \dim\Gamma(m-1,1) + \dim\Gamma(m-1,0).\end{aligned} \tag{27.6.38}$$

Verify this relation using (5.4).

27.7 Structure of $sp(6,\mathbb{R})$

The Lie algebra $sp(6,\mathbb{R})$ is 21 dimensional, and its Cartan subalgebra is 3 dimensional. Therefore, in the Cartan basis, there should be 18 ladder operators. They are labelled by 18 three-component root vectors consisting of 9 vectors and their negatives. For convenience, we will call these 9 vectors $\boldsymbol{\alpha}^j$, $\boldsymbol{\beta}^j$, and $\boldsymbol{\gamma}^j$ where j ranges from 1 through 3. They are given in terms of three orthogonal unit vectors $\boldsymbol{e}^1$ through $\boldsymbol{e}^3$ by the relations

$$\boldsymbol{\alpha}^1 = 2\boldsymbol{e}^1, \tag{27.7.1}$$

$$\boldsymbol{\alpha}^2 = \boldsymbol{e}^1 + \boldsymbol{e}^2, \tag{27.7.2}$$

$$\boldsymbol{\alpha}^3 = \boldsymbol{e}^1 - \boldsymbol{e}^2, \tag{27.7.3}$$

$$\boldsymbol{\beta}^1 = 2\boldsymbol{e}^2, \tag{27.7.4}$$

$$\boldsymbol{\beta}^2 = \boldsymbol{e}^2 + \boldsymbol{e}^3, \tag{27.7.5}$$

$$\boldsymbol{\beta}^3 = \boldsymbol{e}^2 - \boldsymbol{e}^3, \tag{27.7.6}$$

$$\boldsymbol{\gamma}^1 = 2\boldsymbol{e}^3, \tag{27.7.7}$$

$$\boldsymbol{\gamma}^2 = \boldsymbol{e}^3 + \boldsymbol{e}^1, \tag{27.7.8}$$

$$\boldsymbol{\gamma}^3 = \boldsymbol{e}^3 - \boldsymbol{e}^1. \tag{27.7.9}$$

The 18 $sp(6)$ root vectors are shown in Figure 7.1. Note they are all of the form $(\pm\boldsymbol{e}^i \pm \boldsymbol{e}^j)$ with the signs taken independently and the zero vector omitted. They satisfy the normalization relations

$$\sum_{\boldsymbol{\mu}} (\boldsymbol{e}^i \cdot \boldsymbol{\mu})(\boldsymbol{\mu} \cdot \boldsymbol{e}^j) = 16\delta_{ij}. \tag{27.7.10}$$

The Lie algebra $sp(6,\mathbb{R})$ is generated by the monomials $z_a z_b$ with a, b ranging from 1 to 6. In analogy with the case of $sp(4,\mathbb{R})$, it is convenient to use as the basis for the Cartan subalgebra the polynomials

$$c^1 = -(i/2)(p_1^2 + q_1^2), \tag{27.7.11}$$

$$c^2 = -(i/2)(p_2^2 + q_2^2), \tag{27.7.12}$$

$$c^3 = -(i/2)(p_3^2 + q_3^2). \tag{27.7.13}$$

Their associated Lie operators are Hermitian and, when exponentiated, generate a 3-torus which is a maximal torus in $sp(6,\mathbb{R})$. For the ladder operators in $sp(6)$ we use the polynomials

$$r(\pm\boldsymbol{\alpha}^1) = (\sqrt{2}/4)(q_1 \pm ip_1)^2, \tag{27.7.14}$$

$$r(\pm\boldsymbol{\alpha}^2) = (1/2)(q_1 \pm ip_1)(q_2 \pm ip_2), \tag{27.7.15}$$

$$r(\pm\boldsymbol{\alpha}^3) = (i/2)(q_1 \pm ip_1)(q_2 \mp ip_2), \tag{27.7.16}$$

$$r(\pm\boldsymbol{\beta}^1) = (\sqrt{2}/4)(q_2 \pm ip_2)^2, \tag{27.7.17}$$

$$r(\pm\boldsymbol{\beta}^2) = (1/2)(q_2 \pm ip_2)(q_3 \pm ip_3), \tag{27.7.18}$$

$$r(\pm\boldsymbol{\beta}^3) = (i/2)(q_2 \pm ip_2)(q_3 \mp ip_3), \tag{27.7.19}$$

$$r(\pm\boldsymbol{\gamma}^1) = (\sqrt{2}/4)(q_3 \pm ip_3)^2, \tag{27.7.20}$$

$$r(\pm\boldsymbol{\gamma}^2) = (1/2)(q_3 \pm ip_3)(q_1 \pm ip_1), \tag{27.7.21}$$

$$r(\pm\boldsymbol{\gamma}^3) = (i/2)(q_3 \pm ip_3)(q_1 \mp ip_1). \tag{27.7.22}$$

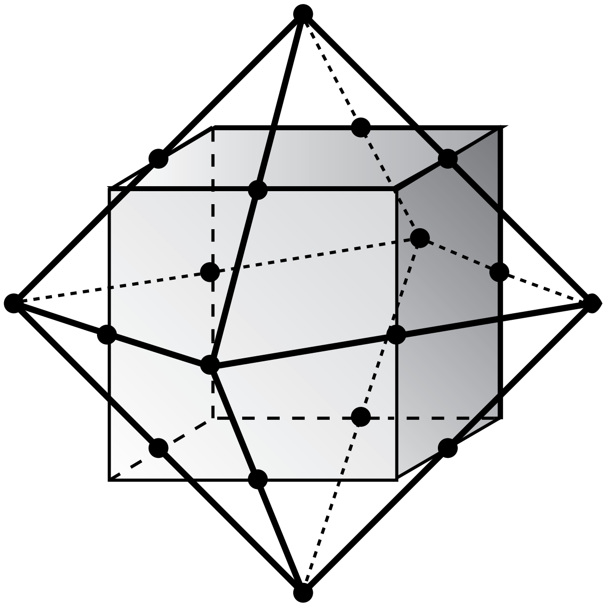

Figure 27.7.1: Root diagram showing the root vectors for $sp(6)$. The 6 tips of the long root vectors $\pm\boldsymbol{\alpha}^1$, $\pm\boldsymbol{\beta}^1$, $\pm\boldsymbol{\gamma}^1$ form the vertices of a regular octahedron. These root vectors have length 2. The remaining 12 short root vectors have length $\sqrt{2}$, and their tips lie at the midpoints of the 12 edges of the unit cube (the cube with edge 2).

Their associated Lie operators obey the standard conjugation relations (4.14). Also, the Lie algebra generated by the c^j and the $r(\boldsymbol{\mu})$ satisfy the standard rules (4.15) through (4.18). For the case of $sp(6)$, the $N(\boldsymbol{\mu},\boldsymbol{\nu})$ have the values $\pm\sqrt{2}$. The positive N's are *. As before, for the scalar product (7.3.12), the basis elements c^j and $r(\boldsymbol{\mu})$ are orthonormal and therefore satisfy the relations (4.19) through (4.22).

We close this section by examining how $sp(4)$, $su(3)$, and $so(3)$ reside within $sp(6)$. The presence of $sp(4)$ within $sp(6)$ is obvious. Comparison of (4.6) and (4.7) with (7.11) and (7.12) shows that the c^j (with $j = 1, 2$) are identical for sp(4) and sp(6). Also, comparison of (4.1) through (4.4) with (7.1) through (7.4) indicates that, apart from labeling, the root vectors of $sp(4)$ are identical to a subset of those for $sp(6)$. Therefore, there is the correspondence

$$\boldsymbol{\alpha} \leftrightarrow \boldsymbol{\alpha}^1,\ \ \boldsymbol{\beta} \leftrightarrow \boldsymbol{\alpha}^2,\ \ \boldsymbol{\gamma} \leftrightarrow \boldsymbol{\beta}^1,\ \ \boldsymbol{\delta} \leftrightarrow -\boldsymbol{\alpha}^3. \tag{27.7.23}$$

Figure 7.2 shows the $sp(6)$ root vectors of Figure 7.1 viewed from above (looking against the $\boldsymbol{e}^3$ axis). From this perspective, it is obvious that the root vectors (7.23) are arranged as required for $sp(4)$. See Figure 4.1. Finally, comparison of (4.10) through (4.13) with (7.14) through (7.17) gives the relations

$$r(\pm\boldsymbol{\alpha}) = r(\pm\boldsymbol{\alpha}^1),\ \ r(\pm\boldsymbol{\beta}) = r(\pm\boldsymbol{\alpha}^2),\ \ r(\pm\boldsymbol{\gamma}) = r(\pm\boldsymbol{\beta}^1),\ \ r(\pm\boldsymbol{\delta}) = r(\mp\boldsymbol{\alpha}^3). \tag{27.7.24}$$

The $sp(4)$ just identified within $sp(6)$ is the obvious one. Continued examination of the $sp(6)$ root diagram of Figure 7.1 indicates that there are two more $sp(4)$ subgroups within $sp(6)$ gotten from the one just described by cyclically permuting the indices $1, 2, 3$ on the variables q_1, q_2, q_3 and p_1, p_2, p_3.

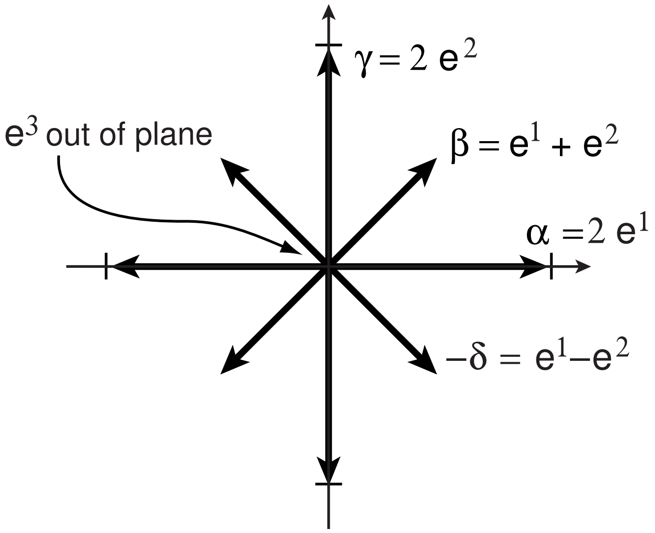

Figure 27.7.2: Top view of $sp(6)$ root vectors of Figure 7.1 showing root vectors of an $sp(4)$ subgroup. Only the $sp(6)$ root vectors in the $\boldsymbol{e}^1$, $\boldsymbol{e}^2$ plane are displayed. For clarity, all others are omitted. The vector $\boldsymbol{e}^3$ is out of the plane of the paper.

The presence of $su(3)$ and $u(3)$ within $sp(6)$ is more subtle. Consider the $sp(6)$ root vectors $\boldsymbol{\alpha}^3$, $\boldsymbol{\beta}^3$, $\boldsymbol{\gamma}^3$ given by (7.3), (7.6), and (7.9). They all have length $\sqrt{2}$. They are also linearly dependent and therefore lie in a plane,

$$\boldsymbol{\alpha}^3 + \boldsymbol{\beta}^3 + \boldsymbol{\gamma}^3 = 0. \tag{27.7.25}$$

Within this plane they radiate from the origin like spokes equally "spaced" by angles of 120°. To verify this assertion, first note that the normal to this plane is given by the vector

$$\boldsymbol{\alpha}^3 \times \boldsymbol{\beta}^3 = \boldsymbol{\beta}^3 \times \boldsymbol{\gamma}^3 = \boldsymbol{\gamma}^3 \times \boldsymbol{\alpha}^3 = \boldsymbol{e}^1 + \boldsymbol{e}^2 + \boldsymbol{e}^3. \tag{27.7.26}$$

Let $\boldsymbol{n}$ be the normal unit vector

$$\boldsymbol{n} = (\boldsymbol{e}^1 + \boldsymbol{e}^2 + \boldsymbol{e}^3)/\sqrt{3}. \tag{27.7.27}$$

Use of (*) shows that there is the relation

$$\boldsymbol{\beta}^3 = R(\boldsymbol{n}, 2\pi/3)\boldsymbol{\alpha}^3, \tag{27.7.28}$$

$$\boldsymbol{\gamma}^3 = R(\boldsymbol{n}, 2\pi/3)\boldsymbol{\beta}^3, \tag{27.7.29}$$

$$\boldsymbol{\alpha}^3 = R(\boldsymbol{n}, 2\pi/3)\boldsymbol{\gamma}^3. \tag{27.7.30}$$

Figure 7.3 shows the $sp(6)$ root vectors of Figure 7.1 viewed against the unit vector $\boldsymbol{n}$. From this perspective it is evident that the vectors $\boldsymbol{\alpha}^3$, $\boldsymbol{\beta}^3$, $\boldsymbol{\gamma}^3$ and their negatives are arranged as required for the root vectors of $su(3)$. Comparison of Figures 5.8.1 and 7.3 gives the correspondence

$$\pm\,\boldsymbol{\alpha} \leftrightarrow \pm\boldsymbol{\alpha}^3,\ \ \pm\boldsymbol{\beta} \leftrightarrow \mp\boldsymbol{\gamma}^3,\ \ \pm\boldsymbol{\gamma} \leftrightarrow \pm\boldsymbol{\beta}^3. \tag{27.7.31}$$

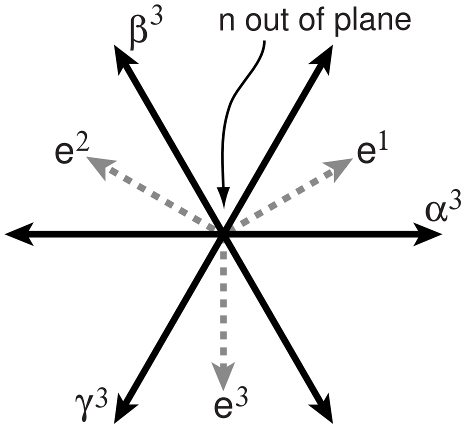

Figure 27.7.3: View against the unit vector $\boldsymbol{n}$ of the $sp(6)$ root vectors of Figure 7.1 showing root vectors of an $su(3)$ subgroup. Only the $sp(6)$ root vectors in the $\boldsymbol{\alpha}^3$, $\boldsymbol{\beta}^3$, $\boldsymbol{\gamma}^3$ plane and the $\boldsymbol{e}^1$, $\boldsymbol{e}^2$, $\boldsymbol{e}^3$ axes are displayed. For clarity, all others are omitted. The vector $\boldsymbol{n}$ is out of the plane of the paper.

Correspondingly, comparison of (7.16), (7.19), and (7.22) with (5.8.35) gives the relations

$$r(\pm\boldsymbol{\alpha}) = r(\pm\boldsymbol{\alpha}^3), \quad r(\pm\boldsymbol{\beta}) = r(\mp\boldsymbol{\gamma}^3), \quad r(\pm\boldsymbol{\gamma}) = r(\pm\boldsymbol{\beta}^3). \tag{27.7.32}$$

Finally, comparison of (5.8.5) with (7.11) through (7.13) gives the relations

$$b^0 = i(c^1 + c^2 + c^3), \quad b^3 = i(c^1 - c^2), \quad b^8 = (i/\sqrt{3})(c^1 + c^2 - 2c^3). \tag{27.7.33}$$

The ladder elements r in (7.32) combined with b^3 and b^8 in (7.33) span $su(3)$; and they all together along with b^0 span $u(3)$.

The $su(3)$ [and corresponding $u(3)$] just identified within $sp(6)$ is one of several such subgroups. Continued examination of Figure 7.1 indicates that there are three more. We know that the root vectors $\pm\boldsymbol{\alpha}^1$, $\pm\boldsymbol{\beta}^1$, $\pm\boldsymbol{\gamma}^1$ form the 6 vertices of a regular octahedron. An octahedron has 8 triangular faces consisting of 4 opposite pairs. There is an $su(3)$ set of root vectors in each plane through the origin lying between and parallel to each pair of opposite faces.

Finally, there is an $so(3)$ subalgebra within $sp(6)$ whose presence is not obvious from looking at the $sp(6)$ root diagram. The L_j defined by (5.8.89) generate simultaneous rotations in the q_1, q_2, q_3 and p_1, p_2, p_3 spaces. By (7.16), (7.19), and (7.22) they are related to elements in the Cartan basis by the equation

$$L_1 = q_2p_3 - q_3p_2 = r(\boldsymbol{\beta}^3) - r(-\boldsymbol{\beta}^3), \tag{27.7.34}$$

$$L_2 = q_3p_1 - q_1p_3 = r(\boldsymbol{\gamma}^3) - r(-\boldsymbol{\gamma}^3), \tag{27.7.35}$$

$$L_3 = q_1p_2 - q_2p_1 = r(\boldsymbol{\alpha}^3) - r(-\boldsymbol{\alpha}^3). \tag{27.7.36}$$

Note that these elements are all within $su(3)$.

Exercises

27.7.1. Verify that, with the scalar product (7.3.12), the basis elements c^j and $r(\boldsymbol{\mu})$ form an orthonormal set.

27.7.2. Verify the relations (7.28) through (7.30).

27.7.3. Verify that there are other $so(3)$ subalgebras in $sp(6)$ associated with the other $su(3)$ subalgebras in $sp(6)$.

27.8 Representations of $sp(6,\mathbb{R})$

The description of representations of $sp(6)$ follows the same general Cartan procedure as described for $su(3)$ in Section 5.8 and $sp(4)$ in Section 21.5. For $sp(6)$, since it has rank 3, there are three fundamental weights $\boldsymbol{\phi}^1$, $\boldsymbol{\phi}^2$ and $\boldsymbol{\phi}^3$. They are given by the relations

$$\boldsymbol{\phi}^1 = \boldsymbol{e}^1 = \boldsymbol{\alpha}^1/2, \tag{27.8.1}$$

$$\boldsymbol{\phi}^2 = \boldsymbol{e}^1 + \boldsymbol{e}^2 = \boldsymbol{\alpha}^2, \tag{27.8.2}$$

$$\boldsymbol{\phi}^3 = \boldsymbol{e}^1 + \boldsymbol{e}^2 + \boldsymbol{e}^3, \tag{27.8.3}$$

and are shown in Figure 8.1 along with the $sp(6)$ root vectors. Thus, for $sp(6)$, every highest weight $\boldsymbol{w}^h$ is of the form

$$\boldsymbol{w}^h = \ell\boldsymbol{\phi}^1 + m\boldsymbol{\phi}^2 + n\boldsymbol{\phi}^3 = (\ell+m+n)\boldsymbol{e}^1 + (m+n)\boldsymbol{e}^2 + n\boldsymbol{e}^3, \tag{27.8.4}$$

where ℓ, m, and n are arbitrary nonnegative integers. Correspondingly, for each ℓ, m, n triplet, there is an irreducible representation $\Gamma(\ell,m,n)$ with highest weight $\boldsymbol{w}^h$ given by (8.4). It can be shown that the dimension of $\Gamma(\ell,m,n)$ is given by the relation

$$\begin{aligned}\dim\Gamma(\ell,m,n) = {} & \frac{1}{720}(\ell+2m+2n+5)(\ell+m+2n+4)(\ell+m+n+3) \\ & \times(\ell+m+2)(m+2n+3)(m+n+2)(\ell+1)(m+1)(n+1).\end{aligned} \tag{27.8.5}$$

Again see Exercise 5.1. The representations are also self conjugate,

$$\overline{\Gamma}(\ell,m,n) = \Gamma(\ell,m,n). \tag{27.8.6}$$

See Exercise 3.7.36. For quick reference the dimensions of the first few representations are listed in Table 8.1 below. Where there is no possibility of confusion, we will sometimes refer to a representation by its dimension. Note that $\Gamma(0,1,0)$ and $\Gamma(0,0,1)$ both have dimension 14.

From a knowledge of the root vectors and the highest weight it is a simple matter to construct weight diagrams for the various low-dimensional representations. Figures 8.2 through 8.5 show weight diagrams for the first few representations. Inspection of these figures and reference to Table 8.1 shows that the weights must have unit multiplicities for the representations $\Gamma(0,0,0)$ and $\Gamma(1,0,0)$. For $\Gamma(0,1,0)$ the weight at the origin has

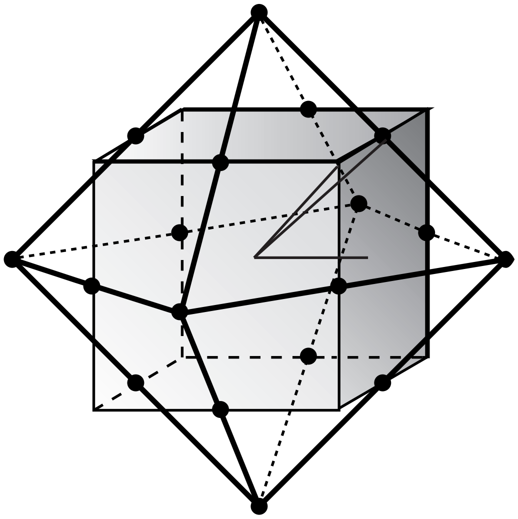

Figure 27.8.1: Fundamental weights $\boldsymbol{\phi}^1$, $\boldsymbol{\phi}^2$ and $\boldsymbol{\phi}^3$ for $sp(6)$. The root vectors are also shown.

Table 27.8.1: Dimensions of Representations of $sp(6)$.

ℓ	m	n	$\dim\Gamma(\ell,m,n)$	ℓ	m	n	$\dim\Gamma(\ell,m,n)$
0	0	0	1	3	0	0	56
1	0	0	6	2	1	0	189
0	1	0	14	2	0	1	216

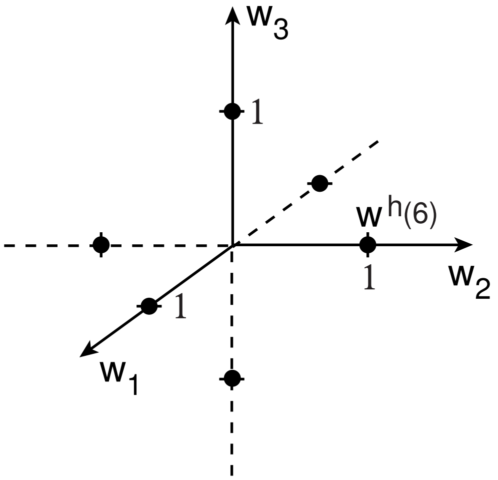

Figure 27.8.3: Weight diagram for the fundamental representation $6 = \Gamma(1,0,0)$.

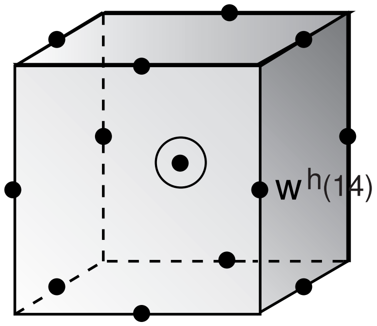

Figure 27.8.4: Weight diagram for the representation $14 = \Gamma(0,1,0)$. The circled weight at the origin has multiplicity 2. Observe from Figure 7.1 that the 12 other weights are located at the tips of the root vectors having length $\sqrt{2}$.

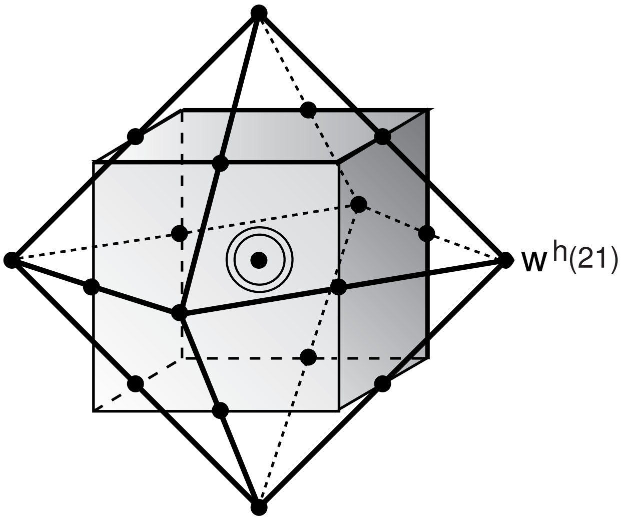

Figure 27.8.5: Weight diagram for the adjoint representation $21 = \Gamma(2,0,0)$. The doubly circled weight at the origin has multiplicity 3. The 18 other weights are located at the tips of the $sp(6)$ root vectors.

multiplicity 2; and for $\Gamma(2,0,0)$, which is the adjoint or regular representation, the weight vector at the origin has multiplicity 3.

Let $\mathcal{P}_\ell$ be the space of homogeneous polynomials of degree ℓ in the variables z_a with $a = 1,6$. Then, by arguments that are now familiar, the space $\mathcal{P}_\ell$ forms a representation of $sp(6,\mathbb{R})$. To see what representations occur we again employ a complex symplectic and unitary $\mathcal{A}(\pi/8)$ now defined by the equation

$$\mathcal{A}(\pi/8) = \exp[-i(\pi/8) : p_1^2 - q_1^2 + p_2^2 - q_2^2 + p_3^2 - q_3^2 :]. \tag{27.8.7}$$

It transforms between the Cartesian and resonance bases by the rule

$$\mathcal{A}(\pi/8)(q_1^{r_1}p_1^{s_1}q_2^{r_2}p_2^{s_2}q_3^{r_3}p_3^{s_3}) = (1/\sqrt{2})^{r_1+s_1+r_2+s_2+r_3+s_3}(i)^{s_1+s_2+s_3} \times$$
$$(q_1+ip_1)^{r_1}(q_1-ip_1)^{s_1}(q_2+ip_2)^{r_2}(q_2-ip_2)^{s_2}(q_3+ip_3)^{r_3}(q_3-ip_3)^{s_3}. \tag{27.8.8}$$

Use of $\mathcal{A}$ gives the transformed Lie basis polynomials $\tilde{c}^j$ and $\tilde{r}(\boldsymbol{\mu})$ listed below:

$$\tilde{c}^j = \mathcal{A}(-\pi/8)c^j = -q_j p_j, \tag{27.8.9}$$

$$\tilde{r}(\boldsymbol{\alpha}^1) = \mathcal{A}(-\pi/8)r(\boldsymbol{\alpha}^1) = (1/\sqrt{2})q_1^2, \tag{27.8.10}$$

$$\tilde{r}(-\boldsymbol{\alpha}^1) = \mathcal{A}(-\pi/8)r(-\boldsymbol{\alpha}^1) = -(1/\sqrt{2})p_1^2, \tag{27.8.11}$$

$$\tilde{r}(\boldsymbol{\alpha}^2) = \mathcal{A}(-\pi/8)r(\boldsymbol{\alpha}^2) = q_1 q_2, \tag{27.8.12}$$

$$\tilde{r}(-\boldsymbol{\alpha}^2) = \mathcal{A}(-\pi/8)r(-\boldsymbol{\alpha}^2) = -p_1 p_2, \tag{27.8.13}$$

$$\tilde{r}(\boldsymbol{\alpha}^3) = \mathcal{A}(-\pi/8)r(\boldsymbol{\alpha}^3) = q_1 p_2, \tag{27.8.14}$$

$$\tilde{r}(-\boldsymbol{\alpha}^3) = \mathcal{A}(-\pi/8)r(-\boldsymbol{\alpha}^3) = q_2 p_1, \tag{27.8.15}$$

$$\tilde{r}(\boldsymbol{\beta}^1) = \mathcal{A}(-\pi/8)r(\boldsymbol{\beta}^1) = (1/\sqrt{2})q_2^2, \tag{27.8.16}$$

$$\tilde{r}(-\boldsymbol{\beta}^1) = \mathcal{A}(-\pi/8)r(-\boldsymbol{\beta}^1) = -(1/\sqrt{2})p_2^2, \tag{27.8.17}$$

$$\tilde{r}(\boldsymbol{\beta}^2) = \mathcal{A}(-\pi/8)r(\boldsymbol{\beta}^2) = q_2q_3, \tag{27.8.18}$$

$$\tilde{r}(-\boldsymbol{\beta}^2) = \mathcal{A}(-\pi/8)r(-\boldsymbol{\beta}^2) = -p_2p_3, \tag{27.8.19}$$

$$\tilde{r}(\boldsymbol{\beta}^3) = \mathcal{A}(-\pi/8)r(\boldsymbol{\beta}^3) = q_2p_3, \tag{27.8.20}$$

$$\tilde{r}(-\boldsymbol{\beta}^3) = \mathcal{A}(-\pi/8)r(-\boldsymbol{\beta}^3) = q_3p_2, \tag{27.8.21}$$

$$\tilde{r}(\boldsymbol{\gamma}^1) = \mathcal{A}(-\pi/8)r(\boldsymbol{\gamma}^1) = (1/\sqrt{2})q_3^2, \tag{27.8.22}$$

$$\tilde{r}(-\boldsymbol{\gamma}^1) = \mathcal{A}(-\pi/8)r(-\boldsymbol{\gamma}^1) = -(1/\sqrt{2})p_3^2, \tag{27.8.23}$$

$$\tilde{r}(\boldsymbol{\gamma}^2) = \mathcal{A}(-\pi/8)r(\boldsymbol{\gamma}^2) = q_3q_1, \tag{27.8.24}$$

$$\tilde{r}(-\boldsymbol{\gamma}^2) = \mathcal{A}(-\pi/8)r(-\boldsymbol{\gamma}^2) = -p_3p_1, \tag{27.8.25}$$

$$\tilde{r}(\boldsymbol{\gamma}^3) = \mathcal{A}(-\pi/8)r(\boldsymbol{\gamma}^3) = q_3p_1, \tag{27.8.26}$$

$$\tilde{r}(-\boldsymbol{\gamma}^3) = \mathcal{A}(-\pi/8)r(-\boldsymbol{\gamma}^3) = q_1p_3. \tag{27.8.27}$$

Since $\mathcal{A}$ is both symplectic and unitary, the transformed basis polynomials also obey the Poisson bracket rules (4.15) through (4.18), and also satisfy the orthonormality conditions (4.19) through (4.22) and the conjugation relations (4.8) and (4.14).

When the $\tilde{c}^j$ and $\tilde{r}(\boldsymbol{\mu})$ act on the monomials $q_1^{r_1}p_1^{s_1}q_2^{r_2}p_2^{s_2}q_3^{r_3}p_3^{s_3}$, there are relations analogous to those in (5.19) through (5.28), and it is evident that $sp(6)$ acts irreducibly on $\mathcal{P}_\ell$. Also, q_1^ℓ is the vector of highest weight in $\mathcal{P}_\ell$ and has the weight $\boldsymbol{w}^h = \ell\boldsymbol{\phi}^1$,

$$:\tilde{c}^1: q_1^\ell = \ell q_1^\ell = (\boldsymbol{e}^1 \cdot \ell\boldsymbol{\phi}^1)q_1^\ell = (\boldsymbol{e}^1 \cdot \boldsymbol{w}^h)q_1^\ell, \tag{27.8.28}$$

$$:\tilde{c}^2: q_1^\ell = 0 = (\boldsymbol{e}^2 \cdot \ell\boldsymbol{\phi}^1)q_1^\ell = (\boldsymbol{e}^2 \cdot \boldsymbol{w}^h)q_1^\ell, \tag{27.8.29}$$

$$:\tilde{c}^3: q_1^\ell = 0 = (\boldsymbol{e}^3 \cdot \ell\boldsymbol{\phi}^1)q_1^\ell = (\boldsymbol{e}^3 \cdot \boldsymbol{w}^h)q_1^\ell. \tag{27.8.30}$$

It follows that $\mathcal{P}_\ell$ carries the representation $\Gamma(\ell,0,0)$. We also have, as expected, the result

$$\dim \mathcal{P}_\ell = N(\ell,6) = (1/120)(\ell+5)(\ell+4)(\ell+3)(\ell+2)(\ell+1) = \dim\Gamma(\ell,0,0). \tag{27.8.31}$$

At this point we observe that the relations (5.8.27) and (5.8.31) can be written in the form

$$\begin{aligned}\Gamma(\ell,0,0) = &\sum_{m+n=\ell}\hat{\Gamma}(m,n) \oplus \sum_{m+n=\ell-2}\hat{\Gamma}(m,n) \oplus \sum_{m+n=\ell-4}\hat{\Gamma}(m,n) \oplus \cdots \\ &\oplus \hat{\Gamma}(0,0), \text{ for } \ell \text{ even;}\end{aligned} \tag{27.8.32}$$

$$\begin{aligned}\Gamma(\ell,0,0) = &\sum_{m+n=\ell}\hat{\Gamma}(m,n) \oplus \sum_{m+n=\ell-2}\hat{\Gamma}(m,n) \oplus \sum_{m+n=\ell-4}\hat{\Gamma}(m,n) \oplus \cdots \\ &\oplus \hat{\Gamma}(1,0) \oplus \hat{\Gamma}(0,1), \text{ for } \ell \text{ odd.}\end{aligned} \tag{27.8.33}$$

[Here we have used the symbols $\hat{\Gamma}(m,n)$ to denote representations of $su(3)$ so as not to be confused with the symbols $\Gamma(m,n)$ used in Section 21.5 to denote representations of $sp(4)$.] That is, $sp(6)$ representations of the form $\Gamma(\ell,0,0)$ can be decomposed into various $\hat{\Gamma}(m,n)$

representations of its $su(3)$ subgroup, and the representations listed occur once and only once.

Finally, as before, we can let $\mathcal{A}(\pi/8)$ act on both sides of 6-variable relations analogous to (5.19) through (5.28). Doing so gives results analogous to those in (2.23) through (2.25). Consequently, as before, the $:c^j:$ and $:r(\boldsymbol{\mu}):$ act on the resonance basis in the same way that the $:\tilde{c}^j:$ and $:\tilde{r}(\boldsymbol{\mu}):$ act on the monomial basis.

Exercises

27.8.1. From (7.14) verify the relation

$$r(\boldsymbol{\alpha}^1) - r(-\boldsymbol{\alpha}^1) = i\sqrt{2}q_1p_1. \tag{27.8.34}$$

Next verify that the transformation

$$\mathcal{U}(\theta) = \exp :i\theta q_1 p_1: \tag{27.8.35}$$

is symplectic and unitary, and satisfies the relations

$$\mathcal{U}(\theta)q_1 = \exp(-i\theta)q_1, \tag{27.8.36}$$

$$\mathcal{U}(\theta)p_1 = \exp(i\theta)p_1. \tag{27.8.37}$$

See Exercise 5.4.4. As a consequence verify the relations

$$\mathcal{U}(\theta)(p_1^2 + q_1^2) = p_1^2\exp(2i\theta) + q_1^2\exp(-2i\theta), \tag{27.8.38}$$

$$\mathcal{U}(\pi/2)(p_1^2 + q_1^2) = -(p_1^2 + q_1^2), \tag{27.8.39}$$

$$\mathcal{U}(\pi/2) :c^1: \mathcal{U}^{-1}(\pi/2) = -:c^1:. \tag{27.8.40}$$

Suppose that C^j and $R(\boldsymbol{\mu})$ are any set of matrices that satisfies the commutation rules analogous to (4.15) through (4.18). That is, the C^j commute and the C^j and $R(\boldsymbol{\mu})$ satisfy the rules (5.8.12) through (5.8.14). By this definition, they provide a matrix representation of $sp(6)$. Since the relation (8.40) is purely a consequence of Lie-algebraic rules, show that there must be the matrix relation

$$U(\pi/2)C^1[U(\pi/2)]^{-1} = -C^1, \tag{27.8.41}$$

where

$$U(\pi/2) = \exp\{(\pi/\sqrt{8})[R(\boldsymbol{\alpha}^1) - R(-\boldsymbol{\alpha}^1)]\}, \tag{27.8.42}$$

$$[U(\pi/2)]^{-1} = \exp\{-(\pi/\sqrt{8})[R(\boldsymbol{\alpha}^1) - R(-\boldsymbol{\alpha}^1)]\}. \tag{27.8.43}$$

Suppose $|w_1w_2w_3\rangle$ is a vector in this representation with the property

$$C^j|w_1w_2w_3\rangle = w_j|w_1w_2w_3\rangle. \tag{27.8.44}$$

Show that the vector $[U(\pi/2)]^{-1}|\boldsymbol{w}\rangle$ has the property

$$C^1[U^{-1}(\pi/2)]^{-1}|\boldsymbol{w}\rangle = -w_1[U(\pi/2)]^{-1}|\boldsymbol{w}\rangle. \tag{27.8.45}$$

Prove that if (w_1, w_2, w_3) is a weight vector, so is $(-w_1, w_2, w_3)$. Generalize this result to show that if (w_1, w_2, w_3) is a weight vector, so are the vectors $(\pm w_1, \pm w_2, \pm w_3)$ where all ± signs are taken independently. Verify similar results for $sp(2)$ and $sp(4)$. Verify that the weight diagrams shown in Sections 21.2, 21.5, and 21.8 have this property.

27.8.2. Verify (8.31).

27.8.3. Verify by a dimension count that $\Gamma(1,0,0)$ is the fundamental representation of $sp(6)$ and $\Gamma(2,0,0)$ is the adjoint representation. Repeat analogous calculations for the cases of $sp(2)$ and $sp(4)$.

27.8.4. Work out the weight diagram for the $sp(6)$ representation $\Gamma(0,0,1)$.

27.9 Symplectic Classification of Analytic Vector Fields in Six Variables

The symplectic classification of analytic vector fields in six variables is similar to the 4-variable case. As before, it suffices to consider homogeneous vector fields. The Hamiltonian vector fields $:h_\ell:$ are transformed into each other under the action of $sp(6,\mathbb{R})$, and carry the representation $\Gamma(\ell,0,0)$. Any $\mathcal{L}_{\boldsymbol{g}^0}$ is a Hamiltonian vector field, and these fields carry the representation $\Gamma(1,0,0)$. The vector field Σ defined by (6.1) with a ranging fron 1 to 6 carries the representation $\Gamma(0,0,0)$.

The 6-dimensional analog of (6.34) shows that in this case the $\mathcal{L}_{\boldsymbol{g}^\ell}$ carry the direct product representation $\Gamma(\ell,0,0)\otimes\Gamma(1,0,0)$. For $sp(6)$ there is the Clebsch-Gordan series result

$$\Gamma(\ell,0,0)\otimes\Gamma(1,0,0)=\Gamma(\ell+1,0,0)\oplus\Gamma(\ell-1,1,0)\oplus\Gamma(\ell-1,0,0). \tag{27.9.1}$$

Consequently, any $\mathcal{L}_{\boldsymbol{g}^\ell}$ with $\ell\geq 1$ has the unique decomposition

$$\mathcal{L}_{\boldsymbol{g}^\ell}=\mathcal{H}^{\ell+1,0,0}+\mathcal{G}^{\ell-1,1,0}+\mathcal{G}^{\ell-1,0,0}. \tag{27.9.2}$$

Here $\mathcal{H}^{\ell+1,0,0}$ is a Hamiltonian vector field that carries the representation $\Gamma(\ell+1,0,0)$, and is of the form $:h_{\ell+1}:$. The quantities $\mathcal{G}^{\ell-1,1,0}$ and $\mathcal{G}^{\ell-1,0,0}$ are non-Hamiltonian vector fields that carry the representations $\Gamma(\ell-1,1,0)$ and $\Gamma(\ell-1,0,0)$, respectively. The vector fields $\mathcal{G}^{\ell-1,0,0}$ are of the form

$$\mathcal{G}^{\ell-1,0,0}=f_{\ell-1}\Sigma \tag{27.9.3}$$

where $f_{\ell-1}$ is any homogeneous polynomial of degree $(\ell-1)$, The construction of the vector fields that span $\mathcal{G}^{\ell-1,1,0}$ requires special effort.

As before we will work out the simplest case $\ell=1$ for which we have the result

$$\mathcal{L}_{\boldsymbol{g}^1}=\mathcal{H}^{2,0,0}+\mathcal{G}^{0,1,0}+\mathcal{G}^{0,0,0}. \tag{27.9.4}$$

Since $\mathcal{L}_{\boldsymbol{g}^1}$ is spanned by the vector fields $z_a(\partial/\partial z_b)$ with $a,b=1$ through 6, it has dimension 36. We know that $\mathcal{H}^{2,0,0}$ has dimension $N(2,6)=21$, and $\mathcal{G}^{0,0,0}$ has dimension 1. It follows that $\mathcal{G}^{0,1,0}$ has dimension $(36-21-1)=14$, which we know is the dimension of $\Gamma(0,1,0)$.

Similar to the case of $sp(4)$ treated in Section 21.6, finding a suitable basis for the vector fields in $\mathcal{H}^{2,0,0}$ is equivalent to finding a suitable basis for the quadratic polynomials in 6-dimensional phase space; and these basis polynomials may be taken to be the $sp(6)$ generators given in the Cartesian Cartan basis by (8.9) through (8.27).

To find a basis for the non-Hamiltonian parts we will begin with the 6 mutually commuting vector fields $z_a(\partial/\partial z_a)$ with $a = 1$ through 6. The 4 vector fields $:\tilde{c}^j:$ and $\tilde{\mathcal{G}}^{0,0,0}_{0,0,0} = \Sigma$ are made from the $z_a(\partial/\partial z_a)$,

$$:\tilde{c}^1 := z_1(\partial/\partial z_1) - z_4(\partial/\partial z_4), \tag{27.9.5}$$

$$:\tilde{c}^2 := z_2(\partial/\partial z_2) - z_5(\partial/\partial z_5), \tag{27.9.6}$$

$$:\tilde{c}^3 := z_3(\partial/\partial z_3) - z_6(\partial/\partial z_6), \tag{27.9.7}$$

$$\tilde{\mathcal{G}}^{0,0,0}_{0,0,0} = \Sigma = z_1(\partial/\partial z_1)+z_2(\partial/\partial z_2)+z_3(\partial/\partial z_3)+z_4(\partial/\partial z_4)+z_5(\partial/\partial z_5)+z_6(\partial/\partial z_6). \tag{27.9.8}$$

Let us define vector fields $\tilde{\Sigma}^j$ by the equations

$$\tilde{\Sigma}^1 = q_1(\partial/\partial q_1) + p_1(\partial/\partial p_1) = z_1(\partial/\partial z_1) + z_4(\partial/\partial z_4), \tag{27.9.9}$$

$$\tilde{\Sigma}^2 = q_2(\partial/\partial q_2) + p_2(\partial/\partial p_2) = z_2(\partial/\partial z_2) + z_5(\partial/\partial z_5), \tag{27.9.10}$$

$$\tilde{\Sigma}^3 = q_3(\partial/\partial q_3) + p_3(\partial/\partial p_3) = z_3(\partial/\partial z_3) + z_6(\partial/\partial z_6). \tag{27.9.11}$$

They are obviously independent of the $:\tilde{c}^j:$ and are also made from the $z_a(\partial/\partial z_a)$.

We already have the $:\tilde{c}^j:$ and the combination

$$\Sigma = \tilde{\Sigma}^1 + \tilde{\Sigma}^2 + \tilde{\Sigma}^3. \tag{27.9.12}$$

As the 5th and 6th such linearly independent vectors we take the elements ${}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0}$ and ${}^8\tilde{\mathcal{G}}^{0,1,0}_{0,0,0}$ defined by the equations

$${}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = \tilde{\Sigma}^1 - \tilde{\Sigma}^2 = z_1(\partial/\partial z_1) + z_4(\partial/\partial z_4) - z_2(\partial/\partial z_2) - z_5(\partial/\partial z_5), \tag{27.9.13}$$

$$\begin{aligned} {}^8\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} &= \tilde{\Sigma}^1 + \tilde{\Sigma}^2 - 2\tilde{\Sigma}^3 \\ &= z_1(\partial/\partial z_1) + z_4(\partial/\partial z_4) + z_2(\partial/\partial z_2) \\ &+ z_5(\partial/\partial z_5) - 2z_3(\partial/\partial z_3) - 2z_6(\partial/\partial z_6). \end{aligned} \tag{27.9.14}$$

Here the superscripts "3" and "8" are used to refer to the analogous diagonal structure of the Gell-Mann matrices λ^3 and λ^8 of Section 5.8. It is easily verified that these 2 vector fields obey the relations

$$\#\tilde{c}^j\#{}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = 0, \tag{27.9.15}$$

$$\#\tilde{c}^j\#{}^8\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = 0, \tag{27.9.16}$$

and therefore are candidates for the center elements of Figure 8.4.

We define the remaining 12 vector fields that occupy the other sites of Figure 8.4 by the equations

$$\tilde{\mathcal{G}}^{0,1,0}_{1,1,0} = (1/2)\#\tilde{r}(\boldsymbol{\alpha}^2)\#{}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = -z_1(\partial/\partial z_5) + z_2(\partial/\partial z_4), \tag{27.9.17}$$

$$\tilde{\mathcal{G}}^{0,1,0}_{-1,-1,0} = (1/2)\#\tilde{r}(-\boldsymbol{\alpha}^2)\#{}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = -z_4(\partial/\partial z_2) + z_5(\partial/\partial z_1), \tag{27.9.18}$$

$$\tilde{\mathcal{G}}^{0,1,0}_{1,-1,0} = (1/2)\#\tilde{r}(\boldsymbol{\alpha}^3)\#{}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = z_1(\partial/\partial z_2) + z_5(\partial/\partial z_4), \tag{27.9.19}$$

$$\tilde{\mathcal{G}}^{0,1,0}_{-1,1,0} = (1/2)\#\tilde{r}(-\boldsymbol{\alpha}^3)\#{}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = -z_2(\partial/\partial z_1) - z_4(\partial/\partial z_5), \tag{27.9.20}$$

$$\tilde{\mathcal{G}}^{0,1,0}_{0,1,1} = \#\tilde{r}(\boldsymbol{\beta}^2)\#{}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = -z_3(\partial/\partial z_5) + z_2(\partial/\partial z_6), \tag{27.9.21}$$

$$\tilde{\mathcal{G}}^{0,1,0}_{0,-1,-1} = \#\tilde{r}(-\boldsymbol{\beta}^2)\#{}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = z_5(\partial/\partial z_3) - z_6(\partial/\partial z_2), \tag{27.9.22}$$

$$\tilde{\mathcal{G}}^{0,1,0}_{0,1,-1} = \#\tilde{r}(\boldsymbol{\beta}^3)\#{}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = -z_2(\partial/\partial z_3) - z_6(\partial/\partial z_5), \tag{27.9.23}$$

$$\tilde{\mathcal{G}}^{0,1,0}_{0,-1,1} = \#\tilde{r}(-\boldsymbol{\beta}^3)\#{}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = z_3(\partial/\partial z_2) + z_5(\partial/\partial z_6), \tag{27.9.24}$$

$$\tilde{\mathcal{G}}^{0,1,0}_{1,0,1} = \#\tilde{r}(\boldsymbol{\gamma}^2)\#{}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = z_3(\partial/\partial z_4) - z_1(\partial/\partial z_6), \tag{27.9.25}$$

$$\tilde{\mathcal{G}}^{0,1,0}_{-1,0,-1} = \#\tilde{r}(-\boldsymbol{\gamma}^2)\#{}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = -z_4(\partial/\partial z_3) + z_6(\partial/\partial z_1), \tag{27.9.26}$$

$$\tilde{\mathcal{G}}^{0,1,0}_{-1,0,1} = \#\tilde{r}(\boldsymbol{\gamma}^3)\#{}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = -z_3(\partial/\partial z_1) - z_4(\partial/\partial z_6), \tag{27.9.27}$$

$$\tilde{\mathcal{G}}^{0,1,0}_{1,0,-1} = \#\tilde{r}(-\boldsymbol{\gamma}^3)\#{}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = z_1(\partial/\partial z_3) + z_6(\partial/\partial z_4). \tag{27.9.28}$$

They obey the relations

$$\#\tilde{c}^j\#\tilde{\mathcal{G}}^{0,1,0}_{k,\ell,m} = \boldsymbol{e}^j \cdot (k\boldsymbol{e}^1 + \ell\boldsymbol{e}^2 + m\boldsymbol{e}^3), \tag{27.9.29}$$

in keeping with the sites they occupy. We note that $\tilde{\mathcal{G}}^{0,1,0}_{1,1,0}$ occupies the highest weight site $\boldsymbol{w}^h$ given by (8.4) for the representation $\Gamma(0,1,0)$. Therefore there should be the ladder relation

$$\#\tilde{r}(\boldsymbol{\alpha}^3)\#\tilde{\mathcal{G}}^{0,1,0}_{1,1,0} = 0. \tag{27.9.30}$$

Direct calculation shows that this relation is true. By comparison, the vector field $:\tilde{r}(\boldsymbol{\alpha}^2):$ has the form

$$:\tilde{r}(\boldsymbol{\alpha}^2) :=: q_1q_2 := z_1(\partial/\partial z_5) + z_2(\partial/\partial z_4). \tag{27.9.31}$$

It occupies the same 1,1,0 site in Figure 8.5,

$$\begin{aligned}\#\tilde{c}^j\# : \tilde{r}(\boldsymbol{\alpha}^2) : &= \{: \tilde{c}^j :, : \tilde{r}(\boldsymbol{\alpha}^2) :\} =: [\tilde{c}^j, \tilde{r}(\boldsymbol{\alpha}^2)] : \\ &= (\boldsymbol{e}^j \cdot \boldsymbol{\alpha}^2) : \tilde{r}(\boldsymbol{\alpha}^2) := [\boldsymbol{e}^j \cdot (\boldsymbol{e}^1 + \boldsymbol{e}^2)] : \tilde{r}(\boldsymbol{\alpha}^2) :,\end{aligned} \tag{27.9.32}$$

and is evidently linearly independent of $\tilde{\mathcal{G}}^{0,1,0}_{1,1,0}$,. It satisfies the relation

$$\#\tilde{r}(\boldsymbol{\alpha}^3)\# : \tilde{r}(\boldsymbol{\alpha}^2) := -(\sqrt{2}) : \tilde{r}(\boldsymbol{\alpha}^1) : . \tag{27.9.33}$$

It can be verified that the ${}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0}$, ${}^8\tilde{\mathcal{G}}^{0,1,0}_{0,0,0}$, and $\tilde{\mathcal{G}}^{0,1,0}_{k,\ell,m}$ satisfy all the ladder relations one expects for the representation $\Gamma(0,1,0)$. For example, there is the relation

$$(1/2)\#\tilde{r}(-\boldsymbol{\alpha}^2)\#\#\tilde{r}(\boldsymbol{\alpha}^2)\#{}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} ={}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} \tag{27.9.34}$$

which shows that ${}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0}$ has no $\Gamma(0,0,0)$ contamination. (See Exercise 6.1.) There is also the relation

$$\#\tilde{r}(-\boldsymbol{\beta}^2)\#\#\tilde{r}(\boldsymbol{\beta}^2)\#{}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = (1/2)({}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} -{}^8\tilde{\mathcal{G}}^{0,1,0}_{0,0,0}) \tag{27.9.35}$$

which shows that ${}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0}$ and ${}^8\tilde{\mathcal{G}}^{0,1,0}_{0,0,0}$ can be transformed into each other, and that ${}^8\tilde{\mathcal{G}}^{0,1,0}_{0,0,0}$ as well has no $\Gamma(0,0,0)$ contamination. There are also the relations

$$\#\tilde{r}(\boldsymbol{\nu})\#{}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = \#\tilde{r}(\boldsymbol{\nu})\#{}^8\tilde{\mathcal{G}}^{0,1,0}_{0,0,0} = 0 \tag{27.9.36}$$

for $\boldsymbol{\nu} = \pm\boldsymbol{\alpha}^1$, $\pm\boldsymbol{\beta}^1$, $\pm\boldsymbol{\gamma}^1$. Note that the sites $\pm2,0,0$ and $0,\pm2,0$ and $0,0,\pm2$ are empty in Figure 8.4 and occupied in Figure 8.5. Therefore (9.32) shows that ${}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0}$ and ${}^8\tilde{\mathcal{G}}^{0,1,0}_{0,0,0}$, and hence the $\tilde{\mathcal{G}}^{0,1,0}_{k,\ell,m}$, have no $\Gamma(2,0,0)$ contamination.

Finally, we observe that the results we have obtained in the monomial basis can be transformed if desired to the resonance basis with the aid of the operator

$$\hat{\mathcal{A}}(\pi/8) = \exp[-i(\pi/8)\#p_1^2 - q_1^2 + p_2^2 - q_2^2 + p_2^3 - q_3^2\#]. \tag{27.9.37}$$

Exercises

27.9.1. Work out the analogs of the relations (9.17) through (9.28) with ${}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0}$ replaced by ${}^8\tilde{\mathcal{G}}^{0,1,0}_{0,0,0}$.

27.9.2. Work out the 6×6 matrices $\tilde{A}$ corresponding to the vector fields $\tilde{\mathcal{G}}^{0,0,0}_{0,0,0}$, ${}^3\tilde{\mathcal{G}}^{0,1,0}_{0,0,0}$, ${}^8\tilde{\mathcal{G}}^{0,1,0}_{0,0,0}$, and $\tilde{\mathcal{G}}^{0,1,0}_{k,\ell,m}$ in analogy to what was done for the 4×4 case at the end of Section 21.6. Show that the matrix JA, when exponentiated and with A given by any multiple of the $\tilde{A}$ associated with $\tilde{\mathcal{G}}^{0,0,0}_{0,0,0}$, produces a positive multiple of the identity matrix. Show that the remaining JA, with A any linear combination of the fourteen $\tilde{A}$ associated with the remaining $\tilde{\mathcal{G}}$ given by (9.13) and (9.14) and (9.17) through (9.28), are traceless and therefore are in $s\ell(6,\mathbb{R})$.

27.9.3. Write and verify the $sp(6)$ analog of (6.38), as given in Exercise 6.3, using (9.1) and (8.5).

27.9.4. In Sections 21.3, 21.6, and 21.9 we learned that Σ always was invariant under the action of $sp(2)$, $sp(4)$, and $sp(6)$. The purpose of this exercise is to show that this invariance is a consequence of a more general result. Consider m-dimensional Euclidean space with coordinates

$$x = (x_1, x_2, \cdots, x_m). \tag{27.9.38}$$

Here m can be even or odd. Define a vector field Σ by the relation

$$\Sigma = \sum_{a=1}^{m} x_a \partial/\partial x_a. \tag{27.9.39}$$

Suppose that each x is sent to $\bar{x}$ under the action of some linear, but invertible, transformation M,

$$\bar{x} = Mx. \tag{27.9.40}$$

Define a transformed vector field $\bar{\Sigma}$ by the rule

$$\bar{\Sigma} = \sum_{a=1}^{m} \bar{x}_a \partial/\partial \bar{x}_a. \tag{27.9.41}$$

You are to show that

$$\bar{\Sigma} = \Sigma. \tag{27.9.42}$$

That is, Σ is invariant under the action of M. Because M is any invertible matrix, we may say that Σ is invariant under the group $GL(m, \mathbb{R})$. Since $Sp(2n, \mathbb{R})$ is a subgroup of $GL(2n, \mathbb{R})$, it follows that Σ is also invariant under the group $Sp(2n, \mathbb{R})$.

Begin by inverting (9.40),

$$x = M^{-1}\bar{x}, \tag{27.9.43}$$

and verify that this relation has the component form

$$x_a = \sum_b (M^{-1})_{ab}\bar{x}_b. \tag{27.9.44}$$

Show it follows that

$$\partial x_a/\partial \bar{x}_b = (M^{-1})_{ab}. \tag{27.9.45}$$

Verify by the chain rule that there is the relation

$$\partial/\partial \bar{x}_a = \sum_c (\partial x_c/\partial \bar{x}_a)\partial/\partial x_c = \sum_c (M^{-1})_{ca}\partial/\partial x_c. \tag{27.9.46}$$

Also, the relation (9.40) has the component form

$$\bar{x}_a = \sum_d M_{ad}x_d. \tag{27.9.47}$$

Verify, by employing (9.46) and (9.47) in (9.41), it follows that there is the relation

$$\begin{aligned}
\bar{\Sigma} &= \sum_{acd} M_{ad}(M^{-1})_{ca}\, x_d\partial/\partial x_c = \sum_{acd}(M^{-1})_{ca}M_{ad}\, x_d\partial/\partial x_c \\
&= \sum_{cd}(M^{-1}M)_{cd}\, x_d\partial/\partial x_c = \sum_{cd}\delta_{cd}\, x_d\partial/\partial x_c \\
&= \sum_c x_c\partial/\partial x_c = \Sigma.
\end{aligned} \tag{27.9.48}$$

For an infinitesimal (Lie-algebraic) version of (9.42), see Exercise 10.8.

27.9.5. Suppose an object of mass m is acted upon by a force $\boldsymbol{F}$ arising from a potential V and a velocity dependent drag force,

$$\boldsymbol{F} = -\boldsymbol{\nabla}V - 2\beta\boldsymbol{v}. \tag{27.9.49}$$

Define the particle's momentum $\boldsymbol{p}$ in the usual way

$$\boldsymbol{p} = m\boldsymbol{v} \tag{27.9.50}$$

and show that Newton's equations of motion can be written in the form

$$\dot{\boldsymbol{q}} = \boldsymbol{\mathcal{L}}\boldsymbol{q},\ \dot{\boldsymbol{p}} = \boldsymbol{\mathcal{L}}\boldsymbol{p} \tag{27.9.51}$$

where $\mathcal{L}$ is the vector field

$$\mathcal{L} = \sum_i (p_i/m)(\partial/\partial q_i) - (\partial V/\partial q_i)(\partial/\partial p_i) - (2\beta/m)p_i(\partial/\partial p_i). \tag{27.9.52}$$

Decompose $\mathcal{L}$ into Hamiltonian and non-Hamiltonian parts to find the result

$$\mathcal{L} =: -[p^2/(2m) + \beta \boldsymbol{p}\cdot\boldsymbol{q} + V] : -\beta\Sigma. \tag{27.9.53}$$

Suppose V is quadratic in the components of $\boldsymbol{q}$. Show that in this case the Hamiltonian H defined by

$$H = p^2/(2m) + \beta\boldsymbol{p}\cdot\boldsymbol{q} + V \tag{27.9.54}$$

evolves according to the rule

$$H = (\text{constant}) \times e^{-2\beta t}. \tag{27.9.55}$$

27.9.6. Consider the case of a six-dimensional phase space and all Lie operators of the form $: f_3 :$. What are the $sp(6)$ transformation properties of the $: f_3 :^\dagger$?

27.10 Scalar Product and Projection Operators for Vector Fields

Section 7.3 described a $USp(2n)$ invariant scalar product for phase-space functions. Here we will see that there is a related scalar product for vector fields, and we will find that the use of this vector-field scalar product illuminates the discussion of previous sections.

For our present purposes it is convenient to employ a vector-field basis slightly different from that used in (5.3.17) and (5.3.18). Let s_α be the various phase-space monomials indexed by α in some covenient way as in Section 7.3 or Section 32.2. Take as vector-field basis elements the quantities $\mathcal{L}_{\alpha a}$ defined by the equation

$$\mathcal{L}_{\alpha a} = s_\alpha : z_a : . \tag{27.10.1}$$

In view of the relations

$$: z_a := \sum_b J_{ab}(\partial/\partial z_b), \tag{27.10.2}$$

$$\partial/\partial z_a = -\sum_b J_{ab} : z_b :,$$

the $\mathcal{L}_{\alpha a}$ manifestly form a satisfactory basis. Now define a scalar product for these basis elements (and hence, by linearity, for all vector fields) by the rule

$$\langle \mathcal{L}_{\alpha a}, \mathcal{L}_{\beta b}\rangle = \langle s_\alpha, s_\beta\rangle\langle z_a, z_b\rangle. \tag{27.10.3}$$

Here the scalar product on the left of (10.3) is the vector-field scalar product, and the scalar products on the right are the phase-space function scalar products of Section 7.3. Evidently the vector-field scalar product defined by (10.3) is positive definite.

Suppose two vector fields $\mathcal{L}_{\boldsymbol{g}}$ and $\mathcal{L}_{\boldsymbol{h}}$ are specified as in (5.3.17). Then, in view of (10.2), use of (10.3) gives the result

$$\langle \mathcal{L}_{\boldsymbol{g}}, \mathcal{L}_{\boldsymbol{h}} \rangle = \sum_a \langle g_a, h_a \rangle. \tag{27.10.4}$$

In the case that $\boldsymbol{g}$ and $\boldsymbol{h}$ are homogeneous, there is the immediate result

$$\langle \mathcal{L}_{\boldsymbol{g}^m}, \mathcal{L}_{\boldsymbol{h}^n} \rangle = 0 \text{ when } m \neq n. \tag{27.10.5}$$

As another interesting case, suppose g_m and h_m are homogeneous phase-space polynomials of degree m. Then use of (10.3) gives the result

$$\langle : g_m :, : h_m : \rangle = m \langle g_m, h_m \rangle. \tag{27.10.6}$$

Let $: f_2 :$ be the Hamiltonian vector field associated with any quadratic polynomial f_2, and consider the corresponding adjoint operator $\# : f_2 : \#$. For the action of $\# : f_2 : \#$ on a general vector-field basis element we have the result

$$\# : f_2 : \# \mathcal{L}_{\alpha a} = (: f_2 : s_\alpha) : z_a : + s_\alpha : (: f_2 : z_a) : . \tag{27.10.7}$$

See (3.25). Now watch closely! Take the scalar product of (10.7) with the general basis vector $\mathcal{L}_{\alpha' a'}$ and manipulate the result to find the relation

$$\begin{aligned}
&\langle \# : f_2 : \# \mathcal{L}_{\alpha a}, \mathcal{L}_{\alpha' a'} \rangle = \langle [(: f_2 : s_\alpha) : z_a : + s_\alpha : (: f_2 : z_a) :], s_{\alpha'} : z_{a'} : \rangle \\
&= \langle (: f_2 : s_\alpha) : z_a :, s_{\alpha'} : z_{a'} : \rangle + \langle s_\alpha : (: f_2 : z_a) :, s_{\alpha'} : z_{a'} : \rangle \\
&= \langle : f_2 : s_\alpha, s_{\alpha'} \rangle \langle z_a, z_{a'} \rangle + \langle s_\alpha, s_{\alpha'} \rangle \langle : f_2 : z_a, z_{a'} \rangle \\
&= \langle s_\alpha, : f_2 :^\dagger s_{\alpha'} \rangle \langle z_a, z_{a'} \rangle + \langle s_\alpha, s_{\alpha'} \rangle \langle z_a, : f_2 :^\dagger z_{a'} \rangle \\
&= \langle s_\alpha : z_a :, (: f_2 :^\dagger s_{\alpha'}) : z_{a'} : \rangle + \langle s_\alpha : z_a :, s_{\alpha'} : (: f_2 :^\dagger z_{a'}) : \rangle \\
&= \langle s_\alpha : z_a :, [(: f_2 :^\dagger s_{\alpha'}) : z_{a'} : + s_{\alpha'} : (: f_2 :^\dagger z_{a'}) :] \rangle \\
&= \langle s_\alpha : z_a :, \# : f_2 :^\dagger \# s_{\alpha'} : z_{a'} : \rangle = \langle \mathcal{L}_{\alpha a}, \# :: f_2 :^\dagger \# \mathcal{L}_{\alpha' a'} : \rangle.
\end{aligned} \tag{27.10.8}$$

Here we have used (7.3.15). And, in view of (7.3.15) and (10.8), we have found the beautiful result

$$\# : f_2 : \#^\dagger = \# : f_2 :^\dagger \#. \tag{27.10.9}$$

In mimicry of (7.3.31), define the analogous operator $\hat{\mathcal{M}}$, which acts on vector fields, by the rule

$$\hat{\mathcal{M}} = \exp(\# : f_2^c : \#) \exp(i \# : f_2^a : \#). \tag{27.10.10}$$

As a consequence of (8.1.11), operators of the form (10.10) give a realization of the group $USp(2n)$ acting on the space of vector fields. Moreover, in view of (7.3.26), (7.3.30), and (10.9), we have the result

$$\hat{\mathcal{M}}^\dagger = \hat{\mathcal{M}}^{-1}. \tag{27.10.11}$$

It follows that the vector-field scalar product defined by (10.3) is also $USp(2n)$ invariant. Finally, as a special case, we see that the operators $\hat{\mathcal{A}}$ defined by (6.24) and (9.37) are symplectic and unitary.

From Section 9 we know that the general homogeneous polynomial vector field (in 6 dimensions) has the decomposition (9.2). Since each term in the decomposition has different $sp(6)$ [and therefore $usp(6)$] transformation properties, we might expect that the different terms in the decomposition would be mutually orthogonal. This is indeed the case. That is, for the scalar product (10.3) and the decomposition (9.2), there are the relations

$$\begin{aligned}\langle \mathcal{H}^{\ell+1,0,0}, \mathcal{G}^{\ell-1,1,0}\rangle &= \langle \mathcal{H}^{\ell+1,0,0}, \mathcal{G}^{\ell-1,0,0}\rangle \\ &= \langle \mathcal{G}^{\ell-1,1,0}, \mathcal{G}^{\ell-1,0,0}\rangle = 0. \end{aligned} \tag{27.10.12}$$

Note that all the vector fields in (10.12) have the same degree of homogeneity. If the degrees are different, the vector fields are automatically orthogonal by (10.5).

The relations (10.12) will be proved in Subsection 11.2 by group-theoretic methods. Here we will begin to describe a complementary result. Section 9 showed that the decomposition (9.2) exists. However, given a specific vector field $\mathcal{L}_{\boldsymbol{g}^\ell}$, the only method proposed for finding $\mathcal{H}^{\ell+1,0,0}$, $\mathcal{G}^{\ell-1,1,0}$, and $\mathcal{G}^{\ell-1,0,0}$ was to construct in detail the bases for these spaces and then match coefficients. Fortunately, there is a more direct approach that accomplishes major aspects of this task. Part of this approach is described below, and the remainder will be described in Subsection 11.2.

Here we will show that there are linear projection operators $\mathcal{P}^H$ and $\mathcal{P}^G$ that can be described explicitly and that act on vector fields $\mathcal{L}_{\boldsymbol{g}^\ell}$ to yield the results

$$\mathcal{P}^H \mathcal{L}_{\boldsymbol{g}^\ell} = \mathcal{H}^{\ell+1,0,0}, \tag{27.10.13}$$

$$\mathcal{P}^G \mathcal{L}_{\boldsymbol{g}^\ell} = \mathcal{G}^{\ell-1,1,0} + \mathcal{G}^{\ell-1,0,0} = \mathcal{G}_{\ell+1}. \tag{27.10.14}$$

They also have the properties

$$(\mathcal{P}^H)^2 = \mathcal{P}^H,\ (\mathcal{P}^G)^2 = \mathcal{P}^G, \tag{27.10.15}$$

$$\mathcal{P}^H \mathcal{P}^G = \mathcal{P}^G \mathcal{P}^H = 0, \tag{27.10.16}$$

$$\mathcal{P}^H + \mathcal{P}^G = \mathcal{I}. \tag{27.10.17}$$

Here $\mathcal{I}$ denotes the identity operator. Finally, the $\mathcal{H}^{\ell+1,0,0}$ and $\mathcal{G}_{\ell+1}$ defined by (10.13) and (10.14) satisfy

$$\langle \mathcal{H}^{\ell+1,0,0}, \mathcal{G}_{\ell+1}\rangle = 0. \tag{27.10.18}$$

We will also show directly that

$$\langle \mathcal{H}^{\ell+1,0,0}, \mathcal{G}^{\ell-1,1,0}\rangle = \langle \mathcal{H}^{\ell+1,0,0}, \mathcal{G}^{\ell-1,0,0}\rangle = 0. \tag{27.10.19}$$

We remark that the relations (10.13) and (10.14) are sufficient to carry out the decomposition required for factorizing general maps as will be done in Section 26.1.

We will first define the projection operators, and then show that they possess the advertised properties. Suppose we are given $\mathcal{L}_{\boldsymbol{g}^\ell}$ and hence $\boldsymbol{g}^\ell(z)$. Then, in the spirit of (7.6.24), we *define* the homogeneous polynomial $h_{\ell+1}$ by the rule

$$h_{\ell+1} = -[1/(\ell+1)] \sum_{ab} g_a^\ell(z) J_{ab} z_b. \tag{27.10.20}$$

Note that $h_{\ell+1}$ depends *linearly* on the g_a^ℓ. We now define $\mathcal{P}^H$ by the rule

$$\mathcal{P}^H \mathcal{L}_{\boldsymbol{g}^\ell} = \mathcal{H}^{\ell+1,0,0} =: h_{\ell+1} : . \tag{27.10.21}$$

Let us compute the action of $: h_{\ell+1} :$ on z_c. We find the intermediate result

$$\begin{aligned} : h_{\ell+1} : z_c &= [h_{\ell+1}, z_c] = -[1/(\ell+1)] \sum_{ab} J_{ab} [g_a^\ell z_b, z_c] \\ &= -[1/(\ell+1)] \sum_{ab} J_{ab} (g_a^\ell [z_b, z_c] + z_b [g_a^\ell, z_c]) \\ &= -[1/(\ell+1)] \{ \sum_{ab} g_a^\ell J_{ab} J_{bc} + \sum_{ab} J_{ab} z_b [g_a^\ell, z_c] \} \\ &= [1/(\ell+1)] \{ g_c^\ell + \sum_{ab} J_{ab} z_b [z_c, g_a^\ell] \}. \end{aligned} \tag{27.10.22}$$

Here we have used (1.7.10) and (3.1.3). Next write the tautology

$$[z_c, g_a^\ell] = [z_a, g_c^\ell] - A_{ac} \tag{27.10.23}$$

where

$$A_{ac} = [z_a, g_c^\ell] - [z_c, g_a^\ell]. \tag{27.10.24}$$

Note that A_{ac} is antisymmetric under the interchange of indices. Insertion of (10.23) into (10.22) gives the further result

$$: h_{\ell+1} : z_c = [1/(\ell+1)] \{ g_c^\ell + \sum_{ab} J_{ab} z_b [z_a, g_c^\ell] - \sum_{ab} J_{ab} z_b A_{ac} \}. \tag{27.10.25}$$

The center term on the right of (10.25) can be evaluated,

$$\begin{aligned} \sum_{ab} J_{ab} z_b [z_a, g_c^\ell] &= \sum_{ab} J_{ab} z_b : z_a : g_c^\ell = -\sum_{ab} J_{ba} z_b : z_a : g_c^\ell \\ &= \Sigma g_c^\ell = \ell g_c^\ell. \end{aligned} \tag{27.10.26}$$

Here (7.6.50), (3.1), and (3.26) have been used. Therefore (10.25) can be rewritten in the form

$$g_c^\ell =: h_{\ell+1} : z_c + [1/(\ell+1)] \sum_{ab} J_{ab} z_b A_{ac}. \tag{27.10.27}$$

The second term on the right can be manipulated further. Use the antisymmetry of J and the fact that a, b are dummy summation indices to write

$$[1/(\ell+1)] \sum_{ab} J_{ab} z_b A_{ac} = -[1/(\ell+1)] \sum_{ab} z_b J_{ba} A_{ac} = -[1/(\ell+1)] \sum_{ab} z_a J_{ab} A_{bc}. \tag{27.10.28}$$

As a result of this manipulation (10.27) can be rewritten in the form

$$g_c =: h_{\ell+1} : z_c - [1/(\ell+1)] \sum_{ab} z_a J_{ab} A_{bc}. \tag{27.10.29}$$

Correspondingly, $\mathcal{L}_{\boldsymbol{g}^\ell}$ can be written in the form

$$\mathcal{L}_{\boldsymbol{g}^\ell} =: h_{\ell+1} : + \mathcal{L}_{{}^G\boldsymbol{g}^\ell} \tag{27.10.30}$$

where

$${}^G g_c^\ell = -[1/(\ell+1)] \sum_{ab} z_a J_{ab} A_{bc}. \tag{27.10.31}$$

Note that ${}^G\boldsymbol{g}^\ell$ is linear in $\boldsymbol{g}^\ell$ since A is linear in $\boldsymbol{g}^\ell$. We now define the projection operator $\mathcal{P}^G$ by the rule

$$\mathcal{P}^G \mathcal{L}_{\boldsymbol{g}^\ell} = \mathcal{G}^{\ell-1,1,0} + \mathcal{G}^{\ell-1,0,0} = \mathcal{G}_{\ell+1} = \mathcal{L}_{{}^G\boldsymbol{g}^\ell}, \tag{27.10.32}$$

which is simply a rewriting of the relation

$$\mathcal{G}_{\ell+1} = \mathcal{L}_{\boldsymbol{g}^\ell} - : h_{\ell+1} : . \tag{27.10.33}$$

With the projection operator definitions (10.21) and (10.32), the relation (10.30) shows that (10.17) holds by construction.

It remains to be shown that the projection operators have the advertised properties. Suppose the $\boldsymbol{g}^\ell$ corresponding to $: h_{\ell+1} :$ is used in (10.31) to compute ${}^G\boldsymbol{g}^\ell$. According to (7.6.7) the matrix A given by (10.24) vanishes in this case. Consequently, ${}^G\boldsymbol{g}^\ell$ is zero. This observation verifies the second assertion in (10.16). Conversely, suppose ${}^G\boldsymbol{g}^\ell$ is used in (10.20) to compute $h_{\ell+1}$. We first observe that (10.31) can be rewritten in the form

$${}^G g_a^\ell = -[1/(\ell+1)] \sum_{cd} z_c J_{cd} A_{da}. \tag{27.10.34}$$

Consequently, we have the result

$$\begin{aligned} h_{\ell+1} &= -[1/(\ell+1)] \sum_{ab} {}^G g_a^\ell J_{ab} z_b \\ &= [1/(\ell+1)^2] \sum_{abcd} z_c J_{cd} A_{da} J_{ab} z_b \\ &= [1/(\ell+1)^2] \sum_{bc} z_c (JAJ)_{cb} z_b. \end{aligned} \tag{27.10.35}$$

However, since both J and A are antisymmetric, it follows that

$$(JAJ)^T = J^T (A)^T J^T = -JAJ. \tag{27.10.36}$$

Therefore the right side of (10.35) vanishes by antisymmetry and we find

$$h_{\ell+1} = 0. \tag{27.10.37}$$

This observation verifies the first assertion in (10.16). Finally, with the aid of (10.16) and (10.17), we find that

$$(\mathcal{P}^H)^2 = \mathcal{P}^H(\mathcal{I} - \mathcal{P}^G) = \mathcal{P}^H - \mathcal{P}^H\mathcal{P}^G = \mathcal{P}^H. \tag{27.10.38}$$

This calculation and its counterpart for $\mathcal{P}^G$ verify (10.15).

To verify (10.18) we first calculate that

$$\begin{aligned} : h_{\ell+1} : z_c &= [h_{\ell+1}, z_c] = \sum_{de} (\partial h_{\ell+1}/\partial z_d) J_{de} (\partial z_c/\partial z_e) \\ &= \sum_{de} (\partial h_{\ell+1}/\partial z_d) J_{de} \delta_{ce} = -\sum_d J_{cd} (\partial h_{\ell+1}/\partial z_d). \end{aligned} \qquad (27.10.39)$$

Consequently, we find using (10.4), (10.34), and (10.39) the intermediate result

$$\begin{aligned} \langle \mathcal{G}_{\ell+1}, \mathcal{H}^{\ell+1,0,0} \rangle &= \langle \mathcal{L}_{G\boldsymbol{g}^\ell}, : h_{\ell+1} : \rangle \\ &= [1/(\ell+1)] \sum_{abcd} J_{ab} J_{cd} \langle z_a A_{bc}, (\partial h_{\ell+1}/\partial z_d) \rangle \\ &= [1/(\ell+1)] \sum_{abcd} J_{ab} J_{cd} \langle A_{bc}, (\partial^2 h_{\ell+1}/\partial z_a \partial z_d)) \rangle. \end{aligned} \qquad (27.10.40)$$

Here, in the last line, (7.3.14) has also been used. Define tensors T^1 and T^2 by the rules

$$T^1_{abcd} = J_{ab} J_{cd}, \qquad (27.10.41)$$

$$T^2_{abcd} = \langle A_{bc}, (\partial^2 h_{\ell+1}/\partial z_a \partial z_d) \rangle. \qquad (27.10.42)$$

From the antisymmetry of J the tensor T^1 has the symmetry property

$$T^1_{dcba} = J_{dc} J_{ba} = J_{ab} J_{cd} = T^1_{abcd}. \qquad (27.10.43)$$

From the antisymmetry of A and the symmetry of $(\partial^2 h_{\ell+1}/\partial z_a \partial z_d)$ the tensor T^2 has the symmetry property

$$\begin{aligned} T^2_{dcba} &= \langle A_{cb}, (\partial^2 h_{\ell+1}/\partial z_d \partial z_a) \rangle \\ &= -\langle A_{bc}, (\partial^2 h_{\ell+1}/\partial z_a \partial z_d) \rangle = -T^2_{abcd}. \end{aligned} \qquad (27.10.44)$$

It follows that

$$\sum_{abcd} J_{ab} J_{cd} \langle A_{bc}, (\partial^2 h_{\ell+1}/\partial z_a \partial z_d) \rangle = \sum_{abcd} T^1_{abcd} T^2_{abcd} = -\sum_{abcd} T^1_{dcba} T^2_{dcba} = 0, \qquad (27.10.45)$$

and consequently

$$\langle \mathcal{G}_{\ell+1}, \mathcal{H}^{\ell+1,0,0} \rangle = 0. \qquad (27.10.46)$$

To verify (10.19) suppose that $\mathcal{L}_{\boldsymbol{g}^\ell}$ is the vector field $\mathcal{G}^{\ell-1,0,0}$ given in (9.3). Then we have the relation

$$g^\ell_c = f_{\ell-1} z_c. \qquad (27.10.47)$$

Consequently, from (10.4), (10.39), and (10.47), we find the result

$$\begin{aligned} \langle \mathcal{G}^{\ell-1,0,0}, \mathcal{H}^{\ell+1,0,0} \rangle &= \langle \mathcal{L}_{\boldsymbol{g}^\ell}, : h_{\ell+1} : \rangle = -[1/(\ell+1)] \sum_{cd} J_{cd} \langle z_c f_{\ell-1}, (\partial h_{\ell+1}/\partial z_d) \rangle \\ &= -[1/(\ell+1)] \sum_{cd} J_{cd} \langle f_{\ell+1}, (\partial^2 h_{\ell+1}/\partial z_c \partial z_d \rangle = 0. \end{aligned} \qquad (27.10.48)$$

Here we have again employed (7.3.14), and used the antisymmetry of J and the symmetry of $(\partial^2 h_{\ell+1}/\partial z_c \partial z_d)$ to infer that the sum in (10.47) vanishes. Finally, in view of (10.46), (10.48), and the definition of $\mathcal{G}_{\ell+1}$ as given in the second part of (10.14) or, equivalently, in (10.33), we conclude that both statements in (10.19) are correct.

Let us evaluate the scalar products between vector fields associated with linear transformations. Let F be any $2n \times 2n$ matrix, possibly complex, and use it to define a vector field $\mathcal{L}_{\boldsymbol{f}^1}$ by the rule

$$\mathcal{L}_{\boldsymbol{f}^1} = \sum_{ab} (JF)_{ab} z_b (\partial/\partial z_a). \tag{27.10.49}$$

Then, comparison of (5.3.17) and (10.49) gives the relation

$$f_a^1 = \sum_b (JF)_{ab} z_b. \tag{27.10.50}$$

From (10.49) we also find the result

$$\mathcal{L}_{\boldsymbol{f}^1} z_c = \sum_d (JF)_{cd} z_d, \tag{27.10.51}$$

which is analogous to (6.26) and (6.27).

Let G be a second $2n \times 2n$ matrix, and use it to define the vector field $\mathcal{L}_{\boldsymbol{g}^1}$. Now compute the scalar product between $\mathcal{L}_{\boldsymbol{f}^1}$ and $\mathcal{L}_{\boldsymbol{g}^1}$. Doing so gives the result

$$\begin{aligned} \langle \mathcal{L}_{\boldsymbol{f}^1}, \mathcal{L}_{\boldsymbol{g}^1} \rangle &= \sum_a \langle f_a^1, g_a^1 \rangle \\ &= \sum_{abc} \langle (JF)_{ab} z_b, (JG)_{ac} z_c \rangle \\ &= \sum_{abc} [(JF)_{ab}]^* (JG)_{ac} \langle z_b, z_c \rangle \\ &= \sum_{abc} [(JF)^\dagger]_{ba} (JG)_{ac} \delta_{bc} = \text{tr } [(JF)^\dagger JG] \\ &= \text{tr } [F^\dagger J^\dagger JG] = \text{tr } (F^\dagger G). \end{aligned} \tag{27.10.52}$$

Here a "*" denotes complex conjugation, and use has been made of (3.1.6). Note that this scalar product is the same as that in (4.4.16).

Suppose S is a real symmetric matrix. Use it to define a quadratic polynomial h_2 as in (7.2.3),

$$h_2 = -(1/2) \sum_{de} S_{de} z_d z_e. \tag{27.10.53}$$

Then, from (7.2.4), there is an associated vector field $\mathcal{L}_{\boldsymbol{s}^1}$ given by the relation

$$\mathcal{L}_{\boldsymbol{s}^1} =: h_2 := \sum_{ab} (JS)_{ab} z_b (\partial/\partial z_a) = \sum_a s_a^1 (\partial/\partial z_a), \tag{27.10.54}$$

with

$$s_a^1 = \sum_b (JS)_{ab} z_b. \tag{27.10.55}$$

Define the Hamiltonian vector field $\mathcal{H}^2$ by writing

$$\mathcal{H}^2 =: h_2 :, \tag{27.10.56}$$

and let $\mathcal{G}_2$ be any non-Hamiltonian vector field of the form (10.49) with F being any real antisymmetric matrix A. Compare with (6.26) and (6.27). Then, using (10.52), we find the result

$$\langle \mathcal{G}_2, \mathcal{H}^2 \rangle = \text{tr }(A^T S) = -\text{tr }(AS) = 0. \tag{27.10.57}$$

Here we have used the easily proved fact that the trace of the product of an antisymmetric and a symmetric matrix is always zero. See (4.4.86). We observe that (10.57) is a special case of the general result (10.46).

We close this section with a further study of first-degree vector fields in $2n$ variables. Consider again the relation (10.49) and decompose F, which we now assume to be real, into symmetric and antisymmetric parts by writing

$$F = S^F + A^F. \tag{27.10.58}$$

That is, we write

$$\mathcal{L}_{\boldsymbol{f}} = \sum_{ab} (JF)_{ab} z_b (\partial/\partial z_a) = \sum_{ab} [J(S^F + A^F)]_{ab} z_b (\partial/\partial z_a) = \mathcal{L}_{\boldsymbol{f}^S} + \mathcal{L}_{\boldsymbol{f}^A} \tag{27.10.59}$$

with

$$\mathcal{L}_{\boldsymbol{f}^S} = \sum_{ab} (JS^F)_{ab} z_b (\partial/\partial z_a) \tag{27.10.60}$$

and

$$\mathcal{L}_{\boldsymbol{f}^A} = \sum_{ab} (JA^F)_{ab} z_b (\partial/\partial z_a). \tag{27.10.61}$$

We will now verify directly, as expected, that $\mathcal{L}_{\boldsymbol{f}^S}$ is a Hamiltonian vector field and $\mathcal{L}_{\boldsymbol{f}^A}$ is a non-Hamiltonian vector field. In particular, we will show that there are the relations

$$\mathcal{P}^H \mathcal{L}_{\boldsymbol{f}^S} = \mathcal{L}_{\boldsymbol{f}^S}, \tag{27.10.62}$$

$$\mathcal{P}^G \mathcal{L}_{\boldsymbol{f}^A} = \mathcal{L}_{\boldsymbol{f}^A}. \tag{27.10.63}$$

Exercises

27.10.1. Show that

$$: f : \ = \sum_a (\partial f/\partial z_a) : z_a : . \tag{27.10.64}$$

27.10.2. Verify (10.4).

27.10.3. Verify (10.6). Hint: You may use brute force or (10.49), (7.3.14), and (7.6.50).

27.10.4. Let $\mathcal{L}_{f_{\ell-1}}$ be the vector field corresponding to (9.3), and let $\mathcal{L}_{f'_{\ell-1}}$ be a second such field. Show that

$$\langle \mathcal{L}_{f_{\ell-1}}, \mathcal{L}_{f'_{\ell-1}} \rangle = (\ell - 1 + 2n)\langle f_{\ell-1}, f'_{\ell-1} \rangle \tag{27.10.65}$$

where $(2n)$ is the phase-space dimension.

27.10.5. Let $h_{\ell+1}$ be any homogeneous polynomial of degree $(\ell+1)$. Find the $\boldsymbol{g}^\ell$ in the $\mathcal{L}_{\boldsymbol{g}^\ell}$ that equals $: h_{\ell+1} :$. Insert this $\boldsymbol{g}^\ell$ in (10.20) and verify that the $h_{\ell+1}$ so produced agrees with the original $h_{\ell+1}$. You have again verified the first result in (10.15).

27.10.6. Consider vector fields that are in $\mathcal{G}^{\ell-1,0,0}$ and therefore can be written in the form (10.47). Insert these $\boldsymbol{g}^\ell$ into (10.20) and show that the $h_{\ell+1}$ they produce vanish.

27.10.7. Verify that the vector fields $\mathcal{H}^{2,0,0}$, $\mathcal{G}^{0,1,0}$, and $\mathcal{G}^{0,0,0}$ found explicitly in Section 9 satisfy (10.12).

27.10.8. Let $z_1, z_2, \cdots z_m$ be m variables. Consider the m^2 vector fields $\mathcal{L}_{ab}$ defined by the rule

$$\mathcal{L}_{ab} = z_a(\partial/\partial z_b). \tag{27.10.66}$$

Show that these vector fields obey the commutation rules

$$\{\mathcal{L}_{ab}, \mathcal{L}_{cd}\} = \delta_{bc}\mathcal{L}_{ad} - \delta_{ad}\mathcal{L}_{cb}. \tag{27.10.67}$$

Let A be an $m \times m$ matrix. Associate with each such matrix the vector field $\mathcal{L}^A$ defined by the rule

$$\mathcal{L}^A = \sum_{ab} A_{ab}\mathcal{L}_{ab}. \tag{27.10.68}$$

Show that there is the relation

$$\{\mathcal{L}^A, \mathcal{L}^B\} = \mathcal{L}^C \tag{27.10.69}$$

where

$$C = \{A, B\}. \tag{27.10.70}$$

That is, verify that the $\mathcal{L}_{ab}$ yield a basis for the general linear group Lie algebra $g\ell(m)$.

Define a vector field Σ by the relation

$$\Sigma = \mathcal{L}^I = \sum_a \mathcal{L}_{aa} \tag{27.10.71}$$

where I is the identity matrix. Verify that there is the relation

$$\{\mathcal{L}_{ab}, \Sigma\} = 0. \tag{27.10.72}$$

You have shown that Σ is invariant under $g\ell(m)$.

27.10.9. Review Exercise 10.8 above. Show that the vector fields spanned by the elements

$$\mathcal{L}_{ab} = z_a(\partial/\partial z_b) - z_b(\partial/\partial z_a) \tag{27.10.73}$$

yield a basis for the Lie algebra $so(m)$. For the cases $m = 2n = 2$, $m = 2n = 4$, and $m = 2n = 6$ decompose these elements into Hamiltonian and non-Hamiltonian parts. Show that in each case the Hamiltonian parts span a Lie algebra, and identify these Lie algebras. What can be said about the non-Hamiltonian parts?

27.10.10. Use the machinery of this section to find the decompositions (3.51) through (3.56).

27.10.11. Consider the matrices $\tilde{A}$ given by (6.28) through (6.33). Relate them to the matrices C^0 through C^3 and E^1 and E^2 given by (4.3.137) through (4.3.140) and (4.3.145) and (4.3.146). Also relate them to the matrices A^1 through A^6 given by (8.2.87) through (8.2.92). Verify directly that the trace of the product of any two different $\tilde{A}$ matrices vanishes. Relate this fact to the assertion (10.12) and the relation (10.52). Show that all matrices of the form $J\tilde{A}(0,1;*,*)$ are traceless, and therefore all matrices of the form $\exp[J\tilde{A}(0,1;*,*)]$ have determinant +1.

27.11 Products and Casimir Operators

In this section we will explore the properties of products of entities when each entity taken by itself has well-defined properties under the action of the symplectic group. For example, if f_ℓ, g_m, h_n, $\cdots$ are homogeneous polynomials, we could ask about the transformation properties of the product $[(f_\ell)(g_m)(h_n)\cdots]$. Or, we could ask about the transformation properties of the product of Lie operators $[:f_\ell::g_m::h_n:\cdots]$. As a third example, we could ask about the properties of the product of adjoint operators $[\#f_\ell\#\#g_m\#\#h_n\#\cdots]$. The first case, the transformation properties of the product $[(f_\ell)(g_m)(h_n)\cdots]$, is simple because the polynomials f_ℓ, g_m, h_n, $\cdots$ can be multiplied together to yield some net polynomial, and the transformation properties of this polynomial are already known. The remaining two cases require more work.

27.11.1 The Quadratic Casimir Operator

We will find that a question of particular interest, and also the simplest, is to determine the transformation properties of the two-element products $[:f_2::g_2:]$ and $[\#f_2\#\#g_2\#]$. In the case of $sp(2)$, we know that $:f_2:$ and $:g_2:$ (and $\#f_2\#$ and $\#g_2\#$) each carry the rerpresentation $\Gamma(2)$, and therefore the product carries the representation $\Gamma(2)\otimes\Gamma(2)$. Also, there is the Clebsch-Gordan series result

$$\Gamma(2)\otimes\Gamma(2)=\Gamma(0)\oplus\Gamma(2)\oplus\Gamma(4). \tag{27.11.1}$$

(This is just the familiar statement for $su(2)$ or $sp(2)$ that spin 1 and spin 1 combine to make spin 0, 1, and 2.)

In the case of $sp(4)$, the corresponding representation for each factor is $\Gamma(2,0)$; and the corresponding Clebsch-Gordan series result is known from group theory to be

$$\Gamma(2,0)\otimes\Gamma(2,0)=\Gamma(0,0)\oplus\Gamma(0,1)\oplus\Gamma(0,2)\oplus\Gamma(2,0)\oplus\Gamma(2,1)\oplus\Gamma(4,0). \tag{27.11.2}$$

Finally, in the case of $sp(6)$, the representation for each factor is $\Gamma(2,0,0)$; and the corresponding Clebsch-Gordan series result is

$$\begin{aligned}&\Gamma(2,0,0)\otimes\Gamma(2,0,0)=\\&\Gamma(0,0,0)\oplus\Gamma(0,1,0)\oplus\Gamma(0,2,0)\oplus\Gamma(2,0,0)\oplus\Gamma(2,1,0)\oplus\Gamma(4,0,0).\end{aligned} \tag{27.11.3}$$

Observe from (11.1) through (11.3) that in each case the *identity* representation [the representations $\Gamma(0)$, $\Gamma(0,0)$, and $\Gamma(0,0,0)$] occurs once and only once. (Strictly speaking, we can only conclude that there is the potential for the identity representation to occur. The sought after quantity may in fact vanish. See Exercise 11.7.) Consequently, there must be some combination of quantities of the form $[: f_2 :: g_2 :]$, or of the form $[\#f_2\#\#g_2\#]$, that is *invariant* (commutes with all generators) under the action of the symplectic group. Moreover, this combination is unique up to an overall multiplicative constant. This combination is called the *Casimir* operator for the symplectic group or symplectic Lie algebra. More particularly, it is called the *quadratic* Casimir operator since it is composed of two factors.

Now that we know that a quadratic Casimir operator exists (and is unique), the problem is to find it explicitly. In effect, what we must do is find the Clebsch-Gordan *coefficients* that produce the identity representations in the series (11.1) through (11.3). We will work up to this task by stages.

Suppose L is a Lie algebra with basis elements B_1, B_2, $\cdots$. Then, as in Section 3.7, the basis elements satisfy Lie product rules of the form

$$[B_\alpha, B_\beta] = \sum_\gamma c^\gamma_{\alpha\beta} B_\gamma. \tag{27.11.4}$$

Here $[,]$ denotes the Lie product (however realized) and the quantities $c^\gamma_{\alpha\beta}$ are the structure constants that specify L.

Next, suppose R is a *realization* of L in terms of $m \times m$ matrices.[2] Then, for each basis element B_α, there will be an associated matrix $\hat{B}_\alpha$, and these matrices will obey the commutation rules

$$\{\hat{B}_\alpha, \hat{B}_\beta\} = \sum_\gamma c^\gamma_{\alpha\beta} \hat{B}_\gamma \tag{27.11.5}$$

with the same structure constants as in (11.4). See Section 3.7.

Since a Lie algebra is a vector space, it is natural to consider the possibility of introducing some kind of scalar product among the elements of L. Suppose B and B' are any two elements in L, and let (B, B') denote their scalar product. Then, by linearity, there is the result

$$(B, B') = \sum_{\alpha\alpha'} b^\alpha (b')^{\alpha'} (B_\alpha, B_{\alpha'}) \tag{27.11.6}$$

where the b^α and $(b')^{\alpha'}$ are the components of B and B',

$$B = \sum_\alpha b^\alpha B_\alpha, \tag{27.11.7}$$

$$B' = \sum_{\alpha'} (b')^{\alpha'} B_{\alpha'}. \tag{27.11.8}$$

[Note that we have taken the scalar product to be *linear* (no complex conjugation), in both the components b^α and $(b')^{\alpha'}$ rather than antilinear (complex conjugation) in one and linear

[2] In this context we use the term *realization* rather than *representation* because in this chapter we wish, for the most part, to use the term *representation* only in the specific/technical sense of referring to some $\Gamma(\cdots)$.

in the other as in (7.3.12).] The relation (11.6) can be rewritten in the form

$$(B, B') = \sum_{\alpha\alpha'} b^{\alpha}(b')^{\alpha'} g_{\alpha\alpha'} \tag{27.11.9}$$

where $g_{\alpha\alpha'}$ is defined by writing

$$g_{\alpha\alpha'} = (B_{\alpha}, B_{\alpha'}). \tag{27.11.10}$$

In view of (11.9), the quantities $g_{\alpha\alpha'}$ may be regarded as the entries in some kind of *metric tensor*, and the scalar product between any two elements in L is specified once the entries $g_{\alpha\alpha'}$ are specified.

In principle, the entries $g_{\alpha\alpha'}$ may be defined at will. However, it is advantageous to define $g_{\alpha\alpha'}$ in a way that involves some properties of the Lie algebra L and has certain desired features. A way to do this is to define $g_{\alpha\alpha'}$ with the aid of the realization R by writing

$$(B_{\alpha}, B_{\alpha'})_R = g^R_{\alpha\alpha'} = \text{ tr } (\hat{B}_{\alpha}\hat{B}_{\alpha'}). \tag{27.11.11}$$

Here we have written the sub and superscript R to indicate that the realization R has been used. See Section 4.4, equation (4.4.39), for an analogous construction.

In the case of *sp*(2), for example, suppose we use as a basis the matrices B^0, F, and G associated with the quadratic phase-space polynomials b^0, f, and g as described in Section 5.6. Then we find the result

$$g^F = \begin{array}{cccc} \backslash & b^0 & f & g \\ b^0 & -2 & 0 & 0 \\ f & 0 & 2 & 0 \\ g & 0 & 0 & 2 \end{array}. \tag{27.11.12}$$

Here we have employed the notation g^F to indicate that for the realization R we have used the 2×2 *fundamental* or defining representation. Also, we have labeled the entries in g^F by the associated quadratic phase-space polynomials. Suppose instead of the basis B^0, F, and G we use the Cartan basis of Section 21.1. The 2×2 matrices associated with these basis elements are easily found. See Exercise 11.1. Using these matrices gives the result

$$g^F = \begin{array}{cccc} \backslash & c^1 & r(+\boldsymbol{\alpha}) & r(-\boldsymbol{\alpha}) \\ c^1 & 2 & 0 & 0 \\ r(+\boldsymbol{\alpha}) & 0 & 0 & 2 \\ r(-\boldsymbol{\alpha}) & 0 & 2 & 0 \end{array} \tag{27.11.13}$$

where we have now labeled the entries by the polynomials associated with the Cartan basis elements.

We observe that g^F is symmetric as is desired for a metric tensor. This symmetry property is true in general for any realization R,

$$g^R_{\alpha\alpha'} = g^R_{\alpha'\alpha}, \tag{27.11.14}$$

because the trace operation has the permutation symmetry property (3.6.124). Indeed, by linearity and symmetry, we have the results

$$(B, B')_R = \text{ tr } (\hat{B}\hat{B}') = \text{ tr } (\hat{B}'\hat{B}) = (B', B)_R.$$

Analogous calculations can be carried out for the cases of $sp(4)$ and $sp(6)$ using the fundamental matrix representations of Sections 5.7 and 5.8. Here it is convenient to introduce additional notation. According to Section 5.5, associated with any quadratic polynomial f there is an associated Hamiltonian matrix JS^f. For any two quadratic polynomials f and g. let us make the definitions

$$\langle f, g\rangle_F = (f, g)_F = (JS^f, JS^g)_F = \text{tr}(JS^f JS^g). \tag{27.11.15}$$

Then, if we use the Cartan bases of Sections 21.4 and 21.7 and the fundamental representations we find, both for $sp(4)$ and $sp(6)$, results analogous to (11.13) that can be written in the general form

$$\langle c^j, c^k\rangle_F = 2\delta_{jk}, \tag{27.11.16}$$

$$\langle c^j, r(\boldsymbol{\mu})\rangle_F = 0, \tag{27.11.17}$$

$$\langle r(\boldsymbol{\mu}), r(\boldsymbol{\nu})\rangle_F = 0, \text{ if } \boldsymbol{\mu} \neq -\boldsymbol{\nu}, \tag{27.11.18}$$

$$\langle r(\boldsymbol{\mu}), r(-\boldsymbol{\mu})\rangle_F = 2. \tag{27.11.19}$$

Note that, as they stand, the relations (11.13) and (11.16) through (11.19) or, equivalently (11.11) with $R = F$, define a scalar product for the elements in the various $sp(2n, \mathbb{R})$ Lie algebras. If we identify the Lie elements with their associated quadratic polynomials in the phase space variables z using relations of the form (5.5.1) and (5.5.3), then we have in effect also defined a scalar product $\langle f, g\rangle_F$ among quadratic polynomials. However, unlike the scalar product of Section 7.3, this scalar product is only defined for *quadratic* polynomials. Exercises 11.1 and 11.3 examine the relation between these two scalar products.

The definition (11.11) has a further desirable property beyond symmetry that is less obvious. Let C be some element in L. Use it to *transform* any basis element B_α into the element B_α^{tr} by the rule

$$\begin{aligned} B_\alpha^{\text{tr}} &= \exp(\epsilon : C :)B_\alpha = B_\alpha + \epsilon : C : B_\alpha + (\epsilon^2/2!) : C :^2 B_\alpha + \cdots \\ &= B_\alpha + \epsilon[C, B_\alpha] + (\epsilon^2/2!)[C, [C, B_\alpha]] + \cdots . \end{aligned} \tag{27.11.20}$$

Here $: C :$ is a differential operator in the case that the Lie product is a Poisson bracket. Otherwise it is simply the *adjoint* operator defined by the property

$$: C : B_\alpha = [C, B_\alpha]. \tag{27.11.21}$$

See (3.7.31) and (5.3.2). The matrix analog of (11.20) in the realization R is the transformation

$$\begin{aligned} \hat{B}_\alpha^{\text{tr}} &= \exp(\epsilon\#\hat{C}\#)\hat{B}_\alpha = \hat{B}_\alpha + \epsilon\#\hat{C}\#\hat{B}_\alpha + (\epsilon^2/2!)\#C\#^2 B_\alpha + \cdots \\ &= \hat{B}_\alpha + \epsilon\{\hat{C}, \hat{B}_\alpha\} + (\epsilon^2/2!)\{\hat{C}, \{\hat{C}, \hat{B}_\alpha\}\} + \cdots . \end{aligned} \tag{27.11.22}$$

At this point we invoke the relation

$$\exp(\epsilon \# \hat{C} \#)\hat{B}_\alpha = \exp(\epsilon\hat{C})\hat{B}_\alpha \exp(-\epsilon\hat{C}), \tag{27.11.23}$$

which is the matrix analog of (8.2.5) and derived in the same way. It follows that (11.22) can be rewritten in the form

$$\hat{B}_\alpha^{\rm tr} = \exp(\epsilon\hat{C})\hat{B}_\alpha \exp(-\epsilon\hat{C}). \tag{27.11.24}$$

Consequently, from (11.11) and (11.15), we have the result

$$\begin{aligned}(B_\alpha^{\rm tr}, B_{\alpha'}^{\rm tr})_R &= {\rm tr}(\hat{B}_\alpha^{\rm tr}\hat{B}_{\alpha'}^{\rm tr}) \\ &= {\rm tr}[\exp(\epsilon\hat{C})\hat{B}_\alpha \exp(-\epsilon\hat{C})\exp(\epsilon\hat{C})\hat{B}_{\alpha'}\exp(-\epsilon\hat{C})] \\ &= {\rm tr}[\exp(\epsilon\hat{C})\hat{B}_\alpha\hat{B}_{\alpha'}\exp(-\epsilon\hat{C})] \\ &= {\rm tr}[\exp(-\epsilon\hat{C})\exp(\epsilon\hat{C})\hat{B}_\alpha\hat{B}_{\alpha'}] = {\rm tr}(\hat{B}_\alpha\hat{B}_{\alpha'}) \\ &= (B_\alpha, B_{\alpha'})_R. \end{aligned} \tag{27.11.25}$$

Here we have again used standard properties of the trace operation. See Exercise 3.6.7.[3] But we know that objects of the form $[\exp(\epsilon : C :)]$ correspond to Lie group elements generated by the Lie algebra L. Therefore, (11.25) shows that the scalar product (11.11) has the remarkable property that it is *invariant* under the action of the group.

The relation (11.25) displays group invariance in *finite* (group) form. It is also instructive to view group invariance in *infinitesimal* (Lie-algebraic) form. This is easily done by retaining only the first two terms in (11.20) and equating powers of ϵ. Doing so in (11.25) gives the result

$$([C, B_\alpha], B_{\alpha'})_R + (B_\alpha, [C, B_{\alpha'}])_R = 0. \tag{27.11.26}$$

Upon setting $C = B_{\alpha''}$ and relabeling indices, (11.26) takes the beautifully symmetric, if less illuminating, forms

$$([B_\alpha, B_{\alpha'}], B_{\alpha''})_R = (B_\alpha, [B_{\alpha'}, B_{\alpha''}])_R, \tag{27.11.27}$$

$$(B_\alpha, [B_{\alpha'}, B_{\alpha''}])_R = (B_{\alpha'}, [B_{\alpha''}, B_\alpha])_R = (B_{\alpha''}, [B_\alpha, B_{\alpha'}])_R.$$

Have you ever encountered relations like (11.26) and (11.27) before? You have. See Exercise 11.8.

The invariance relation (11.25) has implications for the metric tensor g^R. Since the relation (11.20) involves only Lie products and sums, we know from (11.4) that there are transformation coefficients $U_{\alpha\beta}$ such that (11.20) can be rewritten in the form

$$B_\alpha^{\rm tr} = \sum_\beta U_{\alpha\beta}B_\beta. \tag{27.11.28}$$

Inserting this relation into (11.25) gives the results

$$\sum_{\beta\beta'} U_{\alpha\beta}U_{\alpha'\beta'}(B_\beta, B_{\beta'})_R = (B_\alpha, B_{\alpha'})_R, \tag{27.11.29}$$

[3] We are also in the uncomfortable position of using the symbols *tr* to stand both for *transformed* and *trace*. Some flexibility of mind is sometimes required.

or, with the aid of (11.10),

$$\sum_{\beta\beta'} U_{\alpha\beta} U_{\alpha'\beta'} g^R_{\beta\beta'} = g^R_{\alpha\alpha'}. \tag{27.11.30}$$

If we view the quantities $U_{\alpha\beta}$ and $g^R_{\alpha\alpha'}$ as entries in matrices, the relation (11.30) can be written in the compact form

$$U g^R U^T = g^R. \tag{27.11.31}$$

Finally, we know that U is invertible. [Simply change the sign of ϵ in (11.20).] Suppose that g^R is also invertible. We will soon see that it is for the symplectic Lie algebra. [Indeed, g^R can be shown to be invertible for all simple Lie algebras.] Then (11.31) can also be rewritten in the form

$$(U^T)^{-1}(g^R)^{-1}U^{-1} = (g^R)^{-1}, \tag{27.11.32}$$

or

$$U^T(g^R)^{-1}U = (g^R)^{-1}. \tag{27.11.33}$$

We are ready to construct the quadratic Casimir operator. Following the usual procedure, we define a metric tensor $g_R^{\alpha\alpha'}$ with raised indices by the rule

$$g_R^{\alpha\alpha'} = [(g^R)^{-1}]_{\alpha\alpha'}. \tag{27.11.34}$$

Suppose $\hat{B}_\alpha$ is any set of linear operators that obey (11.5), but do not necessarily belong to the reaization R used to define g^R. They might, for example, be differential operators or matrices belonging to some other realization. We define the associated quadratic Casimir operator $\mathcal{C}_2$ by the rule

$$\mathcal{C}_2 = \sum_{\alpha\alpha'} g_R^{\alpha\alpha'} \hat{B}_\alpha \hat{B}_{\alpha'}. \tag{27.11.35}$$

We must now show that $\mathcal{C}_2$ has the desired properties. Suppose $\exp(\epsilon\#\hat{C}\#)$ is applied to both sides of (11.35). Here $\hat{C}$ is some linear combination of the $\hat{B}_\alpha$. Doing so, and making use of (11.22) and the isomorphism property (8.2.14), gives the result

$$\mathcal{C}_2^{\rm tr} = \exp(\epsilon\#\hat{C}\#)\mathcal{C}_2 = \sum_{\alpha\alpha'} g_R^{\alpha\alpha'} \hat{B}^{\rm tr}_\alpha \hat{B}^{\rm tr}_{\alpha'}. \tag{27.11.36}$$

But we know that

$$\hat{B}^{\rm tr}_\alpha = \sum_\beta U_{\alpha\beta}\hat{B}_\beta \tag{27.11.37}$$

since only the structure constants $c^\gamma_{\alpha\beta}$ are involved in the computation of U. See (11.5) and (11.22). Therefore, (11.36) can be rewritten in the form

$$\mathcal{C}_2^{\rm tr} = \sum_{\alpha\alpha'\beta\beta'} g_R^{\alpha\alpha'} U_{\alpha\beta} U_{\alpha'\beta'} \hat{B}_\beta \hat{B}_{\beta'}. \tag{27.11.38}$$

Also, when written in expanded form, (11.33) and (11.34) yield the relation

$$\sum_{\alpha\alpha'} g_R^{\alpha\alpha'} U_{\alpha\beta} U_{\alpha'\beta'} = g_R^{\beta\beta'}. \tag{27.11.39}$$

Consequently, we have result

$$\mathcal{C}_2^{\mathrm{tr}} = \sum_{\beta\beta'} g_R^{\beta\beta'} \hat{B}_\beta \hat{B}_{\beta'} = \mathcal{C}_2. \tag{27.11.40}$$

That is, $\mathcal{C}_2$ is invariant under group action.

As a special case of (11.40), set $\hat{C} = \hat{B}_{\alpha''}$ and equate powers of ϵ in (11.36) and (11.40). Doing so gives the infinitesimal result

$$\#\hat{B}_{\alpha''}\#\mathcal{C}_2 = \{\hat{B}_{\alpha''}, \mathcal{C}_2\} = 0. \tag{27.11.41}$$

That is, all Lie generators commute with $\mathcal{C}_2$. Put yet another way, the raised metric tensor entries $g_R^{\alpha\alpha'}$ are the Clebsch-Gordan coefficients that couple together two copies of the representation associated with the B_α (the adjoint representation) to form the identity representation.

There is still another way of looking at our result. Since the commutator is antisymmetric, the relation (11.41) also states that $\mathcal{C}_2$ commutes with all Lie generators. And from this result, by the linearity and derivation properties of the commutator, we conclude that $\mathcal{C}_2$ commutes with *all* products and sums of products of Lie generators.

27.11.2 Applications of the Quadratic Casimir Operator

Before continuing on to a discussion of higher-order Casimir operators, let us pause to make use of the quadratic Casimir operator for the symplectic group. For our discussion we will use the fundamental representation. Examination of (11.13) and (11.16) through (11.19) shows that in this case

$$(g^F)^2 = 4I \tag{27.11.42}$$

and hence

$$g_F^{\alpha\alpha'} = (1/4) g^F_{\alpha\alpha'}. \tag{27.11.43}$$

Therefore, in view of (11.16) through (11.19) and up to a normalization which we choose for convenience, the quadratic Casimir for the symplectic group is given by the relation

$$\mathcal{C}_2 = \sum_j (C^j)^2 + \sum_{\boldsymbol{\mu}} R(-\boldsymbol{\mu}) R(\boldsymbol{\mu}). \tag{27.11.44}$$

Here the elements C^j and $R(\boldsymbol{\mu})$ are some kind of linear operators or matrices that obey commutation rules analogous to (4.15) through (4.18).

We will soon apply $\mathcal{C}_2$ to the highest weight state $|\boldsymbol{w}^h\rangle$ in some representation Γ. Before doing so, it is useful to rewrite $\mathcal{C}_2$ in a form that is convenient for this purpose. As was the case for weights (see Section 5.8), we define a root $\boldsymbol{\mu}$ to be *positive* if its first nonvanishing component is positive. For example, in the case of $sp(4)$, the roots $\boldsymbol{\alpha}$, $\boldsymbol{\beta}$, $\boldsymbol{\gamma}$, and $-\boldsymbol{\delta}$ are positive. See Figure 4.1. Note that if $\boldsymbol{\mu}$ is positive, then $-\boldsymbol{\mu}$ is not positive. Conversely, if $\boldsymbol{\mu}$ is not positive, then $-\boldsymbol{\mu}$ is positive. Thus, half the root vectors are positive, and the other half (their negatives) are not. With this definition in mind, we may rewrite (11.44) in the form

$$\mathcal{C}_2 = \sum_j (C^j)^2 + \sum_{\boldsymbol{\mu}>0} [R(\boldsymbol{\mu}) R(-\boldsymbol{\mu}) + R(-\boldsymbol{\mu}) R(\boldsymbol{\mu})]. \tag{27.11.45}$$

Here the notation $\boldsymbol{\mu} > 0$ indicates that $\boldsymbol{\mu}$ is positive. Next write the simple identity

$$R(\boldsymbol{\mu})R(-\boldsymbol{\mu}) + R(-\boldsymbol{\mu})R(\boldsymbol{\mu}) = 2R(-\boldsymbol{\mu})R(\boldsymbol{\mu}) + \{R(\boldsymbol{\mu}), R(-\boldsymbol{\mu})\}. \tag{27.11.46}$$

But, by (4.17), we have the relation

$$\{R(\boldsymbol{\mu}), R(-\boldsymbol{\mu})\} = \sum_j (\boldsymbol{e}^j \cdot \boldsymbol{\mu}) C^j. \tag{27.11.47}$$

Consequently, (11.45) can be rewritten in the form

$$\mathcal{C}_2 = \sum_j (C^j)^2 + \sum_{\boldsymbol{\mu}>0} \sum_j (\boldsymbol{e}^j \cdot \boldsymbol{\mu}) C^j + 2 \sum_{\boldsymbol{\mu}>0} R(-\boldsymbol{\mu})R(\boldsymbol{\mu}). \tag{27.11.48}$$

There is one final simplification. Define $\boldsymbol{\mu}^+$ to be the sum of all positive roots,

$$\boldsymbol{\mu}^+ = \sum_{\boldsymbol{\mu}>0} \boldsymbol{\mu}. \tag{27.11.49}$$

With this definition, $\mathcal{C}_2$ takes the form

$$\mathcal{C}_2 = \sum_j [(C^j)^2 + (\boldsymbol{e}^j \cdot \boldsymbol{\mu}^+) C^j] + 2 \sum_{\boldsymbol{\mu}>0} R(-\boldsymbol{\mu})R(\boldsymbol{\mu}). \tag{27.11.50}$$

We are ready to apply $\mathcal{C}_2$ to $|\boldsymbol{w}^h\rangle$. First observe that

$$R(\boldsymbol{\mu})|\boldsymbol{w}^h\rangle = 0 \text{ if } \boldsymbol{\mu} > 0. \tag{27.11.51}$$

Were this not so, $|\boldsymbol{w}^h\rangle$ would not be an eigenvector of the C^j with highest weight. [See (5.8.16).] Now the virtue of writing $\mathcal{C}_2$ in the form (11.50) is apparent. Also, we have the relations

$$\sum_j (C^j)^2 |\boldsymbol{w}^h\rangle = (\boldsymbol{w}^h \cdot \boldsymbol{w}^h)|\boldsymbol{w}^h\rangle, \tag{27.11.52}$$

$$\sum_j (\boldsymbol{e}^j \cdot \boldsymbol{\mu}^+) C^j |\boldsymbol{w}^h\rangle = (\boldsymbol{\mu}^+ \cdot \boldsymbol{w}^h)|\boldsymbol{w}^h\rangle. \tag{27.11.53}$$

It follows that $|\boldsymbol{w}^h\rangle$ is an eigenvector of $\mathcal{C}_2$ having eigenvalue $\lambda(\boldsymbol{w}^h, \boldsymbol{\mu}^+)$,

$$\mathcal{C}_2 |\boldsymbol{w}^h\rangle = \lambda(\boldsymbol{w}^h, \boldsymbol{\mu}^+)|\boldsymbol{w}^h\rangle, \tag{27.11.54}$$

with

$$\lambda(\boldsymbol{w}^h, \boldsymbol{\mu}^+) = (\boldsymbol{w}^h \cdot \boldsymbol{w}^h) + (\boldsymbol{\mu}^+ \cdot \boldsymbol{w}^h). \tag{27.11.55}$$

There is one last observation: We know that every state in a representation can be obtained by suitable linear combinations of products of ladder operators and Cartan subalgebra operators and constants applied to the highest-weight state. Also, $\mathcal{C}_2$ commutes with all these operations. It follows that *all* the vectors in an irreducible representation are eigenvectors of $\mathcal{C}_2$ with the *same* common eigenvalue $\lambda(\boldsymbol{w}^h, \boldsymbol{\mu}^+)$.

For future use, let us work out explicitly the eigenvalues of $\mathcal{C}_2$ for general representations in the cases of $sp(2)$, $sp(4)$, and $sp(6)$. Begin with $sp(2)$. In this case

$$\boldsymbol{w}^h = n\boldsymbol{\phi}^1 = n\boldsymbol{e}^1, \tag{27.11.56}$$

and

$$\boldsymbol{\mu}^+ = \boldsymbol{\alpha} = 2\boldsymbol{e}^1. \tag{27.11.57}$$

Consequently, for the representation $\Gamma(n)$, $\mathcal{C}_2$ has the eigenvalue

$$\lambda(\boldsymbol{w}^h, \boldsymbol{\mu}^+) = n^2 + 2n = n(n+2) = 4j(j+1). \tag{27.11.58}$$

We also note that $\mathcal{C}_2$ has the explicit form

$$\begin{aligned} \mathcal{C}_2 &= (C^1)^2 + R(-\boldsymbol{\alpha})R(\boldsymbol{\alpha}) + R(\boldsymbol{\alpha})R(-\boldsymbol{\alpha}) \\ &= 4\hat{J}_3^2 + 2\hat{J}_-\hat{J}_+ + 2\hat{J}_+\hat{J}_- \\ &= 4(\hat{J}_1^2 + \hat{J}_2^2 + \hat{J}_3^2). \end{aligned} \tag{27.11.59}$$

Here the quantities $\hat{J}_\pm$ and $\hat{J}_3$ (or $\hat{J}_1$ to $\hat{J}_3$) are some kind of linear operators or matrices that obey commutation rules analogous to (1.3), (1.4), or (1.21). The results (11.58) and (11.59) are those expected for $su(2)$. In particular, the quadratic Casimir operator is proportional to the square of the angular momentum, which is known to commute with the $\hat{J}_k$.

For the case of $sp(4)$,

$$\boldsymbol{w}^h = m\boldsymbol{\phi}^1 + n\boldsymbol{\phi}^2 = (m+n)\boldsymbol{e}^1 + n\boldsymbol{e}^2, \tag{27.11.60}$$

and

$$\boldsymbol{\mu}^+ = \boldsymbol{\alpha} + \boldsymbol{\beta} + \boldsymbol{\gamma} + (-\boldsymbol{\delta}) = 4\boldsymbol{e}^1 + 2\boldsymbol{e}^2. \tag{27.11.61}$$

Consequently, for the representation $\Gamma(m,n)$, $\mathcal{C}_2$ has the eigenvalue

$$\lambda(\boldsymbol{w}^h, \boldsymbol{\mu}^+) = m^2 + 2mn + 2n^2 + 4m + 6n. \tag{27.11.62}$$

For the case of $sp(6)$,

$$\boldsymbol{w}^h = \ell\boldsymbol{\phi}^1 + m\boldsymbol{\phi}^2 + n\boldsymbol{\phi}^3 = (\ell+m+n)\boldsymbol{e}^1 + (m+n)\boldsymbol{e}^2 + n\boldsymbol{e}^3, \tag{27.11.63}$$

and

$$\boldsymbol{\mu}^+ = \boldsymbol{\alpha}^1 + \boldsymbol{\alpha}^2 + \boldsymbol{\alpha}^3 + \boldsymbol{\beta}^1 + \boldsymbol{\beta}^2 + \boldsymbol{\beta}^3 + \boldsymbol{\gamma}^1 + \boldsymbol{\gamma}^2 + (-\boldsymbol{\gamma}^3) = 6\boldsymbol{e}^1 + 4\boldsymbol{e}^2 + 2\boldsymbol{e}^3. \tag{27.11.64}$$

Consequently, for the representation $\Gamma(\ell,m,n)$, $\mathcal{C}_2$ has the eigenvalue

$$\lambda(\boldsymbol{w}^h, \boldsymbol{\mu}^+) = \ell^2 + 2m^2 + 3n^2 + 2\ell m + 2\ell n + 4mn + 6\ell + 10m + 12n. \tag{27.11.65}$$

With this background, we are prepared to use the quadratic Casimir operator to prove the orthogonality relations (10.12). Our main tool will be the adjoint Lie operator version of $\mathcal{C}_2$ defined by writing

$$\mathcal{C}_2 = \sum_j (\# : c^j : \#)^2 + \sum_{\boldsymbol{\mu}} \# : r(-\boldsymbol{\mu}) : \#\# : r(\boldsymbol{\mu}) : \#. \tag{27.11.66}$$

From (4.8), (4.14), and (10.9) we find the conjugation relations

$$[(\# : c^j : \#)^2]^\dagger = [(\# : c^j : \#)^\dagger]^2 = (\# : c^j :^\dagger \#)^2 = (\# : c^j : \#)^2, \tag{27.11.67}$$

$$\begin{aligned} &[(\# : r(-\boldsymbol{\mu}) : \#\# : r(\boldsymbol{\mu}) : \#]^\dagger = [\# : r(\boldsymbol{\mu}) : \#]^\dagger [\# : r(-\boldsymbol{\mu}) : \#]^\dagger \\ &= [\# : r(\boldsymbol{\mu}) :^\dagger \#][\# : r(-\boldsymbol{\mu}) :^\dagger \#] = [\# : r(-\boldsymbol{\mu}) : \#\# : r(\boldsymbol{\mu}) : \#]. \end{aligned} \tag{27.11.68}$$

It follows that $\mathcal{C}_2$ is Hermitian,

$$\mathcal{C}_2^\dagger = \mathcal{C}_2. \tag{27.11.69}$$

Apply $\mathcal{C}_2$ to any element of the vector fields $\mathcal{H}^{\ell+1,0,0}$, $\mathcal{G}^{\ell-1,1,0}$, and $\mathcal{G}^{\ell-1,0,0}$. Based on (11.65), we find (writing in short-hand form) the results

$$\mathcal{C}_2\mathcal{H}^{\ell+1,0,0} = [(\ell+1)^2 + 6(\ell+1)]\mathcal{H}^{\ell+1,0,0}, \tag{27.11.70}$$

$$\begin{aligned} \mathcal{C}_2\mathcal{G}^{\ell-1,1,0} &= [(\ell-1)^2 + 2 + 2(\ell-1) + 6(\ell-1) + 10]\mathcal{G}^{\ell-1,1,0} \\ &= [(\ell-1)^2 + 8(\ell-1) + 12]\mathcal{G}^{\ell-1,1,0}, \end{aligned} \tag{27.11.71}$$

$$\mathcal{C}_2\mathcal{G}^{\ell-1,0,0} = [(\ell-1)^2 + 6(\ell-1)]\mathcal{G}^{\ell-1,0,0}. \tag{27.11.72}$$

Next consider matrix elements of the form $\langle \mathcal{H}^{\ell+1,0,0}, \mathcal{C}_2\mathcal{G}^{\ell-1,1,0}\rangle$. From (11.71) we have the result

$$\langle \mathcal{H}^{\ell+1,0,0}, \mathcal{C}_2\mathcal{G}^{\ell-1,1,0}\rangle = [(\ell-1)^2 + 8(\ell-1) + 12]\langle \mathcal{H}^{\ell+1,0,0}, \mathcal{G}^{\ell-1,1,0}\rangle. \tag{27.11.73}$$

However, using (11.69) and (11.70), these matrix elements also satisfy the relation

$$\begin{aligned} &\langle \mathcal{H}^{\ell+1,0,0}, \mathcal{C}_2\mathcal{G}^{\ell-1,1,0}\rangle = \langle \mathcal{C}_2^\dagger\mathcal{H}^{\ell+1,0,0}, \mathcal{G}^{\ell-1,1,0}\rangle = \langle \mathcal{C}_2\mathcal{H}^{\ell+1,0,0}, \mathcal{G}^{\ell-1,1,0}\rangle \\ &= [(\ell+1)^2 + 6(\ell+1)]\langle \mathcal{H}^{\ell+1,0,0}, \mathcal{G}^{\ell-1,1,0}\rangle. \end{aligned} \tag{27.11.74}$$

By combining (11.73) and (11.74) we find the result

$$(2\ell+2)\langle \mathcal{H}^{\ell+1,0,0}, \mathcal{G}^{\ell-1,1,0}\rangle = 0. \tag{27.11.75}$$

In similar fashion we find the results

$$(4\ell+12)\langle \mathcal{H}^{\ell+1,0,0}, \mathcal{G}^{\ell-1,0,0}\rangle = 0, \tag{27.11.76}$$

$$(2\ell+10)\langle \mathcal{G}^{\ell-1,1,0}, \mathcal{G}^{\ell-1,0,0}\rangle = 0. \tag{27.11.77}$$

We observe that none of the quantities in parentheses on the left sides of (11.75) through (11.77) vanish for $\ell \geq 0$. Therefore all the scalar products of the form (10.12) vanish as advertised.

There is a related use of the quadratic Casimir operator that is also important. In Section 21.10 it was shown that there is an operator $\mathcal{P}^{\mathcal{G}}$ that projects out the non-Hamiltonian part of a general homogeneous vector field $\mathcal{L}_{\boldsymbol{g}^\ell}$,

$$\mathcal{P}^{\mathcal{G}}\mathcal{L}_{\boldsymbol{g}^\ell} = \mathcal{G}_{\ell+1}, \tag{27.11.78}$$

and an explicit procedure was given for finding $\mathcal{G}_{\ell+1}$. See (10.20) and (10.33). Now we will show how $\mathcal{C}_2$ can be used to decompose $\mathcal{G}_{\ell+1}$ into its separate parts $\mathcal{G}^{\ell-1,1,0}$ and $\mathcal{G}^{\ell-1,0,0}$,

$$\mathcal{G}_{\ell+1} = \mathcal{G}^{\ell-1,1,0} + \mathcal{G}^{\ell-1,0,0}. \tag{27.11.79}$$

Suppose $\mathcal{C}_2$ is applied to both sides of (11.79). Then, from (11.71) and (11.72), we find the result

$$\begin{aligned}\mathcal{C}_2\mathcal{G}_{\ell+1} &= \mathcal{C}_2\mathcal{G}^{\ell-1,1,0} + \mathcal{C}_2\mathcal{G}^{\ell-1,0,0}\\ &= [(\ell-1)^2 + 8(\ell-1) + 12]\mathcal{G}^{\ell-1,1,0} + [(\ell-1)^2 + 6(\ell-1)]\mathcal{G}^{\ell-1,0,0}.\end{aligned} \tag{27.11.80}$$

The two relations (11.79) and (11.80) can be solved for $\mathcal{G}^{\ell-1,1,0}$ and $\mathcal{G}^{\ell-1,0,0}$ to give the explicit results

$$\mathcal{G}^{\ell-1,1,0} = \{2\ell+10\}^{-1}\{\mathcal{C}_2 - [(\ell-1)^2 + 6(\ell-1)]\}\mathcal{G}_{\ell+1}, \tag{27.11.81}$$

$$\mathcal{G}^{\ell-1,0,0} = -\{2\ell+10\}^{-1}\{\mathcal{C}_2 - [(\ell-1)^2 + 8(\ell-1) + 12]\}\mathcal{G}_{\ell+1}. \tag{27.11.82}$$

Thus, given any homogeneous vector field $\mathcal{L}_{\boldsymbol{g}^\ell}$, we have an explicit procedure for finding its Hamiltonian part $\mathcal{H}^{\ell+1,0,0}$ and its non-Hamiltonian parts $\mathcal{G}^{\ell-1,1,0}$ and $\mathcal{G}^{\ell-1,0,0}$. Of course, this is not the full story. For some purposes we would like to have a complete set of basis vectors for the spaces $\mathcal{H}^{\ell+1,0,0}$, $\mathcal{G}^{\ell-1,1,0}$, and $\mathcal{G}^{\ell-1,0,0}$. This was done for the case $\ell = 1$ in Section 21.9, and we would like to have analogous results for all ℓ, or for at least the first few values of ℓ (say $\ell = 2$ through 6 or so). The spaces $\mathcal{H}^{\ell+1,0,0}$ and $\mathcal{G}^{\ell-1,0,0}$ are relatively easy to handle because the elements of $\mathcal{H}^{\ell+1,0,0}$ are of the form $: h_{\ell+1} :$ and the elements of $\mathcal{G}^{\ell-1,0,0}$ are of the form (9.3). In both cases one is working with homogeneous polynomials and must find suitable basis polynomials that correspond to the various weights in the weight diagrams for the representations $\Gamma(\ell+1,0,0)$ and $\Gamma(\ell-1,0,0)$. This is relatively straightforward except for the problem of finding additional labels and associated properties when the weights have multiplicities higher than 1. Handling the space $\mathcal{G}^{\ell-1,1,0}$ is more difficult. In this case it would be helpful to have explicit knowledge of the Clebsch-Gordan coefficients of $sp(6)$ [and $sp(4)$] for at least the relatively low-dimensional representations.

27.11.3 Higher-Order Casimir Operators

Before leaving the subject of Casimir operators, something should be said about cubic and higher-order Casimirs. For simplicity, only the cubic case will be considered, but the generalization to higher orders should be evident.

As before, we work with some realization R, and let $\hat{B}_\alpha$ denote the basis elements of the Lie algebra in this realization. Then, in analogy to (11.11), we define a rank *three* tensor ${}_3g^R_{\alpha\alpha'\alpha''}$ by writing

$${}_3g^R_{\alpha\alpha'\alpha''} = \text{ tr } (\hat{B}_\alpha\hat{B}_{\alpha'}\hat{B}_{\alpha''}). \tag{27.11.83}$$

In view of (11.24) and the properties of the trace, we have the relation

$$\text{tr } (\hat{B}^{\text{tr}}_\alpha\hat{B}^{\text{tr}}_{\alpha'}\hat{B}^{\text{tr}}_{\alpha''}) = \text{tr } (\hat{B}_\alpha\hat{B}_{\alpha'}\hat{B}_{\alpha''}). \tag{27.11.84}$$

From this relation and (11.28) we deduce that ${}_3g^R$ has the property

$$\sum_{\beta\beta'\beta''} U_{\alpha\beta}U_{\alpha'\beta'}U_{\alpha''\beta''}{}_3g^R_{\beta\beta'\beta''} = {}_3g^R_{\alpha\alpha'\alpha''}, \tag{27.11.85}$$

which is the analog of (11.30).

Next use g_R to raise the indices on ${}_3g^R$ by the rule

$${}_3g_R^{\alpha\alpha'\alpha''} = g_R^{\alpha\gamma}g_R^{\alpha'\gamma'}g_R^{\alpha''\gamma''}\,{}_3g^R_{\gamma\gamma'\gamma''}, \tag{27.11.86}$$

Here, and in what follows, we have and will use the summation convention. The raised tensor ${}_3g_R$ has the property

$${}_3g_R^{\alpha\alpha'\alpha''}U_{\alpha\beta}U_{\alpha'\beta'}U_{\alpha''\beta''} ={}_3 g_R^{\beta\beta'\beta''}, \tag{27.11.87}$$

which is the analog of (11.33). [Note that in (11.85) the summation is over the second indices in the U's, while in (11.87) it is over the first indices.] To verify (11.87), simply compute. From (11.86) we have

$${}_3g_R^{\alpha\alpha'\alpha''}U_{\alpha\beta}U_{\alpha'\beta'}U_{\alpha''\beta''} = g_R^{\alpha\gamma}U_{\alpha\beta}g^{\alpha'\gamma'}U_{\alpha'\beta'}g^{\alpha''\gamma''}U_{\alpha''\beta''}{}_3g^R_{\gamma\gamma'\gamma''}. \tag{27.11.88}$$

However, by changing indices, (11.85) can be written in the form

$${}_3g^R_{\gamma\gamma'\gamma''} = U_{\gamma\delta}U_{\gamma'\delta'}U_{\gamma''\delta''}{}_3g^R_{\delta\delta'\delta''}. \tag{27.11.89}$$

Now substitute (11.89) in (11.88) to get the result

$$\begin{aligned} {}_3g_R^{\alpha\alpha'\alpha''}U_{\alpha\beta}U_{\alpha'\beta'}U_{\alpha''\beta''} &= g_R^{\alpha\gamma}U_{\alpha\beta}U_{\gamma\delta}g_R^{\alpha'\gamma'}U_{\alpha'\beta'}U_{\gamma'\delta'}g_R^{\alpha''\gamma''}U_{\alpha''\beta''}U_{\gamma''\delta''}{}_3g^R_{\delta\delta'\delta''} \\ &= g_R^{\beta\delta}g_R^{\beta'\delta'}g_R^{\beta''\delta''}\,{}_3g^R_{\delta\delta'\delta''} = {}_3g_R^{\beta\beta'\beta''}, \end{aligned} \tag{27.11.90}$$

as claimed. Here repeated use has been made of (11.30).

We are now ready to construct the third-order Casimir operator. As before, suppose $\hat{B}_\alpha$ is any set of linear operators that obey (11.5), but do not necessarily belong to the realization used to define g^R, ${}_3g^R$, and hence ${}_3g_R$. We define the associated cubic Casimir operator $\mathcal{C}_3$ by writing

$$\mathcal{C}_3 = {}_3g_R^{\alpha\alpha'\alpha''}\hat{B}_\alpha\hat{B}_{\alpha'}\hat{B}_{\alpha''}. \tag{27.11.91}$$

As a consequence of (11.87), this operator also has the invariance property

$$\mathcal{C}_3^{\rm tr} = \exp(\epsilon\#C\#)\mathcal{C}_3 = \mathcal{C}_3, \tag{27.11.92}$$

and hence

$$\#\hat{B}_\delta\#\mathcal{C}_3 = \{\hat{B}_\delta, \mathcal{C}_3\} = 0 \text{ for all } \delta. \tag{27.11.93}$$

Indeed, using (11.37) and (11.87), we find the result

$$\begin{aligned} \mathcal{C}_3^{\rm tr} &= {}_3g_R^{\alpha\alpha'\alpha''}\hat{B}_\alpha^{\rm tr}\hat{B}_{\alpha'}^{\rm tr}\hat{B}_{\alpha''}^{\rm tr} \\ &= {}_3g_R^{\alpha\alpha'\alpha''}U_{\alpha\beta}U_{\alpha'\beta'}U_{\alpha''\beta''}\hat{B}_\beta\hat{B}_{\beta'}\hat{B}_{\beta''} \\ &= {}_3g_R^{\beta\beta'\beta''}\hat{B}_\beta\hat{B}_{\beta'}\hat{B}_{\beta''} = \mathcal{C}_3. \end{aligned} \tag{27.11.94}$$

Thus, as anticipated, $\mathcal{C}_3$ also commutes with all Lie generators, and therefore also with all products and sums of products of generators. A special case of this result is that $\mathcal{C}_2$ and $\mathcal{C}_3$ commute.

Finally, we remark that it can be shown that a rank-k simple Lie algebra has k functionally independent Casimir operators. Moreover, the eigenvalues of these Casimir operators, when acting on any vector in an irreducible representation, can be used to determine the representation. For example, in the case of $sp(6)$, the three Casimir operators $\mathcal{C}_2$, $\mathcal{C}_4$, and $\mathcal{C}_6$ are functionally independent and can be used to determine the values of ℓ, m, n in $\Gamma(\ell, m, n)$.

Exercises

27.11.1. Verify (11.12) using (11.11) and the matrices B^0, F, and G given by (5.6.7), (5.6.13), and (5.6.14). Find the 2×2 matrices associated with the elements associated with c^1 and $r(\pm\boldsymbol{\alpha})$ given by (1.11) and (1.12). Use these matrices to verify (11.13). Find g^F for $sp(4)$ using the fundamental representation given by (5.7.42).

For *quadratic* polynomials, using (5.5.1) and (5.5.2) and the correspondences (5.5.3) and (5.5.4), we have made the definition $\langle f, g\rangle_F = (JS^f, JS^g)_F = \text{tr}\,(JS^f JS^g)$. Compare $\langle f, g\rangle$ and $\langle f, g\rangle_F$. See Exercise 7.3.8. Verify the general result $\langle f^a, f^c\rangle_F = (JS^{fa}, JS^{fc})_F = 0$. Use (3.8.14), (3.8.22), (7.2.3), (7.2.4), and (7.3.53); and employ the notation S^{fa} and S^{fc} to denote the parts of S^f that anticommute and commute with J, respectively. See Exercise 7.3.10 for the analogous result $\langle f_2^a, f_2^c\rangle = 0$. For a pair of quadratic polynomials f and g, make the decompositions $f = f^a + f^c$ and $g = g^a + g^c$. Verify the relation $\langle f, g\rangle_F = 2\langle f^a, g^a\rangle - 2\langle f^c, g^c\rangle$. As a special case there is the relation $\langle f, f\rangle_F = 2\langle f^a, f^a\rangle - 2\langle f^c, f^c\rangle$, which shows that the form $\langle f, f\rangle_F$ is neither positive nor negative definite. This is to be expected because $Sp(2n, \mathbb{R})$ is not compact. We also have the relation

$$\langle f^c, f^c\rangle_F = (JS^{fc}, JS^{fc})_F = -2\langle f^c, f^c\rangle < 0,$$

and we know that the JS^{fc} generate $U(n)$, the maximal compact subgroup of $Sp(2n, \mathbb{R})$. See the last comment in Exercise 11.3 below.

27.11.2. Verify the relations (11.16) through (11.19).

27.11.3. Review Exercise 11.1 above. This exercise further explores the relation between the Lie-algebraic metric for the Lie algebra $usp(2n)$ and the $USp(2n)$ invariant scalar product. See Sections 5.10 and 7.3. Consider the $sp(2n)$ Lie-algebraic metric given by (11.16) through (11.19). Define elements Σ and Δ by the rules

$$\Sigma(\boldsymbol{\mu}) = (1/\sqrt{2})[r(\boldsymbol{\mu}) + r(-\boldsymbol{\mu})], \tag{27.11.95}$$

$$\Delta(\boldsymbol{\mu}) = (1/\sqrt{2})[r(\boldsymbol{\mu}) - r(-\boldsymbol{\mu})]. \tag{27.11.96}$$

Evidently, for $\boldsymbol{\mu} > 0$, the elements $\Sigma(\boldsymbol{\mu})$ and $\Delta(\boldsymbol{\mu})$ span the same space as the elements $r(\boldsymbol{\mu})$ and $r(-\boldsymbol{\mu})$. Using (11.16) through (11.19) verify (with $\boldsymbol{\mu}, \boldsymbol{\nu} > 0$) the relations

$$(c^j, \Sigma(\boldsymbol{\mu}))_F = (c^j, \Delta(\boldsymbol{\mu}))_F = 0, \tag{27.11.97}$$

$$(\Sigma(\boldsymbol{\mu}), \Delta(\boldsymbol{\nu}))_F = 0, \tag{27.11.98}$$

$$(\Sigma(\boldsymbol{\mu}), \Sigma(\boldsymbol{\nu}))_F = 2\delta_{\boldsymbol{\mu}\boldsymbol{\nu}}, \tag{27.11.99}$$

$$(\Delta(\boldsymbol{\mu}), \Delta(\boldsymbol{\nu}))_F = -2\delta_{\boldsymbol{\mu}\boldsymbol{\nu}}. \tag{27.11.100}$$

Show that $:\Sigma:$ and $:\Delta:$ obey the conjugacy relations

$$:\Sigma(\boldsymbol{\mu}):^{\dagger} = :\Sigma(\boldsymbol{\mu}):, \tag{27.11.101}$$

$$:\Delta(\boldsymbol{\mu}):^{\dagger} = -:\Delta(\boldsymbol{\mu}):. \tag{27.11.102}$$

Consider as a basis set the elements ic^j, $i\Sigma(\boldsymbol{\mu})$, and $\Delta(\boldsymbol{\mu})$ with $\boldsymbol{\mu} > 0$. Call these elements b_α. Show that their associated Lie operators are all anti-Hermitian,

$$:b_\alpha:^{\dagger} = -:b_\alpha:. \tag{27.11.103}$$

Consequently, they form a basis for $usp(2n)$ and, when exponentiated, generate $USp(2n)$. See Section 7.3. Verify that these elements satisfy the relation

$$(b_\alpha, b_\beta)_F = -2\delta_{\alpha\beta} = -2\langle b_\alpha, b_\beta\rangle. \tag{27.11.104}$$

Here the Lie-algebraic scalar product on the left is that given by (11.16) through (11.19), and the scalar product on the right is that given by (4.19) through (4.22) and arises from the construction of Section 7.3. Since we have been working over the complex field, we know that the Lie-algebraic scalar product is invariant under $Sp(2n, C)$. See (11.25). It is therefore also invariant under $USp(2n)$ because $USp(2n)$ is a subgroup of $Sp(2n, C)$. The relation (11.104) is consistent with this invariance because we already know from Section 7.3 that the scalar product on the right is invariant under $USp(2n)$.

One last comment: From the discussion of Section 5.10 we know that $USp(2n)$ is compact. Inspection of (11.104) shows that the Lie-algebraic metric for $usp(2n)$ is negative definite. It can be shown that for any simple Lie algebra the Lie-algebraic metric is negative definite if and only if the corresponding Lie group is compact. See also (11.109) and (11.110) for the cases of the compact groups $SU(2)$ and $SO(3, \mathbb{R})$.

27.11.4. The relation (11.30) displays the invariance of the metric tensor under finite group action. Show that (11.27) describes this same invariance in infinitesimal form. In particular, use (11.27) to produce the relation

$$c^{\gamma}_{\alpha\alpha'} g^R_{\gamma\alpha''} = c^{\gamma}_{\alpha'\alpha''} g^R_{\gamma\alpha}. \tag{27.11.105}$$

Use the metric tensor g^R to *lower* the upper index on the structure constants by the rule

$$c_{\alpha\alpha'\alpha''} = c^{\gamma}_{\alpha\alpha'} g^R_{\gamma\alpha''}. \tag{27.11.106}$$

Show that the lowered structure constants are completely antisymmetric (antisymmetric under the interchange of any pair of adjacent indices).

27.11.5. Find the analog of the formulas (11.81) and (11.82) for the case of 4-dimensional phase space.

27.11.6. In the case of a 6-dimensional phase space, consider the vector field $\mathcal{L}_{\boldsymbol{g}^2}$ given by the relation

$$\mathcal{L}_{\boldsymbol{g}^2} = (q_1)^2\partial/\partial q_1. \tag{27.11.107}$$

Using the methods of Sections 21.10 and 21.11.2, decompose $\mathcal{L}_{\boldsymbol{g}^2}$ into Hamiltonian and non-Hamiltonian parts $\mathcal{H}^{3,0,0}$, $\mathcal{G}^{1,1,0}$, and $\mathcal{G}^{1,0,0}$.

27.11.7. For the case of a 2-dimensional phase space we know that quadratic functions f_2 and g_2 carry the representation $\Gamma(2)$. Therefore, from (11.1), we might naively expect that the product f_2g_2 might contain the identity representation $\Gamma(0)$. In analogy with (11.59), if the identity representation does occur, it should be a multiple of the polynomial $(J_1^2+J_2^2+J_3^2)$ where the J_j are given by (1.1), (1.2), and (1.20). Show that in fact there is the relation

$$J_1^2 + J_2^2 + J_3^2 = 0. \tag{27.11.108}$$

Thus, in this case, the sought after quantity actually vanishes. In retrospect, this is to be expected because we know from Section 21.2 that quartic polynomials in two variables, of which all polynomials of the form f_2g_2 are examples, carry only the representation $\Gamma(4)$. Note that $\Gamma(4)$ also occurs in the Clebsch-Gordan series (11.1).

27.11.8. The purpose of this exercise is to explore the consequences of the relations (11.27) in the case of $su(2)$, or equivalently, $so(3,\mathbb{R})$. In the case of $su(2)$, suppose we employ the realization provided by the K^α matrices of Exercise 3.7.30. Verify the scalar product results

$$(K^\alpha, K^\beta)_F = \text{ tr } (K^\alpha K^\beta) = (-i/2)^2 \text{ tr } (\sigma^\alpha\sigma^\beta) = -(1/2)\delta_{\alpha\beta} = -(1/2)\boldsymbol{e}_\alpha \cdot \boldsymbol{e}_\beta. \tag{27.11.109}$$

Show that in the cases of $su(2)$ and $so(3,\mathbb{R})$ there are the related results

$$(K^\alpha, K^\beta)_K = (L^\alpha, L^\beta)_F = \text{ tr } (L^\alpha L^\beta) = -2\delta_{\alpha\beta} = -2\boldsymbol{e}_\alpha \cdot \boldsymbol{e}_\beta. \tag{27.11.110}$$

Here the subscript K stands for *Killing* in anticipation of the next section. Next show, using the notation of Exercise 3.2.27, that there are the relations

$$(\boldsymbol{a}\cdot\boldsymbol{K}, \boldsymbol{b}\cdot\boldsymbol{K})_F = -(1/2)\boldsymbol{a}\cdot\boldsymbol{b}, \tag{27.11.111}$$

$$(\boldsymbol{a}\cdot\boldsymbol{K}, \boldsymbol{b}\cdot\boldsymbol{K})_K = (\boldsymbol{a}\cdot\boldsymbol{L}, \boldsymbol{b}\cdot\boldsymbol{L})_F = -2\boldsymbol{a}\cdot\boldsymbol{b}. \tag{27.11.112}$$

Now examine the first relation in (11.27). In the case of $su(2)$, and using the fundamental representation, it reads

$$(\{K_\alpha, K_\beta\}, K_\gamma)_F = (K_\alpha, \{K_\beta, K_\gamma\})_F. \tag{27.11.113}$$

Show that multiplying the left side of (11.113) by the quantity $a_\alpha b_\beta c_\gamma$, and summing over α, β, and γ, yield the result

$$\sum_{\alpha\beta\gamma} a_\alpha b_\beta c_\gamma (\{K_\alpha, K_\beta\}, K_\gamma)_F = (\{\boldsymbol{a}\cdot\boldsymbol{K}, \boldsymbol{b}\cdot\boldsymbol{K}\}, \boldsymbol{c}\cdot\boldsymbol{K})_F = -(1/2)(\boldsymbol{a}\times\boldsymbol{b})\cdot\boldsymbol{c}. \tag{27.11.114}$$

Show that multiplying the right side of (11.113) by the quantity $a_\alpha b_\beta c_\gamma$, and summing over α, β, and γ, yield the result

$$\sum_{\alpha\beta\gamma} a_\alpha b_\beta c_\gamma (K_\alpha, \{K_\beta, K_\gamma\})_F = (\boldsymbol{a}\cdot\boldsymbol{K}, \{\boldsymbol{b}\cdot\boldsymbol{K}, \boldsymbol{c}\cdot\boldsymbol{K}\})_F = -(1/2)\boldsymbol{a}\cdot(\boldsymbol{b}\times\boldsymbol{c}). \quad (27.11.115)$$

You have shown, in the case of $su(2)$, that (11.113) is equivalent to the familiar statement about the interchange of the dot and the cross in three-dimensional vector algebra,

$$(\boldsymbol{a}\times\boldsymbol{b})\cdot\boldsymbol{c} = \boldsymbol{a}\cdot(\boldsymbol{b}\times\boldsymbol{c}). \quad (27.11.116)$$

Carry out the analogous calculation for both the cases of $su(2)$ and $so(3,\mathbb{R})$ using (11.110) to again arrive at the conclusion (11.116). Finally show, in the cases of $su(2)$ and $so(3, R$, that the second relation in (11.27) is equivalent to the relation

$$\boldsymbol{a}\cdot(\boldsymbol{b}\times\boldsymbol{c}) = \boldsymbol{b}\cdot(\boldsymbol{c}\times\boldsymbol{a}) = \boldsymbol{c}\cdot(\boldsymbol{a}\times\boldsymbol{b}). \quad (27.11.117)$$

27.11.9. Show that the first relation in (11.27) can be rewritten in the form

$$(- : B_{\alpha'} : B_\alpha,\ B_{\alpha''})_R = (B_\alpha,\ \ : B_{\alpha'} : B_{\alpha''})_R. \quad (27.11.118)$$

Here we have used the more compact notation

$$: B_{\alpha'} := \text{ad } B_{\alpha'}. \quad (27.11.119)$$

Compare (3.7.71), (5.3.2), and (11.21). Show that (11.118) implies the relation

$$: B_{\alpha'} :^{\dagger} = - : B_{\alpha'} : \quad (27.11.120)$$

with respect to the inner product $(\ ,\ )_R$. That is, $: B_{\alpha'} :$ is anti-Hermitian with respect to this inner product.

27.11.10. Exercise on the Casimir operator for $SO(4,\mathbb{R})$.

27.12 The Killing Form

Section 21.11.1 introduced the concept of a scalar product for the elements of a Lie algebra and defined a metric tensor with the aid of a realizaton R. An important special case of this construction is the Killing form. The *Killing form* is simply the metric tensor g^R in the case that the realizaton R is the *adjoint* representation. See the end of Section 3.7 to review the definition of the adjoint representation. Let us call this tensor g^K in honor of Killing. Then, using (11.11) and (3.7.56), we find the result

$$g^K_{\alpha\alpha'} = \text{ tr } (\hat{B}_\alpha \hat{B}_{\alpha'}) = \sum_{\mu\nu} (\hat{B}_\alpha)_{\mu\nu} (\hat{B}_{\alpha'})_{\nu\mu} = \sum_{\mu\nu} c^\mu_{\alpha\nu} c^\nu_{\alpha'\mu}. \quad (27.12.1)$$

As (12.1) shows, the Killing form (metric tensor) has the advantage that it is constructed directly in terms of the structure constants. It is therefore directly available without further study of the Lie algebra.[4] By contrast, the g^F that we have been using for $sp(2n)$

[4] Suppose a Lie algebra L is specified by presenting its structure constants. Then g^K is computable using (12.1). It can be shown that g^K is invertible if and only if L is semisimple.

is constructed from a knowledge of the fundamental $2n \times 2n$ matrix representation. For most groups these matrices are usually much smaller than the matrices for the adjoint representation, and therefore, *if known*, far easier to use. For example, in the case of $sp(6)$, the fundamental representation involves 6×6 matrices, and the adjoint representation involves 21×21 matrices. [However, it turns out that for $E_8(248)$ the lowest dimensional representation *is* the adjoint representation, and 248×248 matrices are required.]

It can be shown in general for a *simple* Lie algebra that g^K and g^F are proportional. [For example, the identity representation occurs once and only once in the $sp(2n)$ Clebsch-Gordan series (11.1) through (11.3).] From (11.16) we know that for the fundamental representation of $sp(2n)$ there is the relation

$$(\hat{C}^1, \hat{C}^1)_F = 2. \tag{27.12.2}$$

And for the adjoint representation of $sp(2n)$ there is the relation

$$(\hat{C}^1, \hat{C}^1)_K = \sum_{\boldsymbol{\mu}} (\boldsymbol{e}^1 \cdot \boldsymbol{\mu})(\boldsymbol{\mu} \cdot \boldsymbol{e}^1) = 4n + 4. \tag{27.12.3}$$

See Exercise 12.1. It follows that g^K and g^F are related by the equation

$$g^K_{\alpha\alpha'} = (2n+2) g^F_{\alpha\alpha'}. \tag{27.12.4}$$

Still a bit more can be said. As before, let g^R be the metric tensor obtained using the realization R as in (11.11). Then there is a relation of the form

$$g^R_{\alpha\alpha'} = \tau(R) g^F_{\alpha\alpha'}. \tag{27.12.5}$$

where $\tau(R)$ is a *positive* proportionality constant that depends on the realization.[5] According to (12.4), τ has the value $(2n+2)$ for the adjoint representation and the Lie algebra $sp(2n)$.

Exercises

27.12.1. Verify (12.2). Using (3.7.56), show that in the adjoint representation the matrix $\hat{C}^1$ is diagonal and has as its diagonal entries ℓ zeroes (where ℓ is the rank of the Lie algebra) and the numbers $(\boldsymbol{e} \cdot \boldsymbol{\mu})$ where $\boldsymbol{\mu}$ ranges over all the root vectors. Next show that $(\hat{C}^1, \hat{C}^1)_K$ has the value

$$(\hat{C}^1, \hat{C}^1)_K = \text{tr } [(\hat{C}^1)^2] = \sum_{\boldsymbol{\mu}} (\boldsymbol{e}^1 \cdot \boldsymbol{\mu})(\boldsymbol{\mu} \cdot \boldsymbol{e}^1). \tag{27.12.6}$$

Finally, given that the root vectors for $sp(2n)$ are all combinations of the form $\pm \boldsymbol{e}^j \pm \boldsymbol{e}^k$ with the signs taken independently, verify (12.3).

27.12.2. Review Exercise 3.7.30. The 2×2 matrices K^α and the 3×3 matrices L^α displayed there provide the fundamental and adjoint representations of $su(2)$, respectively. Use these matrices to construct metric tensors for $su(2)$. Show that

$$g^F_{\alpha\alpha'} = -(1/2)\delta_{\alpha\alpha'} \tag{27.12.7}$$

[5] We remark that a relation of the form (12.5) holds among the *irreducible* representations of any *simple* Lie algebra. It need not hold in general. See Exercise 12.2.

and

$$g^K_{\alpha\alpha'} = -2\delta_{\alpha\alpha'}. \tag{27.12.8}$$

Note that g^F and g^K are proportional with a positive proportionality constant, as expected because $su(2)$ is simple. Note also that they are negative definite because $SU(2)$ is compact. (Recall that it has the topology of S^3.) Finally, since the Lie algebras $so(3, R$ and $su(2)$ are the same, these g^F and g^K also provide metric tensors for $so(3, \mathbb{R})$.

27.12.3. Use the matrices (4.4.31) through (4.4.34) as a basis for $g\ell(2, \mathbb{R})$ and show that in this case g^F is given by (4.4.40). Find the adjoint representation for $g\ell(2, \mathbb{R})$, which will be a set if 4 × 4 matrices, compute the Killing form g^K, and show that it is *singular*. Thus, (12.5) does not hold in this case. Show that $g\ell(2, \mathbb{R})$ is not *simple* and also not *semisimple*. See also the discussion at the end of Section 3.7.

27.12.4. Using the $sp(4)$ matrices (5.7.42) and matrices of the form JA with the antisymmetric matrices A given by (6.28) through (6.33), find g^F for $g\ell(4, \mathbb{R})$.

27.13 Enveloping Algebra

So far we have been exploring the properties of products of entities when each entity by itself has well-defined properties under the action of some group (in our case, the symplectic group). These entities were either polynomials in some variables on which the group acted, or Lie operators, or adjoint Lie operators. (They could also be matrices or other linear operators. As shown in Section 26.*, they could also be moments of a particle distribution.) They were not necessarily in the Lie algebra of the group, but they had the two properties that they could be multiplied together (multiplication was defined) and they transformed in some systematic way under the action of the Lie algebra.

For some (perhaps mathematical) purposes it is useful to explore what can be done by working directly and abstractly with only the Lie algebra itself rather than various concrete entities such as polynomials, Lie operators, adjoint Lie operators, etc. But now there is a problem because, for an abstract Lie algebra, there is no meaning for the "ordinary" product of any two elements in the Lie algebra. That is, if A and B are elements in a Lie algebra L, the Lie product $[A, B]$ is defined, but there is no meaning to the product AB. In particular, there is no meaning to an associative product ABC such that $(AB)C = A(BC)$. This apparent obstacle can be overcome by a clever construction. We will see that in many ways the *tensor* product can be used to play the role of an ordinary product.

Since L is a vector space, it *is* meaningful to talk about tensor products of the space with itself. For example, if the elements B_α are a basis for L, we may consider the space of all linear combinations of tensor products of the form $B_\alpha \otimes B_{\alpha'}$. We will call this vector space L^2, and write

$$L^2 = L \otimes L. \tag{27.13.1}$$

Similarly, we may consider the space of all linear combinations of tensor products of the form $B_\alpha \otimes B_{\alpha'} \otimes B_{\alpha''}$. Note that for a tensor product there is the associative property

$$B_\alpha \otimes (B_{\alpha'} \otimes B_{\alpha''}) = (B_\alpha \otimes B_{\alpha'}) \otimes B_{\alpha''}. \tag{27.13.2}$$

We will call this vector space L^3, and write

$$L^3 = L \otimes L \otimes L. \tag{27.13.3}$$

It is now obvious how to define still higher-order tensor product spaces L^4, L^5, $\cdots$.

We would also like to define L^1 and L^0. For L^1 we take the Lie algebra itself. That is, L^1 is the vector space consisting of all linear combinations of the B_α. What about L^0? Since L is a vector space, there must be some associated field of scalars (say the complex numbers) with *unit* element 1. Let L^0 be the vector space of all linear combinations (scalar multiples) of 1. Evidently L^0 is a one-dimensional vector space, and consists of the field of scalars associated with L.

Now watch closely! Having defined the vector spaces L^n, we define the vector space $\mathcal{T}$ to be the direct sum of all these vector spaces,

$$\mathcal{T} = L^0 \oplus L^1 \oplus L^2 \oplus L^3 + \cdots . \tag{27.13.4}$$

Suppose $\mathcal{A}$ and $\mathcal{B}$ are any two elements in $\mathcal{T}$. As a simple example, suppose they are of the form

$$\mathcal{A} = a + bB_\alpha = a1 + bB_\alpha, \tag{27.13.5}$$

$$\mathcal{B} = c + dB_\beta = c1 + dB_\beta. \tag{27.13.6}$$

Let us compute their tensor product. Doing so gives the result

$$\mathcal{A} \otimes \mathcal{B} = (a1 + bB_\alpha) \otimes (c1 + dB_\beta) = a1 \otimes c1 + a1 \otimes dB_\beta + bB_\alpha \otimes c1 + bB_\alpha \otimes dB_\beta. \tag{27.13.7}$$

Let us make the obvious rules

$$1 \otimes 1 = 1,\ 1 \otimes B_\beta = B_\beta,\ B_\alpha \otimes 1 = B_\alpha,\ \text{etc.}, \tag{27.13.8}$$

which can be summarized abstractly by writing

$$L^0 \otimes L^0 = L^0,\ L^0 \otimes L^n = L^n,\ L^n \otimes L^0 = L^n. \tag{27.13.9}$$

Then we find the result

$$\mathcal{A} \otimes \mathcal{B} = ac + adB_\beta + bcB_\alpha + bdB_\alpha \otimes B_\beta. \tag{27.13.10}$$

We know that, by construction, $\mathcal{T}$ is a vector space. We now see that it can be also be viewed as an *associative* algebra with the operation of multiplication taken to be the tensor product. The standard nomenclature is to call $\mathcal{T}$ the *tensor algebra* of L.

Our next step is to give $\mathcal{T}$ a Lie-algebraic structure. Suppose again that $\mathcal{A}$ and $\mathcal{B}$ are any two elements in $\mathcal{T}$. We define their commutator by the rule

$$\{\mathcal{A}, \mathcal{B}\} = \mathcal{A} \otimes \mathcal{B} - \mathcal{B} \otimes \mathcal{A}. \tag{27.13.11}$$

It is obvious that this commutator has the desired antisymmetry property (3.7.41). Let us check the Jacobi condition. We find the results

$$\{\mathcal{A}, \{\mathcal{B}, \mathcal{C}\}\} = \mathcal{A} \otimes \mathcal{B} \otimes \mathcal{C} - \mathcal{B} \otimes \mathcal{C} \otimes \mathcal{A} - \mathcal{A} \otimes \mathcal{C} \otimes \mathcal{B} + \mathcal{C} \otimes \mathcal{B} \otimes \mathcal{A}. \tag{27.13.12}$$

$$\{\mathcal{B},\{\mathcal{C},\mathcal{A}\}\} = \mathcal{B}\otimes\mathcal{C}\otimes\mathcal{A} - \mathcal{C}\otimes\mathcal{A}\otimes\mathcal{B} - \mathcal{B}\otimes\mathcal{A}\otimes\mathcal{C} + \mathcal{A}\otimes\mathcal{C}\otimes\mathcal{B}. \tag{27.13.13}$$

$$\{\mathcal{C},\{\mathcal{A},\mathcal{B}\}\} = \mathcal{C}\otimes\mathcal{A}\otimes\mathcal{B} - \mathcal{A}\otimes\mathcal{B}\otimes\mathcal{C} - \mathcal{C}\otimes\mathcal{B}\otimes\mathcal{A} + \mathcal{B}\otimes\mathcal{A}\otimes\mathcal{C}. \tag{27.13.14}$$

Inspection shows that if (13.12) through (13.14) are summed, all the terms on the right cancel in pairs to give the desired result

$$\{\mathcal{A},\{\mathcal{B},\mathcal{C}\}\} + \{\mathcal{B},\{\mathcal{C},\mathcal{A}\}\} + \{\mathcal{C},\{\mathcal{A},\mathcal{B}\}\} = 0. \tag{27.13.15}$$

Thus, $\mathcal{T}$ has been made into a Lie algebra with the Lie product taken to be the tensor product commutator (13.11).

We continue our exploration by defining adjoint operators in the standard way. Suppose $\mathcal{C}$ is some element in $\mathcal{T}$ and let $\mathcal{A}$ be any element in $\mathcal{T}$. Then we define the adjoint operator $\#\mathcal{C}\#$, which maps $\mathcal{T}$ into itself, by the rule

$$\#\mathcal{C}\#\mathcal{A} = \{\mathcal{C},\mathcal{A}\}. \tag{27.13.16}$$

We claim that $\#\mathcal{C}\#$ is a *derivation.* To see this, compute $\#\mathcal{C}\#(\mathcal{A}\otimes\mathcal{B})$ to find the result

$$\begin{aligned}
\#\mathcal{C}\#(\mathcal{A}\otimes\mathcal{B}) &= \{\mathcal{C},\mathcal{A}\otimes\mathcal{B}\} = \mathcal{C}\otimes\mathcal{A}\otimes\mathcal{B} - \mathcal{A}\otimes\mathcal{B}\otimes\mathcal{C} \\
&= \mathcal{C}\otimes\mathcal{A}\otimes\mathcal{B} - \mathcal{A}\otimes\mathcal{C}\otimes\mathcal{B} + \mathcal{A}\otimes\mathcal{C}\otimes\mathcal{B} \\
&- \mathcal{A}\otimes\mathcal{B}\otimes\mathcal{C} + \mathcal{A}\otimes\mathcal{C}\otimes\mathcal{B} - \mathcal{A}\otimes\mathcal{C}\otimes\mathcal{B} \\
&= \{\mathcal{C},\mathcal{A}\}\otimes\mathcal{B} + \mathcal{A}\otimes\{\mathcal{C},\mathcal{B}\} \\
&= (\#C\#\mathcal{A})\otimes\mathcal{B} + \mathcal{A}\otimes(\#C\#\mathcal{B}).
\end{aligned} \tag{27.13.17}$$

Note that (13.17) may be viewed as a rule that tells one how to compute the commutator of $\mathcal{C}$ with a product if one already knows how to compute the commutator of $\mathcal{C}$ with the individual elements that form the product. As a further example of such a rule, consider a commutator of the form $\{\mathcal{A}\otimes\mathcal{B},\mathcal{C}\otimes\mathcal{D}\}$, which is a commutator of two products. By using adjoint operator notation and the result (13.17) we find the relation

$$\begin{aligned}
\{\mathcal{A}\otimes\mathcal{B},\mathcal{C}\otimes\mathcal{D}\} &= \#\mathcal{A}\otimes\mathcal{B}\#(\mathcal{C}\otimes\mathcal{D}) \\
&= (\#\mathcal{A}\otimes\mathcal{B}\#\mathcal{C})\otimes\mathcal{D} + \mathcal{C}\otimes(\#\mathcal{A}\otimes\mathcal{B}\#\mathcal{D}) \\
&= \{\mathcal{A}\otimes\mathcal{B},\mathcal{C}\}\otimes\mathcal{D} + \mathcal{C}\otimes\{\mathcal{A}\otimes\mathcal{B},\mathcal{D}\} \\
&= -\{\mathcal{C},\mathcal{A}\otimes\mathcal{B}\}\otimes\mathcal{D} - \mathcal{C}\otimes\{\mathcal{D},\mathcal{A}\otimes\mathcal{B}\} \\
&= -[\#\mathcal{C}\#(\mathcal{A}\otimes\mathcal{B})]\otimes\mathcal{D} - \mathcal{C}\otimes[\#\mathcal{D}\#(\mathcal{A}\otimes\mathcal{B})] \\
&= -(\#\mathcal{C}\#\mathcal{A})\otimes\mathcal{B}\otimes\mathcal{D} - \mathcal{A}\otimes(\#\mathcal{C}\#\mathcal{B})\otimes\mathcal{D} \\
&-\mathcal{C}\otimes(\#\mathcal{D}\#\mathcal{A})\otimes\mathcal{B} - \mathcal{C}\otimes\mathcal{A}\otimes(\#\mathcal{D}\#\mathcal{B}).
\end{aligned} \tag{27.13.18}$$

We see that (13.18) gives a rule for finding the commutator of two products if we know how to compute the commutators of the constituents.

So far we have only made use of the vector-space structure of L. Let us now also employ its Lie product structure. With the results of the last paragraph still fresh in mind, we observe that the constitutents of any element in $\mathcal{T}$ are ultimately the B_α. Therefore, any commutator in $\mathcal{T}$ can ultimately be reduced to commutators among the B_α. At this point we would like to use the Lie product structure of L to stipulate these commutators by the rule

$$\{B_\alpha, B_\beta\} = B_\alpha \otimes B_\beta - B_\beta \otimes B_\alpha = [B_\alpha, B_\beta] = \sum_\gamma c^\gamma_{\alpha\beta} B_\gamma. \tag{27.13.19}$$

The motivation for this move is that $\mathcal{T}$, because it contains $L^1 = L$ as a subspace, would then also contain a copy of L as a *Lie subalgebra*. Evidently (13.19) (which may be viewed as a *reduction* rule that reduces higher-order tensor products resulting from commutators to lower-order tensor products) is compatible with the antisymmetry and Jacobi properties of the commutator because of (3.7.44) and (3.7.45). There is therefore some hope that it can be enforced *consistently*. [Here is an example question of consistency: We can enforce the condition (13.19) and then multiply or commute. Or, we may first multiply or commute and then enforce the condition. Do these two procedures give the same result?] But hope is not enough when proof is required.

The standard way to show that (13.19) can be invoked consistently is to construct the *enveloping* algebra. Let $O_{\alpha\beta}$ denote the element

$$O_{\alpha\beta} = \{B_\alpha, B_\beta\} - [B_\alpha, B_\beta]. \tag{27.13.20}$$

Next, let O denote the set of all linear combinations of the $O_{\alpha\beta}$,

$$O = \text{ set of all elements in } \mathcal{T} \text{ of the form } \sum_{\alpha\alpha'} b_\alpha b'_{\alpha'} O_{\alpha\alpha'}. \tag{27.13.21}$$

Finally, let $\mathcal{O}$ be the set of all elements formed by tensor multiplying all of O on both the left and right by *all* elements in $\mathcal{T}$ and forming all linear combinations of such elements,

$$\begin{aligned} \mathcal{O} = \; & \text{set of all linear combinations of elements in } \mathcal{T} \\ & \text{of the form } \mathcal{A} \otimes O \otimes \mathcal{B} \text{ for all } \mathcal{A}, \mathcal{B} \in \mathcal{T}. \end{aligned} \tag{27.13.22}$$

Evidently $\mathcal{O}$ is a linear vector space since, by construction, all linear combinations of elements in $\mathcal{O}$ are again in $\mathcal{O}$. The set of $\mathcal{O}$ is also an associative algebra that is *invariant* under tensor multiplication on either the left or right side by any element in $\mathcal{T}$,

$$\mathcal{A}' \otimes \mathcal{O} \in \mathcal{O}, \; \mathcal{O} \otimes \mathcal{B}' \in \mathcal{O} \text{ for all } \mathcal{A}', \mathcal{B}' \in \mathcal{T}. \tag{27.13.23}$$

That is so because all multiplications have also already occurred in the definition (13.22). For this reason, $\mathcal{O}$ is called the *two-sided ideal* generated by the $O_{\alpha\beta}$. (Recall that in Section 8.9 an ideal was defined in the Lie-algebraic context to be the set of all elements invariant under the Lie product. Here the concept is the same except that the product is tensor multiplication from the left and the right.)

Suppose we use the set $\mathcal{O}$ to set up an equivalence relation among all elements in $\mathcal{T}$. We will say that two elements $\mathcal{A}$ and $\mathcal{A}'$ in $\mathcal{T}$ are equivalent if their difference (recall that both $\mathcal{A}$ and $\mathcal{A}'$ are vectors, and therefore can be added and subtracted) is in the set $\mathcal{O}$,

$$\mathcal{A} \sim \mathcal{A}' \Leftrightarrow (\mathcal{A} - \mathcal{A}') \in \mathcal{O}. \tag{27.13.24}$$

It is easily verified, by a discussion analogous to that in Section 8.9, that (13.24) does indeed define an equivalence relation. Next, this equivalence relation can be used to set up equivalence classes. By the standard arguments, when this is done, any element in $\mathcal{O}$ will be in the equivalence class $\{0\}$ that contains the zero vector in $\mathcal{T}$,

$$\mathcal{B} \in \mathcal{O} \Leftrightarrow \{\mathcal{B}\} = \{0\}. \tag{27.13.25}$$

[For the analogous Lie-algebraic case, see (8.9.3).] Finally, let $\mathcal{E}$ be the quotient space of $\mathcal{T}$ with respect to $\mathcal{O}$,

$$\mathcal{E} = \mathcal{T}/\mathcal{O}. \tag{27.13.26}$$

Since $\mathcal{T}$ is an associative algebra and $\mathcal{O}$ is an ideal in $\mathcal{T}$, the quotient space $\mathcal{E}$ will also be an associative algebra. It is called the *enveloping algebra* of L. (It is also often called the *universal* enveloping algebra because it can be shown to be unique up to an isomorphism.)

We note that because of (13.25), all elements in $\mathcal{O}$, (that is, all elements in $\mathcal{T}$ that contain $O_{\alpha\beta}$) are automatically replaced by 0 in $\mathcal{E}$. This is equivalent to enforcing the condition (13.19) in $\mathcal{E}$. And, because $\mathcal{E}$ is an associative algebra, we have verified that this condition can be enforced consistently.

Soon we will use the enveloping algebra to construct Casimir operators. To do so, it is useful to first explore further the property of adjoint operators $\#\mathcal{C}\#$. Since $\#\mathcal{C}\#$ is a derivation, recall (13.17), the operator $\exp(\epsilon\#\mathcal{C}\#)$ is an isomorphism for tensor multiplication,

$$[\exp(\epsilon\#\mathcal{C}\#)](\mathcal{A} \otimes \mathcal{B}) = \{[\exp(\epsilon\#\mathcal{C}\#)]\mathcal{A}\} \otimes \{[\exp(\epsilon\#\mathcal{C}\#)]\mathcal{B}\}. \tag{27.13.27}$$

Indeed, if $\mathcal{F}$ is any element of $\mathcal{T}$ composed of tensor products of the B_α, we have the result

$$\begin{aligned}&[\exp(\epsilon\#\mathcal{C}\#)]\mathcal{F}(B_{\alpha_1}, B_{\alpha_2}, B_{\alpha_3}\cdots) = \\ &\mathcal{F}([\exp(\epsilon\#\mathcal{C}\#)]\mathcal{B}_{\alpha_1}, [\exp(\epsilon\#\mathcal{C}\#)]\mathcal{B}_{\alpha_2}, [\exp(\epsilon\#\mathcal{C}\#)]\mathcal{B}_{\alpha_3}\cdots).\end{aligned} \tag{27.13.28}$$

See Section 8.2 for the standard arguments justifying this result.

Now suppose $\mathcal{C} = C$ where C is some element in L as in (11.20). Then we have the results

$$\#C\#B_\alpha = \{C, B_\alpha\} = [C, B_\alpha] =: C : B_\alpha. \tag{27.13.29}$$

Here we have used (13.19). It follows from (11.20), (11.28), and (13.29) that in this case there is the relation

$$[\exp(\epsilon\#\mathcal{C}\#)]B_\alpha = \exp(\epsilon : C :)B_\alpha = U_{\alpha\beta}B_\beta, \tag{27.13.30}$$

where we have again used the summation convention. Correspondingly, in this case (13.28) can be rewritten in the form

$$[\exp(\epsilon\#\mathcal{C}\#)]\mathcal{F}(B_{\alpha_1}, B_{\alpha_2}, B_{\alpha_3}\cdots) = \mathcal{F}(U_{\alpha_1\beta_1}B_{\beta_1}, U_{\alpha_2\beta_2}B_{\beta_2}, U_{\alpha_3\beta_3}B_{\beta_3}\cdots). \tag{27.13.31}$$

We are now ready to discuss Casimir operators. In analogy with (11.35) we now define the quadratic Casimir operator $\mathcal{C}_2$ to be the quantity

$$\mathcal{C}_2 = \sum_{\alpha\alpha'} g_R^{\alpha\alpha'} B_\alpha \otimes B_{\alpha'}. \tag{27.13.32}$$

Note that in this context $\mathcal{C}_2$ is not first of all an "operator", but rather is an element in the enveloping algebra $\mathcal{E}$. In analogy with (11.38), let us see how it transforms. We find the result

$$\begin{aligned}\mathcal{C}_2^{\rm tr} &= \exp(\epsilon\#\mathcal{C}\#)\mathcal{C}_2 = \sum_{\alpha\alpha'} g_R^{\alpha\alpha'}(U_{\alpha\beta}B_\beta)\otimes(U_{\alpha'\beta'}B_{\beta'}) \\ &= \sum_{\alpha\alpha'} g_R^{\alpha\alpha'}U_{\alpha\beta}U_{\alpha'\beta'}B_\beta\otimes B_{\beta'} \\ &= \sum_{\beta\beta'}(\sum_{\alpha\alpha'} g_R^{\alpha\alpha'}U_{\alpha\beta}U_{\alpha'\beta'})B_\beta\otimes B_{\beta'} \\ &= \sum_{\beta\beta'} g_R^{\beta\beta'}B_\beta\otimes B_{\beta'} = \mathcal{C}_2. \end{aligned} \tag{27.13.33}$$

Here we have used (13.31) and (11.39). We see that $\mathcal{C}_2$ is again invariant. Also, the infinitesimal version of (13.33) with $\mathcal{C} = C = B_{\alpha''}$ gives the result

$$\#B_{\alpha''}\#\mathcal{C}_2 = \{B_{\alpha''}, \mathcal{C}_2\} = 0. \tag{27.13.34}$$

We see that $\mathcal{C}_2$ commutes with all the elements in L. Moreover, since everything in the enveloping algebra is constructed from elements in L, it follows that $\mathcal{C}_2$ commutes with all the elements of the enveloping algebra,

$$\{\mathcal{C}_2, \mathcal{E}\} = 0. \tag{27.13.35}$$

At this point we pause to note that we might use (13.19) to rearrange [in analogy to (11.46) and (11.47)] the terms in $\mathcal{C}_2$ as given by (13.32) to get an expression for $\mathcal{C}_2$ analogous to (11.50). What would happen if we then compute $\{B_{\alpha''}, \mathcal{C}_2\}$ using the rearranged $\mathcal{C}_2$? According to our previous discussion about consistency, $\mathcal{O}$ is an ideal thereby guaranteeing that the quotient space $\mathcal{T}/\mathcal{O} = \mathcal{E}$ is an associative algebra. Therefore the result should be (and is indeed) the same.

The construction of higher-order Casimir operators proceeds in a similar fashion. For example, the analog of (11.86) is

$$\mathcal{C}_3 =_3 g_R^{\alpha\alpha'\alpha''}B_\alpha\otimes B_{\alpha'}\otimes B_{\alpha''}. \tag{27.13.36}$$

Again, it is an element in the enveloping algebra. It too commutes with all the elements in L, and therefore also with all of $\mathcal{E}$. In general, in the context of the present discussion, we may define a Casimir operator to be any element in the enveloping algebra that commutes with *all* the elements in the enveloping algebra. Put another way, the Casimir operators form the *center* of the enveloping algebra.

Exercises

27.13.1. From (13.4) it follows that $\mathcal{T}$, the tensor algebra of L, can be expressed in the form

$$\mathcal{T} = \mathcal{T}^0 \oplus \mathcal{T}^1 \oplus \mathcal{T}^2 \oplus \mathcal{T}^3 \oplus \cdots, \tag{27.13.37}$$

where

$$\mathcal{T}^n = L^n. \tag{27.13.38}$$

Suppose that L has dimension k. Show that each subspace $\mathcal{T}^n$ then has dimension

$$\dim \mathcal{T}^n = k^n. \tag{27.13.39}$$

The algebra $\mathcal{E}$, the enveloping algebra of L, can also be decomposed in the form

$$\mathcal{E} = \mathcal{E}^0 \oplus \mathcal{E}^1 \oplus \mathcal{E}^2 \oplus \mathcal{E}^3 \oplus \cdots , \tag{27.13.40}$$

where each subspace $\mathcal{E}^n$ of "degree" n is spanned by the tensor products of n basis elements $(B_{\alpha_1} \otimes B_{\alpha_2} \otimes B_{\alpha_3} \otimes \cdots B_{\alpha_n})$. However, in the case of $\mathcal{E}$, the relation (13.19) can be used to rearrange the basis elements in each $\mathcal{E}^n$ so that the subscripts have a definite standard ordering. For example, we may arrange them in ascending order,

$$\begin{aligned}&\text{rearranged } (B_{\alpha_1} \otimes B_{\alpha_2} \otimes B_{\alpha_3} \otimes \cdots B_{\alpha_n}) = (B_{\beta_1} \otimes B_{\beta_2} \otimes B_{\beta_3} \otimes \cdots B_{\beta_n})\\ &\text{with } \beta_1 \leq \beta_2 \leq \beta_3 \leq \cdots \beta_n.\end{aligned} \tag{27.13.41}$$

In the rearrangement process various terms of lower degree may be generated, but they simply feed down to $\mathcal{E}^{n-1}$, etc. It follows that the various terms in some standard ordering, say that shown on the right side of (13.41), *span* $\mathcal{E}^n$. It can be shown that they are linearly independent as well, and therefore form a *basis* for $\mathcal{E}^n$. This basis is called the *Poincaré-Birkhoff-Witt* basis. Show that the dimension of $\mathcal{E}^n$ is given by the relation

$$\dim \mathcal{E}^n = N(n, k) \tag{27.13.42}$$

with $N(n, k)$ given by (7.3.40). Hint: Once a standard ordering has been established, the counting of basis elements is the same as counting monomials.

27.13.2. Suppose R is a realization of some Lie algebra L. Thus, if the B_α form a basis of L, there are associated matrices $\hat{B}_\alpha$ in the realization R. Let $\mathcal{R}$ be the *linear* map that sends the B_α to the $\hat{B}_\alpha$,

$$\mathcal{R}(B_\alpha) = \hat{B}_\alpha. \tag{27.13.43}$$

(Note that since both L and the set of $m \times m$ matrices are vector spaces, it makes sense to talk about a linear map that sends one into the other.) Then, by the definition of a realization, we have the relation

$$\begin{aligned}\mathcal{R}([B_\alpha, B_\beta]) &= \mathcal{R}(\sum_\gamma c^\gamma_{\alpha\beta} B_\gamma) = \sum_\gamma c^\gamma_{\alpha\beta} \hat{B}_\gamma = \{\hat{B}_\alpha, \hat{B}_\beta\}\\ &= \{\mathcal{R}(B_\alpha), \mathcal{R}(B_\beta)\}.\end{aligned} \tag{27.13.44}$$

Next, let us extend the definition of $\mathcal{R}$ to have it act on any basis element in the tensor algebra $\mathcal{T}$ by the rule

$$\begin{aligned}\mathcal{R}(B_{\alpha_1} \otimes B_{\alpha_2} \otimes B_{\alpha_3} \cdots) &= \mathcal{R}(B_{\alpha_1})\mathcal{R}(B_{\alpha_2})\mathcal{R}(B_{\alpha_3}) \cdots\\ &= \hat{B}_{\alpha_1}\hat{B}_{\alpha_2}\hat{B}_{\alpha_3} \cdots .\end{aligned} \tag{27.13.45}$$

Show that $\mathcal{R}$ sends any element of the two-sided ideal $\mathcal{O}$ to the zero matrix,

$$\mathcal{R}(O_{\alpha\beta}) = 0,\ \mathcal{R}(O) = 0,\ \mathcal{R}(\mathcal{O}) = 0. \tag{27.13.46}$$

Thus, the image of any element in $\mathcal{T}$ under the action of $\mathcal{R}$ depends only on the equivalence class to which the element belongs, and we may equally well view $\mathcal{R}$ as acting on $\mathcal{T}/\mathcal{O} = \mathcal{E}$. Show that $\mathcal{R}$ sends the Casimir operator (13.32) defined in the enveloping algebra context to the Casimir operator (11.35) defined in the representation context. Show that in general anything that it discovered about Casimir operators in the enveloping algebra context is immediately transferable to the realization context, and vice versa.

27.14 The Symplectic Lie Algebras $sp(8)$ and Beyond

The previous sections in this chapter have treated the cases of $sp(2)$, $sp(4)$, and $sp(6)$. The Lie algebraic structure of all the $sp(2n)$, for example root vectors and fundamental weight vectors, is also known. In particular, for $sp(2n)$, a representation is characterized by n non-negative integers $k_1, k_2, \cdots k_n$ and may be denoted by the symbols $\Gamma(k_1, k_2, \cdots k_n)$. Homogeneous polynomials of degree ℓ in the $2n$ components of z again carry representations of $sp(2n)$, and for these representations there is the result

$$k_1 = \ell, \tag{27.14.1}$$

$$k_j = 0 \text{ for } j = 2, 3, \cdots n. \tag{27.14.2}$$

There is also an analogous Clebsch-Gordon series result of the form (9.1) where all entries in $\Gamma(k_1, k_2, \cdots k_n)$ are zero save for the first two,

$$\begin{aligned}&\Gamma(\ell, 0, 0, \cdots) \otimes \Gamma(1, 0, 0, \cdots)\\&= \Gamma(\ell + 1, 0, 0, \cdots) \oplus \Gamma(\ell - 1, 1, 0, \cdots)\\&\ \oplus \Gamma(\ell - 1, 0, 0, \cdots).\end{aligned} \tag{27.14.3}$$

Thus, the symplectic classification of all analytic vector fields in any (even) dimension is in principle known. Moreover, any $\mathcal{L}_{\boldsymbol{g}^\ell}$ with $\ell \geq 1$ has the unique decomposition

$$\mathcal{L}_{\boldsymbol{g}^\ell} = \mathcal{H}^{\ell+1,0,0,\cdots} + \mathcal{G}^{\ell-1,1,0,\cdots} + \mathcal{G}^{\ell-1,0,0,\cdots}. \tag{27.14.4}$$

Here $\mathcal{H}^{\ell+1,0,0,\cdots}$ is a Hamiltonian vector field that carries the representation $\Gamma(\ell+1, 0, 0, \cdots)$, and is of the form $:h_{\ell+1}:$. The quantities $\mathcal{G}^{\ell-1,1,0,\cdots}$ and $\mathcal{G}^{\ell-1,0,0,\cdots}$ are non-Hamiltonian vector fields that carry the representations $\Gamma(\ell - 1, 1, 0, \cdots)$ and $\Gamma(\ell - 1, 0, 0, \cdots)$, respectively.

Exercises

27.14.1. Show that any $2n \times 2n$ matrix that commutes with all $sp(2n)$ matrices (in the fundamental representation) must be a multiple of I. Show that any $2n \times 2n$ matrix that commutes with all $Sp(2n)$ matrices (in the fundamental representation) must be a multiple of I.

27.15 Momentum Maps and Casimirs

The previous sections, among other things, have shown how to decompose an analytic vector field $\mathcal{L}_{\boldsymbol{g}}$ into Hamiltonian and non-Hamiltonian parts. Here we address a somewhat more restricted question. Suppose we are given a vector field $\mathcal{L}_{\boldsymbol{g}}$, and also know that it came from some Hamiltonian h so that there is in principle the relation

$$\mathcal{L}_{\boldsymbol{g}} =: h : . \tag{27.15.1}$$

That is, $\mathcal{L}_{\boldsymbol{g}}$ is a Hamiltonian vector field. We then say that there is a *momentum map* μ that sends $\mathcal{L}_{\boldsymbol{g}}$ to h,

$$\mu(\mathcal{L}_{\boldsymbol{g}}) = h. \tag{27.15.2}$$

Here the name *momentum* is associated with the fact that in some simple examples the resulting h is some kind of momentum such as linear or angular momentum.

In this section we will develop/review what is required for $\mathcal{L}_{\boldsymbol{g}}$ to be Hamiltonian, and then see how to determine h in terms of $\boldsymbol{g}$. We will also see how momentum maps are related to integrals of motion and, when there are several integrals of motion, how to construct from them integrals of motion that are in involution.

27.15.1 Momentum Maps and Conservation Laws

Why might one be interested in momentum maps? Given a vector field $\mathcal{L}_{\boldsymbol{g}}$, we may define a family of maps $\mathcal{M}(\tau)$, not to be confused with momentum maps, by the rule

$$\mathcal{M}(\tau) = \exp(\tau\mathcal{L}_{\boldsymbol{g}}). \tag{27.15.3}$$

[For a discussion of some of the properties of general Lie operators (general vector fields) and their associated Lie transformations, see Exercises 5.3.10 and 5.4.14.] The maps $\mathcal{M}(\tau)$ send phase space into itself according to the relation

$$\bar{z}(\tau) = \mathcal{M}(\tau)z, \tag{27.15.4}$$

and they evidently form a one-parameter group. Now suppose the motion of some system is governed by some Hamiltonian $H(z,t)$ and suppose that this Hamiltonian is invariant under the action of $\mathcal{M}(\tau)$,

$$\mathcal{M}(\tau)H(z,t) = H(z,t). \tag{27.15.5}$$

From this invariance/symmetry relation and (15.3) we conclude that

$$\mathcal{L}_{\boldsymbol{g}}H(z,t) = 0. \tag{27.15.6}$$

But, if (15.1) holds, (15.6) can be rewritten as

$$\mathcal{L}_{\boldsymbol{g}}H(z,t) =: h : H = [h,H] = 0, \tag{27.15.7}$$

and we see that h is an integral of motion. Thus, the existence of symmetry and a momentum map implies the existence of an integral of motion (a *conserved quantity* or *conservation law*) and vice versa.[6]

[6] Observe that the assumed symmetry described by (15.5) is a *continuous* symmetry. The condition (15.5) is supposed to hold over a continuous range of τ. We also remark that *Emmy Noether* (1882-1935) was the first to explore in detail the connection between continuous symmetries and conservation laws.

How can one test a vector field to see if it is Hamiltonian and therefore there is a momentum map? We have already seen that the maps $\mathcal{M}(\tau)$ form a one-parameter group. Suppose we now require that these maps be symplectic for all τ. That is, we require that

$$[\bar{z}_a(\tau), \bar{z}_b(\tau)] = J_{ab} \text{ for all } \tau. \tag{27.15.8}$$

Put another way, we require that each transformation $\mathcal{M}(\tau)$ *preserve* the symplectic structure of phase space. For small τ we have the result

$$\mathcal{M}(\tau) = \mathcal{I} + \tau \mathcal{L}_{\boldsymbol{g}} + O(\tau^2). \tag{27.15.9}$$

It follows that

$$\bar{z}(\tau)_a = \mathcal{M}(\tau) z_a = z_a + \tau \mathcal{L}_{\boldsymbol{g}} z_a + O(\tau)^2 = z_a + \tau g_a + O(\tau)^2. \tag{27.15.10}$$

Here we have used the result

$$\mathcal{L}_{\boldsymbol{g}} z_a = g_a. \tag{27.15.11}$$

Upon employing (15.10) we find the result

$$\begin{aligned}[\bar{z}_a(\tau), \bar{z}_b(\tau)] &= [z_a, z_b] + \tau\{[z_a, g_b] + [g_a, z_b]\} + O(\tau^2) \\ &= J_{ab} + \tau\{[z_a, g_b] + [g_a, z_b]\} + O(\tau^2).\end{aligned} \tag{27.15.12}$$

Enforcing (15.8) and equating powers of τ give the result

$$[z_a, g_b] + [g_a, z_b] = 0. \tag{27.15.13}$$

We have seen this condition before in Lemma 6.2 of Section 7.6. There we learned that (15.13) implies and is implied by the relation

$$g_a =: h : z_a, \tag{27.15.14}$$

which, in view of (15.11), is equivalent to the relation (15.1). Thus, (15.13) is a necessary and sufficient condition for $\mathcal{L}_{\boldsymbol{g}}$ to be a Hamiltonian vector field.

We also learned how to construct h. It is given, up to an additive constant, by the relation

$$h(z) = -\int_P^z \sum_{cd} g_c(z') J_{cd}\, dz'_d \tag{27.15.15}$$

where P is *any* path ending at the point z. A convenient path is that which connects the origin and z by a straight line,

$$z'(\lambda) = \lambda z \text{ with } \lambda \in [0, 1]. \tag{27.15.16}$$

For this path we find the explicit result

$$h(z) = -\sum_{cd} z_d J_{cd} \int_0^1 d\lambda g_c(\lambda z). \tag{27.15.17}$$

This relation specifies h in terms of the g_c, and hence in terms of $\mathcal{L}_{\boldsymbol{g}}$. It therefore provides the map μ described in (15.2). Note that this specification is equivalent to the *definition* (10.20) of the Hamiltonian part of a general homogeneous vector field.

At this point we remark that in some circumstances one initially has a transformation or a group of transformations whose action is only on the position coordinates q. Such transformations can always be extended to symplectic actions on phase space, and thus in this case the existence of Hamiltonian vector fields is guaranteed. Recall Exercise 6.5.2.

As a first example of the momentum map process, consider (for a 6-dimensional phase space) the case where

$$\begin{aligned} &g_1(z) = 1, \\ &g_a(z) = 0,\ a \neq 1, \end{aligned} \tag{27.15.18}$$

so that

$$\mathcal{L}_{\boldsymbol{g}} = \partial/\partial z_1 = \partial/\partial q_1. \tag{27.15.19}$$

It is easily verified that

$$(\mathcal{L}_{\boldsymbol{g}})^n z = 0 \text{ for } n \geq 2, \tag{27.15.20}$$

from which it follows that

$$\bar{z}_a(\tau) = \exp(\tau\mathcal{L}_{\boldsymbol{g}})z_a = z_a + \tau\delta_{a,1}. \tag{27.15.21}$$

That is, $\mathcal{L}_{\boldsymbol{g}}$ generates translations in phase space along the $z_1 = q_1$ axis. Evidently, the g_a specified by (15.18) satisfy (15.13) so that $\mathcal{L}_{\boldsymbol{g}}$ is a Hamiltonian vector field. Finally, the formula (15.17) for h is easily evaluated to give the result

$$h(z) = -z_4 = -p_1, \tag{27.15.22}$$

the negative of the first component of the linear momentum. Thus, invariance under translation implies the conservation of linear momentum, and vice versa.

As a second example, suppose that

$$\begin{aligned} \mathcal{L}_{\boldsymbol{g}} &= z_1\partial/\partial z_2 - z_2\partial/\partial z_1 + z_4\partial/\partial z_5 - z_5\partial/\partial z_4 \\ &= (q_1\partial/\partial q_2 - q_2\partial/\partial q_1) + (p_1\partial/\partial p_2 - p_2\partial/\partial p_1). \end{aligned} \tag{27.15.23}$$

For this example the nonzero g_a are given by the relations

$$\begin{aligned} g_1(z) &= -z_2, \\ g_2(z) &= z_1, \\ g_4(z) &= -z_5, \\ g_5(z) &= z_4. \end{aligned} \tag{27.15.24}$$

With the $g_a(z)$ in view, it is easily checked that (15.13) holds. It therefore makes sense to continue on to compute h. The integrals appearing on the right side of (15.17) are easy to evaluate because the $h_a(z)$ are homogeneous of degree one. Doing so gives the results

$$\int_0^1 d\lambda g_c(\lambda z) = \int_0^1 d\lambda\lambda g_c(z) = (1/2)g_c(z). \tag{27.15.25}$$

Finally, employing (15.25) in (15.17) gives the result

$$h(z) = -(z_1z_5 - z_2z_4) = -(q_1p_2 - q_2p_1). \tag{27.15.26}$$

From the second line of (15.23) we recognize $\mathcal{L}_{\boldsymbol{g}}$ as the generator of simultaneous rotations in the q_1, q_2 and p_1, p_2 planes, and from (15.26) we see that h is the negative of the third component of the angular momentum. Thus, invariance under rotation implies the conservation of angular momentum, and vice versa.

27.15.2 Use of Casimirs

In general, if a Hamiltonian is invariant under the action of some n-dimensional group that preserves symplectic structure, there will be n associated integrals of motion. These integrals, however, need not be in mutual involution. Think, for example, of the components of angular momentum. Their Poisson bracket Lie algebra provides a realization of $su(2)$ [or, equivalently, $so(3,\mathbb{R})$], and they are therefore not in involution. Generally integrals will be in involution if, and only if, the corresponding Lie operators commute. Recall (5.3.14). In this subsection we will explore briefly how Casimirs can sometimes be used to construct integrals that are in involution.

Suppose that a Hamiltonian H is indeed invariant under the action of some n-dimensional group that preserves symplectic structure, and therefore there are n associated integrals of motion. Call these integrals h^α. Let C be any function of these integrals,

$$C = C(h^1, h^2, \cdots, h^n). \tag{27.15.27}$$

Then we know form Exercise 5.2.4 that C will also be an integral of motion. Our goal will be to construct a C such that it is functionally independent of any one of the h^α, but is also in involution with any of them.

We know that the h^α will form a Lie algebra with the Poisson bracket serving as a Lie product. That is, there will be relations of the form

$$[h^\alpha, h^\beta] = \sum_\gamma c^\gamma_{\alpha\beta} h^\gamma. \tag{27.15.28}$$

(Note that these relations are consistent with Poisson's theorem that states that the Poisson bracket of two integrals of motion is again an integral of motion. See Exercise 5.2.3.) The structure constants $c^\gamma_{\alpha\beta}$ can be used to construct a Killing metric tensor $g^K_{\alpha\alpha'}$, and from $g^K_{\alpha\alpha'}$, assuming it is invertible, we can construct $g_K^{\alpha\alpha'}$. With $g_K^{\alpha\alpha'}$ in hand, we can define the function C_2 by the rule

$$C_2 = \sum_{\alpha\alpha'} g_K^{\alpha\alpha'} h^\alpha h^{\alpha'}. \tag{27.15.29}$$

In analogy to the calculations carried out for the quadratic Casimir operator $\mathcal{C}_2$ in Section 21.11.1, it is easily verified that C_2 is in involution with the h^α. It can happen that C_2 vanishes identically. See Exercise 21.11.7. But, if C_2 does not vanish, we have found two functionally independent integrals in involution, namely C_2 and any one of the h^α.

At this point we might go on to find additional integrals C_3, etc. constructed in analogy to the higher-order Casimir operators. They will also be in involution and, if these integrals are nonvanishing and functionally independent, we will have found additional nontrivial integrals. In general, assuming the Lie algebra in question is simple, we may hope to find as many integrals in involution as there are labels necessary to specify a representation for the Lie algebra and to specify vectors within a representation.

Let us apply this construction to the rotation group example of the previous subsection. Suppose that H has the three integrals

$$h^1 = q_2p_3 - q_3p_2, \tag{27.15.30}$$

$$h^2 = q_3p_1 - q_1p_3, \tag{27.15.31}$$

$$h^3 = q_1p_2 - q_2p_1. \tag{27.15.32}$$

They form an $su(2)$ Lie algebra,

$$[h^1, h^2] = h^3, \text{ etc.} \tag{27.15.33}$$

The metric tensor for $su(2)$ is given in Exercise 21.12.2. It follows, after a convenient renormalization, that we may take for C_2 the quantity

$$C_2 = (h^1)^2 + (h^2)^2 + (h^3)^2, \tag{27.15.34}$$

which is the square of the angular momentum.

Exercises

27.15.1. Verify that (15.5) implies (15.6), and conversely.

27.15.2. Suppose (15.13) holds so that $\mathcal{L}_{\boldsymbol{g}}$ is a Hamiltonian vector field. Suppose also that $\mathcal{L}_{\boldsymbol{g}}$ can be decomposed into a sum of homogeneous parts as in (3.1). (This will certainly be possible if $\mathcal{L}_{\boldsymbol{g}}$ is analytic.) Show that then (10.20) and (15.17) are equivalent.

27.15.3. Verify that use of (15.18) in (15.17) does yield (15.22). Verify that the g_a given by (15.18) and the h given by (15.22) do indeed satisfy (15.1).

27.15.4. Verify, by evaluating the effect of $\exp(\tau\mathcal{L}_{\boldsymbol{g}})$ on phase space, that $\mathcal{L}_{\boldsymbol{g}}$ as given by (15.23) does indeed generate simultaneous rotations in the q_1, q_2 and p_1, p_2 planes. Verify (15.24) through (15.26). Verify that the g_a given by (15.24) and the h given by (15.26) do indeed satisfy (15.1).

27.15.5. Verify the relations (15.33). Verify that C_2 and any one of the h^α are in involution.

Chapter 28

Numerical Study of Stroboscopic Duffing Map

28.1 Introduction

This chapter continues the study of the Duffing equation begun in Section 1.4.3. Recall that we are interested in the behavior of the system governed by the differential equation

$$\ddot{q} + 2\beta\dot{q} + q + q^3 = -\epsilon \sin \omega\tau, \tag{28.1.1}$$

or its equivalent first-order equation pair

$$\begin{aligned} \dot{q} &= p, \\ \dot{p} &= -2\beta p - q - q^3 - \epsilon \sin \omega\tau. \end{aligned} \tag{28.1.2}$$

Because the right sides of (1.1) and (1.2) are periodic with period

$$T = 2\pi/\omega, \tag{28.1.3}$$

we were able to define stroboscopic times

$$\tau^n = nT, \tag{28.1.4}$$

and were able to reduce the study of the long-term behavior of the driven Duffing oscillator to the study of its associated stroboscopic map $\mathcal{M}$ under repeated iteration.

As indicated in Subsection 1.4.3, the driven Duffing oscillator is expected to display an enormously rich behavior that varies widely with the parameter values β, ϵ, and ω. Consequently, even providing an overview of what can happen requires considerable work, and even then we shall be able to discuss only some of its complexity.

Our analysis will parallel that for the logistic map as done in Section 1.2.1. We will find the fixed points of $\mathcal{M}$ for a small value of the driving strength ϵ, and track them in q, p space as the driving frequency ω is varied thereby producing a Feigenbaum/bifurcation diagram. Subsequently we will gradually increase the value of ϵ all the while observing the Feigenbaum/bifurcation diagram for $\mathcal{M}$ as a function of ω. For simplicity, we will hold the damping parameter β at the constant value $\beta = 0.1$.[1]

[1] Of course, one can also make Feigenbaum diagrams in which some other parameter, say ϵ, is varied while

28.2 Review of Simple Harmonic Oscillator Behavior

But first suppose that the q^3 term in (1.1) or (1.2) were missing. Then we know how to solve the differential equation, which is just that of a driven damped simple harmonic oscillator. The solution would consist of a particular solution plus any solution of the homogeneous equation. The particular solution, call it $q_f(\tau)$, is given by the relation

$$q_f(\tau) = -A(\beta,\omega)\epsilon\sin(\omega\tau+\phi) \tag{28.2.1}$$

where

$$A(\beta,\omega) = 1/\sqrt{(1-\omega^2)^2+(2\beta\omega)^2} \tag{28.2.2}$$

and

$$\phi(\beta,\omega) = -\text{Arctan}[(2\beta\omega)/(1-\omega^2)]. \tag{28.2.3}$$

Differentiating (2.1) gives the related result

$$p_f(\tau) = -\omega A(\beta,\omega)\epsilon\cos(\omega\tau+\phi). \tag{28.2.4}$$

Evidently $q_f(\tau)$ and $p_f(\tau)$ are periodic in τ with period T and therefore, as the subscript f is intended to convey, the phase-space point $\{q_f(0), p_f(0)\}$ is a *fixed* point of the stroboscopic map $\mathcal{M}$ for the driven damped simple harmonic oscillator. Moreover, if $\beta > 0$, then all solutions of the homogeneous equation are exponentially damped as $\tau \to \infty$, and therefore $\{q_f(0), p_f(0)\}$ is a stable (and unique) attracting fixed point. We may therefore make the identification

$$\{q_\infty, p_\infty\} = \{q_f(0), p_f(0)\}. \tag{28.2.5}$$

Figures 2.1 and 2.2 display $A(\beta,\omega)$ and $\phi(\beta,\omega)$ as a function of ω for the case $\beta = .1$, and Figures 2.3 and 2.4 show q_∞ and p_∞ as functions of ω (for the case $\beta = 0.1$ and $\epsilon = .15$), and Figure 2.5 shows them both.[2] As expected, there is resonant behavior in the vicinity of $\omega = 1$ since the coefficient of q in (1.1) is unity.[3] Also note that both q_∞ and p_∞ approach zero when ω either goes to zero or to infinity. See Exercise 2.1.

the others, including ω, are held fixed. We choose to vary ω because so doing brings resonance behavior to the fore.

[2] The value $\beta = .1$ for the damping coefficient corresponds to a quality factor $Q \simeq 4.95$. See Exercise 2.2.

[3] It was the desire for q_∞ to exhibit a resonance-like peak as a function of ω that dictated the choice (1.4.28) for ψ.

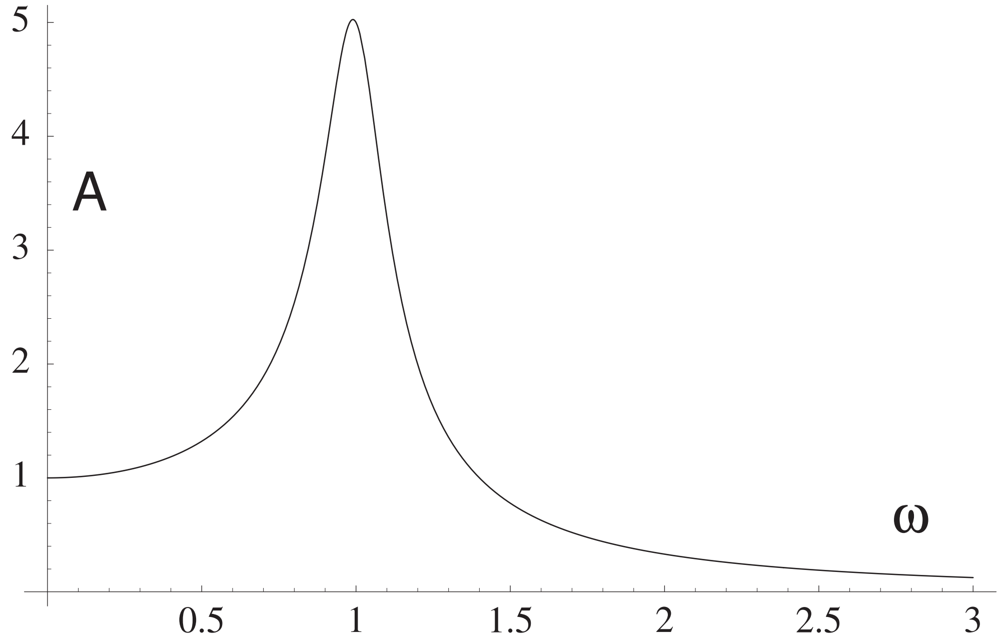

Figure 28.2.1: The quantity $A(\beta, \omega)$ as a function of ω (for the case $\beta = 0.1$).

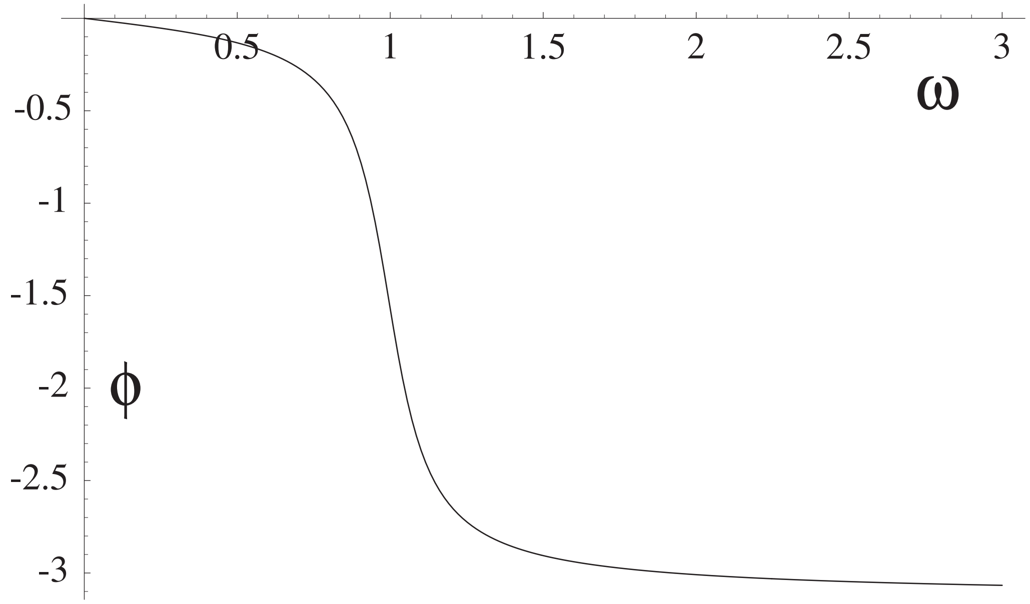

Figure 28.2.2: The quantity $\phi(\beta, \omega)$ as a function of ω (for the case $\beta = 0.1$).

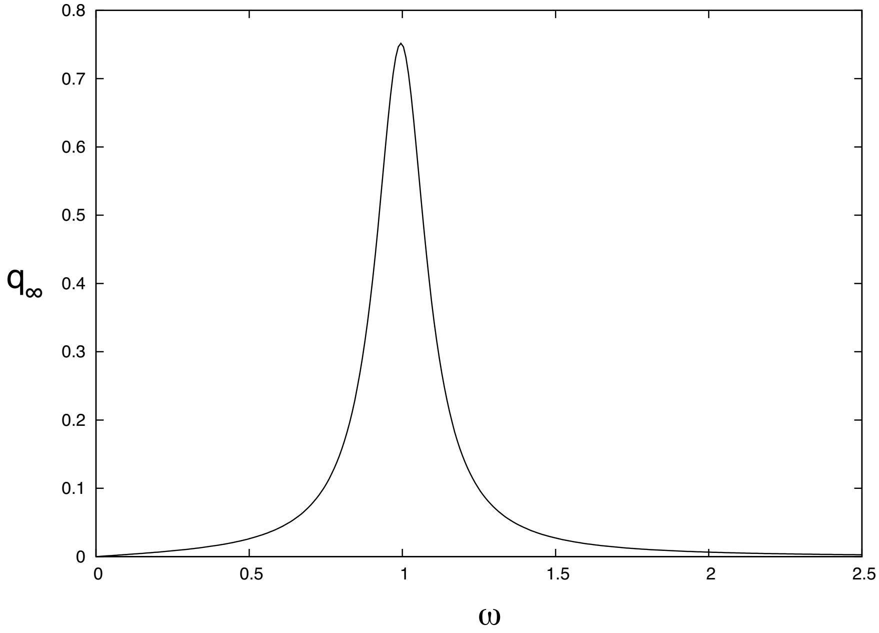

Figure 28.2.3: Feigenbaum diagram showing limiting values q_∞ as a function of ω (when $\beta = 0.1$ and $\epsilon = .15$) for the stroboscopic driven damped simple harmonic oscillator map.

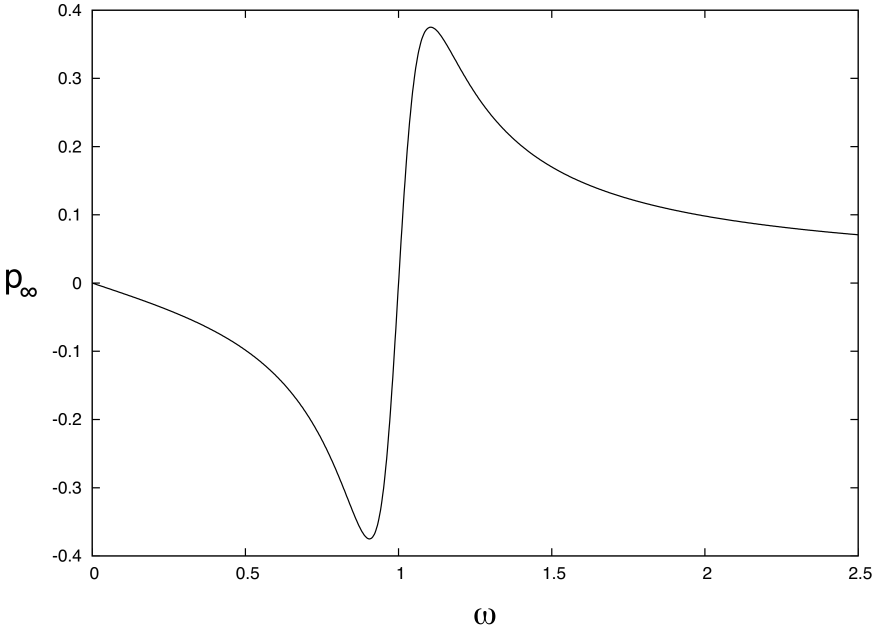

Figure 28.2.4: Feigenbaum diagram showing limiting values p_∞ as a function of ω (when $\beta = 0.1$ and $\epsilon = .15$) for the stroboscopic driven damped simple harmonic oscillator map.

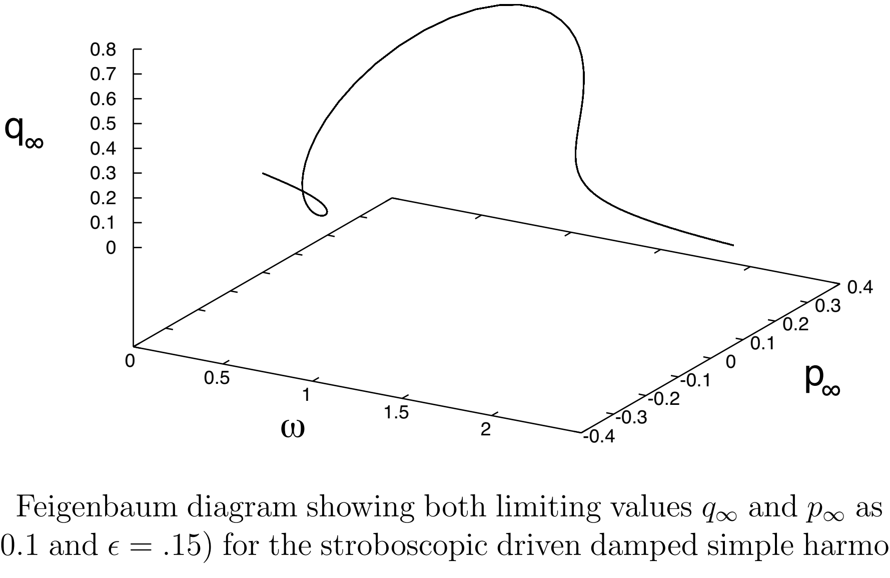

Figure 28.2.5: Feigenbaum diagram showing both limiting values q_∞ and p_∞ as a function of ω (when $\beta = 0.1$ and $\epsilon = .15$) for the stroboscopic driven damped simple harmonic oscillator map.

Exercises

28.2.1. Show, using (2.1), (2.4), and (2.5), that

$$q_\infty = -A(\beta,\omega)\epsilon\sin\phi, \tag{28.2.6}$$

$$p_\infty = -\omega A(\beta,\omega)\epsilon\cos\phi. \tag{28.2.7}$$

Show that using (2.2) and (2.3) in (2.6) and (2.7) gives the equivalent results

$$q_\infty = 2\beta\omega\epsilon/[(\omega^2-1)^2+(2\beta\omega)^2], \tag{28.2.8}$$

$$p_\infty = \omega(\omega^2-1)\epsilon/[(\omega^2-1)^2+(2\beta\omega)^2]. \tag{28.2.9}$$

Determine the behavior of q_∞ and p_∞ as ω either goes to zero or goes to infinity.

28.2.2. The *quality factor* Q of a damped harmonic oscillator is defined by the relation

$$Q = \omega_R/(2\beta) \tag{28.2.10}$$

where ω_R is the resonant frequency. For the normalization used in (1.1),

$$\omega_R^2 = 1-2\beta^2. \tag{28.2.11}$$

Show that $Q \simeq 4.95$ when $\beta = 0.1$.

28.3 Behavior for Small Driving when Nonlinearity is Included

If the driving strength ϵ is small enough and the damping coefficient β is large enough, then we expect $q(\tau)$ to be small, and therefore the q^3 term in (1.1) can indeed be neglected, at least in zeroth approximation. Figure 3.1 shows q_∞ as a function of ω for the case $\beta = 0.1$ and $\epsilon = .15$ when the q^3 term in (1.1) is *retained*, and Figure 3.2 shows both q_∞ and p_∞. Now we are dealing with the stroboscopic Duffing map, and the results shown were obtained by numerical integration. Evidently these figures resemble their simple harmonic oscillator counterparts, Figures 2.3 and 2.5. In particular, there is only *one* fixed point for each value of ω and its basin is the entire q, p plane. (Consequently there are no fixed points for powers of $\mathcal{M}$ apart from the fixed point of $\mathcal{M}$ itself.) Note, however, the appearance of some structure near the value $\omega = 1/3$, and that the resonance peak in q_∞ near $\omega = 1$ is reduced in amplitude and slightly tipped toward the right.

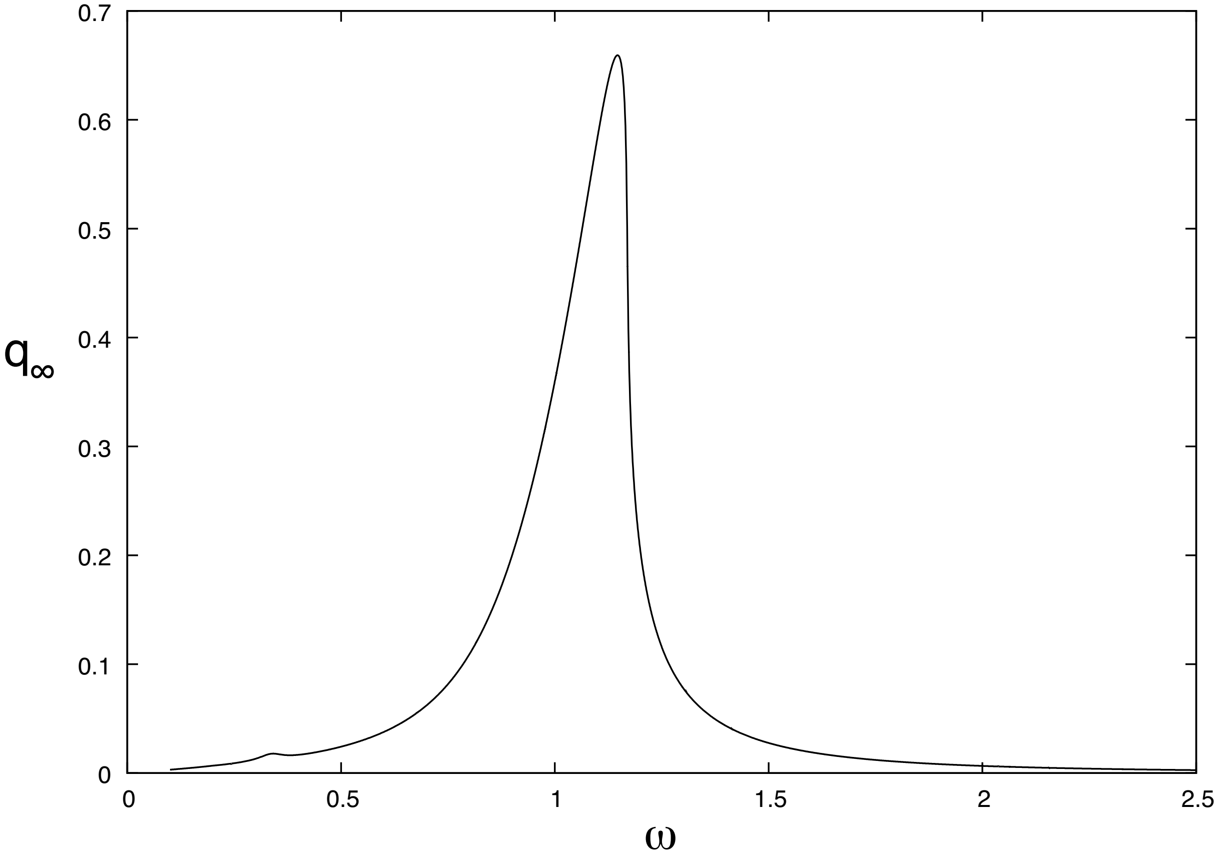

Figure 28.3.1: Feigenbaum diagram showing limiting values q_∞ as a function of ω (when $\beta = 0.1$ and $\epsilon = .15$) for the stroboscopic Duffing map.

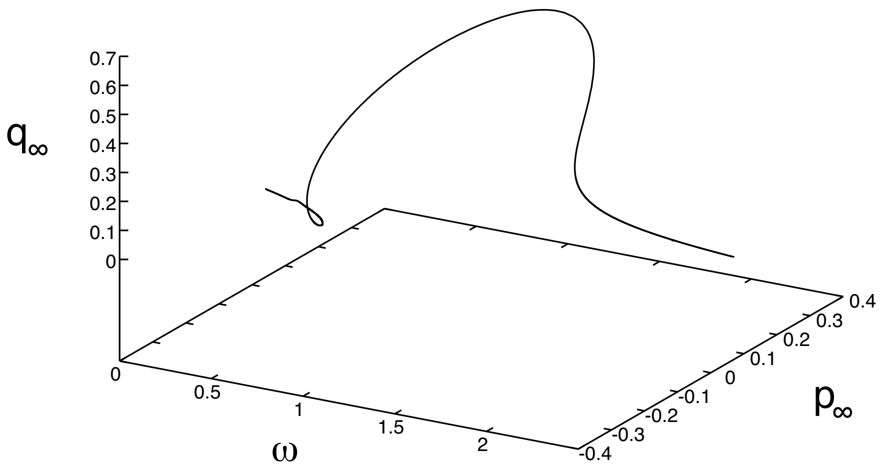

Figure 28.3.2: Feigenbaum diagram showing both limiting values q_∞ and p_∞ as a function of ω (when $\beta = 0.1$ and $\epsilon = .15$) for the stroboscopic Duffing map.

28.4 What Happens Initially When the Driving Is Increased?

28.4.1 Saddle-Node (Blue-Sky) Bifurcations

We have found the Feigenbaum diagram of the stroboscopic Duffing map for small driving strength ϵ. As promised, let us now increase ϵ to see what occurs. Figures 4.1 and 4.2 show results for the case $\epsilon = 1.5$. Evidently the height of the resonance peak has grown in response to the increased driving and has taken on a more complicated structure. And the feature originally near $\omega = 1/3$ has become a clearly defined *subresonant* peak. These peaks have also moved to larger values of ω. This is to be expected since the natural frequency of an oscillator having a hard spring increases with amplitude. Moreover, additional features now appear to the left of those already recognized.

Most striking, for $\omega \in (1.8\cdots, 2.7\cdots)$, there are *three* fixed points in place of the *single* fixed point originally present for the case of less driving. Two of these fixed points are stable and the third, whose coordinates as a function of ω are shown as a red line, is unstable. (How the unstable fixed point can be found is described in Section 29.4.) What happens is that, as ω is increased from small values, a pair of fixed points, one unstable and one stable, is 'born' near $\omega = 1.8\cdots$. This is sometimes called a *saddle-node* bifurcation. (The term *saddle* denotes a particular kind of unstable fixed point, and the term *node* denotes a particular kind of stable fixed point.) It is also called a *blue sky* bifurcation since these fixed points seem to appear out of nowhere, i.e. out of the blue. (They actually come out of the complex domain).[4] Then, as ω is further increased, the unstable fixed point moves to meet and 'annihilate' the original fixed point at $\omega = 2.7\cdots$ in an *inverse* saddle-node (or blue sky) bifurcation thereby leaving behind only the stable fixed point born near $\omega = 1.8\cdots$. All this behavior can be understood on topological grounds. See Section 29.5.

[4] For an example of a blue sky bifurcation in the case of the one-dimensional logistic (quadratic) map, see the end of Exercise 1.2.7.

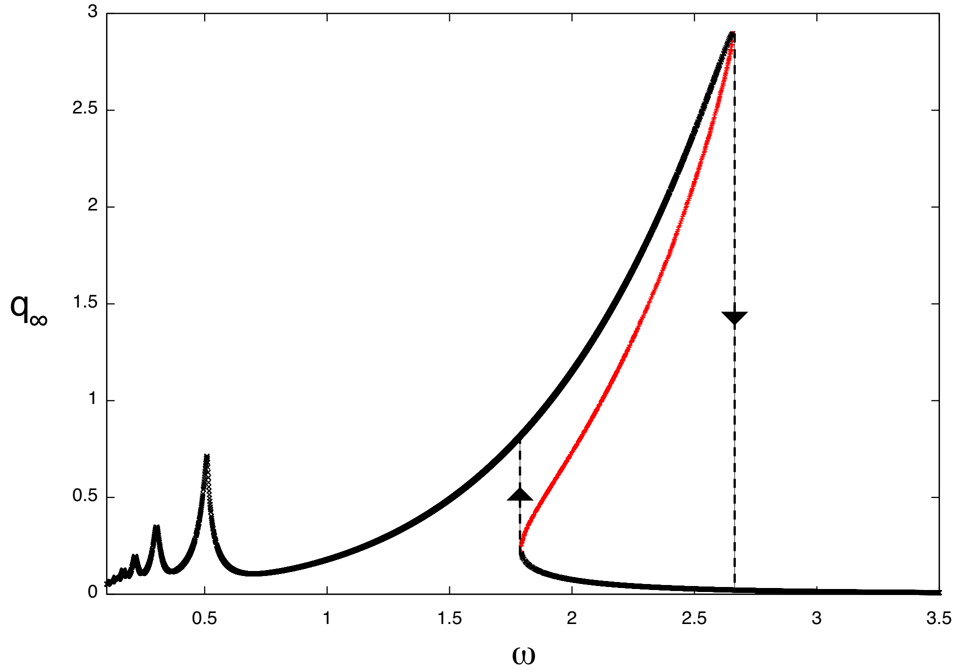

Figure 28.4.1: Feigenbaum/bifurcation diagram showing limiting values q_∞ as a function of ω (when $\beta = 0.1$ and $\epsilon = 1.5$) for the stroboscopic Duffing map. Also shown, in red, is the trail of the unstable fixed point. Finally, jumps in the steady-state amplitude are illustrated by vertical dashed lines at $\omega \simeq 1.8$ and $\omega \simeq 2.6$.

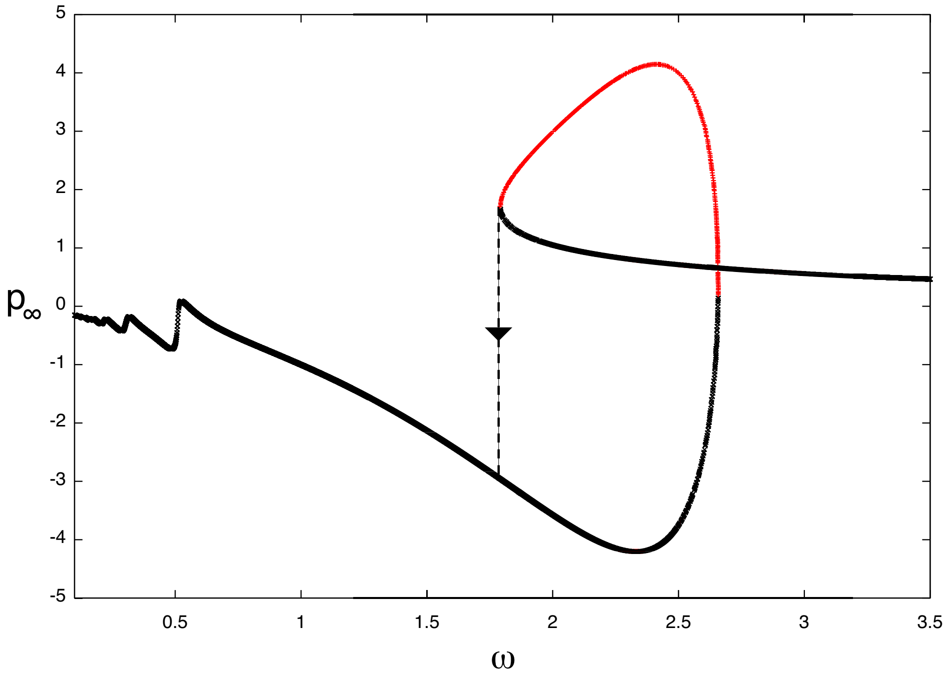

Figure 28.4.2: Feigenbaum/bifurcation diagram showing limiting values of p_∞ as a function of ω (when $\beta = 0.1$ and $\epsilon = 1.5$) for the stroboscopic Duffing map. Also shown, in red, is the trail of the unstable fixed point. Finally, a downward jump in the steady-state value p_∞ at $\omega \simeq 1.8$ is illustrated by a vertical dashed line. There is also an upward jump between the two black curves at $\omega \simeq 2.6$, but this feature is too small to be easily indicated by a second vertical dashed line.

28.4.2 Basins

Figure 4.3 shows the basins of attraction for the two stable fixed points when $\omega = 2.25$. The stable fixed points have the locations

$$w^1 = (q_\infty, p_\infty) = (0.04247237, 0.84035059) \text{ (green)} \tag{28.4.1}$$

and

$$w^2 = (q_\infty, p_\infty) = (1.68001491, -4.14472685) \text{ (red)}. \tag{28.4.2}$$

The unstable fixed point has the location

$$w^3 = (q_\infty, p_\infty) = (1.32261, 3.88274). \tag{28.4.3}$$

Since these two basins together comprise the entire q, p plane, there are no other stable fixed points of $\mathcal{M}$. Moreover, there are no fixed points for powers of $\mathcal{M}$ apart from the fixed points of $\mathcal{M}$ itself. Finally, it can be shown that, unlike the complex logistic map, the basin boundaries are smooth. This is because in this case there are no homoclinic points. See Section 29.6 and Figure 29.6.8. Thus, in this parameter regime, the long-term behavior of the driven Duffing oscillator is relatively simple.[5]

What is the actual motion for the periodic orbits associated with these fixed points? Figure 4.4 shows $q(\tau)$ for the two stable fixed points, and Figure 4.5 shows $q(\tau)$ for the unstable fixed point, all for the case $\omega = 2.25$. At this point one can make two interesting observations.

28.4.3 Symmetry

The first observation is that if $q(\tau)$ is a solution (periodic or otherwise) to Duffing's equation, then so is $\bar{q}(\tau)$ with

$$\bar{q}(\tau) = -q(\tau - \pi/\omega). \tag{28.4.4}$$

Note that, in view of (1.3), there is the relation

$$\pi/\omega = T/2 \tag{28.4.5}$$

so that (4.4) can also be written in the form

$$\bar{q}(\tau) = -q(\tau - T/2). \tag{28.4.6}$$

This property is an example of what is sometimes called *equivariance*, and occurs in this case because the left side of (1.1) is odd in q and does not explicitly contain the time. See Exercise 4.1. Thus, given a solution q of Duffing's equation, use of (4.6) produces a related solution $\bar{q}$. In principle this solution may be different, but it could also be the same as the original one. Inspection of Figures 4.4 and 4.5 reveals that

$$\bar{q}(\tau) = q(\tau) \tag{28.4.7}$$

[5] We remark that there would be no attractors, and consequently no basins, in the zero damping limit $\beta \to 0$, for then the system would be Hamiltonian, and we have learned in Subsections 3.4 and 6.4 that Hamiltonian systems have neither attractors or repellers. That is one reason why the long-term behavior of most Hamiltonian systems is so complicated.

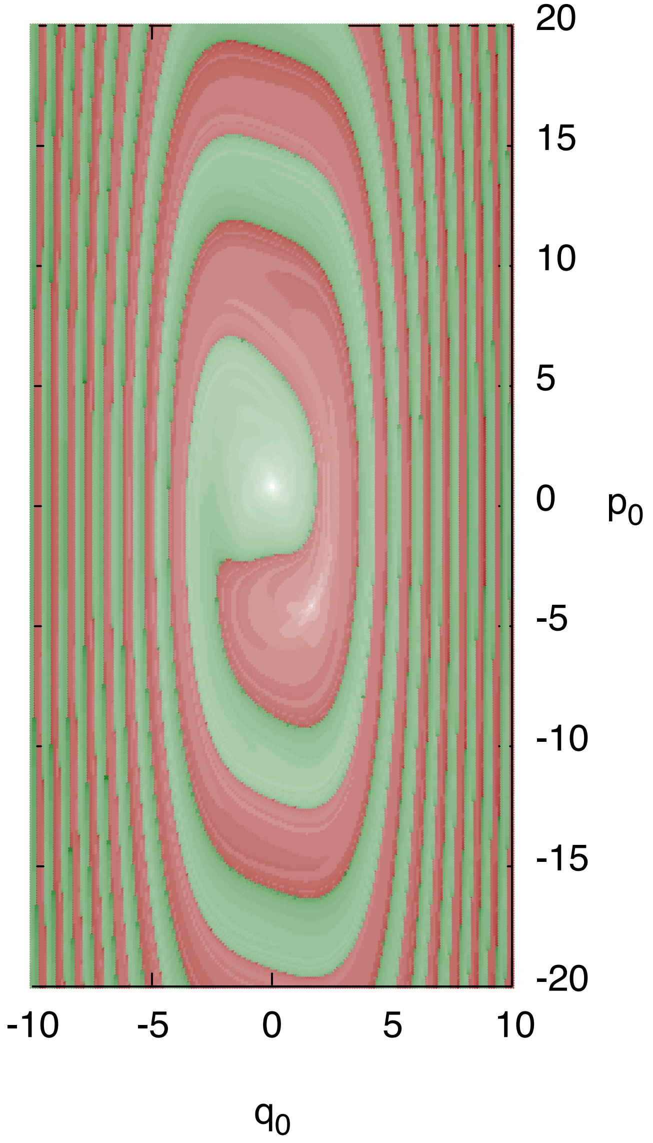

Figure 28.4.3: Basins of attraction for the two stable fixed points (when $\omega = 2.25$, $\beta = 0.1$, and $\epsilon = 1.5$) for the stroboscopic Duffing map. Green points are in the basin of the attracting fixed point w^1 and red points are in the basin of the attracting fixed point w^2. There is also an unstable fixed point w^3. See Figures 29.6.7 and 29.6.8.

for all three periodic orbits shown. Therefore in this case each solution is sent into itself under the 'barring' operation. It can be verified that the same is true for all the periodic solutions associated with all the fixed points found so far.

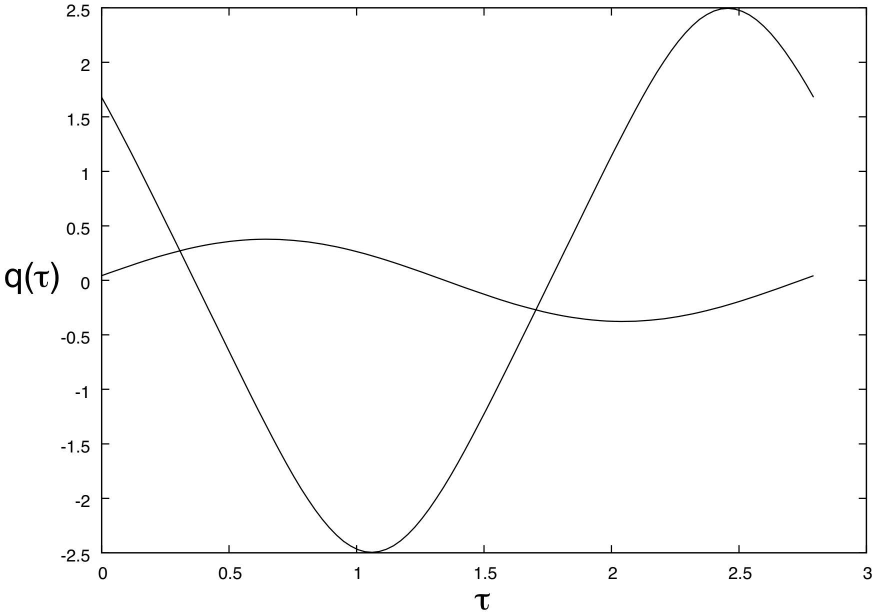

Figure 28.4.4: Stable periodic orbits $q(\tau)$ (when $\omega = 2.25$, $\beta = 0.1$, and $\epsilon = 1.5$) for the Duffing equation.

28.4.4 Amplitude Jumps

The second observation is that the two stable periodic orbits shown in Figure 4.4 have *different* amplitudes. With reference to Figures 4.1 and 4.2, suppose that $\omega \simeq 1.5$ and that the Duffing oscillator has settled down to the periodic orbit associated with the attracting fixed point q_∞, p_∞. (For this value of ω there is only one fixed point, and it is attracting.) Next imagine slowly increasing ω (*slowly* means in a time large compared to the time required to settle down to the attracting periodic orbit). Then the Duffing oscillator will essentially remain on the periodic orbit associated with the value of q_∞ shown as the upper curve in Figure 4.1. This will continue to be the case until ω reaches the value $\omega \simeq 2.6$, at which value the stable fixed point merges with the unstable fixed point and they mutually annihilate. What has happened is that the basin of attraction of this stable fixed point has shrunk to zero. When this occurs, the oscillator orbit finds itself in the basin of the other remaining stable fixed point and is rapidly attracted to the periodic orbit associated with that stable fixed point. Moreover, as Figure 4.1 suggests and Figure 4.4 confirms, the amplitude of oscillation associated with this new periodic orbit is considerably less than that associated with the old. Thus, the Duffing oscillator exhibits an *amplitude jump* (to an appreciably *lower* value) as ω is increased beyond $\omega \simeq 2.6$. This amplitude jump is illustrated by the vertical dashed lines at $\omega \simeq 2.6$ in Figures 4.1 and 4.2.

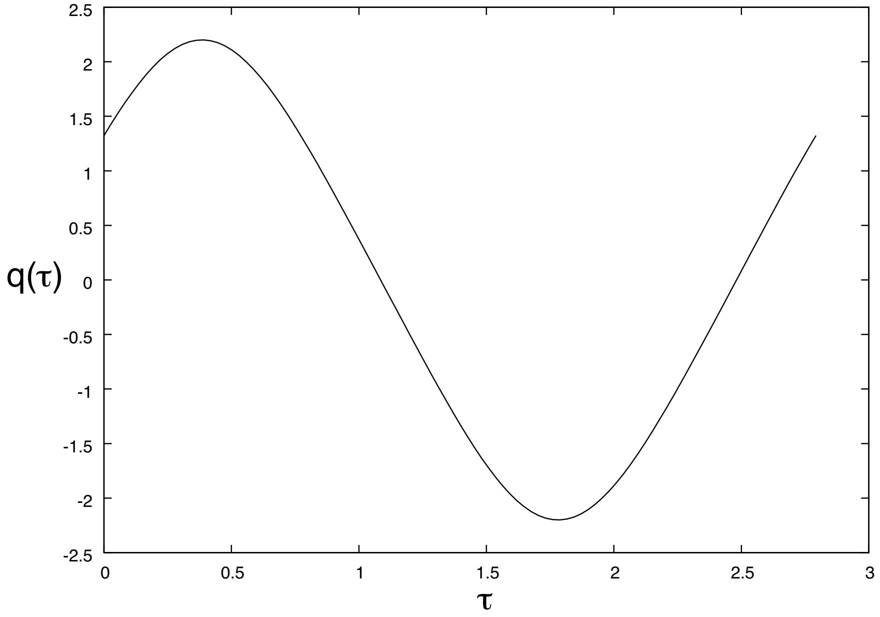

Figure 28.4.5: Unstable periodic orbit $q(\tau)$ (when $\omega = 2.25$, $\beta = 0.1$, and $\epsilon = 1.5$) for the Duffing equation.

28.4.5 Hysteresis

Next suppose that $\omega > 2.6$, say $\omega \simeq 3$, and that the Duffing oscillator has settled down to the periodic orbit associated with the attracting fixed point q_∞, p_∞. (For this value of ω there is again only one fixed point, and it is attracting.) Now slowly decrease ω. Then the Duffing oscillator will essentially remain on the periodic orbit associated with the value of q_∞ shown as the lower curve in Figure 4.1. This will continue to be the case until ω reaches the value $\omega \simeq 1.8$, at which value the stable fixed point in question merges with the unstable fixed point and they mutually annihilate. What has happened is that the basin of attraction of this stable fixed point has now shrunk to zero. When this occurs, the oscillator orbit finds itself in the basin of the other remaining stable fixed point and is rapidly attracted to the periodic orbit associated with that stable fixed point. Now the amplitude of oscillation will jump to a *larger* value. This amplitude jump is also illustrated by vertical dashed lines at $\omega \simeq 1.8$ in Figures 4.1 and 4.2. Note that the ω values for the two amplitude jumps are different. Thus, the steady-state amplitude of the Duffing oscillator exhibits *hysteresis* as ω is slowly varied back and forth over the range in which saddle-node bifurcations occur.

Exercises

28.4.1. Show that the left side of (1.1) changes sign under the replacement of q by $-q$. Show that the right side of (1.1) changes sign under the replacement of τ by $(\tau - \pi/\omega)$. Verify that if $q(\tau)$ is a solution to Duffing's equation, then so is $\bar{q}(\tau)$ as given by (4.4) or (4.6). Let $\bar{\bar{q}}$ denote the result of applying the barring operation to $\bar{q}$. Show that if q is a solution associated with a fixed point of $\mathcal{M}$, and therefore is a periodic solution with period

T, then $\overline{\overline{q}}= q$. Verify that the harmonic oscillator solution (2.1) satisfies (4.7).

28.5 Pitchfork Bifurcations and Symmetry

Let us continue to increase ϵ. Figure 5.1 shows that a qualitatively new feature appears when ϵ is near 2.2: a *bubble* is formed *between* the major resonant peak (the one that has saddle-node bifurcated) and the subresonant peak immediately to its left. To explore the nature of this bubble, let us make ϵ still larger, which, we anticipate, will result in the bubble becoming larger. Figures 5.2 and 5.3 show Feigenbaum diagrams in the case $\epsilon = 5.5$. Now the major resonant peak and the subresonant peak have moved to larger ω values. Correspondingly, the bubble between them has also moved to larger ω values. Moreover, it is larger, yet another smaller bubble has formed, and the subresonant peak between them has also undergone a saddle-node bifurcation. For future use, we will call the major resonant peak the *first* or *leading* saddle-node bifurcation, and we will call the subresonant peak between the two bubbles the *second* saddle-node bifurcation, etc. Also, we will call the bubble just to the left of the first saddle-node bifurcation the *first* or *leading* bubble, and the next bubble will be called the *second* bubble, etc.

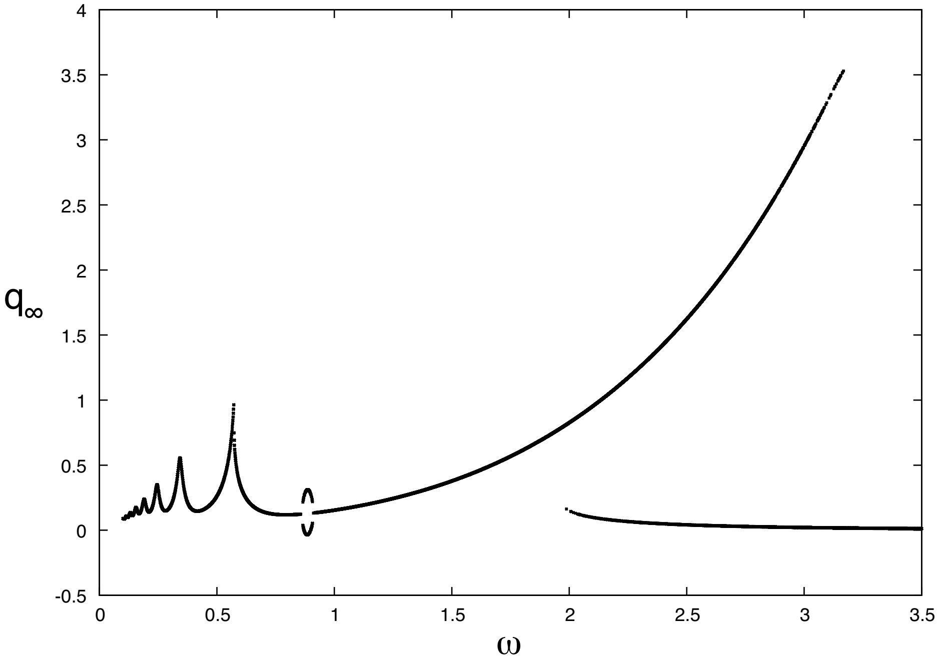

Figure 28.5.1: Feigenbaum diagram showing limiting values q_∞ as a function of ω (when $\beta = 0.1$ and $\epsilon = 2.2$) for the stroboscopic Duffing map. It displays that a bubble has now formed at $\omega \approx .8$.

Figure 5.4 shows the larger (leading) bubble in Figure 5.2 in more detail and with the addition of red lines indicating the trails of unstable fixed points. It reveals that the bubble describes the *simultaneous* bifurcation of a single fixed point into three fixed points. Two of these fixed points are stable and the third, whose q coordinate as a function of ω is shown as

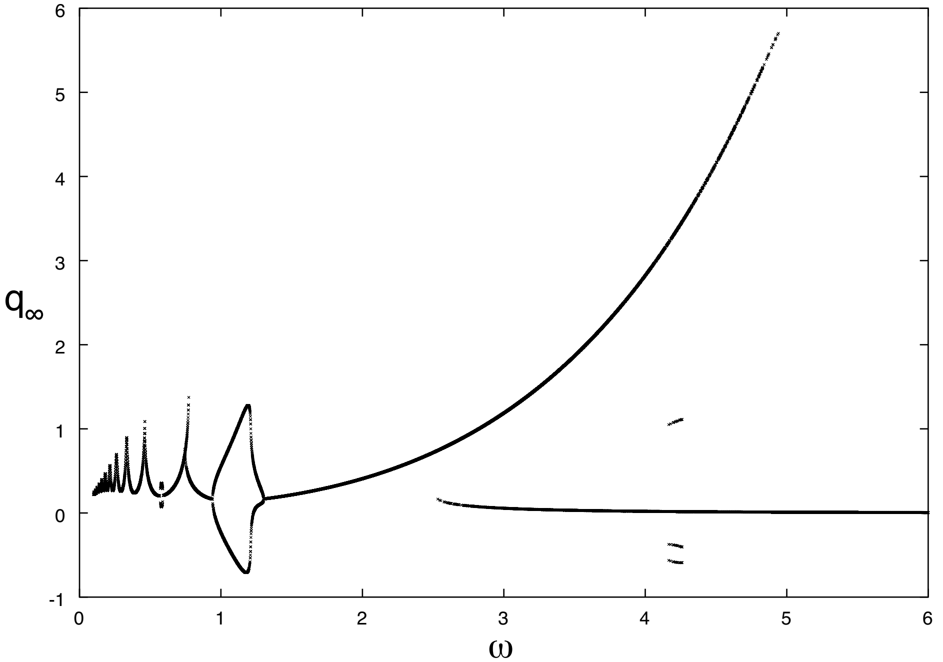

Figure 28.5.2: Feigenbaum diagram showing limiting values q_∞ as a function of ω (when $\beta = 0.1$ and $\epsilon = 5.5$) for the stroboscopic Duffing map. The first bubble has grown, a second smaller bubble has formed to its left, and the sub-resonant peak between them has saddle-node bifurcated to become the second saddle-node bifurcation.

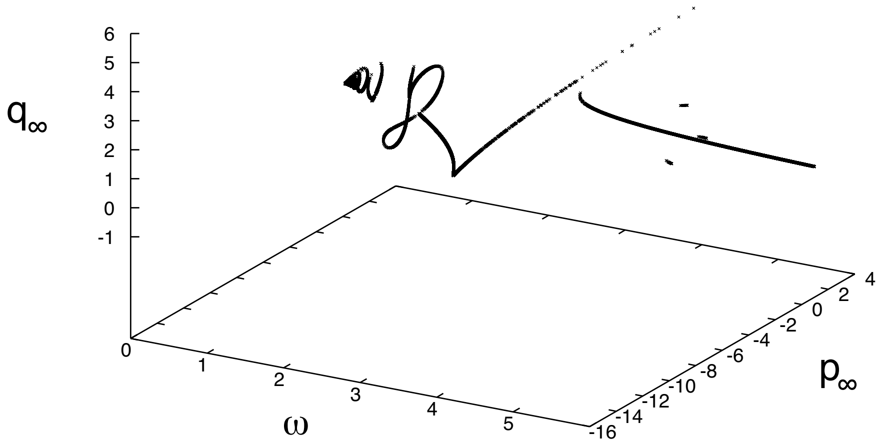

Figure 28.5.3: Feigenbaum diagram showing both limiting values q_∞ and p_∞ as a function of ω (when $\beta = 0.1$ and $\epsilon = 5.5$) for the stroboscopic Duffing map.

a red line, is unstable. What happens is that, as ω is increased, a *single* stable fixed point becomes a *triplet* of fixed points, two of which are stable and one of which is unstable. This is called a *pitchfork* bifurcation. Then, as ω is further increased, these three fixed points again merge, in an inverse pitchfork bifurcation, to form what is again a single stable fixed point. This behavior can also be understood on topological grounds. Again see Section 29.5.

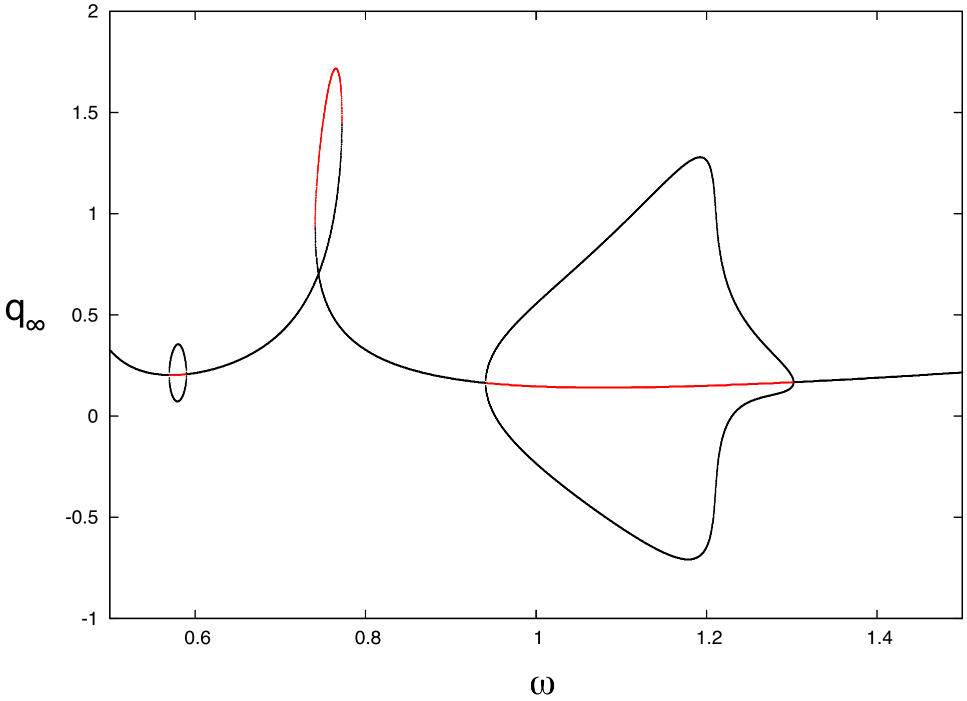

Figure 28.5.4: An enlargement of Figure 5.2 with the addition of red lines indicating the trails of unstable fixed points.

As a side comment, we remark that a pitchfork bifurcation could better be called a pitchfork *trifurcation*. Unlike a saddle-node bifurcation, is this case all three fixed points appear where once there was only one. True pitchfork bifurcations are rare, and only occur in the presence of symmetry, in this case the equivariance symmetry described earlier. However, it can happen, particularly in the case of near symmetry, that a saddle-node bifurcation occurs very close to another stable fixed point so that from a distance what appears to be happening is a pitchfork bifurcation. As an example of near symmetry, the left side of (1.1) could be modified (perturbed) to contain an additional term of the form δq^2 where δ is small. Figure 5.5 illustrates how Figure 5.4 is modified when the term $0.02q^2$ is added to the left side of (1.1). Evidently the pitchfork bifurcation becomes a saddle-node bifurcation. A pair of fixed points, one stable and one unstable, is born in the vicinity of $\omega = 1$, and they move as ω is increased. However, unlike the case of Figure 4.1, they then annihilate *each other* near $\omega = 1.3$ rather than the unstable fixed point moving up to the other fixed point so that this pair is mutually annihilated. Note also that the perturbation destroys the small bubble that was near $\omega = .6$ (which was also a pitchfork bifurcation before the perturbation was introduced).

To continue with the case of the pitchfork bifurcation, and as we did in the case of a

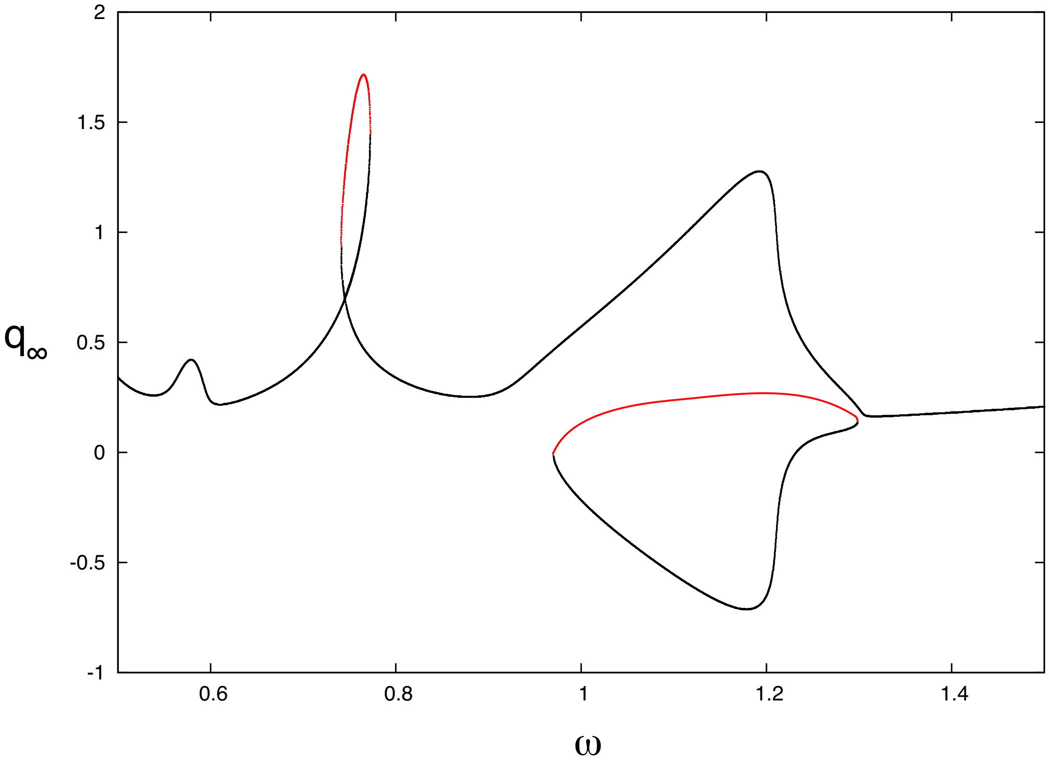

Figure 28.5.5: Transformation of a pitchfork bifurcation into a saddle-node bifurcation due to the inclusion of the symmetry breaking perturbation $0.02q^2$. Also shown as red lines are the trails of unstable fixed points. Note, however, that the stable-unstable pair of fixed points born at $\omega \approx 1$ self annihilates at $\omega \approx 1.3$ rather than the unstable fixed point annihilating the other stable fixed point as happens in Figure 4.1.

saddle-node bifurcation, let us plot the three periodic orbits associated with the three fixed points. Figure 5.6 displays $q(\tau)$ for the two stable fixed points, and Figure 5.7 displays $q(\tau)$ for the unstable fixed point, all for the case $\omega = 1.1$. The stable fixed points have the locations

$$(q_\infty, p_\infty) = (0.942055303, -0.792682910) \tag{28.5.1}$$

and

$$(q_\infty, p_\infty) = (-0.55292184, -1.72277791). \tag{28.5.2}$$

The unstable fixed point has the location

$$(q_\infty, p_\infty) = (0.140706, -1.05507). \tag{28.5.3}$$

In this case inspection shows that the unstable periodic orbit is sent into itself under the barring operation, as before. However, unlike the saddle-node case, the two stable orbits are *interchanged* under the barring operation.[6] Also, since the amplitudes of the two stable periodic oscillations are the same as a result of their being interchanged under the barring operation (see Figure 5.6), there are no amplitude jumps associated with pitchfork bifurcations.

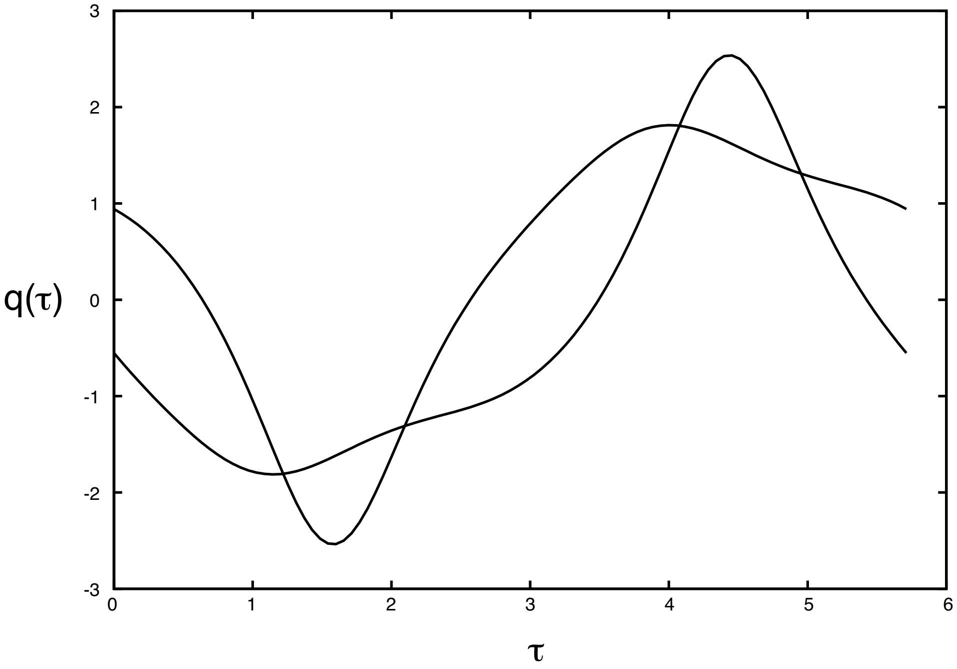

Figure 28.5.6: Stable periodic orbits $q(\tau)$ (when $\omega = 1.1$, $\beta = 0.1$, and $\epsilon = 5.5$) for the Duffing equation.

[6] The change in the nature of periodic Duffing orbits at a pitchfork bifurcation is sometimes described as *dynamical spontaneous symmetry breaking.* For small ϵ values and all ω values, all periodic orbits have the symmetry property of being invariant (sent into themselves) under the barring operation. For larger ϵ values, as ω is varied, some periodic orbits appear that no longer have this symmetry, even though the underlying equations of motion retain the same symmetry for all values of ϵ and ω.

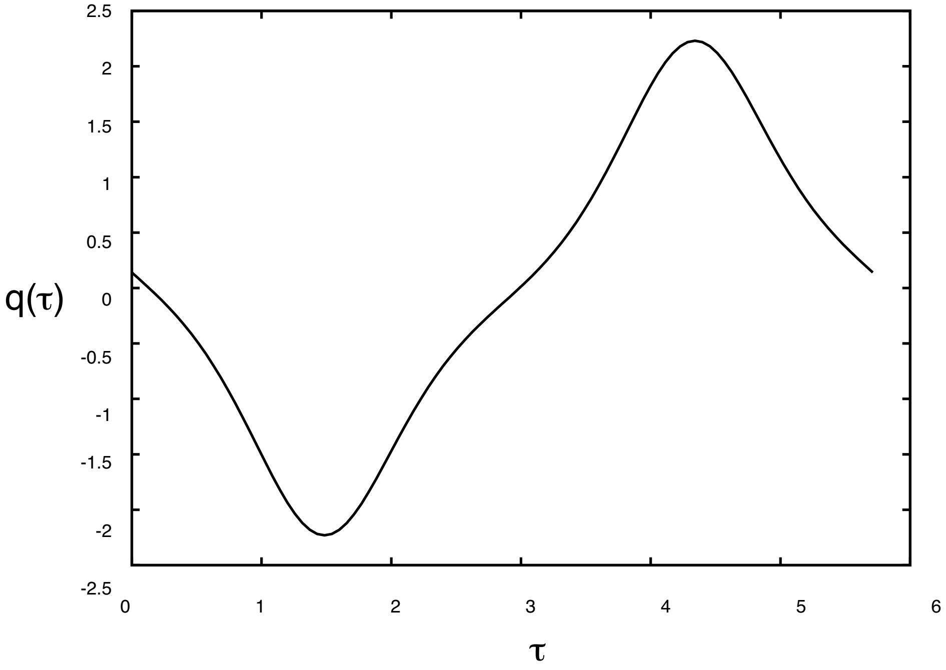

Figure 28.5.7: Unstable periodic orbit $q(\tau)$ (when $\omega = 1.1$, $\beta = 0.1$, and $\epsilon = 5.5$) for the Duffing equation.

28.6 Period Tripling Bifurcations and Fractal Basin Boundaries

Close examination of Figures 5.2 and 5.3 shows that something also happens in the vicinity of $\omega = 4.15$: Three attracting fixed points of $\mathcal{M}^3$ appear and then again vanish as ω is varied. Although these points are fixed points of $\mathcal{M}^3$, they are not fixed points of $\mathcal{M}$, and hence are *period-three* fixed points of $\mathcal{M}$. They correspond to solutions that do not have period T, but rather are periodic with period $3T$. Solutions that are not periodic with the drive period T, but are periodic with a period that is some integer multiple of T, are said to be *subharmonic*.[7]

Figure 6.1 shows an enlargement of that portion of Figure 5.2 where period tripling occurs. The period-three fixed points are shown in green and the period-one fixed points, both stable and unstable and unstable, are shown in red. What happens is that $\mathcal{M}^3$ exhibits saddle-node (blue-sky) bifurcations so that $\mathcal{M}^3$ fixed points are born (and subsequently annihilate) in pairs. Three of each pair, those that are attracting, are shown in Figures 5.2 and 5.3. Figure 6.1 shows the period-one fixed points in red (two stable and one unstable) and the period-three fixed points in green. Inspection of the green features suggests that there are six fixed points of $\mathcal{M}^3$ that occur as stable-unstable pairs. Figures 6.2 through

[7] If a periodic solution has period nT, it has fundamental frequency ω/n. Correspondingly, such a solution is called $1/n$ subharmonic. For the case being discussed here, $n = 3$. It is sometimes stated in the literature that for the driven Duffing equation there is no subharmonic corresponding to the case $n = 2$, which would be the case of period *doubling*. However, we will eventually see that, for sufficiently strong driving, period doubling does occur.

6.4 confirm this analysis. They show each pair of saddle and node fixed points of $\mathcal{M}^3$ as functions of ω.

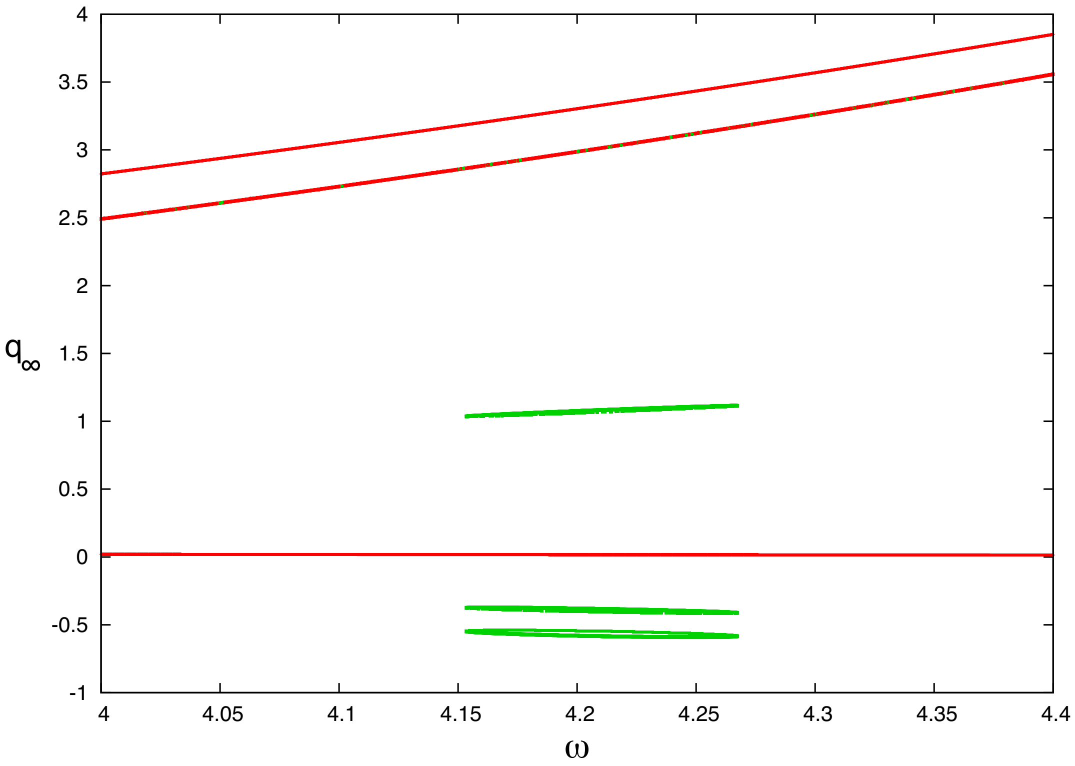

Figure 28.6.1: An enlargement of Figure 5.2 showing, for $\mathcal{M}$, the period-one fixed points in red (two stable and one unstable) and the stable-unstable pairs of period-three fixed points in green.

What can be said about the basin structure of $\mathcal{M}$ and $\mathcal{M}^3$ in this case? Let us set

$$\omega = 4.21, \tag{28.6.1}$$

which is a convenient value roughly midway between the birth and annihilation values of ω for the period-three fixed points in Figures 6.1 through 6.4. Numerical study shows that for this value of ω there are the following attracting fixed points:

$$w^1 = (0.01666814, 1.38706838) \text{ (white)}, \tag{28.6.2}$$

$$w^2 = (3.32944854, -15.41028862) \text{ (blue)}; \tag{28.6.3}$$

$$z^1 = (1.08279489, 1.40756189) \text{ (red)}, \tag{28.6.4}$$

$$z^2 = \mathcal{M}z^1 = (-0.58378622, 0.30474951) \text{ (green)}, \tag{28.6.5}$$

$$z^3 = \mathcal{M}z^2 = (-0.38267261, 2.82716098) \text{ (yellow)}. \tag{28.6.6}$$

The points w^1 and w^2 are the attracting fixed points of $\mathcal{M}$. Of course, they will also be attracting fixed points of $\mathcal{M}^3$. The points z^1, z^2, z^3 are the attracting fixed points of $\mathcal{M}^3$,

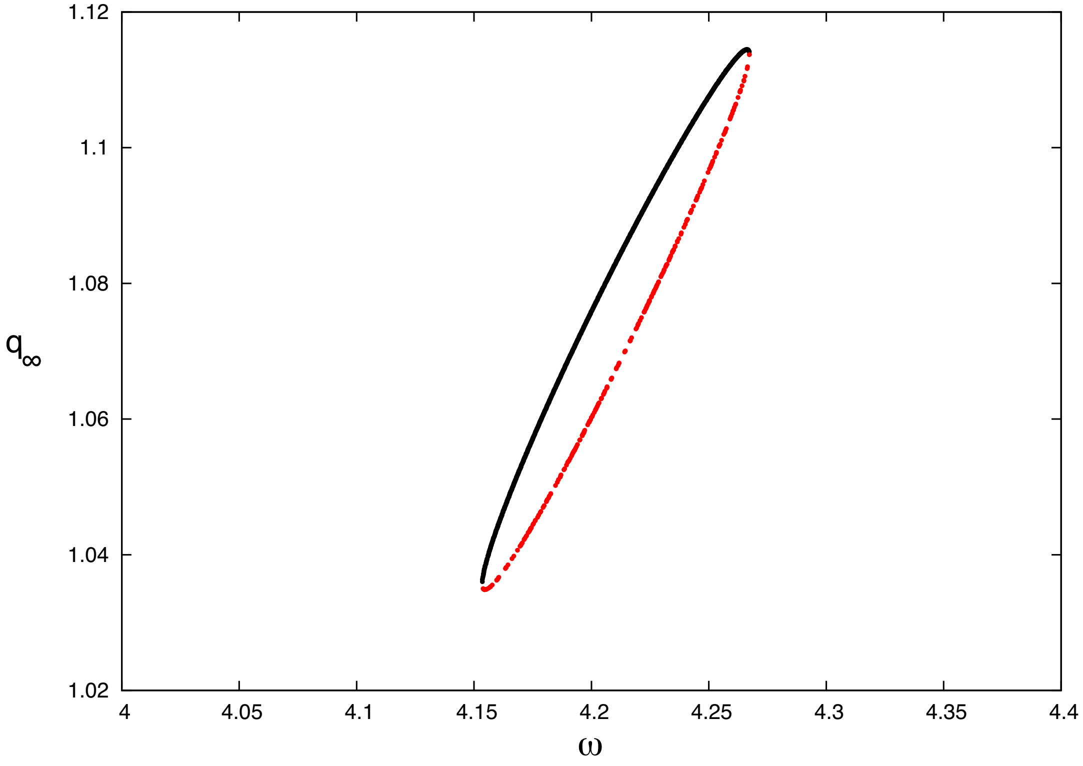

Figure 28.6.2: A blue-sky bifurcation that produces, and then subsequently destroys, a pair of stable (black) and unstable (red) period-three fixed points. These points correspond to the upper green feature shown in Figure 6.1.

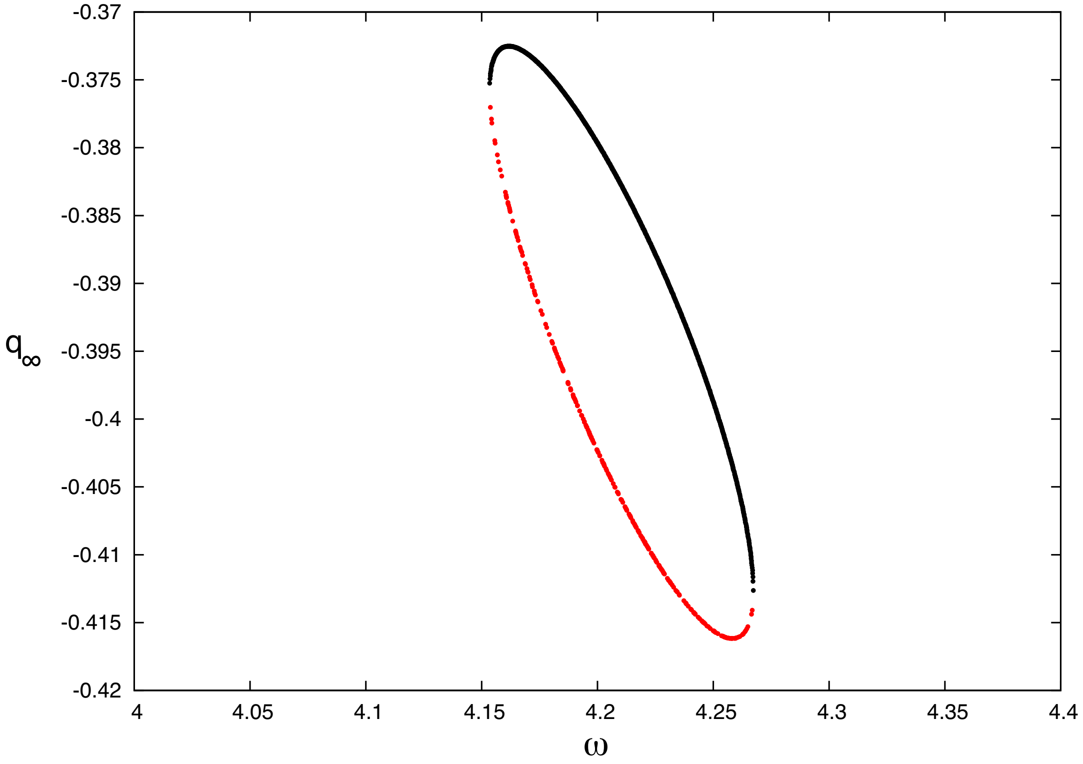

Figure 28.6.3: A blue-sky bifurcation that produces, and then subsequently destroys, a pair of stable (black) and unstable (red) period-three fixed points. These points correspond to the center green feature shown in Figure 6.1.

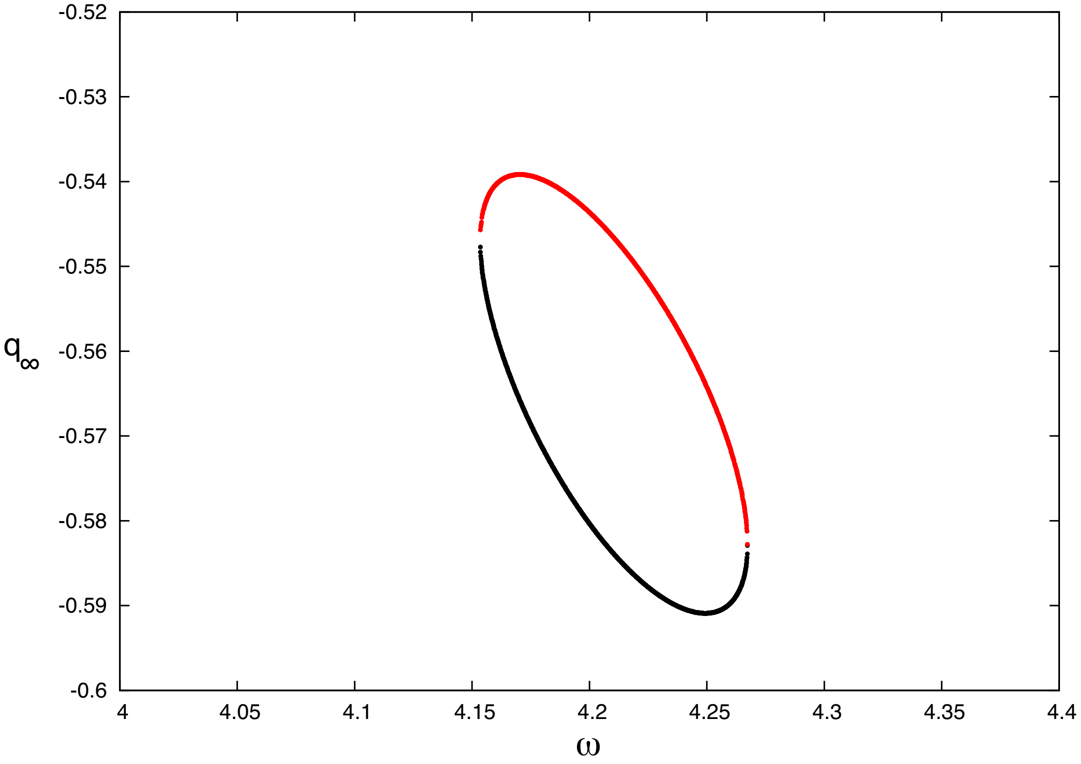

Figure 28.6.4: A blue-sky bifurcation that produces, and then subsequently destroys, a pair of stable (black) and unstable (red) period-three fixed points. These points correspond to the bottom green feature shown in Figure 6.1.

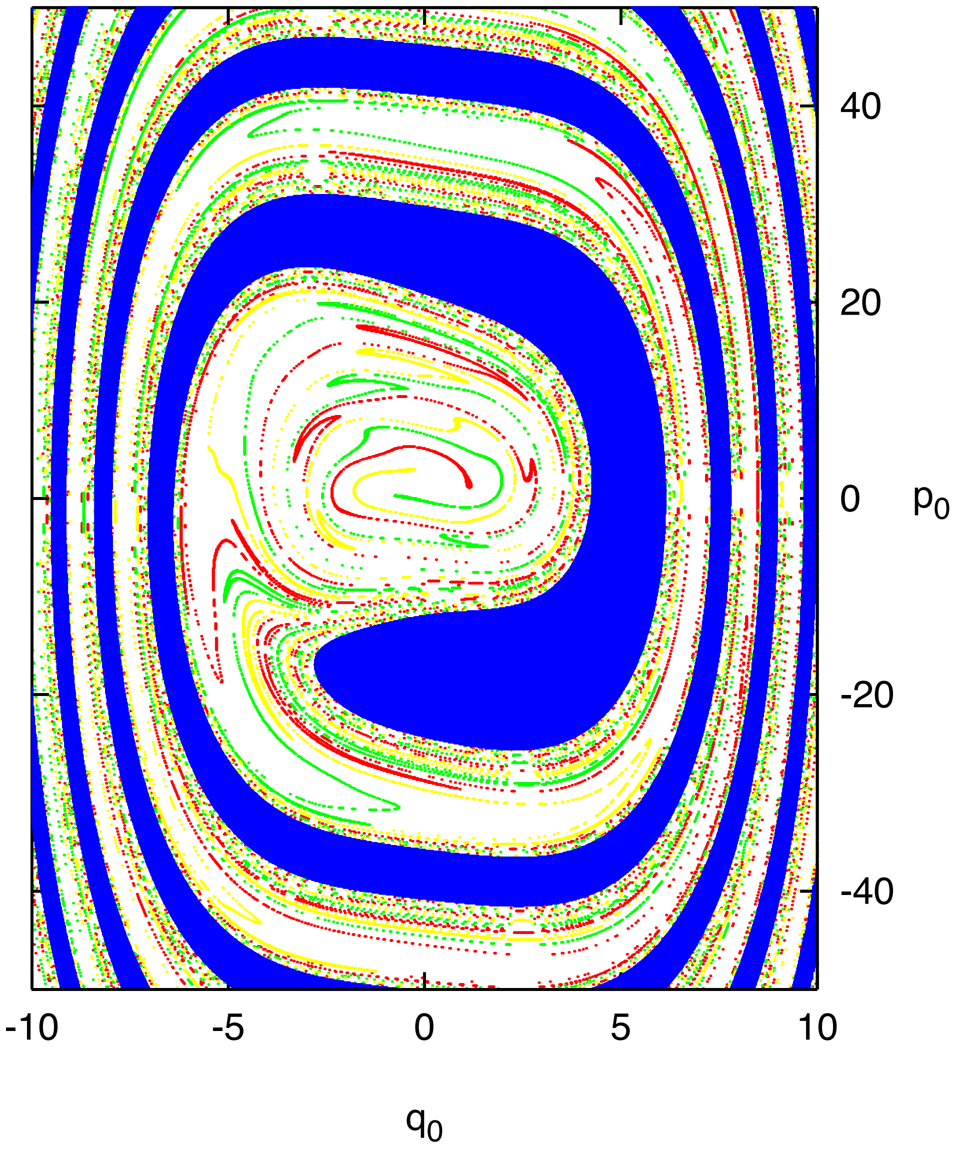

Figure 28.6.5: Basins, using the map $\mathcal{M}^3$ and with $\omega = 4.21$, for the period-one attracting fixed points w^1 (white) and w^2 (blue), and the period-three attracting fixed points z^1 (red), z^2 (green), and z^3 (yellow).

and hence attracting period-three fixed points of $\mathcal{M}$. Figure 6.5 displays, using the map $\mathcal{M}^3$, the basins for all these attracting fixed points.

When viewed from a distance, the basins of w^1 and w^2 in Figure 6.5 look much like those in Figure 4.3. However, closer inspection of the white basin, that of w^1, reveals that it contains within it the basins of the period-three fixed points z^1, z^2, and z^3. Moreover, the basins of the period-three fixed points consist of principal components (which contain the period-three fixed points z^1, z^2, and z^3 themselves) plus what appear to be an infinite number of disconnected pieces. (Recall that all white points are in the basin of w^1.) Finally, the pieces of the period-three basins crowd ever more closely together (but still separated by ever smaller white areas) in the vicinity of the boundary of the w^2 (blue) basin so that this basin-boundary structure becomes fractal. These features are seen even more clearly in Figure 6.6, which is an enlargement (with different q, p scales) of Figure 6.5 in the vicinity of the points w^1, z^1, z^2, and z^3. In this figure the fixed points w^1 and z^1, z^2, and z^3 themselves are shown as small black dots. Because the basin-boundary structure is fractal, the final fate of an orbit launched in the vicinity of the basin boundary (which of the five attracting fixed points w^1, w^2, z^1, z^2, and z^3 it eventually approaches) depends very sensitively on the initial conditions.

28.7 Asymptotic ω Behavior

Examination of all the Feigenbaum/bifurcation diagrams produced so far for the Duffing oscillator shows that their behavior is consistent with the hypothesis

$$\lim_{\omega\to 0} q_\infty = 0, \quad \lim_{\omega\to 0} p_\infty = 0, \tag{28.7.1}$$

$$\lim_{\omega\to \infty} q_\infty = 0, \quad \lim_{\omega\to \infty} p_\infty = 0. \tag{28.7.2}$$

That is, in the limits $\omega \to 0$ or ∞, there is a single attracting fixed point and its basin is the entire q, p plane. Correspondingly, for each value of ϵ (and β) there is only a finite range of ω values that is of interest. In the case of Figures 5.2 and 5.3, for example, extension of the ω range to smaller and larger values shows that the advertised small and large ω asymptotic behavior has already set in so that no new features appear beyond those already seen.

To explore the $\omega \to 0$ limit, rewrite (1.1) in the form

$$q + q^3 = -\epsilon \sin \omega\tau - [\ddot{q} + 2\beta\dot{q}]. \tag{28.7.3}$$

If ω is small, we may expect that $q(\tau)$ will be slowly varying and therefore $\dot{q}$ and $\ddot{q}$ will be small. As an illustration of this expectation, Figure 7.1 displays the quantity $[\ddot{q} + 2\beta\dot{q}]$ as a function of τ for the periodic solution when $\omega = .01$ (and $\beta = .1$ and $\epsilon = 5.5$), the ω value associated with the left end of Figure 5.2. Note that this quantity is small, and numerical calculations verify that asymptotically it goes to zero linearly in ω as ω goes to zero.[8] If this

[8] We remark that the 'wiggles' (ringing) in Figure 7.1 are real. They also appear in $q(\tau)$. If Duffing's equation is linearized around the Ansatz (7.4), then $[\ddot{q} + 2\beta\dot{q}]$ appears as a driving term of the linearized equation. The wiggles are the (damped) response to the sharp peaks in the driving term. Examination of Figure 7.1 reveals that the wiggles occur just to the right of the peaks at $\tau = 0$ and $\tau \simeq 300$.

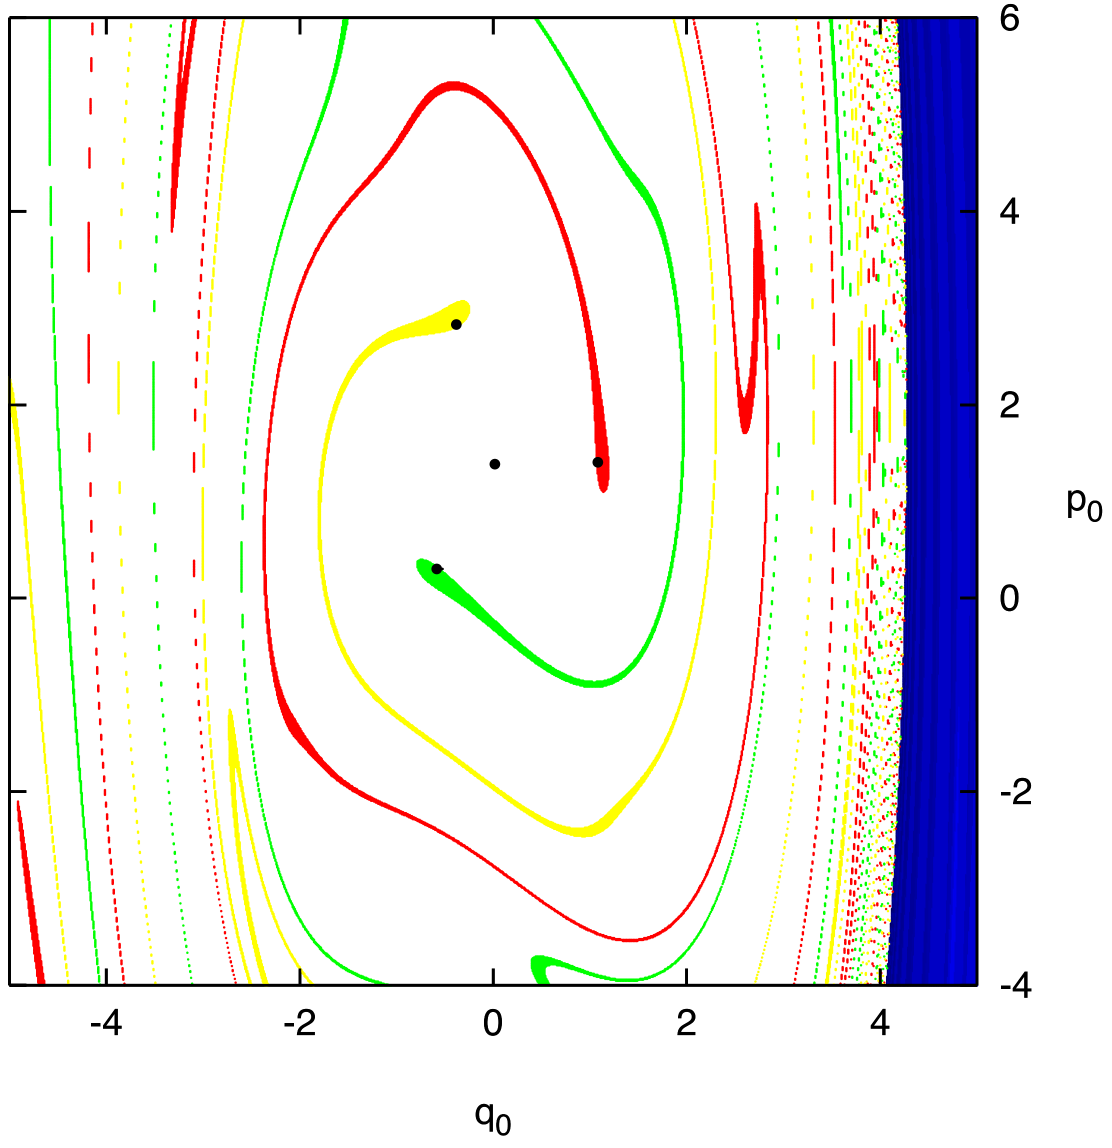

Figure 28.6.6: An enlargement of a portion of Figure 6.5. The fixed points w^1 and z^1, z^2, and z^3 themselves are shown as small black dots. The small black dot at the center of the figure is the fixed point w^1. Three small black dots near the ends of the red, green, and yellow filaments surround w^1. These are the $\mathcal{M}^3$ fixed points z^1, z^2, and z^3, respectively. The principal components of the period-three basins contain the fixed points z^1, z^2, and z^3. Note the crowding of the red, green, and yellow pieces of the period-three basins against the blue basin of w^2 (but still separated by ever smaller white areas) thereby making this basin boundary structure fractal.

quantity is neglected on the right side of (7.3), this relation becomes

$$q + q^3 = -\epsilon \sin \omega\tau \tag{28.7.4}$$

and consequently there is the result

$$q(0) + [q(0)]^3 = 0 \tag{28.7.5}$$

with the solution

$$q(0) = q_\infty = 0. \tag{28.7.6}$$

Moreover, if (7.4) holds, then there is also the relation

$$\dot{q} + 3q^2\dot{q} = -\omega\epsilon \cos \omega\tau, \tag{28.7.7}$$

from which, using (7.6), it follows that

$$\dot{q}(0) = -\omega\epsilon. \tag{28.7.8}$$

From (7.8), in turn, we infer that

$$\lim_{\omega\to 0} \dot{q}(0) = \lim_{\omega\to 0} p_\infty = 0. \tag{28.7.9}$$

Thus, (7.1) is correct.

To explore the $\omega \to \infty$ limit, rewrite (1.1) in the form

$$\ddot{q} = -\epsilon \sin \omega\tau - [2\beta\dot{q} + q + q^3]. \tag{28.7.10}$$

If ω is very large, we may expect that $q(\tau)$ will be rapidly varying and therefore $\ddot{q}$ will be very large compared to the other terms on the left side of (1.1). Correspondingly, the other terms will be small in the large ω limit. As an illustration of this expectation, Figure 7.2 displays the quantity $[2\beta\dot{q} + q + q^3]$ as a function of τ for the periodic solution when $\omega = 15$ (and $\beta = .1$ and $\epsilon = 5.5$), an ω value beyond the right end of Figure 5.2. We see that this quantity is indeed small, and further numerical work reveals that it vanishes as ω goes to infinity. If this quantity is neglected on the right side of (7.10), this relation becomes

$$\ddot{q} = -\epsilon \sin \omega\tau \tag{28.7.11}$$

with the solution

$$\dot{q}(\tau) = (1/\omega)\epsilon \cos \omega\tau, \tag{28.7.12}$$

$$q(\tau) = (1/\omega^2)\epsilon \sin \omega\tau. \tag{28.7.13}$$

From (7.13) we conclude that

$$\lim_{\omega\to\infty} q_\infty = \lim_{\omega\to\infty} q(0) = 0. \tag{28.7.14}$$

And from (7.12) we conclude that

$$\lim_{\omega\to\infty} p_\infty = \lim_{\omega\to\infty} \dot{q}(0) = 0. \tag{28.7.15}$$

We see that (7.2) also holds.

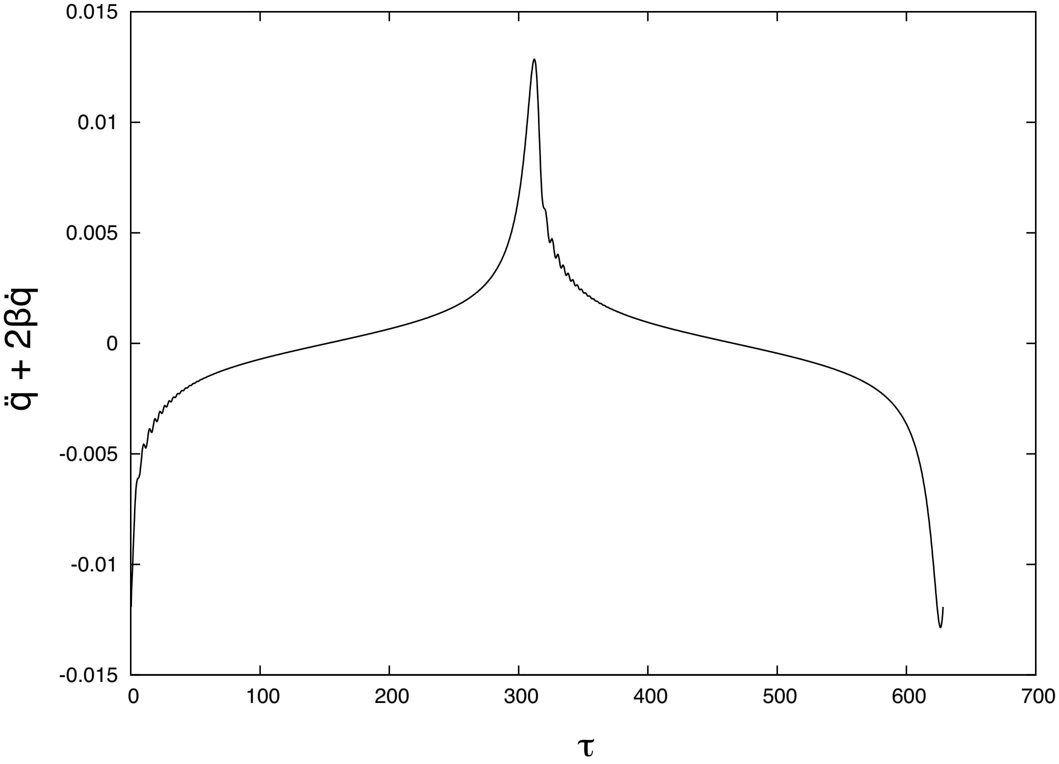

Figure 28.7.1: The quantity $[\ddot{q} + 2\beta\dot{q}]$ as a function of τ for the periodic solution when $\omega = .01$ (and $\beta = .1$ and $\epsilon = 5.5$).

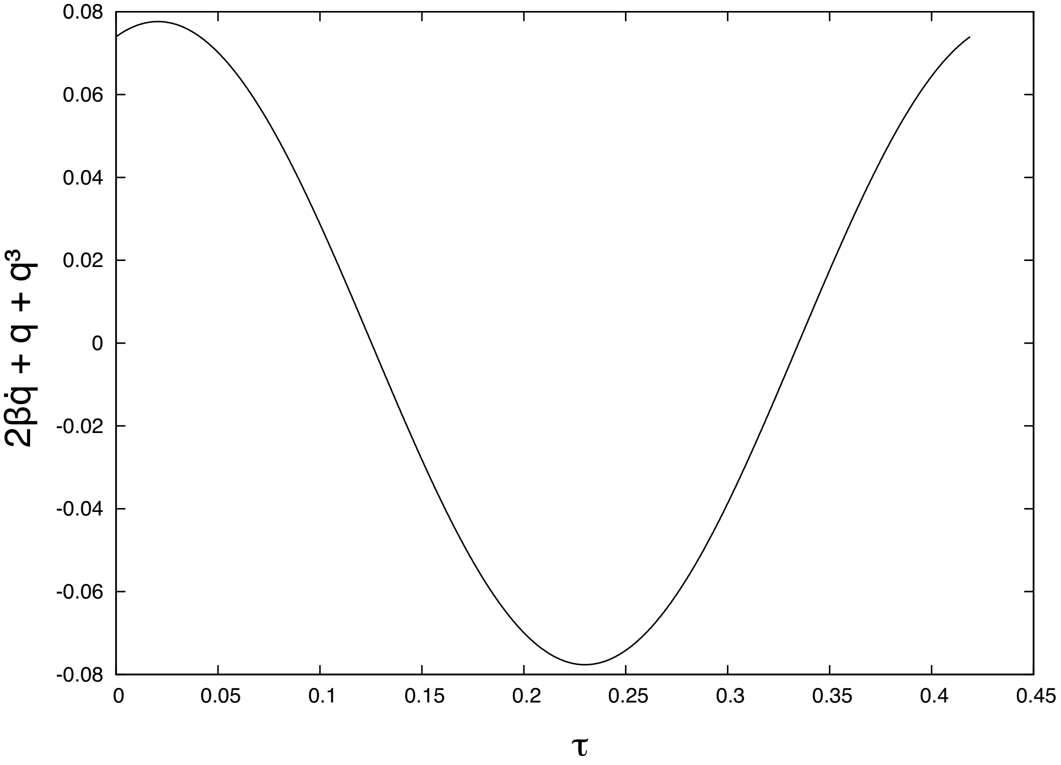

Figure 28.7.2: The quantity $[2\beta\dot{q} + q + q^3]$ as a function of τ for the periodic solution when $\omega = 15$ (and $\beta = .1$ and $\epsilon = 5.5$).

28.8 Period Doubling Cascade

We end our study of the Duffing equation by increasing ϵ from its earlier value $\epsilon = 5.5$ to larger values. Based on our experience so far, we might anticipate that the Feigenbaum diagram would become ever more complicated. That is indeed the case. Figure 8.1 displays q_∞ obtained numerically, when $\beta = 0.1$ and $\epsilon = 22.125$, as a function of ω for the range $\omega \in (0, 12)$. Evidently the behavior of the attractors for the stroboscopic Duffing map, which is what is shown in Figure 8.1, is extremely complicated. There are now a great many fixed points of $\mathcal{M}$ itself and various powers of $\mathcal{M}$. For small values of ω, and as in Figures 4.1, 5.1, and 5.2, there are many resonant peaks and numerous saddle-node and pitchfork bifurcations. For larger values of ω there are more complicated bifurcations. In this figure, and some subsequent figures, the coloring scheme is chosen to guide the eye in following bifurcation trees with colors changing when the period changes. Points with period one are colored red, and points of very high or no discernible period are colored black.

Let us begin by describing the more mundane features of the diagram. As already mentioned, at the left end of the diagram there is a series of saddle-node bifurcations as before, and the first one has moved to larger ω values so that it now occurs over the range $\omega \in (4, 10)$. Also, now more numerous, there are again bubbles for small values of ω. And the first bubble has also moved to larger ω values so that it now ends near $\omega = 2$. For the right end of the diagram, numerical study indicates that there are no new structures beyond $\omega = 12$ so that the asymptotic behavior (7.14) and (7.15) sets in for ω values larger than those shown.

There are also many new features. First, there are numerous higher-period fixed points that appear and disappear through blue-sky bifurcations. Some of them have been color coded in the figure. Moreover, some of the trails of the higher-period fixed points have little bubbles, and some of these little bubbles have an infinite number of sub-bubbles within them. That is, some of the higher-period fixed points (most evidently, those of period three) seem to have complete period doubling cascades with chaotic behavior at the end of the cascade. Figure 8.2 shows this behavior in further detail. It is too complicated to be studied further here.

What we do wish to note in Figure 8.2 is that what we have been calling the the first and second bubbles have within them the *beginnings* of period doubling cascades. Recall that each of these bubbles consists of three period-one fixed points. One of them is unstable, and hence invisible in a Feigenbaum diagram. The other two are stable, and their trails as ω is varied form the bubble. We see that these cascades *do not complete* but rather, after several period doublings, each cascade ceases and then successively undoes itself by a sequence of mergers to ultimately result in what is again a single stable period-one fixed point. This behavior is similar to that exhibited by the simple map described in Appendix J.

Suppose the value of ϵ is increased still further. Figure 8.3 shows the Feigenbaum diagram when $\epsilon = 25$. It looks similar to Figure 8.1 for $\epsilon = 22.125$. For example, there are again no new structures beyond $\omega = 12$ so that the asymptotic behavior (7.14) and (7.15) sets in for ω values larger than those shown. However, Figure 8.4, which is an enlargement of Figure 8.3, shows that the Feigenbaum cascades in the first and second bubbles now go to

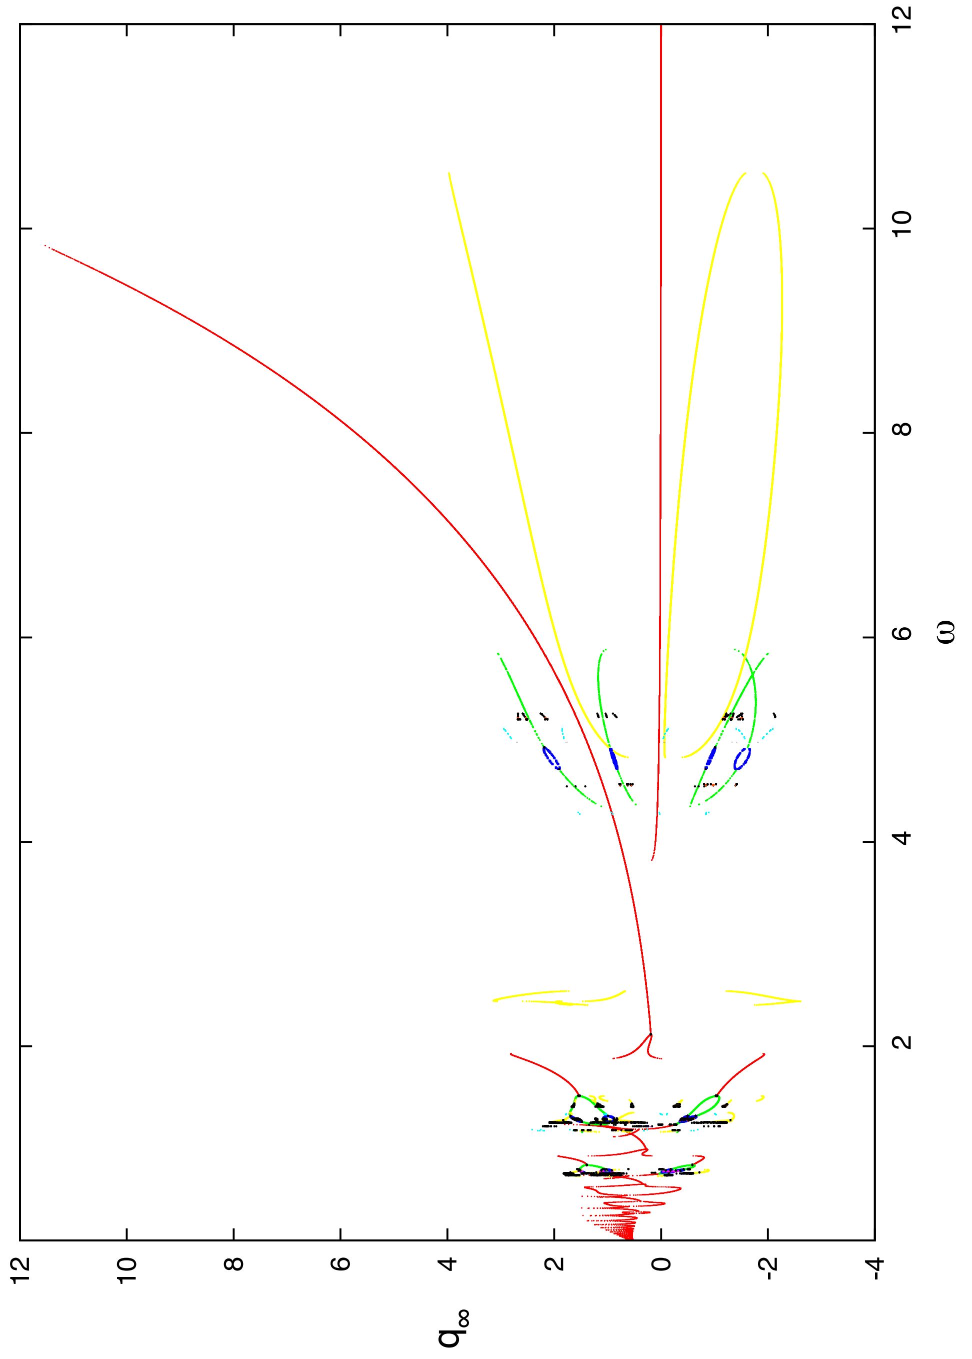

Figure 28.8.1: Feigenbaum diagram showing limiting values q_∞ as a function of ω (when $\beta = 0.1$ and $\epsilon = 22.125$) for the stroboscopic Duffing map.

completion.[9] Then, as ω is further increased, each complete period-doubling cascade again undoes itself. Note also that there appears to be a window of stability (near $\omega = 1.33$) within the completed cascade in the first bubble.

We close this lengthy discussion with a further brief study of some aspects of the period doubling cascade in the first bubble. Figure 8.5 shows an enlargement of part of this cascade. Specifically, it shows the beginnings of the period doubling cascades that occur in the bubble. The bubble has already formed due to the pitchfork bifurcation at the value $\omega \simeq 1.2284$, a value somewhat smaller than the ω values shown, and for which $(q_\infty, p_\infty) \simeq (.3982, 2.332)$. See Figure 8.4. Within the bubble there are two period-doubling cascades that begin when $\omega \simeq 1.268$: a lower one for which $(q_\infty, p_\infty) \simeq (-.228, 1.802)$, and an upper one for which $(q_\infty, p_\infty) \simeq (1.131, 2.215)$. It can be shown that the period-doubling cascades begin at the same ω values in both the upper and lower trails because of equivariance symmetry. See Sections 29.12.2 and 29.12.3. Unfortunately the view of the upper period-doubling bifurcation is somewhat complicated by the simultaneous appearance of a wisp of the trail of the stable stable fixed point associated with the second saddle-node bifurcation (the one mostly to the left of the first bubble) that appears to overlay the period-doubling bifurcation. This is an accident of our plotting scheme that happens to occur when $\epsilon = 25$. It would not overlay the period-doubling bifurcation if we had made a Feigenbaum diagram showing p_∞ versus ω instead of q_∞ versus ω. It also does not overlay the period-doubling bifurcation for other values of ϵ. Examine Figure 8.2 (for which $\epsilon = 22.125$) in the vicinity $\omega \approx 1.22$ and $q_\infty \approx 1.2$.

Let us now examine in more detail the period-doubling cascade that occurs in the upper part of the first bubble. See Figure 8.6. Evidently, for the smaller driving frequencies and in this region of phase space, there is a single period-one fixed point corresponding to an attractor. As the frequency is increased there is an infinite cascade of period doublings, and the motion appears chaotic by $\omega \simeq 1.29$. The resemblance between Figure 8.6 and Figure 1.2.4 for the logistic map is quite striking. In particular, numerical studies indicate that the frequencies ω_j at which successive bifurcations occur behave in a way analogous to (1.2.14) with (to within numerical accuracy) Feigenbaum's value of δ. Of course, as Figure 8.3 illustrates, the Duffing stroboscopic map is vastly more complicated than the logistic map, and its behavior resembles that of the logistic map only in a limited parameter range and only in a limited region of phase space. Note also that the logistic map acts on a one-dimensional space while the Duffing stroboscopic map acts on a two-dimensional space. Figure 1.2.4 tells the full story for the logistic map. By contrast, Figure 8.6 for the Duffing stroboscopic map is a projection onto the q axis of points in the two-dimensional q, p space. For full information one would need a figure made in the style of Figures 3.2 and 5.3.[10]

[9] Further numerical study indicates that the cascade in the first bubble is complete by the time $\epsilon = 22.25$ while that in the second bubble remains incomplete. Shortly thereafter the cascade in the second bubble also completes. Finally, numerical study reveals that the cascades associated with the higher-period blue-sky fixed points do complete for some ϵ values less that 22.125.

[10] See Figure 29.7.5 for such a figure in the case of the damped Hénon map.

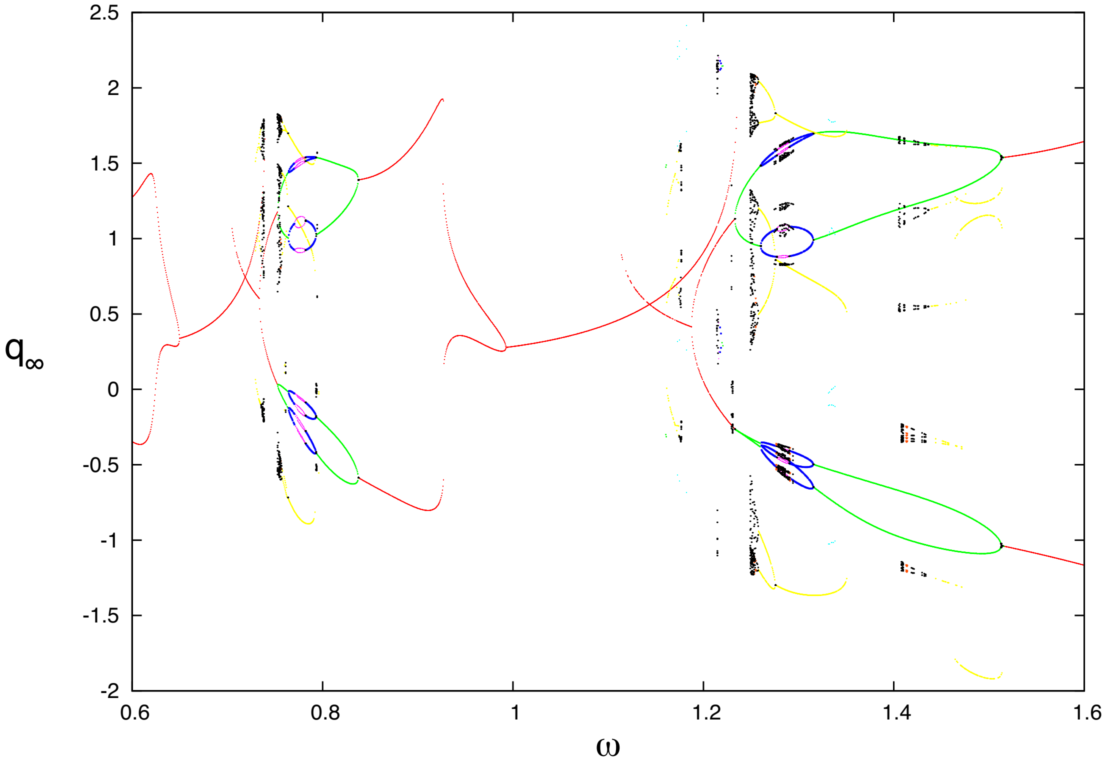

Figure 28.8.2: Enlargement of a portion of Figure 8.1 displaying limiting values of q_∞ as a function of ω (when $\beta = 0.1$ and $\epsilon = 22.125$) for the stroboscopic Duffing map. It shows part of the first bubble at the far right, the second bubble, and part of a third bubble at the far left. Examine the first and second bubbles. Each initially consists of two stable period-one fixed points. Each also contains the beginnings of period-doubling cascades. These cascades do not complete, but rather cease and then undo themselves by successive mergings to again result in a pair of stable period-one fixed points. There are also many higher-period fixed points and their associated cascades.

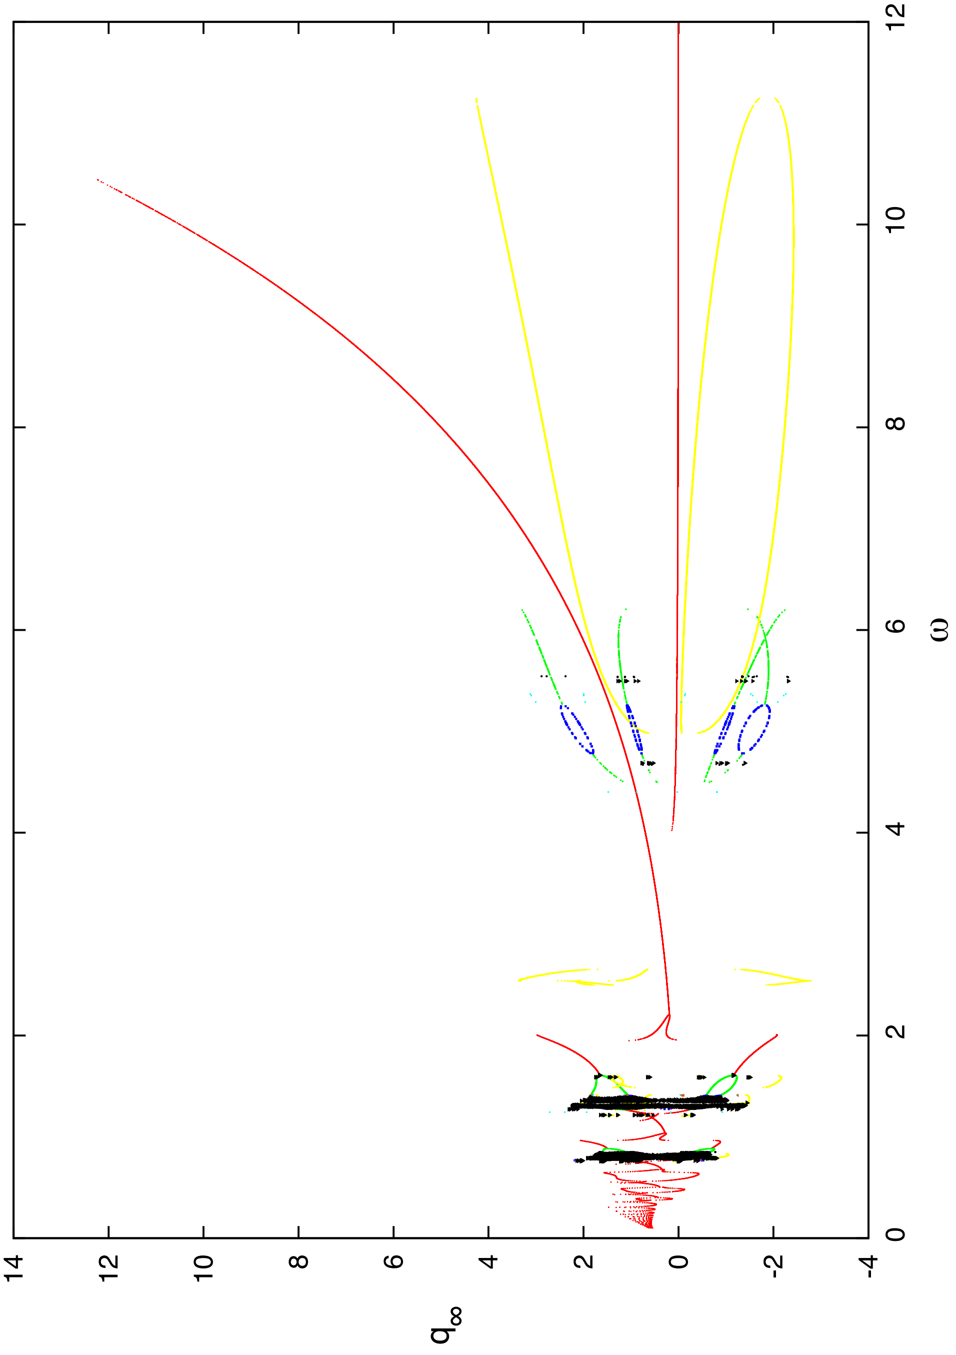

Figure 28.8.3: Feigenbaum diagram showing limiting values q_∞ as a function of ω (when $\beta = 0.1$ and $\epsilon = 25$) for the stroboscopic Duffing map.

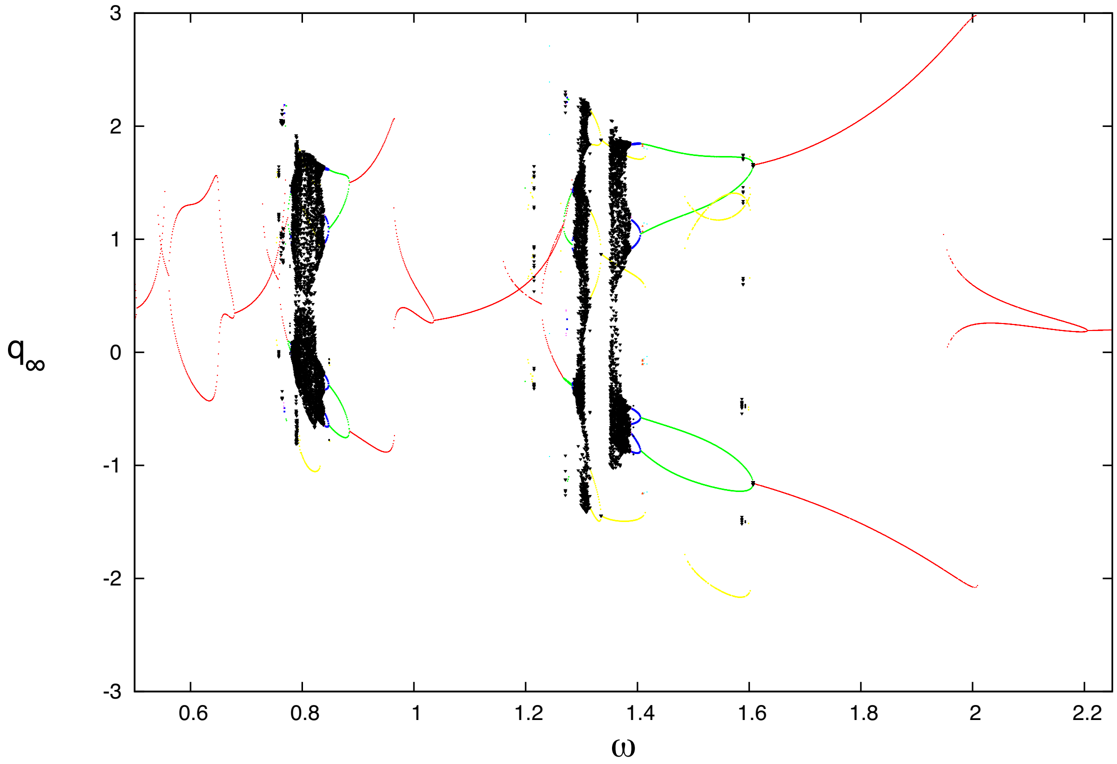

Figure 28.8.4: Enlargement of a portion Figure 8.3 showing the first, second, and third bubbles. The period-doubling cascades in each of the first and second bubbles now complete. Then they undo themselves as ω is further increased. There is no period doubling in the third bubble when $\epsilon = 25$.

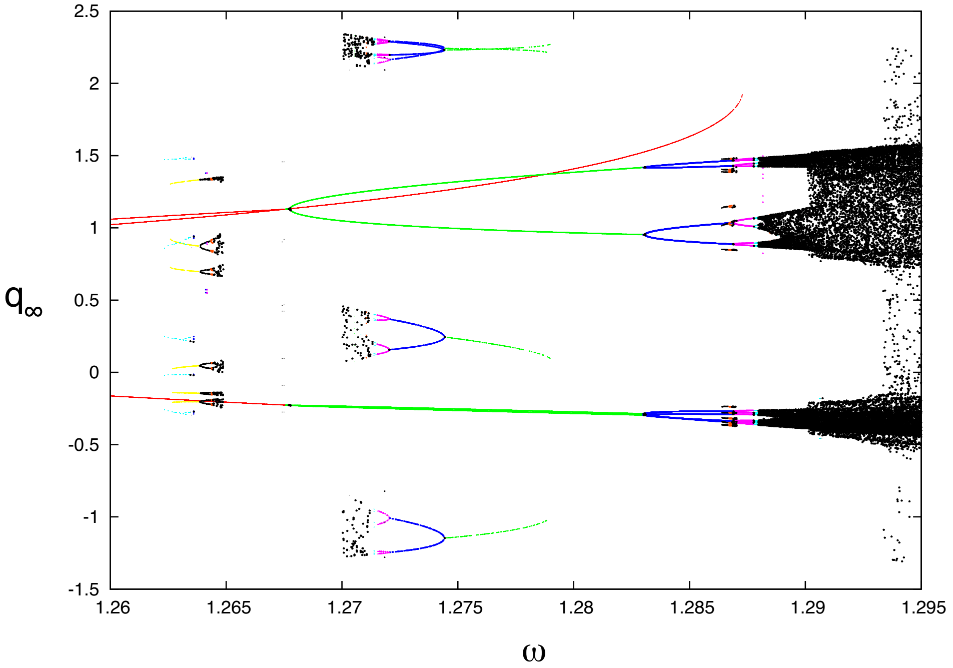

Figure 28.8.5: Detail of part of the first bubble in Figure 8.4 showing upper and lower infinite period-doubling cascades. Part of the trail of the stable fixed point associated with the second saddle-node bifurcation accidentally appears to overlay the upper period doubling bifurcation. Finally, associated with higher-period fixed points, there are numerous cascades and followed by successive mergings.

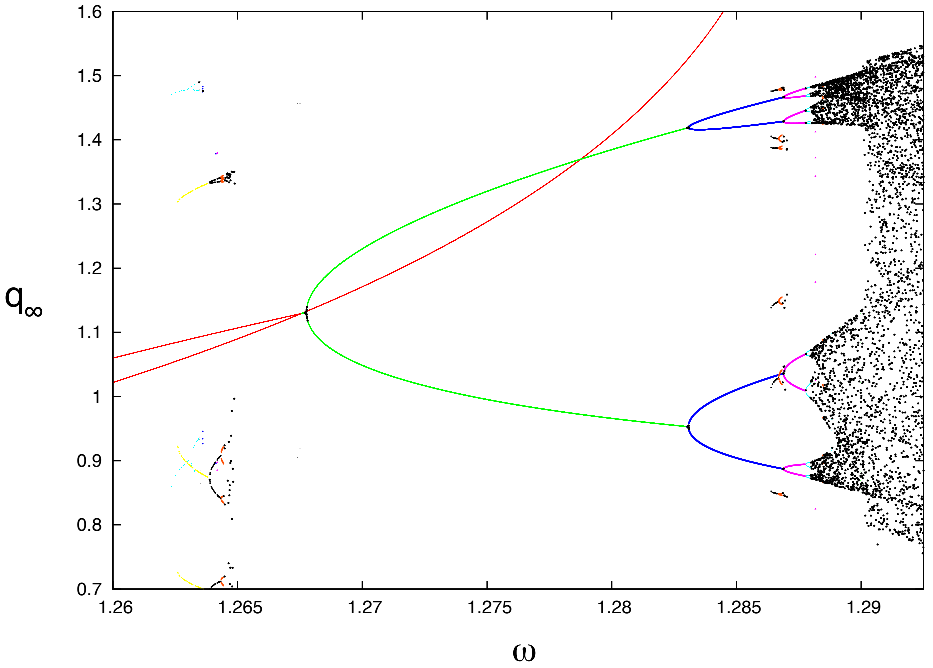

Figure 28.8.6: Detail of part of the upper cascade in Figure 8.5 showing an infinite period-doubling cascade, followed by chaos, for what was initially a stable period-one fixed point.

28.9 Strange Attractor

Finally, Figure 9.1 shows both the q_∞ and p_∞ values associated with Figure 8.6 when $\omega = 1.2902$ (and $\beta = .1$ and $\epsilon = 25$). Evidently the set of points q_∞, p_∞ for ω values just beyond the end of the cascade is quite complicated. By construction the set is an *attractor*. That is, points nearby this set are brought ever closer to the set under repeated action of $\mathcal{M}$. Moreover, numerical evidence suggests that this set has an infinite number of points and that the action of $\mathcal{M}$ on points in this set is to move them about within the set in a very complicated way. Finally, the set appears to be fractal. That is, it displays self similarity under repeated magnification. Therefore it may be an instance of what is called a *strange attractor*. For example, Figure 9.2 shows an enlargement of part of Figure 9.1. Repeated enlargement is expected to show a continued self-similar structure. For an instance of a strange attractor in the case of the damped Hénon map, see Sections 29.7 and 29.9. For more about the Duffing stroboscopic map, see Section 29.12. Finally, we warn the reader that there is no universal agreement among authors about the meaning of the adjective *strange* when applied to attractors. Some simply mean that the attractor has an infinite number of points. Some take fractal behavior to be the defining feature of what it means to be strange. Others require a sensitive dependence on initial conditions. Still others require what is technically called nonuniformly hyperbolic behavior.

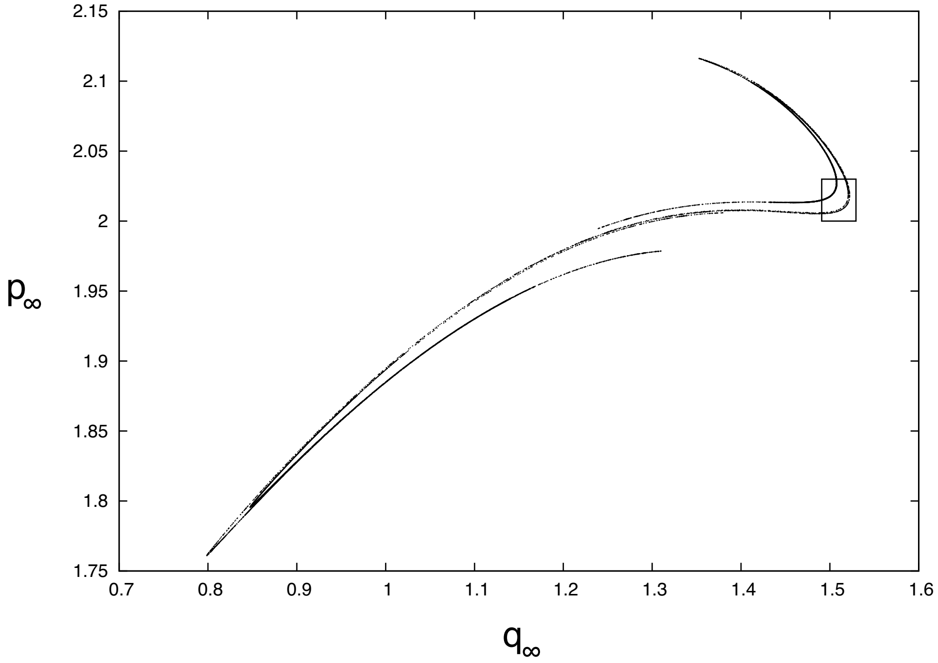

Figure 28.9.1: Limiting values of q_∞, p_∞ for the stroboscopic Duffing map when $\omega = 1.2902$ (and $\beta = .1$ and $\epsilon = 25$). They appear to lie on a strange attractor.

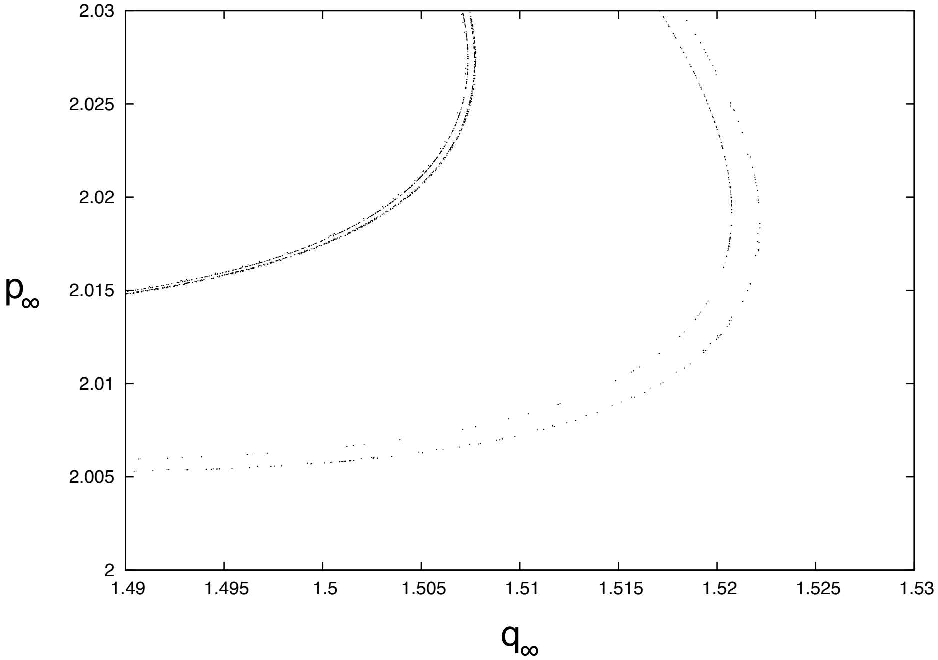

Figure 28.9.2: Enlargement of boxed portion of Figure 9.1 illustrating the beginning of self-similar fractal structure.

28.10 Acknowledgment

Dobrin Kaltchev made major contributions to the work of this chapter.

Some of our figures and some of our discussion of Duffing's equation were motivated by Sections 11.1 through 11.4 of this book. However, we found somewhat different numerical results. Presumably this is because, for the parameter values of interest, the long-term integration of Duffing's equation requires unusual care. For our calculations we used a 10th order Adams integrator started with 6th order Runge Kutta. Integrations were performed for several different step sizes in both double and quadruple (64 and 128 bit) precision to assure satisfactory convergence. See Chapter 2.

Chapter 29

General Maps

Most of this book is devoted to the use of Lie methods for *symplectic* maps. However, Lie methods can also be used for general maps. This chapter treats general maps in an even number of variables and exploits the decomposition of general analytic vector fields (in an even number of variables) into Hamiltonian and non-Hamiltonian parts as described in Chapter 27. Section 1 describes the Lie factorization of general maps. Section 2 classifies all two-dimensional quadratic maps, and Section 3 studies, as an example, the Lie factorization of the general two-dimensional quadratic map. Sections 4 through 6 describe various concepts that are useful for studying maps including fixed points, the Poincaré index, stable and unstable manifolds, homoclinic points, and homoclinic tangles. Section 7 introduces the general Hénon map. Section 8 presents a preliminary study of the general Hénon map by finding and characterizing its fixed points, producing expansions about them, and factorizing the map about them. Section 9 describes period doubling and strange attractors for the general Hénon map, and Section 10 attempts to find integrals. Section 11 describes and studies quadratic symplectic maps in more than two dimensions. Section 12 obtains and studies Taylor approximations to the stroboscopic Duffing map. A final section discusses the expected analytic behavior of fixed points of a map and the eigenvalues of the linear part of the map.

29.1 Lie Factorization of General Maps

Section 7.6 showed that (modulo questions of convergence) any analytic symplectic map can be written in factorized product form. The purpose of this section is to explore what can be done for general analytic maps (in an even number of variables). That is, we will consider the group of all (analytic) diffeomorphisms. We will find that a general map can be written as a product of two factors. One factor is a product of exponentials of non-Hamiltonian Lie operators, and the second factor is an analytic symplectic map.

We begin by copying the expansion (7.6.1) for $\mathcal{M}$,

$$\bar{z}_a = \sum_b L_{ab} z_b + \sum_{bc} T_{abc} z_b z_c + \sum_{bcd} U_{abcd} z_b z_c z_d + \cdots , \qquad (29.1.1)$$

but now no longer require that $\mathcal{M}$ be symplectic. First of all the linear (matrix) part of $\mathcal{M}$, which we now write as L, need not be a symplectic matrix. However, we will require that L

have the symplectic polar decomposition

$$L = RQ. \tag{29.1.2}$$

Here R is symplectic and Q is a J-symmetric matrix that can be written in the form

$$Q = \exp(JA) \tag{29.1.3}$$

where A is antisymmetric. Sufficient conditions on L for (1.2) and (1.3) to hold were established in Section 4.3.

In (24.10.49) employ for F the matrix A of (1.3) and call the result $\mathcal{G}_2$,

$$\mathcal{G}_2 = \mathcal{L}_{\boldsymbol{g}} \tag{29.1.4}$$

with

$$g_b = \sum_d (JA)_{bd} z_d. \tag{29.1.5}$$

From the work of Section 24.10 we know that $\mathcal{G}_2$ is a a non-Hamiltonian vector field with the action

$$\mathcal{G}_2 z_b = \sum_d (JA)_{bd} z_d. \tag{29.1.6}$$

Recall (1.4) and see (24.10.51). It follows that there are the associated relations

$$(\mathcal{G}_2)^m z_b = \sum_d [(JA)^m]_{bd} z_d, \tag{29.1.7}$$

$$[\exp(\mathcal{G}_2)] z_b = \sum_d [\exp(JA)]_{bd} z_d = \sum_d Q_{bd} z_d. \tag{29.1.8}$$

Also, since R is symplectic, there are polynomials $f_2^a(z)$ and $f_2^c(z)$ associated with R. See Section 7.6. By using these polynomials and (1.8) we find the results

$$[\exp(\mathcal{G}_2)\exp(:f_2^c:)\exp(:f_2^a:)] z_b = [\exp(\mathcal{G}_2)] \sum_d R_{bd} z_d$$
$$= \sum_d R_{bd} [\exp(\mathcal{G}_2)] z_d = \sum_{de} R_{bd} Q_{de} z_e = \sum_e L_{be} z_e, \tag{29.1.9}$$

$$[\exp(-:f_2^a:)\exp(-:f_2^c:)\exp(-\mathcal{G}_2)] z_b = \sum_e (L^{-1})_{be} z_e. \tag{29.1.10}$$

These results can be written more compactly in the form

$$\exp(\mathcal{G}_2)\exp(:f_2^c:)\exp(:f_2^a:) z = Lz, \tag{29.1.11}$$

$$\exp(-:f_2^a:)\exp(-:f_2^c:)\exp(-\mathcal{G}_2) z = L^{-1} z. \tag{29.1.12}$$

Finally, since all the factors on the left side of (1.12) are Lie transformations, we have the result

$$\exp(-:f_2^a:)\exp(-:f_2^c:)\exp(-\mathcal{G}_2) h(z) = h(L^{-1}z), \tag{29.1.13}$$

for any function h.

Now, in the spirit of Section 7.6, apply $[\exp(-:f_2^a:)\exp(-:f_2^c:)\exp(-\mathcal{G}_2)]$ to both sides of (1.1). Doing so, and making use of (1.12) and (1.13), give the result

$$\exp(-:f_2^a:)\exp(-:f_2^c:)\exp(-\mathcal{G}_2)\overline{z}_b = z_b + r_b(>1). \tag{29.1.14}$$

Here, as before, the notation $r_b(>m)$ denotes *any* “remainder” series consisting of terms of degree higher than m. To proceed further, suppose the remainder terms $r_b(>1)$ are decomposed into second degree terms $g_b(2;z)$ and higher degree terms by writing the relations

$$r_b(>1) = g_b(2;z) + r_b(>2). \tag{29.1.15}$$

With this notation, we may rewrite (1.14) in the form

$$\exp(-:f_2^a:)\exp(-:f_2^c:)\exp(-\mathcal{G}_2)\overline{z}_b = z_b + g_b(2;z) + r_b(>2). \tag{29.1.16}$$

Let $\mathcal{L}_{\boldsymbol{g}^2}$ be the vector field defined by the equation

$$\mathcal{L}_{\boldsymbol{g}^2} = \sum_b g_b(2;z)(\partial/\partial z_b) = \boldsymbol{g}(2;z)\cdot\boldsymbol{\partial}. \tag{29.1.17}$$

Apply $\exp(-\mathcal{L}_{\boldsymbol{g}^2})$ to both sides of (1.16),

$$\begin{aligned}&\exp(-\mathcal{L}_{\boldsymbol{g}^2})\exp(-:f_2^a:)\exp(-:f_2^c:)\exp(-\mathcal{G}_2)\overline{z}_b = \\ &\exp(-\mathcal{L}_{\boldsymbol{g}^2})z_b + \exp(-\mathcal{L}_{\boldsymbol{g}^2})g_b(2;z) + \exp(-\mathcal{L}_{\boldsymbol{g}^2})r_b(>2).\end{aligned} \tag{29.1.18}$$

In analogy with (7.6.14) there is the general relation

$$(\mathcal{L}_{\boldsymbol{g}^m})f_n \in \mathcal{P}_{m+n-1}. \tag{29.1.19}$$

From this relation we deduce the results

$$\exp(-\mathcal{L}_{\boldsymbol{g}^2})z_b = z_b - (\mathcal{L}_{\boldsymbol{g}^2})z_b + (1/2)(\mathcal{L}_{\boldsymbol{g}^2})^2 z_b + \cdots = z_b - g_b(2;z) + r_b(>2), \tag{29.1.20}$$

$$\exp(-\mathcal{L}_{\boldsymbol{g}^2})g_b(2;z) = g_b(2;z) - (\mathcal{L}_{\boldsymbol{g}^2})g_b(2;z) + \cdots = g_b(2;z) + r_b(>2), \tag{29.1.21}$$

$$\exp(-\mathcal{L}_{\boldsymbol{g}^2})r_b(>2) = r_b(>2) - (\mathcal{L}_{\boldsymbol{g}^2})r_b(>2) + \cdots = r_b(>2) + r_b(>3). \tag{29.1.22}$$

Consequently, (1.18) can be rewritten in the form

$$\exp(-\mathcal{L}_{\boldsymbol{g}^2})\exp(-:f_2^a:)\exp(-:f_2^c:)\exp(-\mathcal{G}_2)\overline{z}_b = z_b + r_b(>2). \tag{29.1.23}$$

Now decompose the remainder terms $r_b(>2)$ into third degree terms $g_b(3,z)$ and higher degree terms by writing the relations

$$r_b(>2) = g_b(3;z) + r_b(>3). \tag{29.1.24}$$

Finally, substitute this decomposition into (1.23) to get the result

$$\exp(-\mathcal{L}_{\boldsymbol{g}^2})\exp(-:f_2^a:)\exp(-:f_2^c:)\exp(-\mathcal{G}_2)\overline{z}_b = z_b + g_b(3;z) + r_b(>3). \tag{29.1.25}$$

Clearly the process that led from (1.16) to (1.25) can be repeated at will. Consequently, there exist uniquely defined vector fields $\mathcal{L}_{\boldsymbol{g}^2}, \mathcal{L}_{\boldsymbol{g}^3}, \cdots$ such that for any n there is a relation of the form

$$\begin{aligned}&\exp(-\mathcal{L}_{\boldsymbol{g}^n})\exp(-\mathcal{L}_{\boldsymbol{g}^{n-1}})\cdots\exp(-\mathcal{L}_{\boldsymbol{g}^2})\times\\ &\exp(-:f_2^a:)\exp(-:f_2^c:)\exp(-\mathcal{G}_2)\bar{z}_b = z_b + r_b(>n).\end{aligned} \tag{29.1.26}$$

Now rewrite (1.26) in the form

$$\bar{z}_b = \exp(\mathcal{G}_2)\exp(:f_2^c:)\exp(:f_2^a:)\exp(\mathcal{L}_{\boldsymbol{g}^2})\cdots\exp(\mathcal{L}_{\boldsymbol{g}^n})z_b + r_b(>n), \tag{29.1.27}$$

and let $n \to \infty$. Then, if the remainder term tends to zero, we obtain the result

$$\bar{z} = \mathcal{M}z \tag{29.1.28}$$

with $\mathcal{M}$ expressed as the product

$$\mathcal{M} = \exp(\mathcal{G}_2)\exp(:f_2^c:)\exp(:f_2^a:)\exp(\mathcal{L}_{\boldsymbol{g}^2})\exp(\mathcal{L}_{\boldsymbol{g}^3})\cdots. \tag{29.1.29}$$

Otherwise the result is true only formally. In this latter case the infinite product (1.29) is also not convergent.

There is still more that can be done. From (24.14.3) we know that each vector field $\mathcal{L}_{\boldsymbol{g}^\ell}$ in (1.29) can be written in the form

$$\mathcal{L}_{\boldsymbol{g}^\ell} =: h_{\ell+1} : + \mathcal{G}^{\ell-1,1,0,\cdots} + \mathcal{G}^{\ell-1,0,0,\cdots} =: h_{\ell+1} : + \mathcal{G}''_{\ell+1}. \tag{29.1.30}$$

Here we have lumped the non-Hamiltonian parts together and simply called the result $\mathcal{G}''_{\ell+1}$. Note that the methods of Section 24.10 are adequate for this purpose since they allow us to find $h_{\ell+1}$ and $\mathcal{G}''_{\ell+1}$, and we do not need to further decompose $\mathcal{G}''_{\ell+1}$ into $\mathcal{G}^{\ell-1,1,0,\cdots}$ and $\mathcal{G}^{\ell-1,0,0,\cdots}$. With the aid of the BCH series (3.7.33) and (3.7.39) [or, equivalently the Zassenhaus series (8.8.1) and (8.8.2)] as applied to vector fields, and in view of the grading relation (24.3.5), we may rewrite the product $[\exp(\mathcal{L}_{\boldsymbol{g}^2})\exp(\mathcal{L}_{\boldsymbol{g}^3})\cdots]$ in the form

$$\exp(\mathcal{L}_{\boldsymbol{g}^2})\exp(\mathcal{L}_{\boldsymbol{g}^3})\cdots = \exp(\mathcal{G}'_3)\exp(\mathcal{G}'_4)\cdots\exp(:f_3:)\exp(:f_4):\cdots. \tag{29.1.31}$$

Here use has been made of the decomposition (1.30). We see that all non-Hamiltonian vector fields have been brought to the left, and all Hamiltonian vector fields have been brought to the right. Because of the grading relation (24.3.5), only a finite number of vector field commutators need be evaluated to compute each $\mathcal{G}'_m$ and f_m. Here we have dropped one prime from the $\mathcal{G}''_m$ and changed h_m to f_m to indicate that both are generally changed as a result of the various commutators involved.

As a result of the refactorization (1.31) the map $\mathcal{M}$ as given by (1.29) can be rewritten in the form

$$\begin{aligned}\mathcal{M} = \;&\exp(\mathcal{G}_2)\exp(:f_2^c:)\exp(:f_2^a:)\exp(\mathcal{G}'_3)\exp(\mathcal{G}'_4)\cdots\times\\ &\exp(:f_3:)\exp(:f_4:)\cdots.\end{aligned} \tag{29.1.32}$$

The terms $[(\mathcal{G}_3')\exp(\mathcal{G}_4')\cdots]$ can be moved past the terms $[\exp(:f_2^c:)\exp(:f_2^a:)]$ with the aid of the relations

$$\begin{aligned}&\exp(:f_2^c:)\exp(:f_2^a:)\exp(\mathcal{G}_3')\exp(\mathcal{G}_4')\cdots =\\ &\exp(:f_2^c:)\exp(:f_2^a:)\exp(\mathcal{G}_3')\exp(\mathcal{G}_4')\cdots\exp(-:f_2^a:)\exp(-:f_2^c:)\times\\ &\exp(:f_2^c:)\exp(:f_2^a:),\end{aligned}\tag{29.1.33}$$

and

$$\begin{aligned}&\exp(:f_2^c:)\exp(:f_2^a:)\exp(\mathcal{G}_3')\exp(\mathcal{G}_4')\cdots\exp(-:f_2^a:)\exp(-:f_2^c:) =\\ &\exp(\mathcal{G}_3)\exp(\mathcal{G}_4)\cdots\,.\end{aligned}\tag{29.1.34}$$

Here we have used the fact that the non-Hamiltonian vector fields are transformed among themselves under the action of $sp(2n,\mathbb{R})$, and have dropped the prime from each $\mathcal{G}_m'$ to indicate the result of this transformation. Putting everything together gives the final result

$$\begin{aligned}\mathcal{M} = \;&\exp(\mathcal{G}_2)\exp(\mathcal{G}_3)\exp(\mathcal{G}_4)\cdots\times\\ &\exp(:f_2^c:)\exp(:f_2^a:)\exp(:f_3:)\exp(:f_4:)\cdots\,.\end{aligned}\tag{29.1.35}$$

We see that, as promised, $\mathcal{M}$ has been written as a product of two factors. The first factor is a product of exponentials of non-Hamiltonian vector fields, and the second is the by now familiar general (origin preserving) symplectic map.

The last item to discuss is the inclusion of translations. That is, suppose the map $\mathcal{M}$ is of the general form (7.7.7). In that case, in view of the work of Section 7.1, there is the simple modification

$$\begin{aligned}\mathcal{M} = \;&\exp(\mathcal{G}_2)\exp(\mathcal{G}_3)\exp(\mathcal{G}_4)\cdots\times\\ &[\exp(:f_2^c:)\exp(:f_2^a:)\exp(:f_3:)\exp(:f_4:)\cdots]\exp(:g_1:).\end{aligned}\tag{29.1.36}$$

Exercises

29.1.1. For the complex logistic map (1.2.29) in the two-dimensional real form given by (1.2.102) and (1.2.103) make the identifications

$$x = q,\tag{29.1.37}$$

$$y = p,\tag{29.1.38}$$

so that in terms of q and p the map takes the form

$$q_{n+1} = \alpha q_n - \beta p_n - \alpha(q_n^2 - p_n^2) + 2\beta q_n p_n,\tag{29.1.39}$$

$$p_{n+1} = \beta q_n + \alpha p_n - \beta(q_n^2 - p_n^2) - 2\alpha q_n p_n.\tag{29.1.40}$$

Make a polar decomposition of the control parameter

$$\gamma = \alpha + i\beta\tag{29.1.41}$$

by writing

$$\gamma = \rho \exp(i\phi). \tag{29.1.42}$$

Show that in terms of the parameters ρ, ϕ the linear part of the map about the origin (which is a fixed point) takes the form

$$R = \rho \begin{pmatrix} \cos\phi & -\sin\phi \\ \sin\phi & \cos\phi \end{pmatrix}. \tag{29.1.43}$$

29.1.2. Forest map.

29.2 Classification of General Two-Dimensional Quadratic Maps

The general quadratic map, even in the case of only two variables, is a complicated object. We know, for example, that the complex logistic map produces fractal sets in the mapping plane and the fantastically complicated Mandelbrot set in the control plane. See Section 1.2 and Exercise 1.2.2. We also suspect that the Hénon map, another two-dimensional quadratic map, exhibits even more complicated behavior. Again see Section 1.2. In this section we will make a preliminary classification of general two-dimensional quadratic maps. What we will do is make an *affine* transformation on both z and $\bar{z}$ (the same transformation on each), and consider two maps *equivalent* if one can be transformed into the other by such a change of variables. (An affine transformation is a translation followed by a linear transformation. These transformations evidently form a group called the affine group. Moreover, we observe that if a map is quadratic, then it will remain quadratic under any change of variables that is an affine transformation.) Indeed, the two maps will be *conjugate* as described in Chapter 19.

Let $\mathcal{N}$ denote the nonlinear quadratic map

$$\begin{aligned} \bar{q} &= q + b_1 q^2 + 2b_2 qp + b_3 p^2 = q + (z, Bz), \\ \bar{p} &= p + c_1 q^2 + 2c_2 qp + c_3 p^2 = p + (z, Cz). \end{aligned} \tag{29.2.1}$$

Here we have used the notation $z = (q, p)$ and

$$\begin{aligned} B &= \begin{pmatrix} b_1 & b_2 \\ b_2 & b_3 \end{pmatrix}, \\ C &= \begin{pmatrix} c_1 & c_2 \\ c_2 & c_3 \end{pmatrix}. \end{aligned} \tag{29.2.2}$$

Let $\mathcal{R}$ denote the linear map

$$\begin{aligned} \bar{\bar{q}} &= r\bar{q} + s\bar{p}, \\ \bar{\bar{p}} &= t\bar{q} + u\bar{p}. \end{aligned} \tag{29.2.3}$$

Finally, let $\mathcal{T}$ denote the translation map

$$\bar{\bar{\bar{q}}} = \bar{\bar{q}} + d,$$

$$\overset{\equiv}{p}=\overset{=}{p}+e. \tag{29.2.4}$$

Then we speculate that the *general quadratic map*, which we will denote as $\mathcal{M}_{gq}$ can be written in the form

$$\mathcal{M}_{gq} = \mathcal{TRN}. \tag{29.2.5}$$

Here we have employed the usual mathematical ordering convention as described in the beginning of Section 8.3. Carrying out the operations indicated in (2.5) shows that $\mathcal{M}_{gq}$ has the explicit representation given by the relations below.

Action of $\mathcal{M}_{gq}$:

$$\overset{\equiv}{q}= d + rq + sp + (z, B'z),$$

$$\overset{\equiv}{p}= e + tq + up + (z, C'z), \tag{29.2.6}$$

where B' and C' are the symmetric matrices

$$B' = rB + sC,$$

$$C' = tB + uC. \tag{29.2.7}$$

We see that $\mathcal{M}_{gq}$ will in fact be the general quadratic map in two variables provided B' and C' can be *any* two symmetric matrices. Let R be the matrix defined by the equation

$$R = \begin{pmatrix} r & s \\ t & u \end{pmatrix}, \tag{29.2.8}$$

and let V be the vector with *matrix* entries B and C,

$$V = \begin{pmatrix} B \\ C \end{pmatrix}, \tag{29.2.9}$$

Define V' analogously. With this notation (2.7) can be rewritten in the form

$$V' = RV. \tag{29.2.10}$$

This relation can be inverted if R is invertible ($\det R \neq 0$),

$$V = R^{-1}V'. \tag{29.2.11}$$

Evidently if R is invertible, we can always find symmetric matrices B and C such that B' and C' are any desired symmetric matrices: we simply use the matrices B and C given by (2.11). Note also that R is the Jacobian matrix of $\mathcal{M}_{gq}$ at the origin,

$$R = M_{gq}(0). \tag{29.2.12}$$

See Exercise 1.4.6 and Section 6.1. Finally we remark that, driven by a shortage of symbols, in this section and in some subsequent sections we have used $\mathcal{R}$ and R to denote *general* linear maps and matrices rather than *symplectic* linear maps and matrices as was our previous convention.

For economy of notation, let us rewrite $\mathcal{M}_{gq}$, as given by (2.6), in the form

Action of $\mathcal{M}_{gq}$:

$$\bar{q} = d + rq + sp + (z, Bz),$$
$$\bar{p} = e + tq + up + (z, Cz), \tag{29.2.13}$$

where, again, B and C are arbitrary symmetric matrices. At this point, if not before, it is evident that $\mathcal{M}_{gq}$ is specified by 12 parameters: d and e for the translation part, r through u for the linear part, and the two symmetric matrices B and C for the nonlinear part. We now seek to simplify $\mathcal{M}_{gq}$, as given by (2.13), by a suitable change of variables, and we will allow this change of variables to be parameter dependent. We will then learn that 6 of the dimensions in the 12-parameter space may be viewed as associated with the choice of variables, and 6 may be viewed as being intrinsic to $\mathcal{M}_{gq}$ itself. And, as a result of suitably changing variables, we will find a *transformed* map $\mathcal{M}_{gq}^{tr}$ that depends on 6 parameters.

Begin with a *displacement* (translation) transformation of variables by writing

$$q = q' + \alpha,$$
$$p = p' + \beta; \tag{29.2.14}$$
$$\bar{q} = \bar{q}' + \alpha,$$
$$\bar{p} = \bar{p}' + \beta. \tag{29.2.15}$$

We also express (2.14) and (2.15) in more compact form by writing

$$z = z' + \gamma \ , \ \ \bar{z} = \bar{z}' + \gamma \tag{29.2.16}$$

where γ is a two-vector with components α and β. Under this change of variables (2.13) takes the form

$$\bar{q}' = -\alpha + d + r\alpha + s\beta + (\gamma, B\gamma) + rq' + sp' + 2(z', B\gamma) + (z', Bz'),$$
$$\bar{p}' = -\beta + e + t\alpha + u\beta + (\gamma, C\gamma) + tq' + up' + 2(z', C\gamma) + (z', Cz'). \tag{29.2.17}$$

Suppose we now require that the transformed map given by (2.17) have no *constant* terms. That is, the transformed map should have no translation part, and therefore should send the origin into itself. This requirement leads to the equations

$$\alpha = d + r\alpha + s\beta + (\gamma, B\gamma), \tag{29.2.18}$$

$$\beta = e + t\alpha + u\beta + (\gamma, C\gamma). \tag{29.2.19}$$

We see, as might have been expected, that we have made the equivalent requirement that γ be a *fixed* point of $\mathcal{M}_{gq}$. That is, γ is a solution of the equations

$$q = d + rq + sp + (z, Bz), \tag{29.2.20}$$

$$p = e + tq + up + (z, Cz). \tag{29.2.21}$$

Taken separately, (2.20) and (2.21) each describe conic sections in the q, p plane; and taken jointly they specify the intersection of these two conic sections. The nature of these conic sections is governed by the *discriminants* (determinants) of the quadratic forms (z, Bz) and (z, Cz). For example, if

$$\det B = b_1 b_3 - b_2^2 > 0, \text{ (2.20) describes an ellipse;}$$

$$\det B = 0, \text{ (2.20) describes a parabola;}$$

$$\det B < 0, \text{ (2.20) describes a hyperbola.}$$

According to a theorem of *Bézout*, two polynomials of degrees m and n in two variables intersect in mn points that may be complex, may be at infinity, and may be repeated. For two conic sections, $m = n = 2$; so we expect *four* intersections. For our purposes we assume that the coefficients that appear in (2.20) and (2.21), which are all taken to be real, are such that there is at least one such *real* intersection so that $\mathcal{M}_{gq}$ has a real fixed point. Upon taking γ to be such a real fixed point, (2.17) takes the general form

$$\bar{q}' = \tilde{r}q' + \tilde{s}p' + (z', Bz'),$$

$$\bar{p}' = \tilde{t}q' + \tilde{u}p' + (z', Cz'). \tag{29.2.22}$$

Here we have replaced r, s, t, u by $\tilde{r}, \tilde{s}, \tilde{t}, \tilde{u}$ to take into account the linear terms $2(z', B\gamma)$ and $2(z', C\gamma)$ that "feed down" from the quadratic terms (z, Bz) and (z, Cz) as a result of the displacement (2.14). Since γ is assumed to be real, the quantities $\tilde{r}, \tilde{s}, \tilde{t}, \tilde{u}$ will also be real. Upon dropping the prime and tilde notation, we see that we are interested in studying maps of the simpler form

$$\bar{q} = rq + sp + (z, Bz),$$

$$\bar{p} = tq + up + (z, Cz). \tag{29.2.23}$$

Using the notation (2.8) and (2.9), the map (2.23) can be written more compactly in the form

$$\bar{z} = Rz + V(z). \tag{29.2.24}$$

Now make the linear change of variables

$$q = a_{11}q' + a_{12}p',$$

$$p = a_{21}q' + a_{22}p', \tag{29.2.25}$$

which can be written more compactly as

$$z = Az' \tag{29.2.26}$$

where A is the matrix

$$A = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}. \tag{29.2.27}$$

Corresponding to (2.26), we also define $\bar{z}'$ by writing

$$\bar{z} = A\bar{z}'. \tag{29.2.28}$$

With this change of variables the map (2.24) takes the form

$$A\bar{z}' = RAz' + V(Az'), \tag{29.2.29}$$

or

$$\bar{z}' = A^{-1}RAz' + A^{-1}V(Az'). \tag{29.2.30}$$

Under the assumption that the map is orientation preserving (see Exercise 1.4.6), R will have a positive determinant. In this case, define a matrix S by the rule

$$S = R/(\det R)^{1/2}. \tag{29.2.31}$$

According to Exercise 3.1.3, S will be symplectic. Moreover we know, from the discussion of Section 3.4 for the instance of 2×2 symplectic matrices, that there are five possible cases for S. For each of these cases we can select a suitable matrix A such that the *transformed* S given by

$$S^{tr} = A^{-1}SA \tag{29.2.32}$$

has a particularly simple form, which we will call a *normal* form. For example, if the eigenvalues of S lie on the unit circle (Case 3, elliptic), S can be transformed so that S^{tr} is of the form (3.5.58). As a second example, suppose the eigenvalues of S are positive (Case 1, hyperbolic). Then there is a choice of A such that S^{tr} takes the diagonal form

$$S^{tr} = \begin{pmatrix} \lambda & 0 \\ 0 & 1/\lambda \end{pmatrix}. \tag{29.2.33}$$

To continue with the hyperbolic case, let $D(\mu,\nu)$ denote the diagonal matrix

$$D(\mu,\nu) = \begin{pmatrix} \mu & 0 \\ 0 & \nu \end{pmatrix}. \tag{29.2.34}$$

Upon combining (2.31) through (2.33) we see that in the hyperbolic case there is an A (which is real) such that

$$A^{-1}RA = D(\mu,\nu) \tag{29.2.35}$$

where μ and ν are the eigenvalues of R. With this choice of A the map (2.30) takes the form

$$\bar{z}' = D(\mu,\nu)z' + V'(z') \tag{29.2.36}$$

where here

$$V'(z') = A^{-1}V(Az'). \tag{29.2.37}$$

To improve notation, we again drop the primes to rewrite (2.36) in the general form

$$\bar{z} = D(\mu,\nu)z + V(z). \tag{29.2.38}$$

There is one further simplifying transformation that can be made. Make the further linear change of variables

$$z = D(\sigma,\tau)z', \tag{29.2.39}$$

$$\bar{z} = D(\sigma,\tau)\bar{z}'. \tag{29.2.40}$$

With this change of variables the map (2.38) takes the form

$$\begin{aligned}\bar{z}' &= D^{-1}(\sigma,\tau)D(\mu,\nu)D(\sigma,\tau)z' + D^{-1}(\sigma,\tau)V[D(\sigma,\tau)z'] \\ &= D(\mu,\nu)z' + D^{-1}(\sigma,\tau)V[D(\sigma,\tau)z'].\end{aligned} \tag{29.2.41}$$

Here we have used the fact that diagonal matrices commute. We will call this map the *transformed general quadratic* map and denote it by $\mathcal{M}_{gq}^{tr}$.

Let us again drop primes and write out (2.41), the transformed two-variable general quadratic map $\mathcal{M}_{gq}^{tr}$, more explicitly in the form below.

Action of $\mathcal{M}_{gq}^{tr}$:

$$\begin{aligned}&\bar{q} = \mu q + (1/\sigma)[b_1\sigma^2 q^2 + 2b_2\sigma\tau qp + b_3\tau^2 p^2], \\ &\bar{p} = \nu p + (1/\tau)[c_1\sigma^2 q^2 + 2c_2\sigma\tau qp + c_3\tau^2 p^2].\end{aligned} \tag{29.2.42}$$

We now see that σ and τ can be selected in such a way that *any two* of the six coefficients b_1 through b_3 and c_1 through c_3 can be normalized to one. Thus, in the hyperbolic case, there is a six-parameter family of maps labeled by μ and ν and *four* of the six coefficients b_1 through b_3 and c_1 through c_3 with the remaining two coefficients set to 1.

A broad picture now emerges: The general two-dimensional quadratic map $\mathcal{M}_{gq}$ (assuming it has a real fixed point) can be classified according to the nature of its linear part about the fixed point. This linear part can next be brought to a normal form that is generally labelled by two parameters. There is then an associated two parameter family of linear transformations that leaves the normal form unchanged, and these transformations can be used to simplify the nonlinear part V of the map so that it is described by $6-2=4$ parameters. Thus, after a suitable choice of variables, the general two-dimensional quadratic map $\mathcal{M}_{gq}$ is brought to the form $\mathcal{M}_{gq}^{tr}$, and this transformed map is described by 6 parameters: 2 for the linear part in normal form, and 4 for the nonlinear part.

Exercises

29.2.1. Application to harmonic maps and the complex logistic map.

29.2.2. Application to Tinkerbell map.

29.3 Lie Factorization of General Two-Dimensional Quadratic Maps

We next turn to the problem of factorizing $\mathcal{M}_{gq}$ as given by (2.5) in Lie form. We know that $\mathcal{T}$ can always be written in Lie form. See Section 7.7. We also know that $\mathcal{R}$ can be written as a product of at most three Lie transformations if det $R > 0$. See the discussion at the end of Section 4.3 and the beginning of Section 18.1. What remains is to explore the Lie factorization of $\mathcal{N}$. See (2.1). In general it appears that $\mathcal{N}$ will have an infinite number of Lie factors. See Exercise 3.1. In this section we will study under what conditions a quadratic map in two variables can be factored into a product of a *finite* number of Lie transformations. In particular, we will require that $\mathcal{N}$ have a *single-factor* Lie representation.

Let $\mathcal{L}_{\boldsymbol{g}^2}$ be the Lie operator defined by the equation

$$\begin{aligned}\mathcal{L}_{\boldsymbol{g}^2} &= (z,Bz)(\partial/\partial q)+(z,Cz)(\partial/\partial p)\\ &= (b_1q^2+2b_2qp+b_3p^2)(\partial/\partial q)+(c_1q^2+2c_2qp+c_3p^2)(\partial/\partial p). \qquad (29.3.1)\end{aligned}$$

Then we have the result

$$\begin{aligned}\exp(\mathcal{L}_{\boldsymbol{g}^2})q &= q+\mathcal{L}_{\boldsymbol{g}^2}q+(1/2!)(\mathcal{L}_{\boldsymbol{g}^2})^2q+\cdots\\ &= q+(z,Bz)+(1/2!)(\mathcal{L}_{\boldsymbol{g}^2})^2q+\cdots\\ &= \bar{q}+(1/2!)(\mathcal{L}_{\boldsymbol{g}^2})^2q+\cdots,\end{aligned}$$

$$\begin{aligned}\exp(\mathcal{L}_{\boldsymbol{g}^2})p &= p+\mathcal{L}_{\boldsymbol{g}^2}p+(1/2!)(\mathcal{L}_{\boldsymbol{g}^2})^2p+\cdots\\ &= p+(z,Cz)+(1/2!)(\mathcal{L}_{\boldsymbol{g}^2})^2p+\cdots\\ &= \bar{p}+(1/2!)(\mathcal{L}_{\boldsymbol{g}^2})^2p+\cdots. \qquad (29.3.2)\end{aligned}$$

Here we have used (2.1). We conclude that $\mathcal{N}$ will have the single-factor Lie representation

$$\mathcal{N}=\exp(\mathcal{L}_{\boldsymbol{g}^2}) \qquad (29.3.3)$$

if $\mathcal{L}_{\boldsymbol{g}^2}$ satisfies the relations

$$(\mathcal{L}_{\boldsymbol{g}^2})^2q=0, \qquad (29.3.4)$$

$$(\mathcal{L}_{\boldsymbol{g}^2})^2p=0, \qquad (29.3.5)$$

for then each series in (3.2) will terminate after the first two terms. Otherwise, $\mathcal{N}$ will in general have an infinite number of Lie factors. We also note for future reference that $\mathcal{L}_{\boldsymbol{g}^2}$ has the decomposition

$$\mathcal{L}_{\boldsymbol{g}^2}=:h_3:+\mathcal{G}^1 \qquad (29.3.6)$$

where

$$h_3=(1/3)[c_1q^3+(2c_2-b_1)q^2p+(c_3-2b_2)qp^2-b_3p^3], \qquad (29.3.7)$$

$$\mathcal{G}^1=(2/3)[(b_1+c_2)q+(b_2+c_3)p]\Sigma. \qquad (29.3.8)$$

See (21.3.15) and (21.3.16).

Imposition of (3.4) produces the relations

$$b_1^2+b_2c_1=0, \qquad (29.3.9)$$

$$3b_1b_2+2b_2c_2+b_3c_1=0, \qquad (29.3.10)$$

$$2b_2^2+b_1b_3+b_2c_3+2b_3c_2=0, \qquad (29.3.11)$$

$$b_2b_3+b_3c_3=b_3(b_2+c_3)=0; \qquad (29.3.12)$$

and imposition of (3.5) produces the relations

$$b_1c_1+c_1c_2=c_1(b_1+c_2)=0, \qquad (29.3.13)$$

$$b_1c_2 + 2b_2c_1 + c_1c_3 + 2c_2^2 = 0, \tag{29.3.14}$$

$$2b_2c_2 + b_3c_1 + 3c_2c_3 = 0, \tag{29.3.15}$$

$$b_3c_2 + c_3^2 = 0. \tag{29.3.16}$$

Let us focus on those generic solutions of (3.9) through (3.16) for which $b_3 \neq 0$ and $c_1 \neq 0$. In this case, from (3.12) and (3.13), we find the results

$$b_2 + c_3 = 0 \text{ or } b_2 = -c_3, \tag{29.3.17}$$

$$b_1 + c_2 = 0 \text{ or } c_2 = -b_1. \tag{29.3.18}$$

Inspection of (3.7) and (3.8) shows that in this case $\mathcal{G}^1$ vanishes,

$$\mathcal{G}^1 = 0, \tag{29.3.19}$$

and h_3 takes the form

$$h_3 = (1/3)(c_1q^3 - 3b_1q^2p + 3c_3qp^2 - b_3p^3). \tag{29.3.20}$$

Also, the remaining relations in the collection (3.9) through (3.16) take the form

$$b_1^2 - c_1c_3 = 0, \tag{29.3.21}$$

$$-b_1c_3 + b_3c_1 = 0, \tag{29.3.22}$$

$$c_3^2 - b_1b_3 = 0. \tag{29.3.23}$$

Without loss of generality we may make the Ansätze

$$c_1 = \alpha^3 \ , \ b_3 = \beta^3. \tag{29.3.24}$$

We then find that (3.21) through (3.23) have the unique solution

$$b_1 = \alpha^2\beta, \tag{29.3.25}$$

$$c_3 = \alpha\beta^2; \tag{29.3.26}$$

and the remaining quantities have the values

$$c_2 = -\alpha^2\beta, \tag{29.3.27}$$

$$b_2 = -\alpha\beta^2. \tag{29.3.28}$$

As a result of these relations h_3 takes the form

$$h_3 = (1/3)(\alpha q - \beta p)^3. \tag{29.3.29}$$

Note that h_3 is the cube of a first-order polynomial. Consequently, we imediately have the properties

$$: h_3 : q = [h_3, q] = \beta(\alpha q - \beta p)^2, \tag{29.3.30}$$

$$: h_3 :^2 q = (\beta/3)[(\alpha q - \beta p)^3, (\alpha q - \beta p)^2] = 0; \tag{29.3.31}$$

$$: h_3 : p = [h_3, p] = \alpha(\alpha q - \beta p)^2, \tag{29.3.32}$$

$$: h_3 :^2 p = (\alpha/3)[(\alpha q - \beta p)^3, (\alpha q - \beta p)^2] = 0. \tag{29.3.33}$$

Correspondingly, $\mathcal{N}$ is a *symplectic* map with the Lie representation

$$\mathcal{N} = \exp : (1/3)(\alpha q - \beta p)^3 :, \tag{29.3.34}$$

and the Taylor expansion of this map terminates beyond second degree terms as a result of (3.31) and (3.33). This expansion is given explicitly by the relations

$$\bar{q} = q + \beta(\alpha q - \beta p)^2 = q + \alpha^2\beta q^2 - 2\alpha\beta^2 qp + \beta^3 p^2, \tag{29.3.35}$$

$$\bar{p} = p + \alpha(\alpha q - \beta p)^2 = p + \alpha^3 q^2 - 2\alpha^2\beta qp + \alpha\beta^2 p^2. \tag{29.3.36}$$

In this case the full map $\mathcal{M}_{gq}$ takes a form which we will call $\mathcal{M}_{ffq}$ to indicate that it is a *quadratic* map that has a *finite* product *factorization.*

Action of $\mathcal{M}_{ffq}$:

$$\overset{\equiv}{q} = d + rq + sp + (r\alpha^2\beta + s\alpha^3)q^2 - 2(r\alpha\beta^2 + s\alpha^2\beta)qp + (r\beta^3 + s\alpha\beta^2)p^2, \tag{29.3.37}$$

$$\overset{\equiv}{p} = e + tq + up + (t\alpha^2\beta + u\alpha^3)q^2 - 2(t\alpha\beta^2 + u\alpha^2\beta)qp + (t\beta^3 + u\alpha\beta^2)p^2. \tag{29.3.38}$$

There are two properties of $\mathcal{M}_{ffq}$ that are worth noting. First we observe from (3.34) that $\mathcal{N}$ is invertible with the Lie representation

$$\mathcal{N}^{-1} = \exp : -(1/3)(\alpha q - \beta p)^3 :, \tag{29.3.39}$$

and in view of (3.31) and (3.33) the Taylor expansion of this inverse map also terminates beyond terms of degree two. From (2.4) we know that $\mathcal{T}$ is invertible, and (2.3) shows that $\mathcal{R}$ is invertible if R given by (2.8) satisfies $\det R \neq 0$. Therefore, from (2.5) we conclude that $\mathcal{M}_{ffq}$ is also invertible in this case,

$$\mathcal{M}_{ffq}^{-1} = \mathcal{N}^{-1}\mathcal{R}^{-1}\mathcal{T}^{-1}. \tag{29.3.40}$$

Moreover, it is easily verified that the Taylor expansion for $\mathcal{M}_{ffq}^{-1}$ also terminates beyond terms of degree two.

The second observation concerns the Jacobian matrix M_{ffq} of $\mathcal{M}_{ffq}$. The Jacobian matrix of $\mathcal{T}$ is the identity I and the Jacobian matrix of $\mathcal{R}$ is R. Let N be the Jacobian matrix of $\mathcal{N}$. Then from (2.5) and the chain rule we have the matrix relation

$$M_{ffq} = IRN. \tag{29.3.41}$$

Since in this case $\mathcal{N}$ is a symplectic map, N will be a symplectic matrix and therefore have determinant one. It follows that the determinant of M_{ffq} in this case satisfies the relation

$$\det M_{ffq} = \det R. \tag{29.3.42}$$

We see that the imposition of the requirement that $\mathcal{M}_{qg}$ be factorable into a *finite* product of Lie transformations leads generically to the result that the determinant of its Jacobian matrix must be constant, and cannot depend on where in phase space it is evaluated. Such maps are sometimes called *Cremona* maps. However, we shall use this designation to refer to maps that are both symplectic and polynomial (have Taylor series that terminate beyond some finite order). See Section 29.6.

There is one other important observation to be made. We have seen that requiring that $\mathcal{N}$ have a finite number of Lie factors generically forces $\mathcal{N}$ to be symplectic, which in turn forces N to have a constant (unit) determinant. What if we reverse the situation, and require that N have a constant determinant? From (2.1) we find that N has the form

$$N = \begin{pmatrix} (1+2b_1q+2b_2p) & (2b_2q+2b_3p) \\ (2c_1q+2c_2p) & (1+2c_2q+2c_3p) \end{pmatrix}; \tag{29.3.43}$$

and its determinant is of the form

$$\det N = 1 + \text{ linear terms } + \text{ quadratic terms} \tag{29.3.44}$$

with

$$\text{linear terms } = (2b_1+2c_2)q + (2b_2+2c_3)p, \tag{29.3.45}$$

$$\text{quadratic terms } = 4q^2(b_1c_2 - b_2c_1) + 4qp(b_1c_3 - b_3c_1) + 4p^2(b_2c_3 - b_3c_2). \tag{29.3.46}$$

Forcing N to have constant determinant yields the relations

$$b_1 + c_2 = 0 \text{ or } c_2 = -b_1, \tag{29.3.47}$$

$$b_2 + c_3 = 0 \text{ or } b_2 = -c_3; \tag{29.3.48}$$

$$b_1c_2 - b_2c_1 = 0, \tag{29.3.49}$$

$$b_1c_3 - b_3c_1 = 0, \tag{29.3.50}$$

$$b_2c_3 - b_3c_2 = 0. \tag{29.3.51}$$

We see that (3.47) and (3.48) agree with (3.18) and (3.17); and (3.50) agrees with (3.22). Moreover, substituting (3.47) and (3.48) into (3.49) produces the relation

$$-b_1^2 + c_1c_3 = 0, \tag{29.3.52}$$

which agrees with (3.21); and substituting (3.47) and (3.48) into (3.51) produces the relation

$$-c_3^2 + b_1b_3 = 0, \tag{29.3.53}$$

which agrees with (3.23). It follows that the quantities b_1 through b_3 and c_1 through c_3 are again given by the relations (3.24) through (3.28). Thus, requiring $\mathcal{N}$ to have a constant Jacobian determinant is equivalent to requiring that $\mathcal{N}$ have a finite number of Lie factors, and vice versa. And either requirement forces $\mathcal{N}$ to be symplectic.

In the spirit of the previous section, let us classify maps $\mathcal{M}_{ffq}$ of the form given by (3.37) and (3.38). Upon replacement of $\overset{\equiv}{q}$ by $\bar{q}$ and $\overset{\equiv}{p}$ by $\bar{p}$, and after some algebraic rearrangement, these maps can be written as

Action of $\mathcal{M}_{ffq}$:

$$\bar{q} = d + rq + sp + (r\beta + s\alpha)(\alpha q - \beta p)^2,$$

$$\bar{p} = e + tq + up + (t\beta + u\alpha)(\alpha q - \beta p)^2. \tag{29.3.54}$$

We will seek a sequence of affine transformations that simplifies (3.54) as much as possible. This sequence will be quite long; patience on the part of the reader will be required.

Because of the special form of the nonlinear terms on the right side of (3.54), it is advantageous to make a linear change of variables even before dealing with the translation part. Define new variables z' and $\bar{z}'$ by the relations

$$z' = Az, \tag{29.3.55}$$

$$\bar{z}' = A\bar{z}, \tag{29.3.56}$$

where A is the matrix

$$A = \gamma^{-1} \begin{pmatrix} \alpha & -\beta \\ \beta & \alpha \end{pmatrix} \tag{29.3.57}$$

with

$$\gamma = (\alpha^2 + \beta^2)^{1/2}. \tag{29.3.58}$$

Evidently A is symplectic and orthogonal so that it has the inverse

$$A^{-1} = A^T = \gamma^{-1} \begin{pmatrix} \alpha & \beta \\ -\beta & \alpha \end{pmatrix}. \tag{29.3.59}$$

When this change of variables is made, $\mathcal{M}_{ffq}$ is transformed to the map that we will call $\mathcal{M}^*_{ffq}$. It takes the form

Action of $\mathcal{M}^*_{ffq}$:

$$\bar{q}' = d' + r'q' + s'p' + s'\gamma(q')^2, \tag{29.3.60}$$

$$\bar{p}' = e' + t'q' + u'p' + u'\gamma(q')^2, \tag{29.3.61}$$

where

$$d' = (\alpha d - \beta e)/\gamma, \tag{29.3.62}$$

$$e' = (\beta d + \alpha e)/\gamma, \tag{29.3.63}$$

$$r' = [\alpha^2 r - \alpha\beta(s + t) + \beta^2 u]/\gamma^2, \tag{29.3.64}$$

$$s' = [\alpha^2 s - \alpha\beta(-r + u) - \beta^2 t]/\gamma^2, \tag{29.3.65}$$

$$t' = [\alpha^2 t - \alpha\beta(-r + u) - \beta^2 s]/\gamma^2, \tag{29.3.66}$$

$$u' = [\alpha^2 u + \alpha\beta(s + t) + \beta^2 r]/\gamma^2. \tag{29.3.67}$$

Now seek the fixed points of the map $\mathcal{M}^*_{ffq}$ as given by (3.60) and (3.61). Upon dropping primes this map, again call it $\mathcal{M}^*_{ffq}$, takes the form

Action of $\mathcal{M}^*_{ffq}$:

$$\bar{q} = d + rq + sp + s\gamma q^2, \tag{29.3.68}$$

$$\bar{p} = e + tq + up + u\gamma q^2. \tag{29.3.69}$$

The fixed point equations, after completing squares, give the conditions

$$0 = [d - (r-1)^2/(4s\gamma)] + sp + s\gamma[q + (r-1)/(2s\gamma)]^2, \tag{29.3.70}$$

$$0 = [e - t^2/(4u\gamma)] + (u-1)p + u\gamma[q + t/(2u\gamma)]^2. \tag{29.3.71}$$

These two conditions describe two parabolas, both whose principal axes are parallel to the p axis. There are therefore (see Exercise 3.4) two finite fixed points with each fixed point having a multiplicity of one, or there is a single finite fixed point with multiplicity two. It can also happen that there is a single finite fixed point with multiplicity one. In addition there are two or three fixed points at infinity whose presence becomes apparent with the use of homogeneous coordinates.

Suppose the fixed-point equations (3.70) and (3.71) have a *real* solution, call it $\tilde{q}, \tilde{p}$. Again make a displacement change of variables of the form

$$q = q' + \tilde{q}\ ,\ \ p = p' + \tilde{p}; \tag{29.3.72}$$

$$\bar{q} = \bar{q}' + \tilde{q}\ ,\ \ \bar{p} = \bar{p}' + \tilde{p}. \tag{29.3.73}$$

With this change of variables the map $\mathcal{M}^*_{ffq}$ given by (3.68) and (3.69) is transformed to the origin preserving map $\mathcal{M}^{**}_{ffq}$ of the form

Action of $\mathcal{M}^{**}_{ffq}$:

$$\bar{q}' = r'q' + s'p' + s'\gamma(q')^2, \tag{29.3.74}$$

$$\bar{p}' = t'q' + u'p' + u'\gamma(q')^2, \tag{29.3.75}$$

where

$$r' = r + 2s\gamma\tilde{q}, \tag{29.3.76}$$

$$s' = s, \tag{29.3.77}$$

$$t' = t + 2u\gamma\tilde{q}, \tag{29.3.78}$$

$$u' = u. \tag{29.3.79}$$

Again dropping primes, the map now becomes

Action of $\mathcal{M}^{**}_{ffq}$:

$$\bar{q} = rq + sp + s\gamma q^2, \tag{29.3.80}$$

$$\bar{p} = tq + up + u\gamma q^2. \tag{29.3.81}$$

To continue assume, as a possible case, that R [see (2.8)] has real eigenvalues, and one can select an A such that R is diagonalized as in (2.35). When this is done, the map $\mathcal{M}^{**}_{ffq}$ is transformed to become the map $\mathcal{M}^{***}_{ffq}$ which takes the general form

Action of $\mathcal{M}^{***}_{ffq}$:

$$\bar{q} = \mu(q + b_1q^2 + 2b_2qp + b_3p^2), \tag{29.3.82}$$

$$\bar{p} = \nu(p + c_1q^2 + 2c_2qp + c_3p^2). \tag{29.3.83}$$

What can be said about the coefficients b_1 through b_3 and c_1 through c_3? Evidently the map $\mathcal{M}^{***}_{ffq}$ given by (3.82) and (3.83) has the Jacobian matrix M^{***}_{ffq} given by

$$M^{***}_{ffq} = \begin{pmatrix} \mu(1+2b_1q+2b_2p) & \mu(2b_2q+2b_3p) \\ \nu(2c_1q+2c_2p) & \nu(1+2c_2q+2c_3p) \end{pmatrix}. \tag{29.3.84}$$

Also, the changes of variables we have been making consist of making the *same* affine transformations on both z and $\bar{z}$. See, for example, (2.14), (2.15), (2.26), and (2.28). The determinants of their Jacobian matrices are all constant (z independent). Therefore, by the chain rule, these variable changes cannot alter the determinant of the Jacobian matrix of the various forms of $\mathcal{M}_{ffq}$, and there must be the relation

$$\det M^{***}_{ffq} = \det M_{ffq} = \det R. \tag{29.3.85}$$

From (3.84) we find the result

$$\det M^{***}_{ffq} = \mu\nu(1 + \text{ linear terms } + \text{ quadratic terms}), \tag{29.3.86}$$

and comparison with (3.43) and (3.44) shows that the linear terms and quadratic terms are the same as those given by (3.45) and (3.46). According to (3.85) these terms must vanish. Therefore, by a now familiar argument, the coefficients b_1 through b_3 and c_1 through c_3 must be given by relations of the form (3.24) through (3.28). Correspondingly, the map given by (3.82) and (3.83) takes the form

Action of $\mathcal{M}^{***}_{ffq}$:

$$\bar{q} = \mu(q + \alpha^2\beta q^2 - 2\alpha\beta^2 qp + \beta^3 p^2), \tag{29.3.87}$$

$$\bar{p} = \nu(p + \alpha^3 q^2 - 2\alpha^2\beta qp + \beta^2 p^2). \tag{29.3.88}$$

Let us make one last change of variables. Make the transformations

$$q' = \alpha^2\beta q\ ,\ p' = \alpha\beta^2 p; \tag{29.3.89}$$

$$\bar{q}' = \alpha^2\beta\bar{q}\ ,\ \bar{p}' = \alpha\beta^2\bar{p}. \tag{29.3.90}$$

Multiply both sides of (3.87) by $\alpha^2\beta$ and both sides of (3.88) by $\alpha\beta^2$. So doing gives the results

$$\alpha^2\beta\bar{q} = \mu(\alpha^2\beta q + \alpha^4\beta^2 q^2 - 2\alpha^3\beta^3 qp + \alpha^2\beta^4 p^2), \tag{29.3.91}$$

$$\alpha\beta^2\bar{p} = \nu(\alpha\beta^2 p + \alpha^4\beta^2 q^2 - 2\alpha^3\beta^3 qp + \alpha^2\beta^4 p^2). \tag{29.3.92}$$

In view of (3.89) and (3.90) these results can be rewritten in the form

$$\bar{q}' = \mu[q' + (q')^2 - 2q'p' + (p')^2] = \mu[q' + (q' - p')^2], \tag{29.3.93}$$

$$\bar{p}' = \nu[p' + (q')^2 - 2q'p' + (p')^2] = \nu[p' + (q' - p')^2]. \tag{29.3.94}$$

The map $\mathcal{M}^{***}_{ffq}$ has been *transformed* to become the final map $\mathcal{M}^{tr}_{ffq}$. Dropping the primes gives the final relations

Action of $\mathcal{M}^{tr}_{ffq}$:

$$\bar{q} = \mu[q + (q-p)^2]. \tag{29.3.95}$$

$$\bar{p} = \nu[p + (q-p)^2]. \tag{29.3.96}$$

Thanks to heroic effort, we have shown that if a map $\mathcal{M}_{ffq}$ given by relations of the form (3.37) and (3.38) has a real fixed point, and if the linear part of the map about this fixed point has two distinct real eigenvalues μ and ν, then under a suitable affine change of variables this map is equivalent to the transformed map $\mathcal{M}^{tr}_{ffq}$ given by the far simpler relations (3.95) and (3.96). Subsequently, in Sections 18.7 and 18.8, we will find that there is no loss of generality in the assumption we have made about the eigenvalues of the linear part. We will find that the map has a second fixed point, and that the other eigenvalue possibilities are realized by the linear part of the map about the second fixed point when, about the origin, the map has the form given by (3.95) and (3.96).

In summary, we conclude that the condition that the nonlinear part of $\mathcal{M}_{gq}$ have a finite number of Lie factors (or, equivalently, a constant Jacobian determinant) reduces the number of free nonlinear parameters (see the end of Section 18.2) from 4 to 0. Consequently, such maps are labelled completely by the *two* real parameters, μ and ν, that describe their linear (when brought to normal form) parts.

Exercises

29.3.1. Look again at Exercise 1.2.8. It examined the general single-complex-variable analytic quadratic map, which evidently depends on three complex parameters a, b, and c. Hence it depends on six real parameters. In addition, the exercise showed that, under the affine change of variables (1.2.115), this map could be brought to the simpler form (1.2.111) which depends on only one complex parameter μ, and hence on two real parameters. Moreover, Exercise 1.2.7 showed that this simpler form is equivalent to the complex logistic map which, according to (1.37) and (1.38), yields a two-parameter family of quadratic maps of the plane into itself.

In Section 24.2 we found that $\mathcal{M}_{gq}$, the general quadratic map in two variables, depends on twelve real parameters. See (2.13). Among these maps will be the two-parameter subset (1.37) and (1.38). We also found that, under a suitable affine change of variables, $\mathcal{M}_{gq}$ could be brought to the form $\mathcal{M}^{tr}_{gq}$ whose action is described by (2.42), and that $\mathcal{M}^{tr}_{gq}$ depends on six real parameters.

In this section we found that requiring $\mathcal{M}_{gq}$ to have a finite product Lie factorization produced the subset of maps $\mathcal{M}_{ffq}$ given by (3.54). This subset of maps is characterized by eight real parameters, namely d, e, r, s, t, u, α, and β. Also we found that these maps are globally invertible; and we found that under an affine transformation each could be brought to the two-parameter form $\mathcal{M}^{tr}_{ffq}$ described by (3.95) and (3.96). Show that, unlike $\mathcal{M}_{ffq}$, complex logistic maps are not globally invertible.

29.3.2. Find $\mathcal{N}$ for the complex logistic map given by (1.37) and (1.38), and show that it appears to have an infinite number of Lie factors.

29.3.3. Find the decomposition (3.6) using the machinery of Section 21.10.

29.3.4. Verify that the relations (3.9) through (3.16) follow from (3.4) and (3.5). Verify that the choice (3.17) and (3.18) reduces the set of relations (3.9) through (3.16) to the set of relations (3.21) through (3.23). Verify that they have the unique solutions (3.24) through (3.26). Explore what happens when one considers the non-generic possibilities for which a_3 and/or b_1 equal zero.

29.3.5. Exercise on fixed point counting.

29.4 Fixed Points

We have been studying two-variable quadratic maps. There is still more to be done on this subject, and we will do that in Sections 29.7 through 29.10. But before doing so, it is useful to interrupt our discussion to take up the study of fixed points for maps in general, and two-variable maps in particular. We will then be better prepared for our further study of two-variable quadratic maps, and we will also find important results having wide application.

29.4.1 Attack a Map at its Fixed Points

We have seen in Chapter 1 that maps, even the simplest maps, generally exhibit extremely complicated behavior under iteration so that it is difficult to know where to begin in characterizing them. One fruitful starting point for the analysis of a map is to find and classify its fixed points. As Poincaré wrote,

> ⋯ what renders these periodic solutions so precious is that they are, so to speak, the only breach through which we may try to penetrate a stronghold previously reputed to be impregnable.

This section and the next summarize some important aspects of fixed-point analysis.

29.4.2 Fixed Points are Generally Isolated

We begin by observing that the fixed points of a map are, in general, *isolated*. That is, if z^α is a fixed point of a map $\mathcal{M}$, then there is no other fixed point in a neighborhood of z^α providing this neighborhood is sufficiently small. To verify this result, assume the contrary: Suppose there is a second fixed point z^β in any neighborhood of z^α. Then we have the relations

$$\mathcal{M}z^\alpha = z^\alpha, \tag{29.4.1}$$

$$\mathcal{M}z^\beta = z^\beta, \tag{29.4.2}$$

$$z^\beta = z^\alpha + \delta, \tag{29.4.3}$$

where δ is a small vector. Taken together, (4.2) and (4.3) give the result

$$\mathcal{M}(z^\alpha + \delta) = z^\alpha + \delta. \tag{29.4.4}$$

Now let $\mathcal{L}_\alpha$ be the linear part of $\mathcal{M}$ at z^α so that there is the relation

$$\mathcal{M}(z^\alpha + \delta) = z^\alpha + \mathcal{L}_\alpha\delta + O(\delta^2) = z^\alpha + L_\alpha\delta + O(\delta^2). \tag{29.4.5}$$

Here L_α is the matrix that represents $\mathcal{L}_\alpha$. By combining (4.4) and (4.5) we find the result

$$L_\alpha \delta = \delta - O(\delta^2). \tag{29.4.6}$$

Since δ can be arbitrarily small (we have assumed *any* neighborhood), we conclude that L_α must have an eigenvector with eigenvalue +1, and hence

$$\det(L_\alpha - I) = 0. \tag{29.4.7}$$

In general, (4.7) will not be true. We conclude that if L_α does not have +1 as an eigenvalue, then z^α is an isolated fixed point of $\mathcal{M}$. Note that this analysis makes no assumption about the number of variables involved. In particular, it also holds for one-dimensional maps. See, for example, Exercise 1.2.1 where it was found that two fixed points for the logistic map coincided when the eigenvalue μ of the linear part took the value +1, but were isolated for all other values of μ.

If linear analysis is sufficient to demonstrate that a fixed point is isolated, we will call such a fixed point *manifestly* isolated. If (4.7) holds at a fixed point, a beyond linear analysis is required to determine whether or not it is isolated. A fixed point that requires beyond linear analysis to show that it is isolated might be called *expectant* since, as we will see in some examples, what often happens in this case is that as some parameter is varied an expectant fixed point gives birth to additional fixed points. In the analytic case, where complex analysis can be employed, these additional fixed points exist for all parameter values, but may be complex. They merge during the birth process to a common real point and then again separate while now remaining within the real domain. Finally, there are cases where a fixed point lies on a line, or in some higher dimensional domain, all of whose points are fixed points, and therefore such a fixed point is indeed not isolated.

29.4.3 Finding Fixed Points with Contraction Maps

To find a fixed point of $\mathcal{M}$ it is useful to construct a *contraction* map $\mathcal{C}$. Suppose z^{fx} is a *fixed* point of some map $\mathcal{M}$,

$$\mathcal{M} z^{fx} = z^{fx}, \tag{29.4.8}$$

and suppose z^e is an *arbitrary* point in the *vicinity* of z^{fx}. The contraction map will be shown to have the remarkable property

$$\lim_{n\to\infty} \mathcal{C}^n z^e = z^{fx}. \tag{29.4.9}$$

That is, a good guess as to the location of a fixed point is sufficient starting information to contract in on it exactly.

The construction of $\mathcal{C}$ is a generalization of Newton's method to the case of several variables. Suppose z^α is an arbitrary point, and suppose it is sent to the point z^β under the action of $\mathcal{M}$,

$$\mathcal{M} z^\alpha = z^\beta. \tag{29.4.10}$$

Let $\mathcal{L}_\alpha$ be the linear part of $\mathcal{M}$ at z^α. That is, $\mathcal{L}_\alpha$ has the property

$$\mathcal{M}(z^\alpha + \delta) = z^\beta + \mathcal{L}_\alpha \delta + O(\delta^2) \tag{29.4.11}$$

where δ is small. Evidently the action of $\mathcal{L}_\alpha$ can be represented by a matrix L_{z^α},

$$\mathcal{L}_\alpha \delta = L_{z^\alpha}\delta. \tag{29.4.12}$$

(In the differential equation case this matrix is the solution to the *linear* variational equations when $z^d(t^i) = z^\alpha$. See Section 10.12) The map $\mathcal{C}$ is now defined by requiring that its action on the arbitrary point z^α be given by the rule

$$\mathcal{C}z^\alpha = z^\alpha - (I - L_{z^\alpha})^{-1}(z^\alpha - \mathcal{M}z^\alpha). \tag{29.4.13}$$

It is easily verified that $\mathcal{C}$ as defined by (4.13) has the advertised property (4.9). First, suppose that z^{fx} is a fixed pont of $\mathcal{M}$. Then, from (4.13), z^{fx} is also a fixed point of $\mathcal{C}$,

$$\mathcal{C}z^{fx} = z^{fx}. \tag{29.4.14}$$

Next, suppose that z^e is some point in the vicinity of z^{fx}. Then z^e is of the form

$$z^e = z^{fx} + \delta \tag{29.4.15}$$

where δ is small. Upon inserting (4.15) into (4.13), we find after a short calculation the result

$$\begin{aligned} \mathcal{C}z^e &= \mathcal{C}(z^{fx}+\delta) = z^{fx} + \delta - (I - L_{z^{fx}+\delta})^{-1}[(z^{fx}+\delta) - \mathcal{M}(z^{fx}+\delta)] \\ &= z^{fx} + \delta - (I - L_{z^{fx}+\delta})^{-1}[(I - L_{z^{fx}})\delta + O(\delta^2)] = z^{fx} + O(\delta^2). \end{aligned} \tag{29.4.16}$$

Here we have used the relation

$$\mathcal{M}(z^{fx}+\delta) = z^{fx} + L_{z^{fx}}\delta + O(\delta^2) \tag{29.4.17}$$

and the observation that

$$L_{z^{fx}+\delta} = L_{z^{fx}} + O(\delta). \tag{29.4.18}$$

Thus, according to (4.16), although the initial point z^e differs from the desired fixed point z^{fx} by an amount δ, the point $\mathcal{C}z^e$ differs from the point z^{fx} only by an amount of order δ^2. Similarly, the point $\mathcal{C}^2z^e$ difffers from z^{fx} only by an amount of order $(\delta^2)^2$, and $\mathcal{C}^nz^e$ differs from z^{fx} only by an amount of order δ^{2^n}. Consequently, as expected for Newton's method, the convergence of the limit (4.9) to z^{fx} is extremely fast. Note also that Newton's method succeeds even if z^{fx} is *not* an attractor. Indeed, any isolated fixed point of $\mathcal{M}$, whether stable or unstable, is a super stable fixed point of $\mathcal{C}$. See Exercise 1.2.1.

In order to complete the discussion it is necessary to check whether the matrix $(I - L_{z^{fx}})$ has an inverse. Evidently the inverse exists provided the related determinant satisfies the condition

$$\det(L_{z^{fx}} - I) \neq 0. \tag{29.4.19}$$

That is, the matrix $L_{z^{fx}}$ does not have +1 as an eigenvalue. (As we have seen, this requirement is sufficient to guarantee that z^{fx} be isolated.) Therefore, the procedure (4.9) will succeed as long as z^e is sufficiently close to z^{fx} and L_{z^e} does not have +1 as an eigenvalue for all z^e in the vicinity of z^{fx}.

29.4.4 Persistence of Fixed Points

Even more can be said. Suppose the map $\mathcal{M}$ has a fixed point. Do maps near $\mathcal{M}$ (in map space) also have fixed points? Suppose $\mathcal{M}$ has the fixed point z^{fx}, and that $\mathcal{M}'$ is a map near $\mathcal{M}$. Let us speculate that $\mathcal{M}'$ has a fixed point of the form $z^{fx} + \Delta$ where Δ is small,

$$\mathcal{M}'(z^{fx} + \Delta) \overset{?}{=} z^{fx} + \Delta. \tag{29.4.20}$$

Define a map $\mathcal{N}$ by the equation

$$\mathcal{N} = \mathcal{M}^{-1}\mathcal{M}' \tag{29.4.21}$$

so that we have the relation

$$\mathcal{M}' = \mathcal{M}\mathcal{N}. \tag{29.4.22}$$

Since $\mathcal{M}'$ is assumed to be near $\mathcal{M}$, $\mathcal{N}$ is a map near the identity map. Inserting (4.22) in (4.20) gives the hypothesis

$$\mathcal{M}\mathcal{N}(z^{fx} + \Delta) \overset{?}{=} z^{fx} + \Delta. \tag{29.4.23}$$

However, since $\mathcal{N}$ is near the identity map, we must have a result of the form

$$\mathcal{N}(z^{fx} + \Delta) = z^{fx} + \Delta + \tilde{\Delta} \tag{29.4.24}$$

where $\tilde{\Delta}$ is also small. Therefore, we now have the equivalent speculation

$$\mathcal{M}(z^{fx} + \Delta + \tilde{\Delta}) \overset{?}{=} z^{fx} + \Delta. \tag{29.4.25}$$

However, using the relation (4.17), we may rewrite (4.25) in the form

$$z^{fx} + L_{z^{fx}}(\Delta + \tilde{\Delta}) \overset{?}{=} z^{fx} + \Delta, \tag{29.4.26}$$

which is equivalent to the speculation

$$(I - L_{z^{fx}})\Delta \overset{?}{=} L_{z^{fx}}\tilde{\Delta}. \tag{29.4.27}$$

(Here we have omitted higher order terms in Δ and $\tilde{\Delta}$.) We see that (4.27) can be solved for Δ, and therefore our speculation is correct, provided the matrix $(I - L_{z^{fx}})$ is invertible. We conclude that if $\mathcal{M}$ is varied over some path in map space and $\mathcal{M}$ initially has a fixed point, then its fixed point persists and moves over some path in z space, provided that over that path $L_{z^{fx}}$ never has +1 as an eigenvalue.[1]

Suppose the path in map space and the corresponding path in z space are parameterized by some parameter τ. That is, we write $\mathcal{M} = \mathcal{M}(\tau)$, and suppose that for each value of τ the map $\mathcal{M}(\tau)$ has the fixed point $z^{fx}(\tau)$. We will now show that there is a differential equation, whose solution is $z^{fx}(\tau)$, that can be used to "track" z^{fx} as τ is varied.

In the spirit of Section 6.4.2, make the action of $\mathcal{M}(\tau)$ explicit by writing the relations

$$\bar{z}_a(\tau) = u_a(z, \tau). \tag{29.4.28}$$

[1] See Exercise 9.2.6 for an $ISp(2n, \mathbb{R})$ example of this result.

Again define functions $w_a(z,\tau)$ by the rule

$$w_a(z,\tau) = \partial u_a(z,\tau)/\partial\tau. \tag{29.4.29}$$

By definition the fixed point $z^{fx}(\tau)$ obeys the relation

$$z_a^{fx}(\tau) = u_a(z^{fx}(\tau),\tau). \tag{29.4.30}$$

Since (4.30) is presumed to hold for a range of τ values, there is also the relation

$$z_a^{fx}(\tau+d\tau) = u_a(z^{fx}(\tau+d\tau),\tau+d\tau). \tag{29.4.31}$$

The left side of (4.31) has the expansion

$$z_a^{fx}(\tau+d\tau) = z_a^{fx}(\tau) + (dz_a^{fx}/d\tau)d\tau. \tag{29.4.32}$$

The right side of (4.31) has the expansion

$$u_a(z^{fx}(\tau+d\tau),\tau+d\tau) = u_a(z^{fx}(\tau),\tau) + d\tau[\partial u_a/\partial\tau + \sum_b(\partial u_a/\partial z_b)(dz_b^{fx}/d\tau)]. \tag{29.4.33}$$

Equating powers of $d\tau$ in (4.31) through (4.33) and using (4.30) gives the result

$$dz_a^{fx}/d\tau = \partial u_a/\partial\tau + \sum_b(\partial u_a/\partial z_b)(dz_b^{fx}/d\tau). \tag{29.4.34}$$

The second term on the right side of (4.34) contains L, the Jacobian matrix for the map $\mathcal{M}$,

$$L_{ab} = \partial u_a/\partial z_b. \tag{29.4.35}$$

Consequently with the aid of (4.29) and (4.35), and employing vector and matrix notation, the relation (4.34) can also be written in the form

$$(I-L)(dz^{fx}/d\tau) = w. \tag{29.4.36}$$

Finally, again under the assumption the $(L-I)$ is invertible, we obtain the desired result,

$$dz^{fx}/d\tau = (I-L_{z^{fx}})^{-1}w(z^{fx},\tau). \tag{29.4.37}$$

Of course, to solve (4.37) requires an initial condition. That is, we must know $z^{fx}(\tau^i)$ for some initial τ^i. It might be possible to choose τ^i in such a way that $\mathcal{M}(\tau^i)$ has an obvious fixed point, perhaps by construction. Or it might be necessary to do a Newton search or apply some other procedure to find $z^{fx}(\tau^i)$.

Suppose the map in question arises from integrating a differential equation with independent variable t and parameter dependence τ. Then the map will be of the form $\mathcal{M} = \mathcal{M}(t;\tau)$. If we simply wish to find a fixed point for a specified value of τ using Newton's method, then the required Jacobian matrix L could be found by simultaneously integrating the variational equations. See Exercise 4.6 of Section 1.4. We could write a computer program with two nested loops. The inner loop would integrate the equations of motion along with the variational equations in order to compute $\mathcal{M}z$ and L. These are the required ingredients for $\mathcal{C}$. The outer loop would apply $\mathcal{C}$ to achieve a Newton iteration.

If we wish to find a fixed point for a range of τ values, then in this case the Jacobian matrix L and the vector w could be found by integrating "augmented" variational equations where deviations are made in both the original phase-space variables z and the parameter τ. That is, the set of variables and associated variational equations would be enlarged. See Section 10.12.6. We could again write a computer program with two nested loops. Now the inner loop would integrate the equations of motion along with the augmented variational equations in order to compute L and w, and the outer loop would integrate the equations (4.36).

29.4.5 Application to Accelerator Physics

The fixed-point considerations we have described so far have implications for accelerator physics. Suppose $\mathcal{M}$ is the one-turn map for a circular machine. Then a fixed point of $\mathcal{M}$ corresponds to a closed orbit. We know that L is the Jacobian matrix for the map $\mathcal{M}$. (Elsewhere, we have sometimes denoted this Jacobian matrix by the symbols M or R.) In the case that $\mathcal{M}$ is a symplectic map, L will be a symplectic matrix. According to Section 3.4, all the eigenvalues of a symplectic matrix generally differ from +1. Moreover, an eigenvalue taking on the value +1 corresponds to an integer tune. See (3.5.39) and (3.5.40) of Section 3.5. Suppose $\mathcal{M}^{\text{ideal}}$ is the one-turn map for an ideal machine operating at its design energy, and suppose the design tunes do not have integer values. By design, the ideal machine has a closed orbit and therefore $\mathcal{M}^{\text{ideal}}$ has a fixed point. Moreover, this fixed point is isolated since the design tunes are assumed to not have integer values. Now, the difference between an ideal machine operating at its design energy and the imperfect machine realized in actual construction and operating at some nearby energy may be regarded as the result of a variation in $\mathcal{M}^{\text{ideal}}$. Consequently, according to the previous discussion, if the tunes for the closed design orbit in the ideal machine have noninteger values, then the imperfect machine will also have a closed orbit at the design energy (and other nearby energies as well) provided the perturbations in the machine lattice are not so large as to drive some tune to an integer value. In particular, small imperfections in a machine lattice, such as arise from magnet misalignment and misplacement, magnet under or over powering, magnetic fringe fields and general magnetic field inhomogeneities, etc., do not destroy the existence of a closed orbit but merely cause it to be slightly distorted. (See also Exercise 3.4.3.) Therefore, in accelerator physics, integer tunes should be avoided in order to assure the continued existence of a closed orbit under unavoidable perturbations/imperfections.

Exercises

29.4.1. A function f is called *invariant* under the action of a map $\mathcal{M}$ if it has the property

$$f(\mathcal{M}z) = f(z). \tag{29.4.38}$$

[See Section 5.2 and review the discussion surrounding (7.1.12).] For our definition to have significance, we exclude the trivial case where f is simply a constant function (which will always be invariant) and therefore assume that ∇f is generally nonzero. An invariant function is also called an *integral* of $\mathcal{M}$.

Suppose the map $\mathcal{M}$ has the manifestly isolated fixed point z^α, and also has an integral f. You are to prove that then $\nabla f = 0$ at this point. Show from (4.38) that for arbitrary δ there is the relation

$$f[\mathcal{M}(z^\alpha + \delta)] = f(z^\alpha + \delta). \tag{29.4.39}$$

Next show from (4.5) that for small δ there is the relation

$$f[z^\alpha + L_\alpha \delta + O(\delta^2)] = f(z^\alpha + \delta). \tag{29.4.40}$$

Now expand both sides of (4.40) in a Taylor series to get the result

$$f(z^\alpha) + (L_\alpha \delta) \cdot \nabla f = f(z^\alpha) + \delta \cdot \nabla f + O(\delta^2), \tag{29.4.41}$$

from which it follows that

$$[(L_\alpha - I)\delta] \cdot \nabla f = 0. \tag{29.4.42}$$

Suppose that $(L_\alpha - I)$ is invertible. Let ϵ be an arbitrary vector and specify δ by the relation

$$\delta = (L_\alpha - I)^{-1}\epsilon. \tag{29.4.43}$$

Deduce the relation

$$\epsilon \cdot \nabla f = 0. \tag{29.4.44}$$

Since ϵ is assumed to be arbitrary, it must follow that $\nabla f = 0$ at the point z^α. Therefore ∇f must vanish at any manifestly isolated fixed point. Conversely, suppose (as we would generally like to be the case) that ∇f does not vanish at some fixed point z^α. Then, $(L_\alpha - I)$ must not be invertible, $\det(L_\alpha - I)$=0 and hence L_α has +1 as an eigenvalue, and z^α is not manifestly isolated. For example, if $\mathcal{M}$ arises from integrating Hamilton's equations of motion for a time-independent Hamiltonian H, then H is an integral and the L_α for any periodic orbit must have +1 as an eigenvalue. Moreover, since L_α is symplectic in the Hamiltonian case, this eigenvalue must have even multiplicity (generally two, but possibly higher). See Section 3.4.

29.4.2. Consider the map $\mathcal{M}$ given by the relations

$$\bar{q} = q, \tag{29.4.45}$$

$$\bar{p} = p + q. \tag{29.4.46}$$

Show that $\mathcal{M}$ has the origin as a fixed point and that the linear part of $\mathcal{M}$ about the origin is given by the matrix (3.8.28). Verify that this matrix has eigenvalue +1. Show that all points on the p axis are fixed points of $\mathcal{M}$, and thus the origin is not an isolated fixed point. Review Exercise 4.1. Show that the function f given by

$$f(z) = q \tag{29.4.47}$$

is an invariant function under the action of $\mathcal{M}$, and that ∇f does not vanish anywhere despite the existence of all these fixed points.

29.4.3. The logistic map (1.2.5) has the fixed points (1.2.8) and (1.2.9). Verify that these fixed points obey (4.37) when λ is taken to to be the parameter.

29.5 Poincaré Index

For the two-dimensional case the study of the nature of fixed points is facilitated by use of the Poincaré index. It is defined as follows: Use the map $\mathcal{M}$ to produce a vector $v(z)$ at each point z in phase space by the rule

$$v(z) = \mathcal{M}z - z. \tag{29.5.1}$$

Geometrically, $v(z)$ is the vector that extends from z to $\mathcal{M}z$. By construction, $v(z)$ vanishes if and only if z is a fixed point of $\mathcal{M}$. Now consider the two-dimensional case, and let z^α be an isolated fixed point of $\mathcal{M}$. Draw a circle c around z^α small enough that no other fixed points are enclosed and none of the points on the circle itself are fixed points. The vector $v(z)$ for all points z on c can never vanish because, by hypothesis, none of the points on the circle are fixed points. Moreover, since $\mathcal{M}$ is assumed to be continuous, this vector will vary continuously over c. For each point z on c draw, in a separate plane, a vector that is parallel to $v(z)$ and has its tail at the origin. See Figure 5.1. Start at some point on c and traverse c once in the counterclockwise direction to return to this starting point. The "translated" vector $v(z)$ in the separate plane will then vary continuously as well, and will ultimately return to its starting value. The *Poincaré index* of the fixed point z^α is defined to be the number of counterclockwise revolutions that this vector undergoes as c is traversed once in the counterclockwise direction. Evidently the Poincaré index will be a positive or negative *integer* or *zero*. Moreover, its value would be unchanged had we chosen to traverse c in the clockwise direction and correspondingly counted the number of revolutions made by v in the clockwise direction. Finally, if c is continuously deformed to become another closed curve c', the index remains unchanged provided all the intermediate closed curves and the final closed curve c' contain no fixed points.

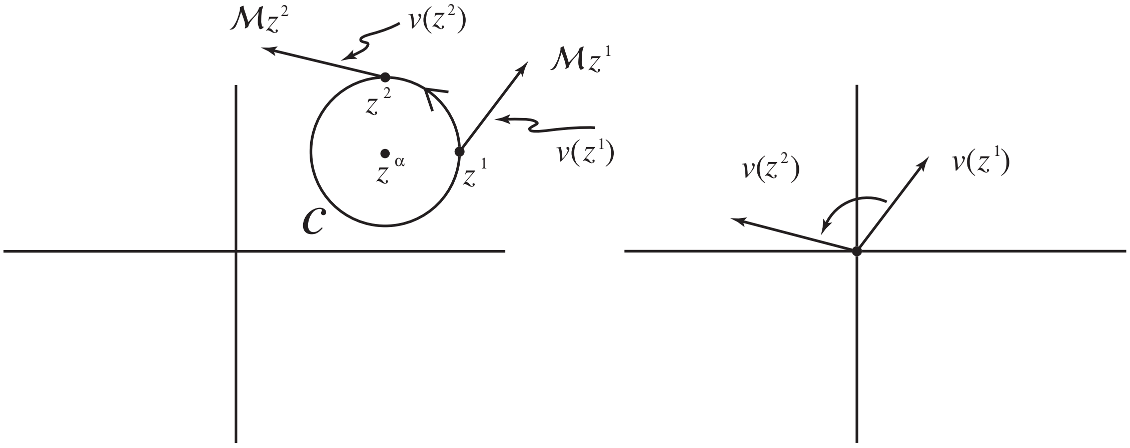

Figure 29.5.1: The isolated fixed point z^α surrounded by a small circle c and the associated vectors $v(z)$ drawn from the common origin (0,0).

If the circle c about the isolated fixed point z^α is small enough, the behavior of $\mathcal{M}$ for $z \in c$ is well approximated by the linear part of $\mathcal{M}$ at z^α; and (since the index is known to be an integer) this approximation can be used to compute the index of z^α. That is, the index of z^α is completely determined by the nature of the matrix L_α.

To see this suppose z^α is a fixed point and $z = z^\alpha + \delta$ is a nearby point. We then have from (4.5) and (5.1) the result

$$v(z) = \mathcal{M}z - z = (L_\alpha - I)\delta + O(\delta^2). \tag{29.5.2}$$

Now let δ be sufficiently small so that terms of order δ^2 can be neglected. It is easily verified that as the points δ traverse a circle about the origin, the points $(L_\alpha - I)\delta$ will, in general, traverse an ellipse about the origin provided $(L_\alpha - I)$ is invertible. (Here we assume that z^α is manifestly isolated.) Moreover, the circle and ellipse will be traversed in the *same* sense if $\det(L_\alpha - I) > 0$, and in the *opposite* sense if $\det(L_\alpha - I) < 0$. See Exercise 5.1. Finally, suppose that N is the normal form of L_α. That is, there is the relation

$$L_\alpha = ANA^{-1} \tag{29.5.3}$$

where A is a matrix that brings L_α to normal form. Then there is also the relation

$$L_\alpha - I = A(N - I)A^{-1}, \tag{29.5.4}$$

and consequently

$$\det(L_\alpha - I) = \det(N - I). \tag{29.5.5}$$

Therefore the index of z^α depends only on the normal form N of L_α, which in turn depends only on the spectrum of L_α. Specifically, the index of z^α is $+1$ if $\det(N - I) > 0$, and -1 if $\det(N - I) < 0$.

As in Section 3.4, let λ_1 and λ_2 be the eigenvalues of L_α. Then (under the assumption that $\mathcal{M}$ is orientation preserving so that $\det L_\alpha > 0$), there are the following possibilities, and for each possibility it is a simple matter to compute the sign of $\det(N - I)$ to determine the index:

1. Both λ_1 and λ_2 are real and positive. For this case the normal forms N for L_α are

$$N = \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix} \text{ if } \lambda_1 \neq \lambda_2 \text{ or } \lambda_1 = \lambda_2 \text{ but } L_\alpha \text{ is diagonalizable,} \tag{29.5.6}$$

$$N = \begin{pmatrix} \lambda & 1 \\ 0 & \lambda \end{pmatrix} \text{ if } \lambda_1 = \lambda_2 = \lambda \text{ and } L_\alpha \text{ is not diagonalizable.} \tag{29.5.7}$$

For this case there are 4 subcases:

(a) Both $0 < \lambda_1 < 1$ and $0 < \lambda_2 < 1$. In this subcase z^α is called *attracting*. It is also sometimes called a *node*. The normal forms N for L_α are either (5.6) or (5.7). The index in this subcase is $+1$.

(b) Both $\lambda_1 > 1$ and $\lambda_2 > 1$. In this subcase z^α is called *repelling*. The possible normal forms are again given by (5.6) and (5.7). The index in this subcase is $+1$.

(c) One eigenvalue, say λ_1, satisfies $0 < \lambda_1 < 1$ and the other satisfies $\lambda_2 > 1$. In this subcase z^α is called *hyperbolic*, and the normal form is given by (5.6). It is also sometimes called a *saddle*. The index in this subcase is -1.

   (d) At least one eigenvalue is 0 or is +1. The first possibility is excluded by the requirement $\det L_\alpha > 0$, and the second (which is called *parabolic*) is excluded by the requirement that z^α be manifestly isolated.

2. Both λ_1 and λ_2 are real and negative. For this case there are 4 subcases:

   (a) Both $\lambda_1 < -1$ and $\lambda_2 < -1$. In this subcase z^α is called *inversion repelling*. The possible normal forms are given by (5.6) or (5.7). The index in this subcase is +1.

   (b) Both $-1 < \lambda_1 < 0$ and $-1 < \lambda_2 < 0$. In this subcase z^α is called *inversion attracting*, and the possible normal forms are given by (5.6) or (5.7). The index in this subcase is +1.

   (c) One eigenvalue, say λ_1, satisfies $-1 < \lambda_1 < 0$ and the other satisfies $\lambda_2 < -1$. In this subcase z^α is called *inversion hyperbolic*, and the normal form is given by (5.6). The index in this case is +1.

   (d) One or both eigenvalues is -1. In this subcase z^α is called *inversion parabolic*, and the normal form is given by (5.6) or (5.7). The index in this subcase is +1.

3. Both λ_1 and λ_2 are complex. Since L_α is a real matrix, its eigenvalues will in fact be complex conjugate so that they can be written in the form

$$\lambda_1 = \mu e^{i\phi}, \tag{29.5.8}$$

$$\lambda_2 = \mu e^{-i\phi}, \tag{29.5.9}$$

   with

$$\mu > 0. \tag{29.5.10}$$

   In this case the normal form is given by

$$N = \mu \begin{pmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{pmatrix}. \tag{29.5.11}$$

   There are now 3 subcases:

   (a) The quantity μ satisfies $\mu > 1$. In this subcase z^α is called *repelling*. The index is +1.

   (b) The quantity μ satisfies $0 < \mu < 1$. In this subcase z^α is called *attracting*. It is also sometimes called a *node*. The index is +1.

   (c) The quantity μ satisfies $\mu = 1$. (We also must then have $\phi \neq 2n\pi$ because, if not, $N = I$, which in turn implies $L_\alpha = I$ so that L_α has +1 as an eigenvalue contrary to the requirement that z^α be manifestly isolated. See Exercise 5.2.) In this subcase z^α is called *elliptic*. The index is +1.

We conclude that the Poincaré index of a manifestly isolated fixed point z^α is always $+1$ unless z^α is hyperbolic, in which case the index is -1.

Let C be a closed curve that may surround several manifestly isolated fixed points, but does not itself contain any fixed points. That is, no points on C are fixed. We have seen how to define the index of a manifestly isolated fixed point. We will now see that we can also define the index of C. By assumption the vector $v(z)$ given by (5.1) does not vanish on C, and therefore we may count the number of counterclockwise revolutions it makes as C is traversed once in the counterclockwise direction. Call this (integer or zero) number the index of C. As before, the index of C does not change if C is continuously deformed as long as no enclosed fixed points are crossed during the deformation process.

Let n^+ and n^- be the number of fixed points, all surrounded by C, with indices $+1$ and -1, respectively. Then there is the remarkable relation

$$\text{index of } C = n^+ - n^-. \tag{29.5.12}$$

That is, the index of C is the sum of the indices of the fixed points it surrounds. To verify this result, shrink C in a manner analogous to contour integration in such a way that none of the enclosed fixed points are crossed as C is deformed to become C'. Then the index of C' will be the same as that of C. See Figure 5.2. Evidently the contributions to the index of C' made by the anti-parallel portions of C' cancel, and the only nonzero contributions are those made by the small loops around the enclosed fixed points. By the previous discussion, the contribution of each of these is ±1, and these contributions all add. Therefore (5.12) is correct.

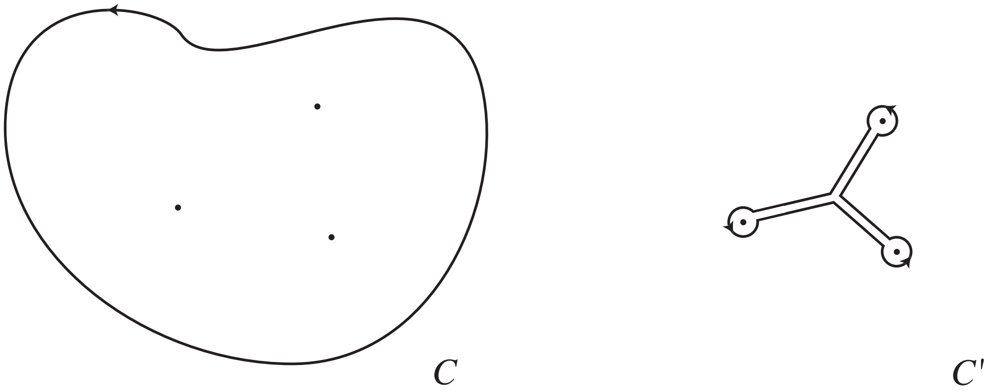

Figure 29.5.2: A closed curve C that surrounds several fixed points, and the curve C' formed by shrinking C.

As an illustration of how the index relation (5.12) can be employed, let us make a detour to consider again the stroboscopic Duffing map of Section 1.4.3 and Chapter 23. Multiply both sides of the Duffing equation of motion (23.1.1) by p and rearrange terms to find the result

$$p(\ddot{q} + q + q^3) = -2\beta p\dot{q} - \epsilon p \sin \omega\tau. \tag{29.5.13}$$

Define a quantity E, which may be viewed as the oscillator *energy*, by the rule

$$E = (1/2)p^2 + (1/2)q^2 + (1/4)q^4. \tag{29.5.14}$$

Then, recalling that $p = \dot{q}$, (5.13) can be rewritten in the form

$$dE/dt = -2\beta p^2 - \epsilon p \sin \omega \tau. \tag{29.5.15}$$

Correspondingly, ΔE, the change in E over one drive period, is given by the integral

$$\Delta E = \int_0^T (-2\beta p^2 - \epsilon p \sin \omega \tau) d\tau. \tag{29.5.16}$$

We next claim that if the initial conditions are such that E is initially sufficiently large (and "largeness" will depend on the values of the parameters β, ϵ, and ω), then ΔE will be negative. That is, there will be a net decrease in the energy over the course of a drive period. There are two reasons to believe this claim. Note that the first term in the integrand of (5.16) is always negative (we assume $\beta > 0$) while the second is generally oscillatory. If E is large, then we expect that p will be large over most of the driving period, and therefore the first term in the integrand will dominate the second since p^2 will generally greatly exceed the magnitude of p. Moreover, if the amplitude of oscillation is large, as it will be if E is large, then the frequency of oscillation will also be large (the frequency of oscillation increases with amplitude in the case of a hard spring) so that the integral over the second term will essentially average to zero.

Let us see how this works out by looking at a numerical example. Figure 5.3 shows two contours $C(E_j)$ in the q, p plane consisting of those points that satisfy (5.14) for the values $E_1 = 25$ and $E_2 = 100$. Also shown are selected (and labeled) points $z = (q, p)$ on the outer contour, their images $\mathcal{M}z$ under the action of the stroboscopic Duffing map $\mathcal{M}$, and the vector joining them. That is, the vectors $v(z)$ given by (5.1) are also shown. (For simplicity we have used the same values for β, ϵ, and ω as those employed in making the basins illustration, Figure 23.4.3.) Evidently all the vectors point inward and terminate on some lesser energy contour thereby indicating that $\Delta E < 0$ for all initial conditions that lie on the outer contour, as desired. We further suppose that $\Delta E < 0$ for all initial conditions that lie on all other contours $C(E_k)$ having $E_k > E_2$. By the above discussion we know this will be true if E_2 is large enough. From this supposition we infer that all fixed points of $\mathcal{M}$, if any, must lie within the inner region bounded by the outer contour. For imagine some fixed point lay outside the contour $C(E_2)$. Then there must be some contour $C(E_\ell)$, with $E_\ell > E_2$, on which this fixed point lies. But, if we use this fixed point as an initial condition, we must have $\Delta E = 0$ since for this point $\mathcal{M}z = z$ and therefore E cannot change. We have arrived at a contradiction; therefore no fixed points lie outside $C(E_2)$. Similarly we conclude that, for each choice of the parameters β, ϵ, and ω (with $\beta > 0$), the fixed points of $\mathcal{M}$ must lie within a bounded region of phase space surrounding the origin.

Even more can be said. Figure 5.4 shows the vectors $v(z)$ labeled and drawn from a common origin as in Figure 5.1. Evidently these vectors make one counterclockwise revolution as the points on $C(E_2)$ make one counterclockwise revolution. We conclude that, for any choice of $\beta > 0$, ϵ, and ω, the index of $C(E_2)$ is $+1$ providing E_2 is large enough. Therefore, by (5.12), the stroboscopic Duffing map must have at least one fixed point for each choice of parameters, and the number of fixed points with positive index must exceed by one the number with negative index. Observe that all the fixed points described in Chapter 23 have this property.

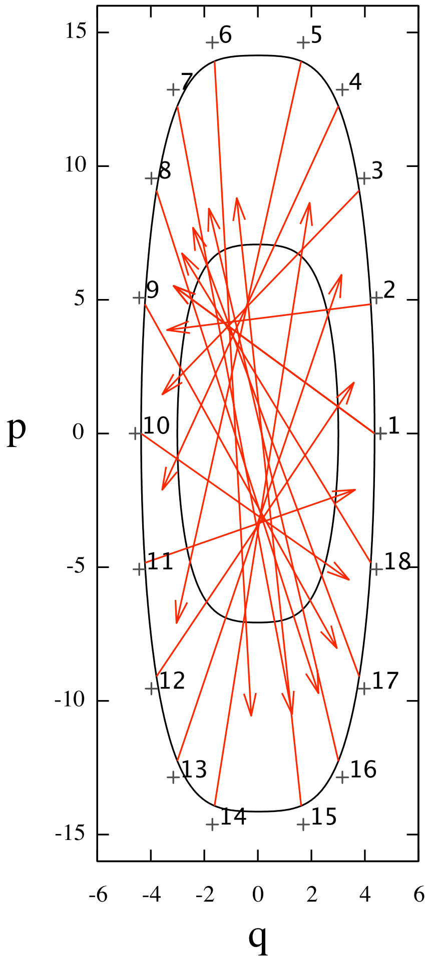

Figure 29.5.3: The contours $C(E_1)$ (inner) and $C(E_2)$ (outer) for the values $E_1 = 25$ and $E_2 = 100$. Also shown are the vectors $v(z)$ for selected (and labeled) points z on $C(E_2)$. Observe that all vectors point inward and terminate on some lesser (inner) energy contour. The Duffing parameters have the values $\omega = 2.25$, $\beta = .1$, and $\epsilon = 1.5$.

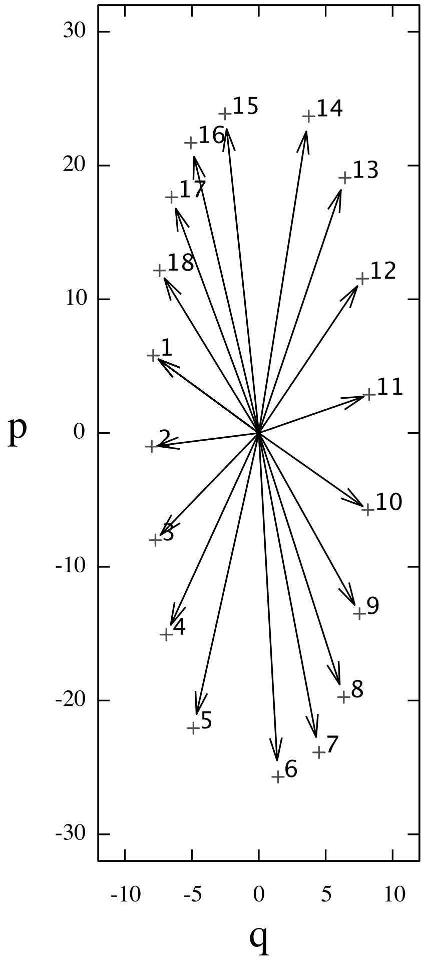

Figure 29.5.4: The vectors $v(z)$ of Figure 5.3 labeled and drawn from the common origin $(0, 0)$. As the points z on $C(E_2)$ make one counterclockwise revolution, the vectors $v(z)$ undergo one counterclockwise revolution, thereby indicating that $C(E_2)$ has index $+1$.

Let us return to our main discussion. From what we have learned it follows that fixed points cannot be born or die (disappear) singly as some parameter τ in a problem is varied. To see this, surround the region where the fixed point is to be born or die by some closed curve C that is free of fixed points (and therefore has a well-defined index) and surrounds no other fixed points. Before the fixed point is born or after it dies, the index of C will be zero. (Reader, verify that the index of a closed curve that can be deformed to a point without encountering any fixed points must be zero.) But since the index is also a continuous function of τ, it must remain zero as τ is varied, and therefore no single fixed point can appear or disappear inside C. Instead, fixed points must be born or die in pairs, and the two fixed points in a pair must be initially infinitesimally nearby and have opposite indices. Moreover, from the discussion leading to (4.7), an eigenvalue of L_α must have the value $+1$ at the birth or death of a pair. This is what occurs at saddle-node bifurcations. As an example, again see the discussion of the Duffing stroboscopic map in Chapter 23.

It can also happen that the index of a fixed point can change as some parameter is varied. If this happens, additional fixed points with compensating indices must also be born or disappear infinitesimally nearby in such a way that the sum of all the indices remains unchanged. This is what occurs at pitchfork bifurcations. Once again see the discussion of the Duffing stroboscopic map in Chapter 23.

The tools used to analyze the fixed points of a map $\mathcal{M}$ can also be applied to analyze the fixed points of $\mathcal{M}^2$. Suppose z_f is a fixed point of $\mathcal{M}$ so that we may write

$$\mathcal{M}(z_f+\delta)=z_f+L_f\delta+O(\delta^2) \tag{29.5.17}$$

where L_f is the linear part of $\mathcal{M}$ about the point z_f. The map $\mathcal{M}^2$ will also have z_f as a fixed point, and we find the relation

$$\mathcal{M}^2(z_f+\delta)=\mathcal{M}(z_f+L_f\delta)+O(\delta^2)=z_f+(L_f)^2\delta+O(\delta^2). \tag{29.5.18}$$

We see that at a fixed point of $\mathcal{M}$ the linear part of $\mathcal{M}^2$ is the square of the linear part of $\mathcal{M}$. Moreover, if λ is an eigenvalue of L_f with associated eigenvector v, then we find that

$$(L_f)^2v=L_f\lambda v=\lambda^2v. \tag{29.5.19}$$

Thus, at a fixed point of $\mathcal{M}$ the eigenvalues of the linear part of $\mathcal{M}^2$ are the squares of the eigenvalues of the linear parts of $\mathcal{M}$.

Now suppose that z_f is initially stable and, as some parameter is varied, suppose also that some eigenvalue of L_f takes the value -1. Then we expect that z_f will become unstable, but will remain isolated. However, the linear part of $\mathcal{M}^2$ will have $+1$ as an eigenvalue, and we may expect bifurcation for $\mathcal{M}^2$ as some parameter is varied. After the bifurcation, $\mathcal{M}^2$ may be expected to have three fixed points. One of them will be the now unstable fixed point of $\mathcal{M}$ itself. The remaining two, call them z_a and z_b, will not be fixed points of $\mathcal{M}$ (since z_f remains isolated), but will have the property

$$\mathcal{M}z_a=z_b, \tag{29.5.20}$$

$$\mathcal{M}z_b=z_a, \tag{29.5.21}$$

from which it follows, of course, that

$$\mathcal{M}^2 z_a = \mathcal{M} z_b = z_a, \tag{29.5.22}$$

$$\mathcal{M}^2 z_b = \mathcal{M} z_a = z_b. \tag{29.5.23}$$

Thus, *period doubling* has occurred. Note that, strictly speaking, a period doubling bifurcation is not a bifurcation of $\mathcal{M}$, for there is only one fixed point of $\mathcal{M}$ both before and after the bifurcation. Rather, it is a bifurcation of $\mathcal{M}^2$, for there is one fixed point of $\mathcal{M}^2$ before the bifurcation (namely z_f), and three fixed points after the bifurcation (z_f, z_a, and z_b). Finally, from index considerations, z_a and z_b will be stable fixed points of $\mathcal{M}^2$. This must be true because, before the bifurcation, z_f had index $+1$ with respect to $\mathcal{M}^2$; and after the bifurcation, z_f must have index -1 with respect to $\mathcal{M}^2$. Thus, to preserve the total index, the fixed points z_a and z_b must have index $+1$ with respect to $\mathcal{M}^2$.

Note that this is what can happen if a storage ring is operated near a half-integer tune. Then, under perturbation, an eigenvalue pair can leave the unit circle through the value -1 so that the fixed point corresponding to the closed orbit becomes inversion hyperbolic. See Figure 3.4.1. The closed orbit persists under perturbation, but becomes unstable. At the same time, a pair of fixed points of $\mathcal{M}^2$ appears, and these fixed points are stable. Correspondingly, there are then two nearby stable orbits that close after *two* turns (but not one turn). Under normal circumstances such a situation is undesirable because the beam is then less well confined. A possible counter-situation might arise if one were thinking about beam extraction.

What can be said about the eigenvalues of the linear part of $\mathcal{M}^2$ at the fixed points z_a, and z_b? Suppose that (5.20) and (5.21) hold. Then we may write the relations

$$\mathcal{M}(z_a + \delta) = z_b + L_a\delta + O(\delta^2), \tag{29.5.24}$$

$$\mathcal{M}(z_b + \delta) = z_a + L_b\delta + O(\delta^2), \tag{29.5.25}$$

from which it follows that

$$\mathcal{M}^2(z_a + \delta) = \mathcal{M}(z_b + L_a\delta) + O(\delta^2) = z_a + L_bL_a\delta + O(\delta^2), \tag{29.5.26}$$

$$\mathcal{M}^2(z_b + \delta) = \mathcal{M}(z_a + L_b\delta) + O(\delta^2) = z_b + L_aL_b\delta + O(\delta^2). \tag{29.5.27}$$

We see that the linear part of $\mathcal{M}^2$ about the fixed point z_a is described by the matrix L_bL_a, and the linear part about the fixed point z_b is described by the matrix L_aL_b. According to Exercise 3.17.15, these matrices have the same eigenvalues. Therefore, the linear parts of $\mathcal{M}^2$ about the corresponding fixed points z_a and z_b have the same eigenvalues.

Exercises

29.5.1. In the two-dimensional case define the matrix B by writing

$$B = L_\alpha - I, \tag{29.5.28}$$

and consider the locus of points Δ produced by the relation

$$\Delta = B\delta \tag{29.5.29}$$

as δ traces out a circle about the origin in the counterclockwise direction. Using (orthogonal) polar decomposition, write B in the form

$$B = PO. \tag{29.5.30}$$

Since P is positive-definite symmetric, there is a proper orthogonal matrix R such that

$$P = RDR^{-1} \tag{29.5.31}$$

where D is a diagonal matrix of the form

$$D = \begin{pmatrix} \Lambda_1 & 0 \\ 0 & \Lambda_2 \end{pmatrix} \tag{29.5.32}$$

and the Λ_i are positive. Correspondingly, verify that B can be rewritten as

$$B = RDO' \tag{29.5.33}$$

where O' is the orthogonal matrix given by the relation

$$O' = R^{-1}O. \tag{29.5.34}$$

Now there are two possibilities: First, it could happen that O' is proper orthogonal (has determinant $+1$) in which case we write $O' = R'$ and (5.22) becomes

$$B = RDR'. \tag{29.5.35}$$

Show that for this possibility

$$\det B > 0. \tag{29.5.36}$$

In the second possibility O' has determinant -1. Show that in this possibility O' can be written in the form

$$O' = R'\sigma^3 \tag{29.5.37}$$

where R' is again a proper orthogonal matrix and σ^3 is the improper orthogonal (reflection) matrix given by (5.7.3). Now (5.22) becomes

$$B = RDR'\sigma^3 \tag{29.5.38}$$

and

$$\det B < 0. \tag{29.5.39}$$

In the first possibility we have the relation

$$\Delta = RDR'\delta. \tag{29.5.40}$$

For this possibility verify that as δ traces out a counterclockwise circle, the matrix R' simply rotates this circle by a fixed amount, D squashes and/or stretches it, and R again rotates it by a fixed amount. Verify that the net result is that Δ traces out an ellipse in the counterclockwise direction. Correspondingly, the fixed point z^α has index $+1$, and this fact is to be correlated with the condition (5.25).

In the second possibility we have the relation

$$\Delta = RDR'\sigma^3\delta. \tag{29.5.41}$$

Show that $(\sigma^3\delta)$ traces out a circle in the *clockwise* direction when δ traces out a counterclockwise circle. Referring to (5.30), show that R' now rotates this circle by fixed amount, D squashes and/or stretches it, and R again rotates it by a fixed amount. Verify that the net result is that Δ now traces out an ellipse in the *clockwise* direction. Correspondingly, the fixed point z^α has index -1, and this fact is to be correlated with the condition (5.28).

Verify the index assignments for all the fixed-point cases listed at the beginning of this section.

29.5.2. For N as given by (5.11) show that $\det(N-I) \geq 0$. In the case that $\det(N-I) = 0$, show that $\mu = 1$ and $\phi = 2n\pi$. You may use (5.10).

29.5.3. Let $\mathcal{M}$ be the map defined by

$$\mathcal{M} = \exp : h : \tag{29.5.42}$$

where

$$h = \lambda(p^2 + q^2)^2 \tag{29.5.43}$$

and λ is a parameter. Show that $\mathcal{M}$ has the origin as an isolated, but not manifestly isolated, fixed point. Find the index of this fixed point. Show that $\mathcal{M}$ also has an infinite number of fixed points that are not isolated. Review Exercise 4.1. Show that $f = (p^2 + q^2)$ is an integral of $\mathcal{M}$. At what fixed points does $\nabla f = 0$?

29.5.4. Let $\mathcal{M}$ be the map defined by

$$\mathcal{M} = \exp : h : \tag{29.5.44}$$

where

$$h = p^3 - 3q^2p. \tag{29.5.45}$$

Show that $\mathcal{M}$ has the origin as an isolated, but not manifestly isolated, fixed point. Find the index of this fixed point. Hint: Review Exercise 21.3.13. For the function $w = f(z) = z^2$, verify that if z traces out in a counter-clockwise direction a circular path about the origin of the complex plane, then w goes about the origin twice in the counter-clockwise direction, and $\bar{w}$ goes about the origin twice in the clockwise direction. To do this, write z in the polar form $z = r\exp(i\theta)$. Comment: Let p, q, and r be three Cartesian coordinates. The surface $r = p^3 - 3q^2p$ is called a *monkey saddle.* A cowboy/girl saddle has two up-going parts before and behind the rider, and two down-going parts for the rider's legs. A monkey saddle has three down-going parts, two for the monkey's legs and one for its tail. The monkey saddle also has three up-going parts, with one such up-going part lying between every down-going part. Google on *monkey saddle* to see pictures of them.

29.5.5. Review Section 1.2.2. Show that the complex logistic map $\mathcal{M}$ given by (1.2.29) has the fixed points

$$z_f = 0 \tag{29.5.46}$$

and

$$z_f = (\gamma - 1)/\gamma = 1 - 1/\gamma. \tag{29.5.47}$$

See (1.2.8) and (1.2.9). Exercise 1.1 provides the linear part of $\mathcal{M}$ about the fixed point (5.35). Find the linear part of $\mathcal{M}$ about the second fixed point (5.36). Classify each of these fixed points according to its stability and index, and give each its associated name according to the possibilities 1 through 3 found in this section. According to Exercise 1.2.6 the complex logistic map also has ∞ as a fixed point. Classify this fixed point. Consider a large circular contour C about the origin, large enough to contain both the fixed points (5.35) and (5.36). Compute the index of C. Explain why Douady's γ value, see Figures 1.2.6 and 1.2.8 and Exercise 1.2.12, results in $\mathcal{M}$ having three complex period-three fixed points z^1, z^2, and z^3. What value should γ have for $\mathcal{M}$ to have four complex period-four fixed points? Would this question be any easier to answer for an analysis about the fixed point at the origin using (1.41)? Hint: Given γ, define γ' by the rule

$$\gamma' = 2 - \gamma. \tag{29.5.48}$$

Show that γ and γ' lead to the same value of μ. See Exercise 1.2.7. Call Douady's γ value γ_D,

$$\gamma_D = 2.55268 - .959456i \tag{29.5.49}$$

and define γ'_D by the relation

$$\gamma'_D = 2 - \gamma_D = -.55268 + .959456i. \tag{29.5.50}$$

Figure 5.5 shows the basin structure structure for the complex logistic map $\mathcal{M}$ when $\gamma = \gamma'_D$. Evidently, as expected, the result is again a rabbit (or cactus), but the rabbit now sits more symmetrically on the page. The period-three fixed points are located at

$$z^1 = 0.500003730675024 + (6.968273875812428d - 6)i \;\; \text{(red)}, \tag{29.5.51}$$

$$z^2 = -0.138169999969259 + (0.239864000061970)i \;\; \text{(green)}, \tag{29.5.52}$$

$$z^3 = -0.238618870661709 - (0.264884797354373)i \;\; \text{(yellow)}. \tag{29.5.53}$$

Show that the fixed points of $\mathcal{M}$ itself are located at

$$z_f = 0, \tag{29.5.54}$$

$$z_f = 1 - 1/\gamma'_D = 1.450795 + .7825835i, \tag{29.5.55}$$

$$z_f = \infty. \tag{29.5.56}$$

Verify from Figure 5.5 that the three major lobes on the left, which contain the period-three fixed points z^1, z^2, and z^3, meet at the fixed point $z_f = 0$, and their counterparts on the right meet at the point

$$z' = 1. \tag{29.5.57}$$

Verify analytically that

$$\mathcal{M}z' = z_f = 0, \tag{29.5.58}$$

which explains the symmetry present in Figure 5.5.

Locate γ'_D in Figure 1.2.7. You should find that it lies in the sprout located at the eleven-o'clock position of the left disc. Show, referring to Exercise 1.1, that it has the polar decomposition

$$\rho = 1.1072538, \tag{29.5.59}$$

$$\phi = 119.943^\circ \simeq 2\pi/3. \tag{29.5.60}$$

It follows, see Exercise 1.1, that the effect of $\mathcal{M}$ on points near the origin consists of a counterclockwise rotation about the origin of very nearly 120° followed by scaling (dilation) by a factor of ρ. Consequently, verify that the relations (1.2.33) through (1.2.38) again hold. What value should γ' have in order to achieve $\phi \simeq 90^\circ$ and ρ slightly greater than 1?

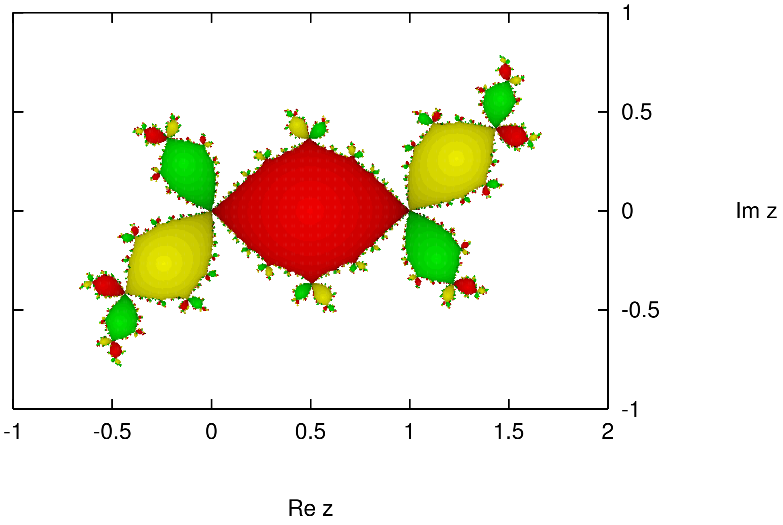

Figure 29.5.5: The basin structure for the complex logistic map when $\gamma = \gamma'_D = -.55268 + .959456i$. The origin is a repelling fixed point, and the three lobes that meet at the origin each contain one of the three attracting period-three fixed points z^1 (red), z^2 (green), and z^3 (yellow). The action of $\mathcal{M}$ on points near the origin is essentially a counterclockwise rotation about the origin by 120°.

29.5.6. Suppose C is a closed curve that is free of fixed points (of some map $\mathcal{M}$ of some two-dimensional space into itself) and suppose that C can be deformed to a point without encountering any fixed points. That is, C does not surround any fixed points. Show that the index of C must be zero.

29.6 Manifolds, and Homoclinic Points and Tangles

Assume for the time being that phase space is 2 dimensional. Suppose z^α is a fixed point of $\mathcal{M}$ and consider the repeated action of $\mathcal{M}$ (and $\mathcal{M}^{-1}$) on points near z^α. In the linear approximation these points are *translates* from the origin to z^α of points obtained by the repeated action of L_α (and ${L_\alpha}^{-1}$) on points near the origin. See Exercise 6.1 and (6.10). Next consider the two-dimensional case and suppose that z^α is a *hyperbolic* fixed point. As Exercise 6.1 goes on to show, in the hyperbolic case the repeated action of $\mathcal{M}$ on points near z^α produces (in the linear approximation) points lying on (transformed) hyperbolas and their asymptotes [or (transformed) generalized hyperbolas and their asymptotes] centered on z^α. Figure 6.1 illustrates these points schematically. The lines $v_<$ and $v_>$ are the translates of the points σv_1 and σv_2 described in Exercise 6.1, and they form the asymptotes of the hyperbolas. According to (6.10), under the repeated action of $\mathcal{M}$ (and in the linear approximation) points on $v_<$ are moved inward toward z^α, and points on $v_<$ are moved outward. See (6.20) and recall that we have assumed $\lambda_1 < 1$ and $\lambda_2 > 1$. Thus, points on $v_<$ are *stable* in the linear approximation, and points on $v_>$ are *unstable*. Points not on the asymptotes move on hyperbolas. They are all unstable since they eventually move away from z^α under the repeated action of $\mathcal{M}$.

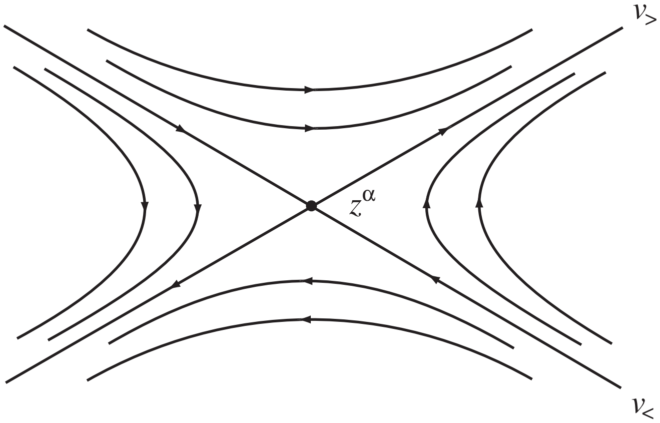

Figure 29.6.1: Schematic illustration of the action of $\mathcal{M}$ on points near z^α in the linear approximation. Points on $v_<$ are moved inward toward z^α, and points on $v_>$ are moved outward. Others are moved on hyperbolas.

When all nonlinearities are taken into account, it can be shown that (in the hyperbolic case) the repeated action of $\mathcal{M}$ on points near z^α is similar. Indeed, according to a celebrated theorem of *Hartman* whose proof lies beyond the scope of our current discussion, in the hyperbolic case there is a conjugating map $\mathcal{A}$ such that in the vicinity of z^α there is a relation of the form

$$\mathcal{M} = \mathcal{A}\mathcal{L}_\alpha\mathcal{A}^{-1} \tag{29.6.1}$$

where $\mathcal{A}^{-1}$ maps z^α to the origin and $\mathcal{L}_\alpha$ is the linear part of $\mathcal{M}$ at z^α. In particular there are *stable* and *unstable manifolds* W_s and W_u that are the analogs of the asymptotes $v_<$ and $v_>$, and nearly coincide with them in the vicinity of z^α where the linear approximation is valid. The stable manifold is defined to be the set of all points that are sent into z^α under the action of $\mathcal{M}^n$ in the limit of large n,

$$W_s = \{z| \lim_{n\to\infty} \mathcal{M}^n z = z^\alpha\}. \tag{29.6.2}$$

The definition of W_u is a bit more subtle. Note that in the linear approximation points on $v_>$ are moved *inward* under the action of $\mathcal{M}^{-1}$. We therefore define the unstable manifold to be the set of all points that are sent into z^α under the action of $\mathcal{M}^{-n}$ in the limit of large n,

$$W_u = \{z| \lim_{n\to\infty} \mathcal{M}^{-n} z = z^\alpha\}. \tag{29.6.3}$$

We observe that thanks to Hartman's theorem W_s and W_u are one dimensional in the neighborhood of z^α. Moreover, if S is a point on W_s, then by the definition (6.2) so are the points $\mathcal{M}^m S$ for any positive or negative values of m. Similarly, if U is a point on W_u, so are the points $\mathcal{M}^m U$. Consequently, if W_u is known in the neighborhood of z^α, it can be extended away from z^α by repeatedly applying $\mathcal{M}$ to the known portion. Similarly, W_s can extended away from its known portion near z^α by repeated application of $\mathcal{M}^{-1}$. Finally, since $\mathcal{M}$ is assumed to be continuous (and dimensionality is conserved by a continuous map), W_s and W_u must be one dimensional globally.

An illuminating example of the behavior of stable and unstable manifolds is provided by the map $\mathcal{M}$ given by (3.95) and (3.96). For simplicity, specify μ and ν by a single parameter Λ by writing the relations

$$\mu = \Lambda,\ \nu = 1/\Lambda. \tag{29.6.4}$$

When this is done, the map becomes symplectic. Next, for purposes of illustration, assign Λ the value $\Lambda = 3$. Inspection of (3.95) and (3.96) shows that in this case the origin in q,p space is a hyperbolic fixed point, and the q and p axes are the unstable and stable asymptotes $v_>$ and $v_<$, respectively. We therefore expect the unstable and stable manifolds W_u and W_s to lie along the q and p axes, respectively, in the neighborhood of the origin.

Further examination of (3.95) and (3.96) shows that $\mathcal{M}$ has a second fixed point given (when $\Lambda = 3$) by

$$\{q,p\} = \{-3/8, 1/8\}, \tag{29.6.5}$$

and that this fixed point is elliptic with a tune $T = .1959\cdots$. See Exercise 6.2.

Figure 6.2 shows the actual unstable and stable manifolds in the vicinity of the origin and somewhat beyond. (See Exercise 6.3 for a description of how they can be calculated.) It also displays the elliptic fixed point and the behavior, under repeated action of $\mathcal{M}$, of points near the elliptic fixed point. Evidently points near the elliptic fixed point do seem to move on ellipses as predicted by the linear analysis of Exercise 6.1. However, we will subsequently learn that their behavior is in fact generally much more complicated. With regard to the unstable and stable manifolds, they do appear to lie along the q,p axes in the neighborhood of the origin. However, they veer away from the axes when farther away from the origin. In particular, the piece of W_u that originated along the negative q axis and the piece of W_s

that originated along the positive p axis *intersect* at the point K.[2] Moreover they do not join smoothly at K, but rather *intersect* with a finite angle of intersection. (They are said to intersect *transversally.*) This point K is called a (transverse) *homoclinic* point, and the angle of intersection is called the *homoclinic angle.* (The word *homoclinic*, a nomenclature due to Poincaré, means “falling into itself”: Since K is on W_u, it must have come from points arbitrarily near z^α under the repeated action of $\mathcal{M}$, and since it is also on W_s, it must also be sent back to points arbitrarily near z^α under the repeated action of $\mathcal{M}$. It can happen that a map has two or more hyperbolic fixed points, and that the unstable manifold of one intersects the stable manifold of another. Such an intersection is called a *heteroclinic* point.) The pieces of W_u and W_s that originated along the positive q and negative p axes, respectively, appear to go off to infinity without intersecting.

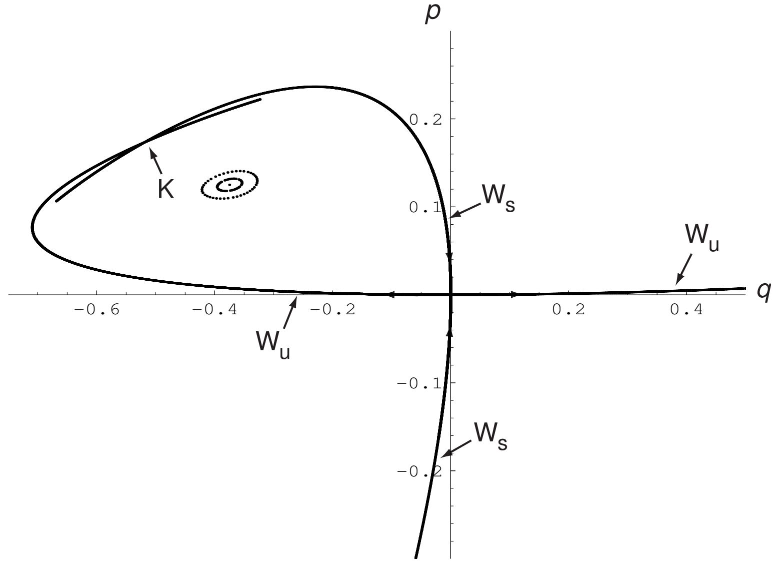

Figure 29.6.2: The (transverse) intersection of the unstable and stable manifolds emanating from a hyperbolic fixed point resulting in a homoclinic point K. Also displayed is the elliptic fixed point and the behavior of points near the elliptic fixed point.

We next claim that the existence of one homoclinic point implies the existence of an infinite number of homoclinic points. To see this, suppose K is a homoclinic point and consider all the points $\mathcal{M}^n K$ for n both positive and negative. Since by assumption K lies on W_u, we know from our earlier discussion that the points $\mathcal{M}^n K$ must also lie on W_u. And since K lies on W_s as well, the points $\mathcal{M}^n K$ must also lie on W_s. Therefore W_u and W_s must intersect at all the points $\mathcal{M}^n K$. Moreover, if the homoclinic angle at K is nonzero,

[2] Suppose an autonomous Hamiltonian system with two degrees of freedom has a periodic orbit. As described in Section 6.9, in the vicinity of this orbit one can set up a Poincaré two-dimensional surface of section return map $\mathcal{M}$, and the periodic orbit will then correspond to a fixed point of $\mathcal{M}$. Suppose this fixed point is hyperbolic. Then, points on its stable manifold correspond to an orbit that asymptotically approaches the periodic orbit as $t \rightarrow +\infty$, and points on its unstable manifold correspond to an orbit that asymptotically approaches the periodic orbit as $t \rightarrow -\infty$. Supose the stable and unstable manifolds intersect. Then these two orbits are part of a common orbit which is said (following Poincaré) to be *doubly asymptotic.*

the homoclinic angles at all the points $\mathcal{M}^n K$ must be finite. See Exercise 6.4.

Figure 6.3 shows the same pieces of the manifolds W_u and W_s that do not go off to infinity as shown on Figure 6.2, but also shows more of them to exhibit some of the points $\mathcal{M}^n K$. We now observe that between any two successive homoclinic points of the form $\mathcal{M}^n K$ there is an *additional* homoclinic point. Why should this be so?

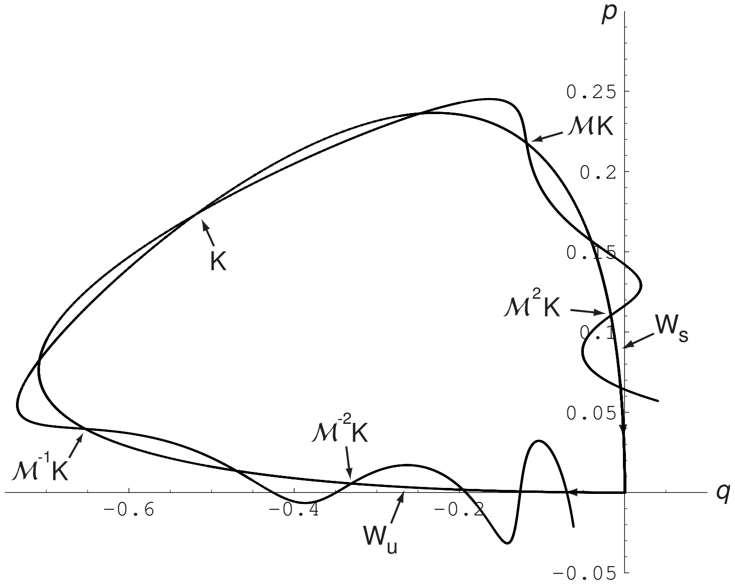

Figure 29.6.3: Successive homoclinic intersections of the unstable and stable manifolds showing the first few points $\mathcal{M}^n K$. The other halves of W_u and W_s, those pieces that go off to infinity, are not shown. Also not shown are the elliptic fixed point and the behavior of points near it.

Consider the closed curve consisting of the part of W_u that extends from z^α to K and the part of W_s that extends from K back to z^α, and let $\mathcal{R}$ be the region enclosed by this curve. Next consider the closed curve consisting of the part of W_u that extends from z^α to $\mathcal{M}K$ and the part of W_s that extends from $\mathcal{M}K$ back to z^α, and let $\bar{\mathcal{R}}$ be the region enclosed by this curve. By construction the boundary of $\mathcal{R}$ is mapped onto the boundary of $\bar{\mathcal{R}}$ under the action of $\mathcal{M}$. It can also be shown that $\mathcal{M}$ maps the interior of $\mathcal{R}$ to the interior of $\bar{\mathcal{R}}$. That is, we may also view $\bar{\mathcal{R}}$ as being the set of points produced by $\mathcal{M}$ acting on all the points in $\mathcal{R}$,

$$\bar{\mathcal{R}} = \mathcal{M}\mathcal{R}. \tag{29.6.6}$$

Let A and $\bar{A}$ be the areas of $\mathcal{R}$ and $\bar{\mathcal{R}}$, respectively,

$$A = \int_{\mathcal{R}} d^2 z, \tag{29.6.7}$$

$$\bar{A} = \int_{\bar{\mathcal{R}}} d^2 \bar{z}. \tag{29.6.8}$$

We claim these two areas are equal. Indeed, by changing variables of integration, we have the result

$$\bar{A} = \int_{\bar{\mathcal{R}}} d^2 \bar{z} = \int_{\mathcal{R}} [\det M(z)] d^2 z = A. \tag{29.6.9}$$

Here we have used the fact that $\mathcal{M}$ is symplectic, and therefore $\det M(z) = 1$. What we have done is recapitulate Liouville's theorem in two dimensions. Recall Subsection 6.6.1.

Now look at Figure 6.4. The left panel displays $\mathcal{R}$; the right displays $\bar{\mathcal{R}}$ and, as a dashed line, the part of W_s that is "removed" under the action of $\mathcal{M}$. We see, because the homoclinic angle is finite, that as a result of the extending action of $\mathcal{M}$ the manifold W_u initially dives under the dashed portion of W_s that is removed. If it did not eventually also curve upward so as to finally lie above the dashed portion of W_s, the result would be $\bar{A} < A$. Therefore W_u must cross W_s between K and $\mathcal{M}K$, thereby producing an intermediate homoclinic point. Moreover, the two small regions (*lobes*) pointed out in the right panel, those that result from the oscillation of W_u about the dashed portion of W_s, must have *equal* areas in order for the relation $\bar{A} = A$ to hold.

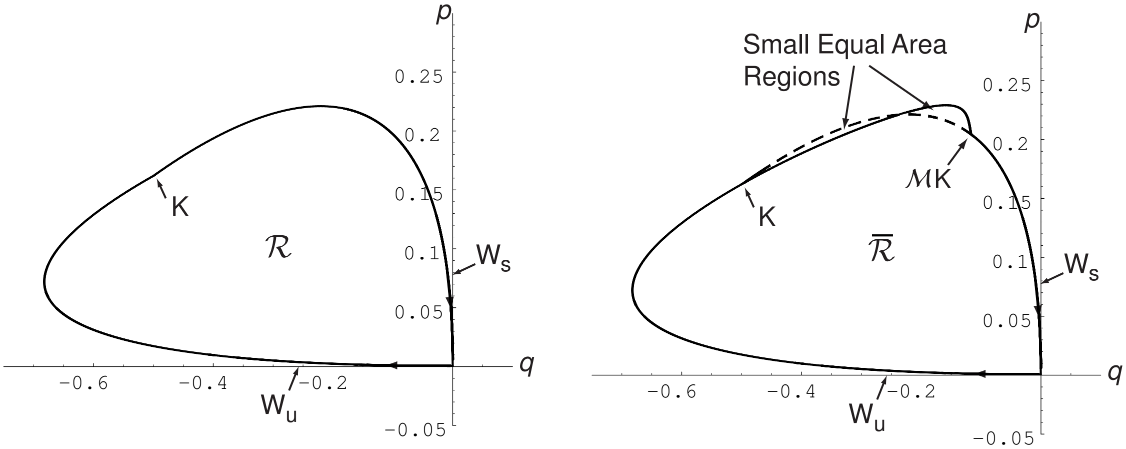

Figure 29.6.4: The regions $\mathcal{R}$ and $\bar{\mathcal{R}}$. Observe that, in the right panel, the unstable manifold "oscillates" about the stable manifold in the interval between K and $\mathcal{M}K$. When $\mathcal{M}$ is symplectic, the two small regions produced by this oscillation must have equal areas.

Let us examine more of the homoclinic points $\mathcal{M}^n K$ by computing more of W_s and W_u. Figure 6.5 shows the result. We see that W_u, as it heads back toward z^α, makes more and more oscillations about W_s and that these oscillations have ever increasing amplitude. Similarly, W_s, as it heads back toward z^α, makes more and more oscillations about W_u with ever increasing amplitude. Why should this be? We have learned that the two lobes in Figure 6.4 must have the same area. A moment's reflection reveals that all the other lobes are images of these lobes under the action of $\mathcal{M}^n$ for suitable positive or negative values of n. See Figure 6.3. Moreover, since $\mathcal{M}$ is symplectic and therefore area preserving, *all* these lobes must have the same area. Finally, in the vicinity of z^α, Exercise 6.1 shows that the spacing of successive homoclinic points must decrease geometrically (exponentially). As a consequence of Hartman's theorem, asymptotically their distances from the origin must be governed by relations of the form (6.15), which in turn imply that their spacings must decrease exponentially. Therefore, in order to maintain constant area, the amplitude (in linear approximation) must grow exponentially. (We remark that a similar phenomena holds in the case of heteroclinic points when the heteroclinic intersection is transverse: The two intersecting manifolds again oscillate about each other with ever finer spacing and ever increasing amplitude as they approach the two associated hyperbolic points.)

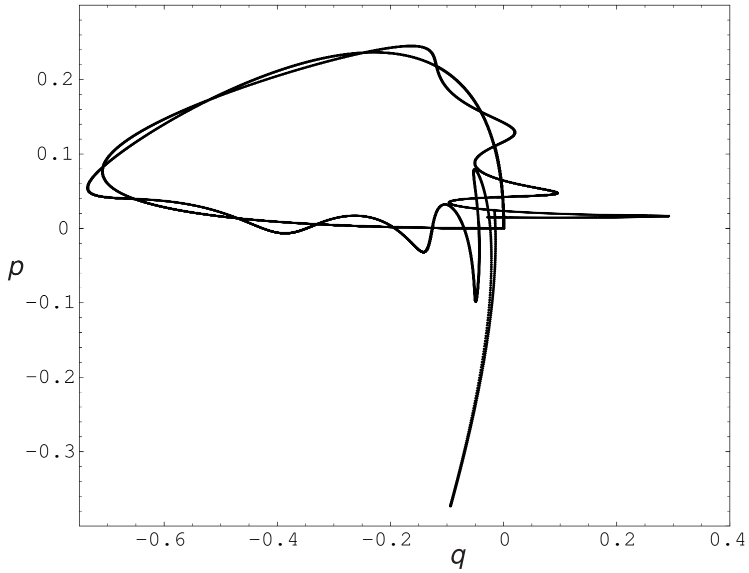

Figure 29.6.5: Successive oscillations of W_u about W_s and of W_s about W_u in the vicinity of the hyperbolic fixed point. The spacing between successive oscillations becomes exponentially finer, and the oscillation amplitude becomes exponentially larger.

The net effect of these oscillations of increasing amplitude is that near the hyperbolic fixed point the oscillations of W_u about W_s must *intersect* the oscillations of W_s about W_u to produce even more homoclinic points. As a result the hyperbolic fixed point is the corner of an ever "denser" cloud of homoclinic points. This property is illustrated in Figure 6.6.

Poincaré first discovered this structure, which we now call a *homoclinic tangle*, without the aid of a computer and computer graphics. About this discovery he wrote:

> *When we try to represent the figure formed by these two curves and their infinitely many intersections, each corresponding to a doubly asymptotic solution, these intersections form a type of trellis, tissue, or grid with infinitely fine mesh. Neither of the two curves must ever cut across itself again, but it must bend back upon itself in a very complex manner in order to cut across all of the meshes in the grid an infinite number of times.*
>
> *The complexity of this figure is striking, and I shall not even try to draw it. Nothing is more suitable for providing us with an idea of the complex nature of the three-body problem, and of all the problems of dynamics in general, where there is no uniform integral and where the Bohlin series are divergent.*

In Exercise 6.5 you will have the pleasure of verifying Poincaré's assertion that W_s cannot intersect itself, nor can W_u intersect itself. And in Exercise 6.6 you will be led to show that the existence of a homoclinic point, which happens generically for nonlinear maps (including those arising from nonlinear systems), precludes the existence of analytic integrals. Indeed, it can be shown that the existence of a homoclinic point implies that there is an infinite

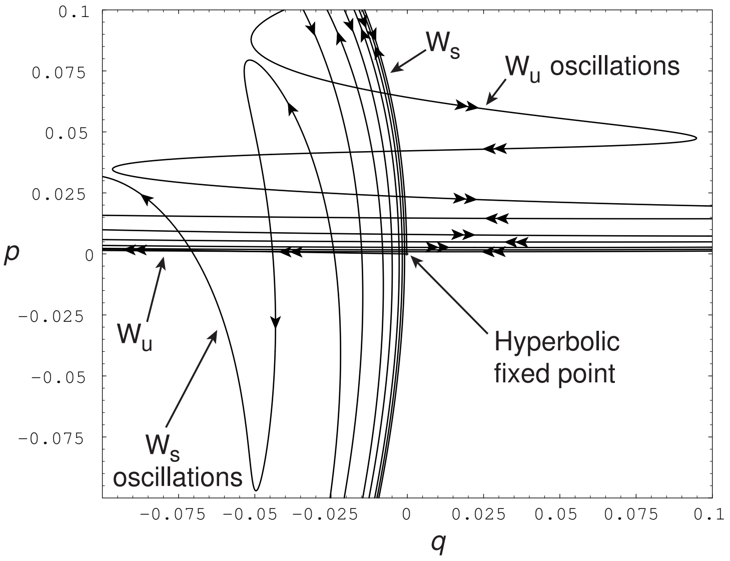

Figure 29.6.6: A continuation of Figure 6.5 near the origin (the hyperbolic fixed point) showing the formation of a grid of intersecting lines. The spacing of the grid becomes finer and finer as it approaches the hyperbolic fixed point. Each grid intersection is a homoclinic point. The result of all these intersections is an ever denser cloud of homoclinic points that has the hyperbolic fixed point as a limit point.

collection of points for which the action of $\mathcal{M}$ is equivalent to that of a Bernoulli shift. (Recall Exercise 1.2.8 for the definition of a Bernoulli shift.) Therefore, most nonlinear problems are not integrable. Finally, it may be remarked that the homoclinic tangle has the same topological structure as that resulting from *Smale's* famous *horseshoe* map.

Strictly speaking, we have only been discussing the two-dimensional case. The higher dimensional cases are still more complicated, and much less detail is known about them. It is known, however, that stable and unstable manifolds and homoclinic (and heteroclinic) behavior also exist in higher dimensions, and that there are additional complex phenomena such as *Arnold diffusion*.

We close this section by noting that, in generically rare cases (but characteristic of maps arising from soluble systems), the unstable and stable manifolds may join smoothly without going into homoclinic oscillations about each other. In such a case their union is called a *separatrix* since (in two dimensions) points inside the separatrix remain so under the repeated action of $\mathcal{M}$, and points outside are eventually mapped to infinity. When the unstable and stable manifolds intersect transversally at a homoclinic point (as is generically the case), this phenomenon is sometimes referred to as separatrix *splitting*.

It can also happen, in systems with sufficient damping, that the stable and unstable manifolds do not intersect at all. As an example, consider the stroboscopic Duffing map with the same parameter values used to make the basins illustration, Figure 23.4.3. Figure 6.7 shows the unstable (*hyperbolic*) fixed point (23.4.3) and the eigenvector v_1, the eigenvector of the linear part of $\mathcal{M}$ about the unstable fixed point, associated with the eigenvalue λ_1 that lies in the interval $0 < \lambda_1 < 1$. Note that the unstable fixed point is on, and v_1 points along, the boundary between the two basins. (Reader, show that this is to be expected.)

Figure 6.8 shows the stable and unstable manifolds associated with the unstable fixed point (23.4.3). They do not intersect, and therefore the stroboscopic Duffing map does not have homoclinic points for these parameter values. Points on the two branches of the unstable manifold spiral into the two stable fixed points (23.4.1) and (23.4.2), the stable manifold separates the two basins, and points on the stable manifold are moved toward the unstable fixed point (23.4.3).

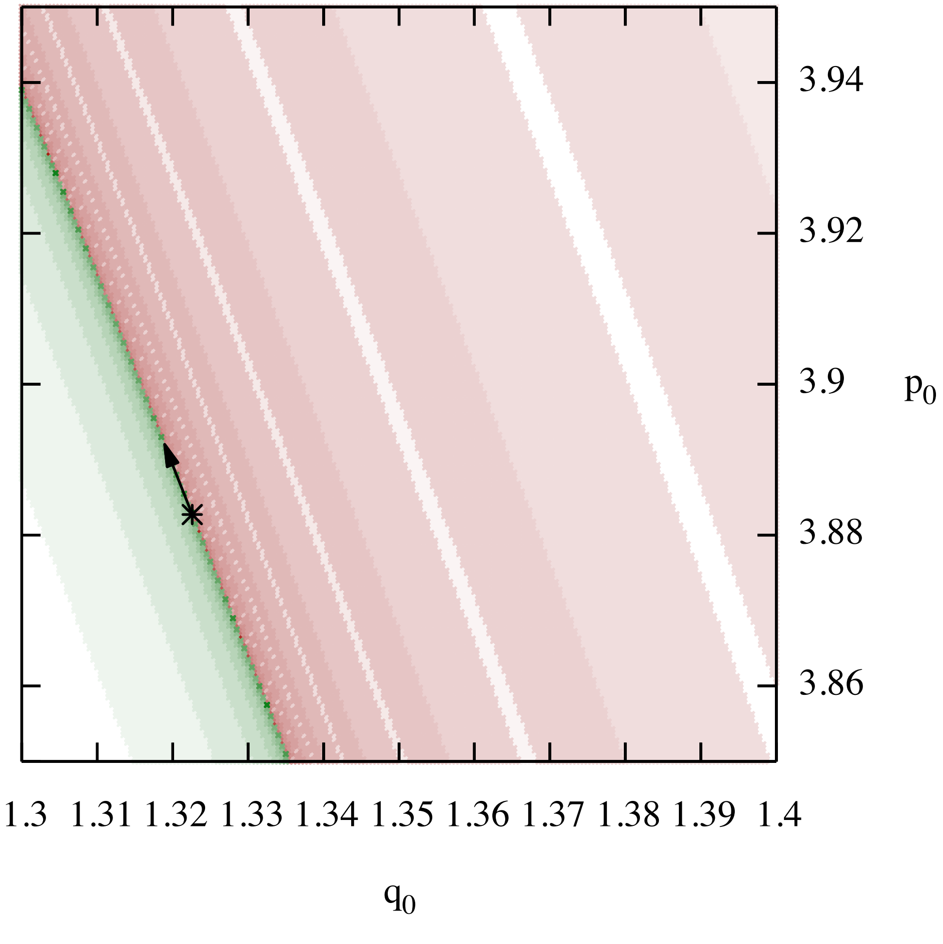

Figure 29.6.7: A blow up of part of Figure 23.4.3 illustrating the basins of attraction, the unstable fixed point (23.4.3), and the eigenvector v_1 (the one with eigenvalue less than 1) for the stroboscopic Duffing map. The unstable fixed point lies on, and the vector v_1 points along, the boundary between the two basins.

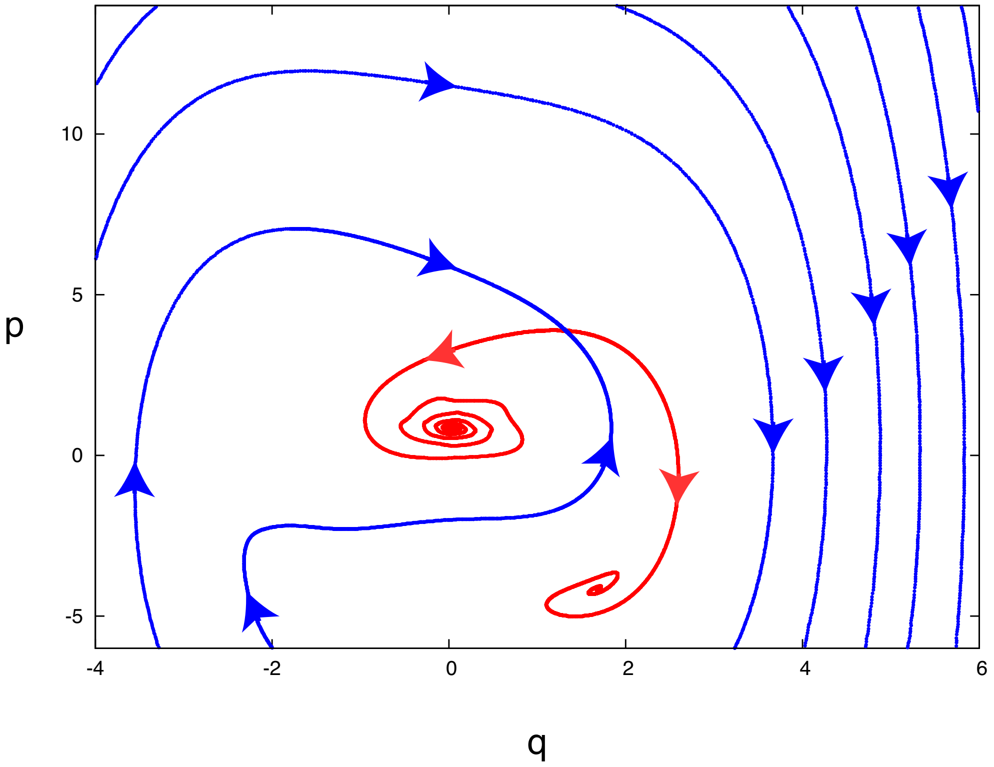

Figure 29.6.8: The stable (blue) and unstable (red) manifolds for the unstable fixed point (23.4.3) of the stroboscopic Duffing map. Note that the unstable manifold spirals into the stable fixed points (23.4.1) and (23.4.2), and the stable manifold lies along the basin boundaries. The stable and unstable manifolds do not intersect, so there are no homoclinic points.

Exercises

29.6.1. Show from (4.5) that there is the relation

$$\mathcal{M}^n(z^\alpha + \delta) = z^\alpha + (L_\alpha)^n \delta + O(\delta^2). \tag{29.6.10}$$

Therefore the behavior of points sufficiently near z^α under repeated action of $\mathcal{M}$ is governed by $(L_\alpha)^n$. From (5.3) there is the relation

$$(L_\alpha)^n = AN^nA^{-1}, \tag{29.6.11}$$

and hence $(L_\alpha)^n$ is in turn governed by N^n.

Now consider the two-dimensional case. For any two-vector $\epsilon^{(0)}$, let $\delta^{(0)} = A\epsilon^{(0)}$ and introduce the notation

$$\epsilon^{(n)} = (N)^n \epsilon^{(0)}, \tag{29.6.12}$$

$$\delta^{(n)} = (L_\alpha)^n \delta^{(0)}. \tag{29.6.13}$$

Deduce the relation

$$\delta^{(n)} = A\epsilon^{(n)}. \tag{29.6.14}$$

For any initial point $\epsilon^{(0)}$, find the successive points $\epsilon^{(n)}$ for all the kinds of fixed points listed at the beginning of this section.

Three cases are of particular interest: Show that in case 3b (see Section 18.5) the successive points $\epsilon^{(n)}$ spiral into the origin; and in the elliptic case, case 3c, the successive points lie on a circle. For the hyperbolic case, case 1c, Show that successive points obey the relation

$$(\epsilon^{(n)})_i = {\lambda_i}^n (\epsilon^{(0)})_i \tag{29.6.15}$$

so that they lie on the "generalized" hyperbola

$$[(\epsilon^{(n)})_1]^a [(\epsilon^{(n)})_2]^{1/a} = [(\epsilon^{(0)})_1]^a [(\epsilon^{(0)})_2]^{1/a} \tag{29.6.16}$$

where a is given by the relation

$$a = [-\log(\lambda_2)/\log(\lambda_1)]^{1/2}. \tag{29.6.17}$$

Let e_1 and e_2 be unit vectors such that

$$Ne_i = \lambda_i e_i. \tag{29.6.18}$$

Show that the vectors σe_i, where σ is any scalar, are the asymptotes of this generalized hyperbola. Verify that the generalized hyperbola becomes an "ordinary" hyperbola in the (symplectic) case $\lambda_1\lambda_2 = 1$.

Finally, verify that the effect of A, which transforms (maps) $\epsilon^{(n)}$ to $\delta^{(n)}$ by (6.14), is simply that of possible reflection followed by possible rotation, possible squashing and/or stretching, and a final possible rotation. Thus, the behavior of the points $\delta^{(n)}$ is similar to that of the $\epsilon^{(n)}$. Hint: As done for B in Exercise 5.1, use polar decomposition for A. When, without loss of generality, may one assume $\det A = 1$?

For the hyperbolic case in particular define vectors v_i by the relation

$$v_i = Ae_i. \tag{29.6.19}$$

Verify that they obey the rule

$$L_\alpha v_i = \lambda_i v_i, \tag{29.6.20}$$

and that the vectors σv_i are the asymptotes of the transformed generalized hyperbola.

29.6.2. Show that the map $\mathcal{M}$ given by (3.95), (3.96), and (4.23) has two fixed points. The first is the origin $\{0, 0\}$. Verify that the second is given by

$$q_f = -\Lambda(\Lambda - 1)/(\Lambda + 1)^2, \tag{29.6.21}$$

$$p_f = (\Lambda - 1)/(\Lambda + 1)^2. \tag{29.6.22}$$

Verify (6.5) for the case $\Lambda = 3$. Show that the linear part of $\mathcal{M}$ about the second fixed point is described by the matrix

$$M_f = \begin{pmatrix} -\Lambda(\Lambda-3)/(\Lambda+1) & 2\Lambda(\Lambda-1)/(\Lambda+1) \\ -2(\Lambda-1)/[\Lambda(\Lambda+1)] & (3\Lambda-1)/[\Lambda(\Lambda+1)] \end{pmatrix}, \tag{29.6.23}$$

and therefore the trace of M_f is given by the relation

$$\operatorname{tr} M_f = -(\Lambda^2 - 4\Lambda + 1)/\Lambda. \tag{29.6.24}$$

Verify, using (3.5.39) through (3.5.41), that when $\Lambda = 3$ the tune T of M_f is given by

$$T = .1959\cdots . \tag{29.6.25}$$

29.6.3. Verify that the map $\mathcal{M}$ given by (3.95), (3.96), and (4.23) has the inverse

$$q = \bar{q}/\Lambda - (\bar{q}/\Lambda - \Lambda\bar{p})^2, \tag{29.6.26}$$

$$p = \Lambda\bar{p} - (\bar{q}/\Lambda - \Lambda\bar{p})^2. \tag{29.6.27}$$

Set $\Lambda = 3$. Consider L equally spaced points along the q axis lying in the small interval $[-\epsilon, 0)$ where ϵ is some small number. Also consider L equally spaced points along the p axis lying in the small interval $(0, \epsilon]$. Let N be some modest positive integer. Apply the maps $\mathcal{M}^n$, for $n = 0$ through N, to the equally spaced set of points along the q axis. Apply the maps $\mathcal{M}^{-n}$, again for $n = 0$ through N, to the equally spaced set of points along the p axis. Use double precision (64 bit) or still higher precision arithmetic. Try, for starters, the case $L = 100$, $\epsilon = .03$, and $N = 5$. Verify that so doing should give (for the case $\Lambda = 3$) some approximation to points lying on the initial portion of some pieces of W_u and W_s, respectively. What pieces can be gotten this way? How can the other pieces be found? For an improved approximation, replace ϵ by ϵ/Λ and N by $N + 1$. Verify that making this replacement repeatedly leads to more and more accurate results for W_u and W_s. Experiment with various values of L, ϵ, and N to get satisfactory graphics.

29.6.4. All homoclinic angles are finite.

29.6.5. W_u and W_s cannot self-intersect.

29.6.6. Existence of homoclinic point implies non-integrability.

29.7 The General Hénon Map

We are now prepared to resume our study of two-variable quadratic maps. Consider the map $\mathcal{M}_{ffq}$ given by (3.37) and (3.38), or by (3.54), for the parameter values

$$d = 1 \ , \ e = 0 \ , \ r = 0 \ , \ s = 1 \ , \ t = b \ , \ u = 0 \ , \ \alpha^3 = -a \ , \ \beta = 0. \tag{29.7.1}$$

This map is called the *general* (not necessarily symplectic) *Hénon* map. We will denote it by $\mathcal{M}_h$. For it the matrix R takes the form

$$R = \begin{pmatrix} 0 & 1 \\ b & 0 \end{pmatrix}; \tag{29.7.2}$$

and, after replacing $\overset{\equiv}{q}$, $\overset{\equiv}{p}$ by the symbols $\bar{q}$, $\bar{p}$ for the sake of improved notation, the map $\mathcal{M}_h$ itself takes the form

Action of $\mathcal{M}_h$:

$$\bar{q} = 1 + p - aq^2, \tag{29.7.3}$$

$$\bar{p} = bq. \tag{29.7.4}$$

The determinant of its Jacobian matrix has the value

$$\det M_h = \det R = -b. \tag{29.7.5}$$

Consequently, the Hénon map is orientation preserving only when $b < 0$, and symplectic only when $b = -1$.

We have discovered that the general Hénon map is an instance of the class of two-dimensional quadratic maps whose nonlinear parts have a finite product Lie factorization (or, equivalently, have a constant Jacobian determinant.) In Section 8.3 we learned that all such maps are equivalent (conjugate), under affine changes of variables, to a two-parameter family of maps. See, for example, (3.95) and (3.96). Note that the Hénon maps also form a two-parameter family. Therefore, as we will eventually confirm, it must also be possible to bring any Hénon map to some standard form. Indeed, the general Hénon map and the class of quadratic two-dimensional maps having a finite Lie product factorization are equivalent.

The general Hénon map has been much studied for the case $b = .3$ and variable a. This case is non-symplectic and non-orientation preserving. For given values of a and b, repeated iteration of $\mathcal{M}_h$ will produce a set in the q, p plane. Figure 7.1 shows the projection of this set onto the q axis as a a function of a. Projection of this set on the p axis gives a similar picture. [See (7.4).] Evidently the Feigenbaum diagram for the general Hénon map is similar to that of the logistic map. See Figures 1.2.2 and 1.2.10. There is a cascade at period doublings followed by what appears to be chaotic behavior. Numerical calculation shows that the sequence of period doublings is again governed by the Feigenbaum constant δ as given by (1.2.13). However, closer inspection of Figure 7.1 reveals additional features in the vicinity of $a = 1.08$ in the form of additional cascades. Figure 7.2 shows an enlargement of one of these features revealing that it is an independent cascade. This is but one indication that the behavior of the Hénon map under iteration is far more complicated than that of the logistic map.

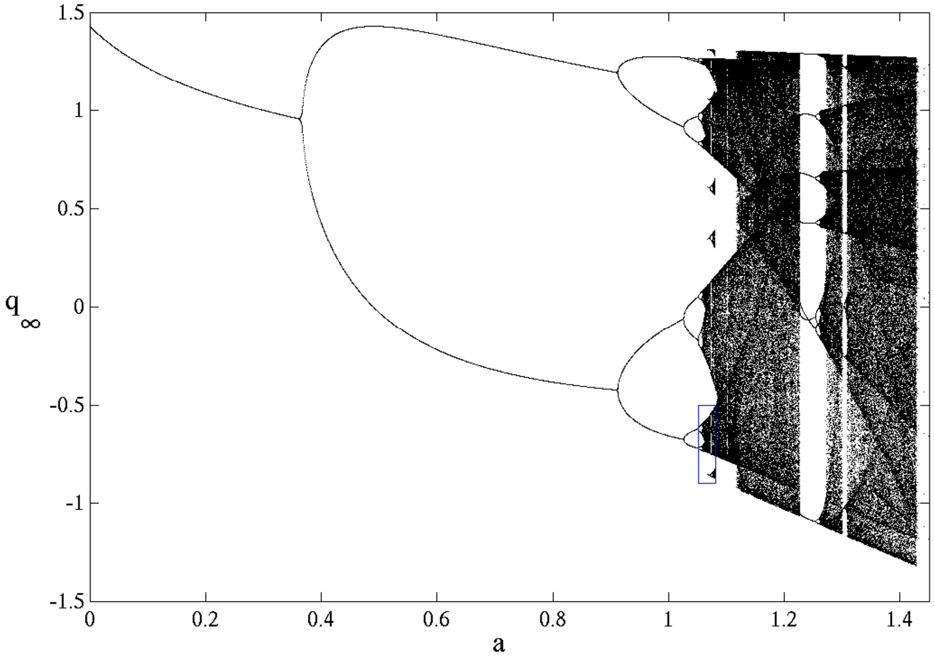

Figure 29.7.1: Feigenbaum diagram showing limiting values q_∞ as a function of a (and b held at $b = +.3$) for a non-orientation preserving case of the general Hénon map.

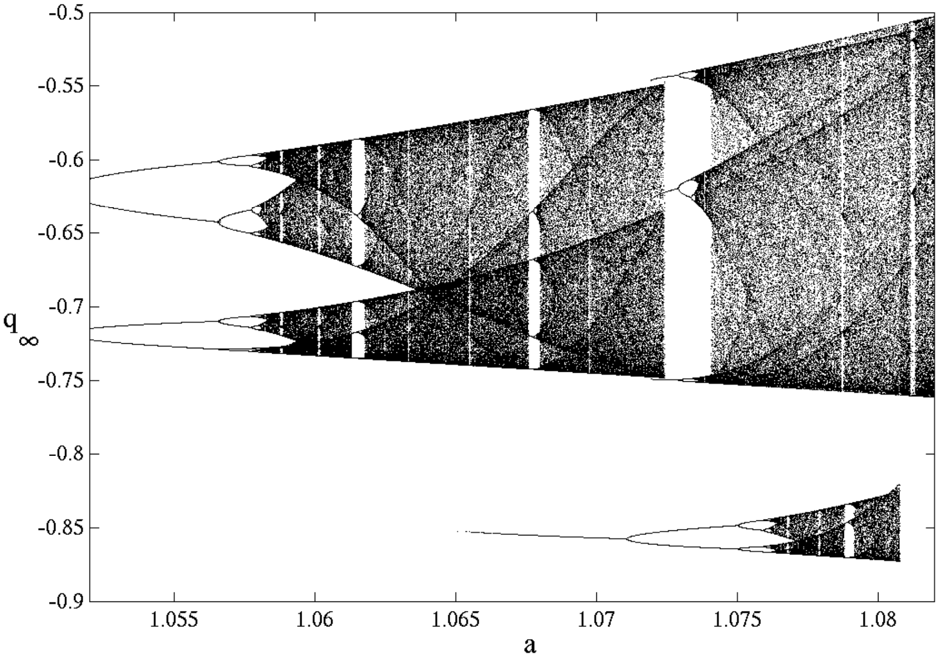

Figure 29.7.2: Enlargement of the boxed region in Figure 7.1. The upper cascade is that readily visible in the box in Figure 7.1. The lower cascade, which seems to appear out of nowhere and then terminate abruptly, corresponds to the small speck near the bottom of the box in Figure 7.1.

Figures 7.3 show various portions of the full set in the q, p plane for the parameter values $b = .3$ and $a = 1.4$. In the first figure there seem to be three curves that form part of an attractor. The next figure shows an enlargement of the "boxed" portion of the first figure. At this magnification it is evident that the top curve in the first figure is "thicker" then the other two. The third figure shows an enlargement of the boxed portion of the second figure. Now it is evident that the thick curve is itself composed of three curves spaced in a way that is similar to the three curves in the first figure. A fourth figure shows a further enlargement. Evidentally the attractor appears to be *fractal*.

There is also the (for us) much more interesting *orientation preserving* case for which $b < 0$, for only then can the general Hénon map model a transfer map arising from a differential equation. [See (7.5) and Exercise 1.4.6.] Indeed, by following a procedure similar to that used in Section 1.2 to produce the symplectic Hénon map, one can use the vector fields appearing in an analogous factorization of the orientation preserving general Hénon map to produce a differential equation whose time-one transfer map is the general Hénon map (with $b < 0$). We will also want the map to be symplectic or area contracting (but not area expanding). Therefore we are primarily interested in the cases $-1 \leq b < 0$. That is, we are mainly interested in maps that describe Hamiltonian or damped systems.

Suppose we give b the value $b = -.3$, and then study the properties of $\mathcal{M}_h$ for various values of a. Repeated iteration of $\mathcal{M}_h$ will again produce a set in the q, p plane. Figure 7.4 shows the projection of this set onto the q axis as a function of a. The graphic is similar to that of Figure 1.2.9: There is an infinite sequence of period doublings as a increases, and this cascade seems to be complete (and then some) by the time a reaches the value $a = 2.11$. However, there are also again additional cascades, this time in the vicinity of $a = 1.9$. In order to provide a complete picture of the attracting set, Figure 7.5 shows, in 3-dimensional perspective, both q_∞ and p_∞ as a function of a.

Figures 7.6 show various portions of the full set in the q, p plane for the parameter values $b = -.3$ and $a = 2.11$. That is, Figures 7.6 show the intersection of Figure 7.5 with the plane $a = 2.11$. In the first figure there again seem to be three curves that form part of an attractor. The remaining three figures show successive enlargements of the "boxed" portion of the previous figure. Again there appears to be a fractal structure, and this evidence suggests that there can also be a strange attractor for the case $b < 0$. However, the fractal structure is more complicated than that of the corresponding Figures 7.3 for the non-orientation preserving case. For the case of Figures 7.3, there is a similarity between every successive picture in the magnification sequence. In Figures 7.6 there is a similarity between every other picture in the magnification sequence.

Why is there a resemblance between the Feigenbaum diagram for the general Hénon map and that of the logistic map? Iterate once the Hénon map, as given by (7.3) and (7.4), to get the result

$$\bar{\bar{q}} = 1 + \bar{p} - a\bar{q}^2, \tag{29.7.6}$$

$$\bar{\bar{p}} = b\bar{q}. \tag{29.7.7}$$

Now imagine that b is small. Then, in view of (7.4), the relations (7.6) and (7.7) can be expanded in the form

$$\bar{\bar{q}} = 1 - a\bar{q}^2 + O(b), \tag{29.7.8}$$

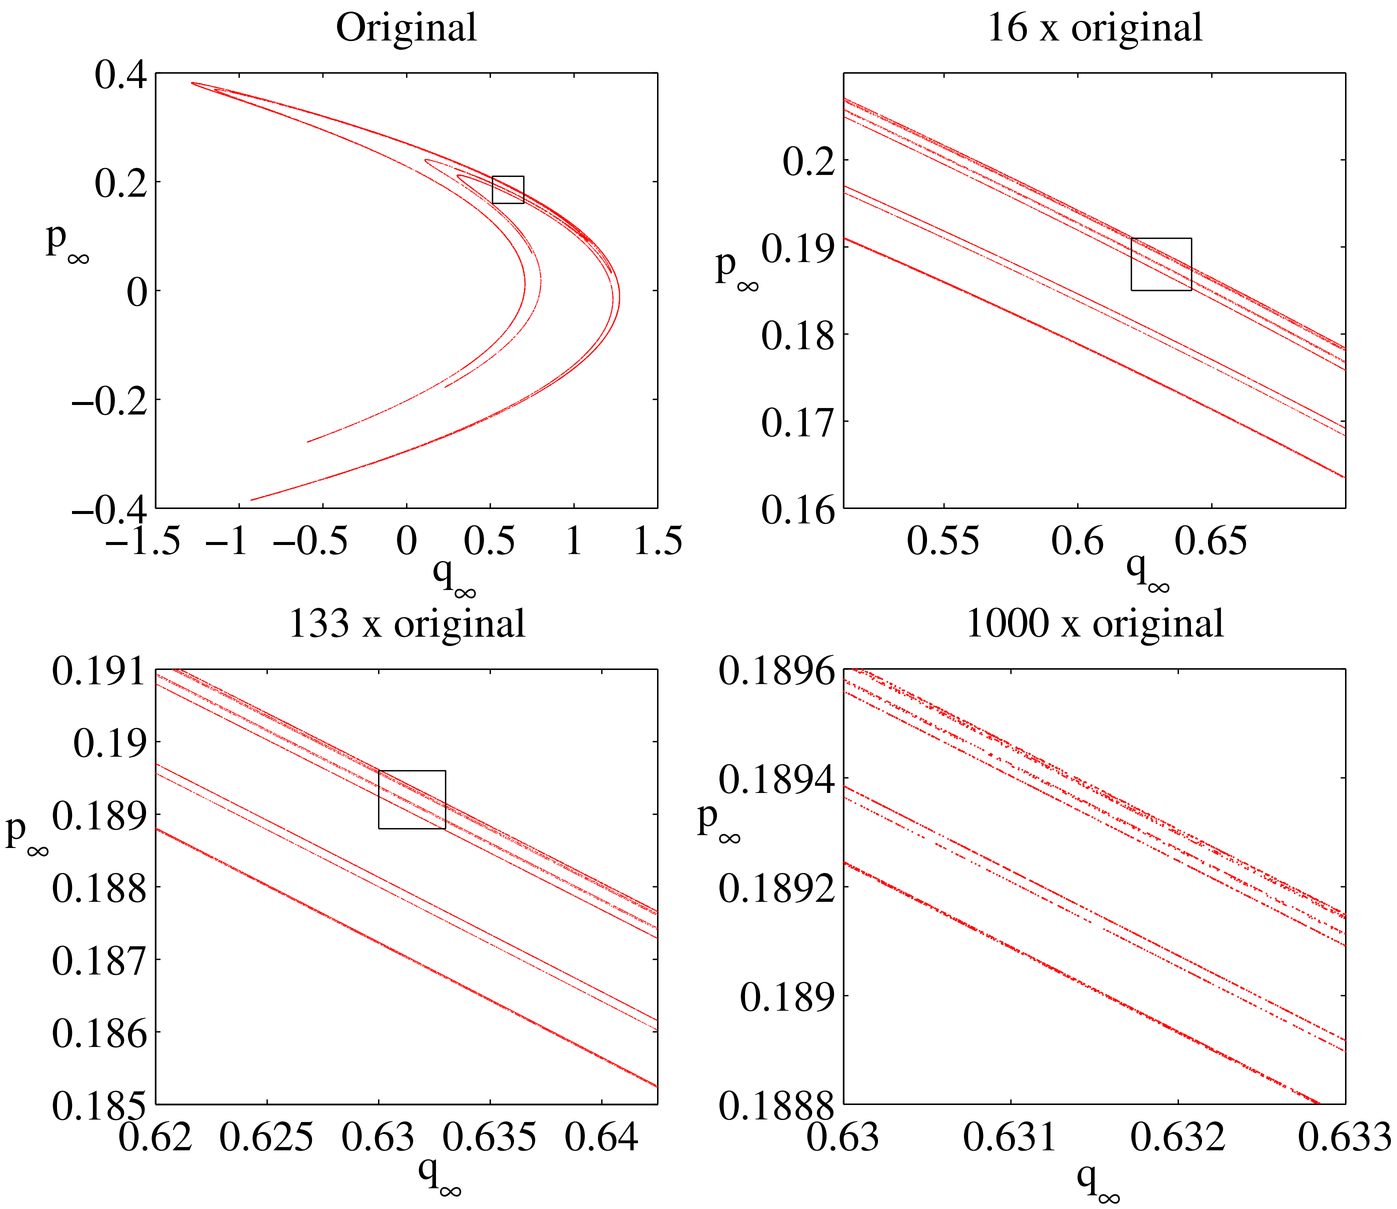

Figure 29.7.3: Successive enlargements of the attracting set q_∞, p_∞ for a non-orientation preserving case of the general Hénon map ($a = 1.4$, $b = +.3$). The attractor appears to be fractal, and therefore strange.

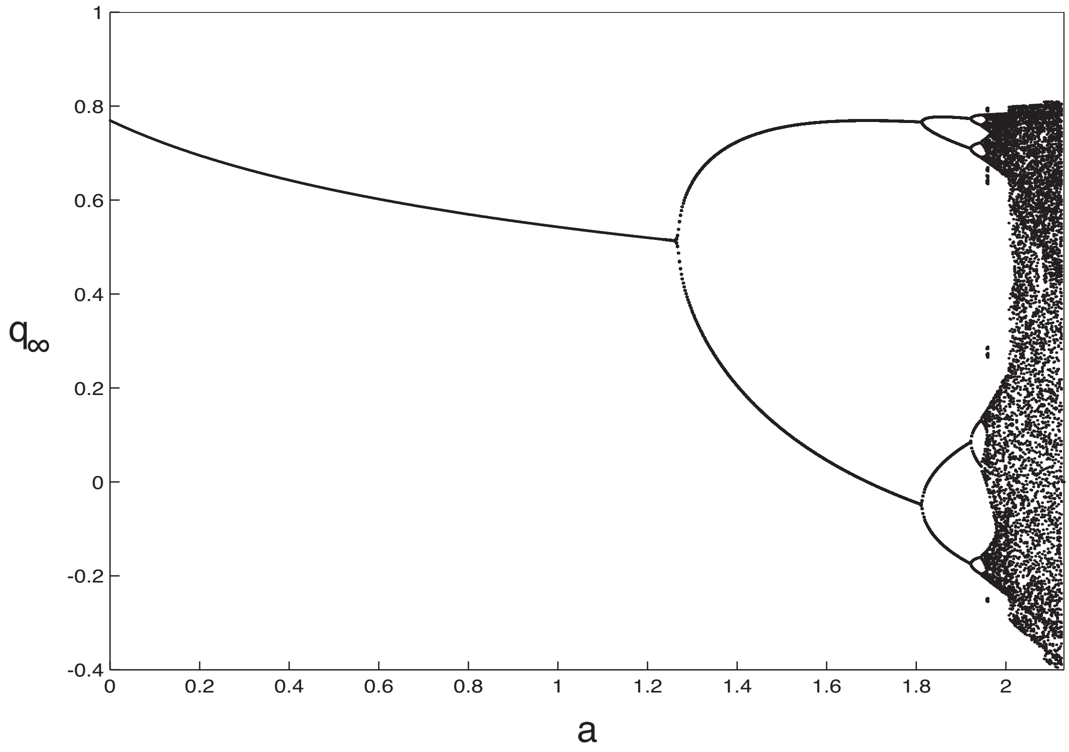

Figure 29.7.4: (Partial) Feigenbaum diagram showing limiting values q_∞ as a function of a (and b held at $b = -.3$) for an orientation preserving case of the general Hénon map.

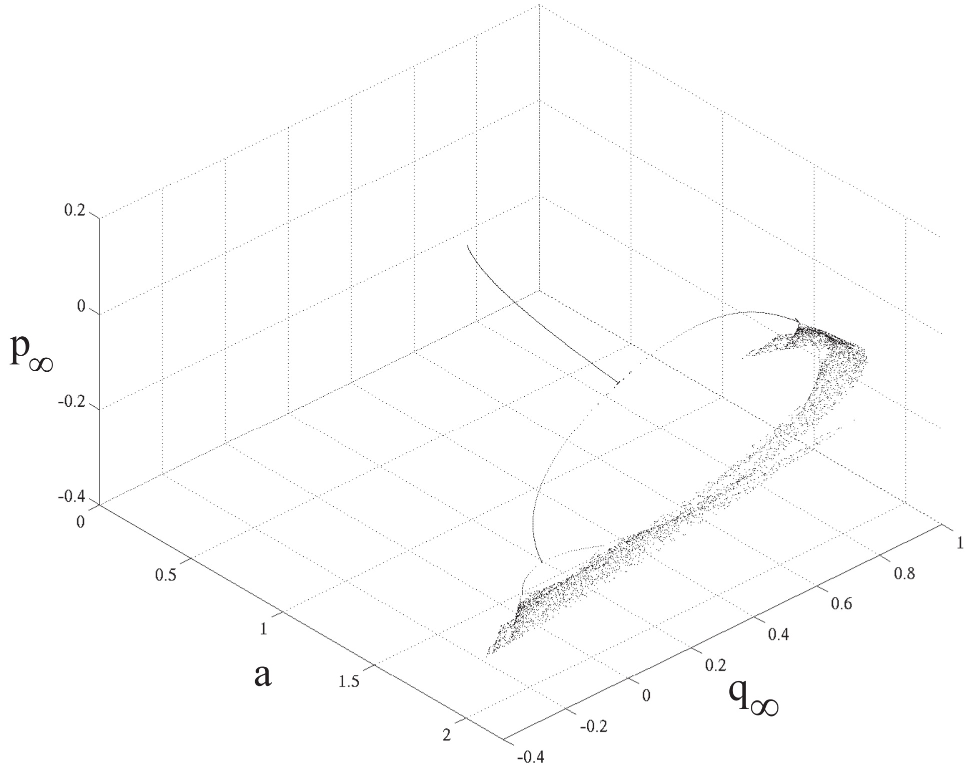

Figure 29.7.5: Full Feigenbaum diagram showing limiting values q_∞ and p_∞ as a function of a (and b held at $b = -.3$) for an orientation preserving case of the general Hénon map.

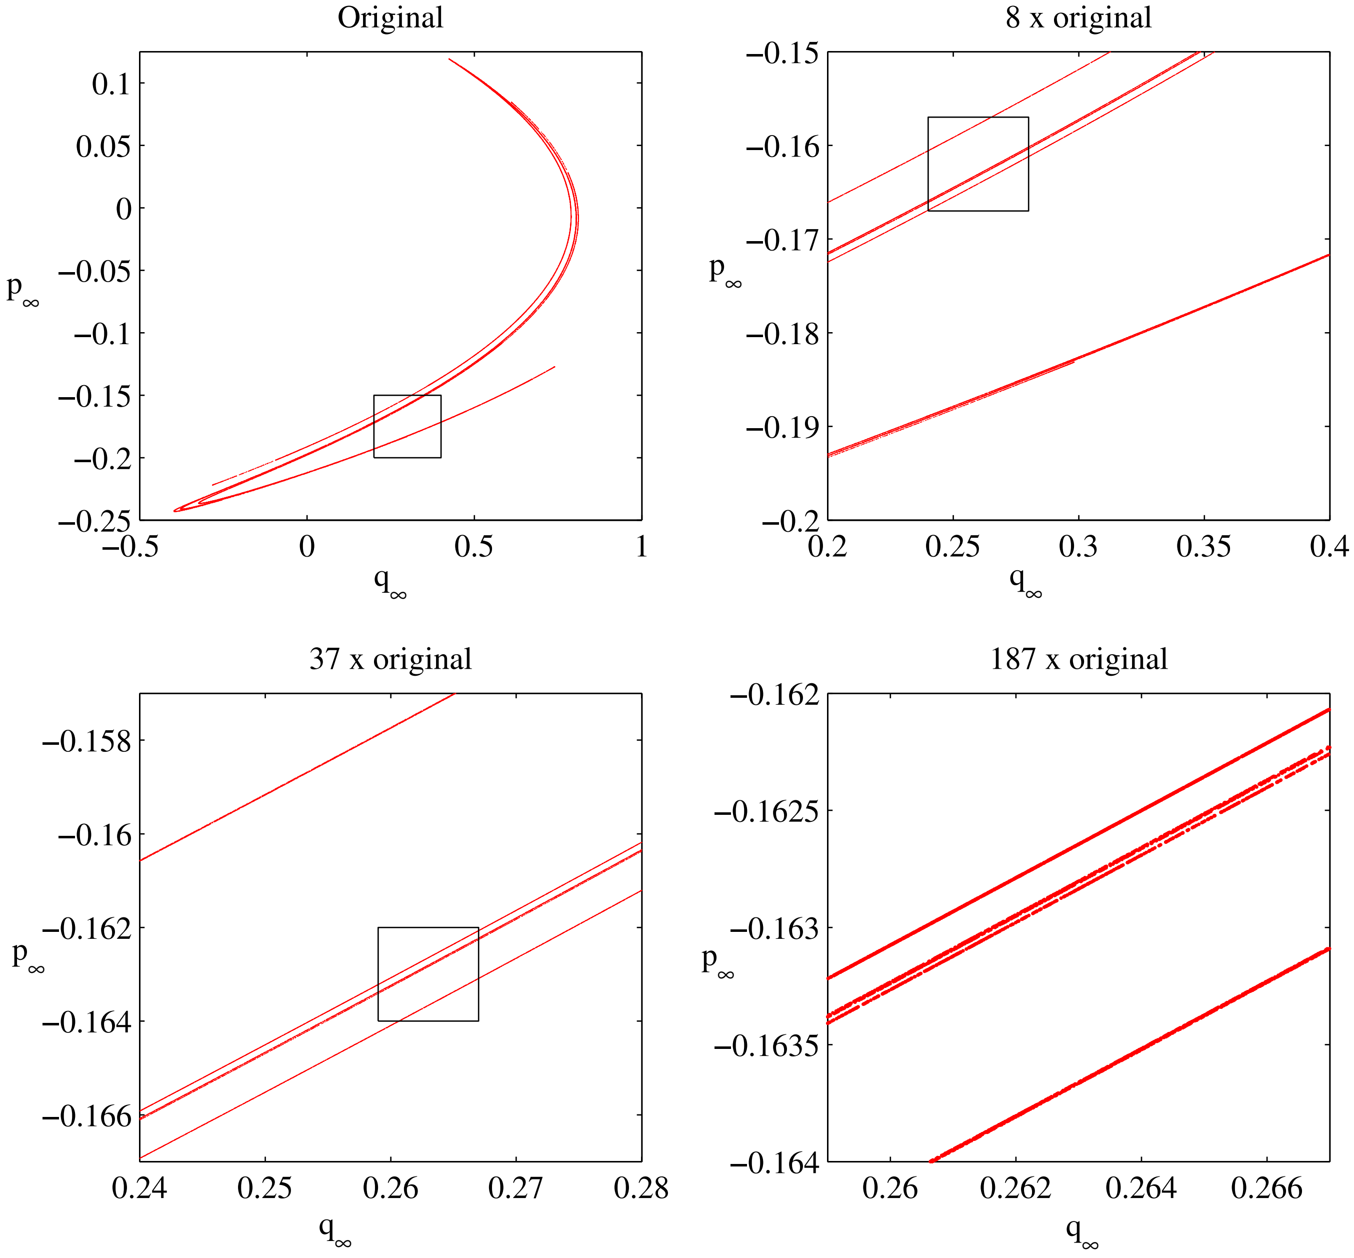

Figure 29.7.6: Successive enlargements of the attracting set q_∞, p_∞ for an orientation preserving case of the general Hénon map ($a = 2.11$, $b = -.3$). The attractor appears to be fractal, and therefore strange.

$$\bar{\bar{p}} = 0 + O(b). \tag{29.7.9}$$

Now make the change of variable

$$\bar{q} = -\bar{w}/a. \tag{29.7.10}$$

When this done (7.8) takes the form

$$\bar{\bar{w}} = -a + \bar{w}^2 + O(b) \tag{29.7.11}$$

which, up to $O(b)$ corrections, is the logistic map in the form (1.2.56) with $\mu = a$. Thus, for sufficiently small b, the Hénon map may be viewed as a *perturbation* of the logistic map. We therefore expect that the general Hénon map will exhibit all the richness of the logistic map and, as Figures 7.1, 7.2, 7.4, and 7.5 hint, even more.

At this point, it is still unclear what produces the strange (fractal) attractors illustrated in Figures 7.3 and 7.6, and where they are located relative to other significant sites in the mapping plane. We will study this question in subsequent sections. For simplicity, we will consider only the orientation preserving case $b < 0$. We will begin with the observation that the general Hénon map has two fixed points, and then factorize the map about each of these points.

Exercises

29.7.1. Here is another way to see that there is a relation between the logistic map and the Hénon map. For the general Hénon map in the form given by (7.3) and (7.4) make the change of variables

$$q = -Q/a \ , \ \bar{q} = -\bar{Q}/a; \tag{29.7.12}$$

$$p = -bP/a \ , \ \bar{p} = -b\bar{P}/a. \tag{29.7.13}$$

Show that in terms of these variables the general Hénon map takes the form

$$\bar{Q} = -a + bP + Q^2, \tag{29.7.14}$$

$$\bar{P} = Q, \tag{29.7.15}$$

which is evidently a perturbation of the logistic map. Indeed, in the limit $b = 0$ the relation (7.14) degenerates to the map

$$\bar{Q} = -a + Q^2, \tag{29.7.16}$$

29.7.2. Use the machinery of Section 18.1 to show that in the orientation preserving case the general Hénon map given by (7.3) and (7.4) has the Lie factorization

$$\mathcal{M}_h = \exp(\mathcal{G}_2)\mathcal{R}\exp[(a/3b^2) : p^3 :]\exp(- : p :) \tag{29.7.17}$$

where

$$\mathcal{G}_2 = \mathcal{G}^0 = (1/2)\log(-b)\Sigma, \tag{29.7.18}$$

$$\mathcal{R} = \exp[-(\pi/4) : q^2 + p^2 :]\exp(1/2)\log(-b) : qp :]. \tag{29.7.19}$$

29.8 Preliminary Study of General Hénon Map

In this section we begin a study of the general Hénon map. We start by locating its fixed points, and find there are two. Next we expand the map about each of these fixed points and analyze their natures. We learn that one of them, without loss of generality, can always be taken to be hyperbolic, or to at least have a diagonal linear part with positive eigenvalues. We then translate this hyperbolic fixed point to the origin, factor the map about it, and show that this factorized map depends on two parameters. Next we explore how the location (relative to the origin) of the second fixed point and its nature depend on these parameters. Finally, we translate the second fixed point to the origin and factor the map about it. In all our work we take particular care to exhibit whatever symmetries exist in the Hénon map.

29.8.1 Location, Expansion About, and Nature of Fixed Points

It is easily verified that the Hénon map $\mathcal{M}_h$ in the form (7.3) and (7.4) has *two* fixed points $q_f^{\pm}, p_f^{\pm}$ given by the relations

$$q_f^+ = \{-(1-b) + [(1-b)^2 + 4a]^{1/2}\}/(2a) = 2/\{(1-b) + [(1-b)^2 + 4a]^{1/2}\},$$

$$q_f^- = \{-(1-b) - [(1-b)^2 + 4a]^{1/2}\}/(2a), \tag{29.8.1}$$

$$p_f^{\pm} = bq_f^{\pm}, \tag{29.8.2}$$

and these fixed points are real when

$$a \geq -(1-b)^2/4. \tag{29.8.3}$$

In our future discussion we will refer to $\{q_f^-, p_f^-\}$ as the *first* fixed point and to $\{q_f^+, p_f^+\}$ as the *second* fixed point.

Figure 8.1 shows $q_f^{\pm}$ as a function of a for the case $b = -.3$, the same b value used in Figure 7.4. [The plot employs values of a for which (8.3) is satisfied.] The behavior of $p_f^{\pm}$ is similar as can be inferred from (8.2). Observe that $\{q_f^-, p_f^-\}$ are singular at $a = 0$. Inspection of (7.3) shows that $\mathcal{M}_h$ becomes *linear* at this value of a, and therefore this case is of less interest.

We will be primarily concerned with maps that are nearly symplectic, the case where $b \simeq -1$. Figure 8.2 shows $q_f^{\pm}$ as a function of a in the case $b = -.9$, an instance where the general Hénon map is more nearly symplectic. From (8.1) and (8.2) it is evident that $\{q_f^-, p_f^-\}$ and $\{q_f^+, p_f^+\}$ *coincide* when a takes on the minimum value allowed by (8.3),

$$a_{\min} = -(1-b)^2/4. \tag{29.8.4}$$

Calculation shows that for this value of a there are the relations

$$q_f^- = q_f^+ = 2/(1-b), \tag{29.8.5}$$

$$p_f^- = p_f^+ = 2b/(1-b). \tag{29.8.6}$$

Look at Figures 8.1 and 8.2, and see Exercise 8.1.

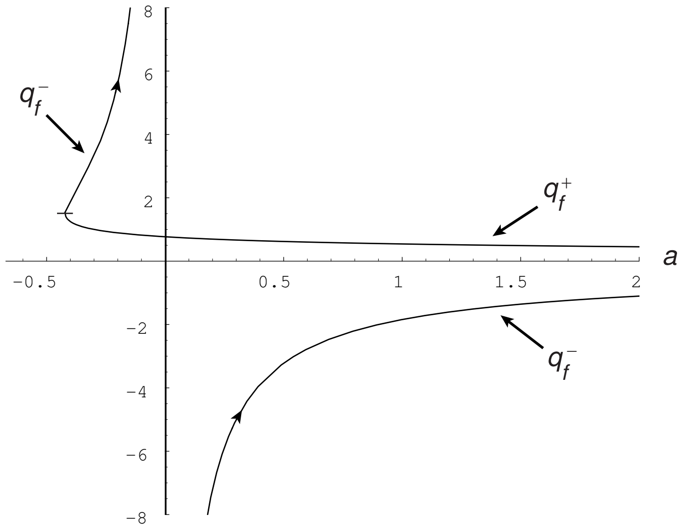

Figure 29.8.1: Values of $q_f^{\pm}$, when $b = -.3$, as a function of a. A horizontal tic mark indicates where q_f^+ and q_f^- meet when $a = a_{\min}$.

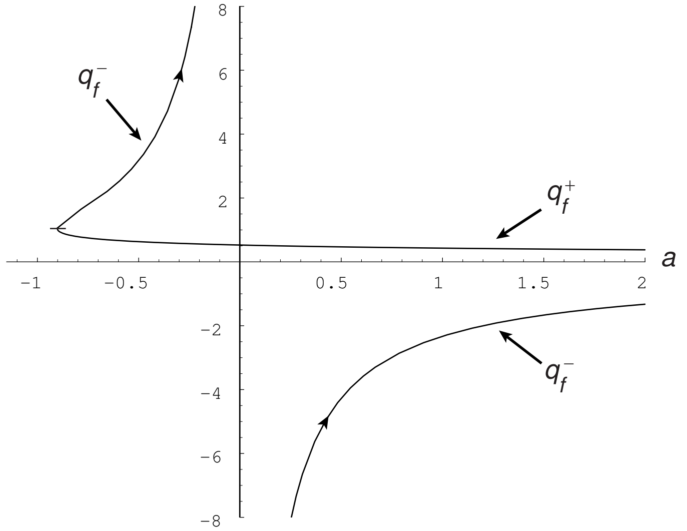

Figure 29.8.2: Values of $q_f^{\pm}$, when $b = -.9$, as a function of a. A horizontal tic mark indicates where q_f^+ and q_f^- meet when $a = a_{\min}$.

We observe that both fixed points *move* as the parameters a and b are varied, and consequently this form of the Hénon map is awkward for further analysis. To overcome this problem, introduce deviation (about a fixed point) variables Q, P by writing

$$q = q_f + Q \ , \ p = p_f + P; \tag{29.8.7}$$

$$\bar{q} = q_f + \bar{Q} \ , \ \bar{p} = p_f + \bar{P}. \tag{29.8.8}$$

So doing brings the general Hénon map $\mathcal{M}_h$ given by (7.3) and (7.4) to the transformed map $\mathcal{M}_h^*$ given by the relation

Action of $\mathcal{M}_h^*$:

$$\bar{Q} = -2aq_fQ + P - aQ^2,$$

$$\bar{P} = bQ, \tag{29.8.9}$$

and we see that the linear part R_h^* of the map about the fixed point (now the origin) is given by the relation

$$R_h^*(q_f, p_f) = \begin{pmatrix} -2aq_f & 1 \\ b & 0 \end{pmatrix}. \tag{29.8.10}$$

Let us find the eigenvalues of R_h^*. They satisfy the equation

$$P(\lambda) = \det(R_h^* - \lambda I) = (-2aq_f - \lambda)(-\lambda) - b = 0, \tag{29.8.11}$$

and are given by the relation

$$\lambda = -aq_f \pm \sqrt{(aq_f)^2 + b}. \tag{29.8.12}$$

The eigenvalues will be real if

$$(aq_f)^2 + b \geq 0, \tag{29.8.13}$$

and complex if

$$(aq_f)^2 + b < 0. \tag{29.8.14}$$

Note that, by (8.1), there is the relation

$$aq_f^{\pm} = \{-(1-b) \pm [(1-b)^2 + 4a]^{1/2}\}/2, \tag{29.8.15}$$

which can be employed in (8.12) through (8.14).

When the eigenvalues are complex, they will be complex conjugate as (8.12) shows. Therefore by (8.10), when the eigenvalues are complex, there will be the relation

$$\lambda\bar{\lambda} = \det R_h^* = -b, \tag{29.8.16}$$

and hence

$$|\lambda| = \sqrt{-b}. \tag{29.8.17}$$

That is, when a varies and b is fixed (and the eigenvalues are complex), the eigenvalues must move on a circle of radius $\sqrt{-b}$ in the complex plane.

Figure 8.3 shows the eigenvalues of R_h^* given by (8.12), for the case $q_f = q_f^-$ and $b = -.3$, as a function of a. Figure 8.4 shows the same thing when $b = -.9$, the more nearly symplectic instance. As expected, both eigenvalues are *real* for $q_f = q_f^-$ because (8.13) is then satisfied, and both are *positive*. Moreover, if $a > a_{\rm min}$, one of them satisfies $\lambda > 1$ and the other satisfies $0 < \lambda < 1$ so that $\{q_f^-, p_f^-\}$ is a hyperbolic fixed point. Finally, when $a = a_{\rm min}$, the eigenvalues take the values

$$\lambda = 1, -b. \tag{29.8.18}$$

See Exercise 8.3. That one of the eigenvalues then has the value +1 should not surprise us. For as a approaches $a_{\rm min}$, we have already seen that $\mathcal{M}_h$ has two fixed points that coincide, and the results of Section 18.4 then apply.

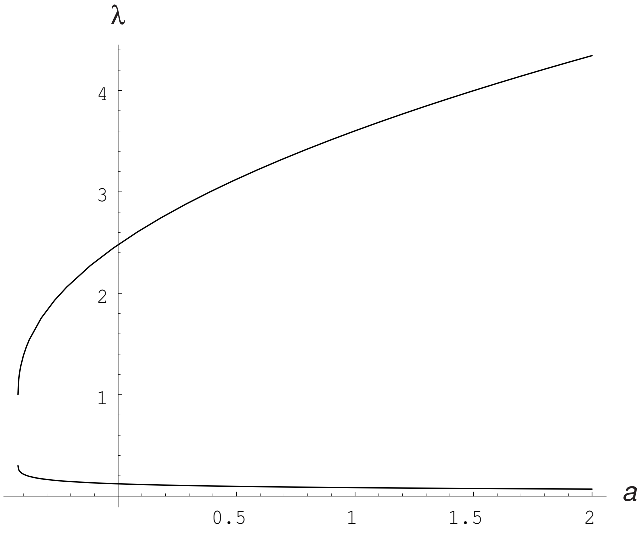

Figure 29.8.3: Eigenvalues λ of R_h^*, when $b = -.3$ and $q_f = q_f^-$, as a function of a.

The eigenvalues can become complex in the case $q_f = q_f^+$ because (8.14) can then be satisfied. As explained earlier, when this happens the eigenvalues are complex conjugate and their magnitude is given by (8.17). Figures 8.5 and 8.6 display the eigenvalues for the case $q_f = q_f^+$ as a function of a when b has the values $b = -.3$ and $b = -.9$, respectively. As the figures show, the eigenvalues are either positive, complex, or negative. When they are complex only their negative magnitude, shown as a dashed line, is plotted when $a > 0$, and only their positive magnitude, also shown as a dashed line, is plotted when $a < 0$. As a increases (and b is held fixed) the eigenvalues can leave the complex plane and become negative. This happens when

$$a = [(1 + \sqrt{-b})^4 - (1 - b)^2]/4. \tag{29.8.19}$$

See Exercise 8.4. Just as they become real and negative, according to (8.16), they both must have the value $-\sqrt{-b}$. As a increases further one of the eigenvalues can eventually take on the value -1. It can be shown that this occurs when

$$a = (3/4)(1 - b)^2, \tag{29.8.20}$$

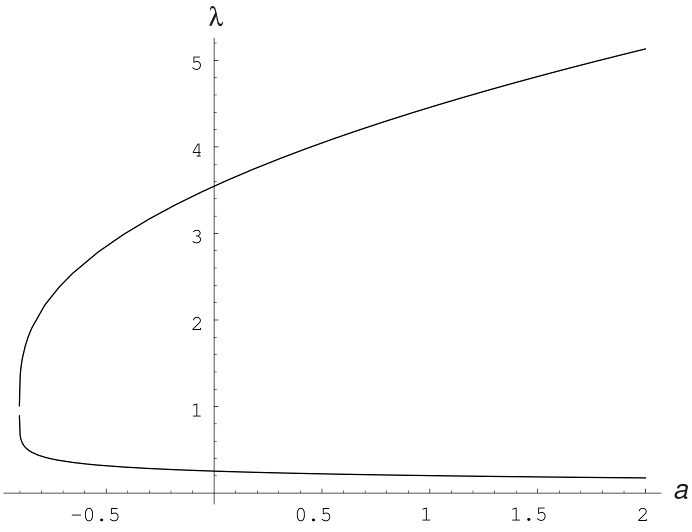

Figure 29.8.4: Eigenvalues λ of R_h^*, when $b = -.9$ and $q_f = q_f^-$, as a function of a.

again see Exercise 8.4, and in Section 18.9 we will learn that this is the condition for the first period doubling. Specifically, for $b = -.3$, we expect period doubling when $a = 1.2675$, which is consistent with Figure 7.4. For $a < 1.2675$ both eigenvalues satisfy $|\lambda| < 1$, and therefore the fixed point $\{q_f^+, p_f^+\}$ will be an attractor so that $q_\infty = q_f^+$. Comparison of Figures 7.4 and 8.5 verifies numerically that this is the case. We also note that for sufficiently small a the eigenvalues can leave the complex plane and become positive. This happens when

$$a = [(1 - \sqrt{-b})^4 - (1 - b)^2]/4. \tag{29.8.21}$$

Yet again see Exercise 8.4. Again according to (8.16), just as they become real and positive, they both must have the value $+\sqrt{-b}$. Finally, when $a = a_{\min}$, the fixed points coincide and therefore the eigenvalues for the case $q_f = q_f^+$ must also satisfy (8.18) at this value of a.

So far we have characterized the the general Hénon map by the parameters a and b. However, inspection of Figures 8.3 through 8.6 shows that (as a and b are varied over their allowed ranges and for a suitable choice of fixed point) the associated eigenvalue pair can take on *any positive* pair of values. Therefore, according to the work of Section 18.3, there is a linear (affine) change of variables that will always bring the general Hénon map to the form given by (3.95) and (3.96), and we may equally well use μ and ν as parameters in place of a and b. Finally, in order to conserve symbols, it is convenient to replace μ, ν by r, u. This replacement makes μ, ν available for a different use later on. With this replacement, the relations (3.95) and (3.96) become

Action of $\mathcal{M}_{ffq}^{tr}$:

$$\begin{aligned} \bar{q} &= r[q + (q-p)^2], \\ \bar{p} &= u[p + (q-p)^2]. \end{aligned} \tag{29.8.22}$$

For this map, consistent with our discussion, we will select the parameter ranges

$$r > 0, \quad u > 0. \tag{29.8.23}$$

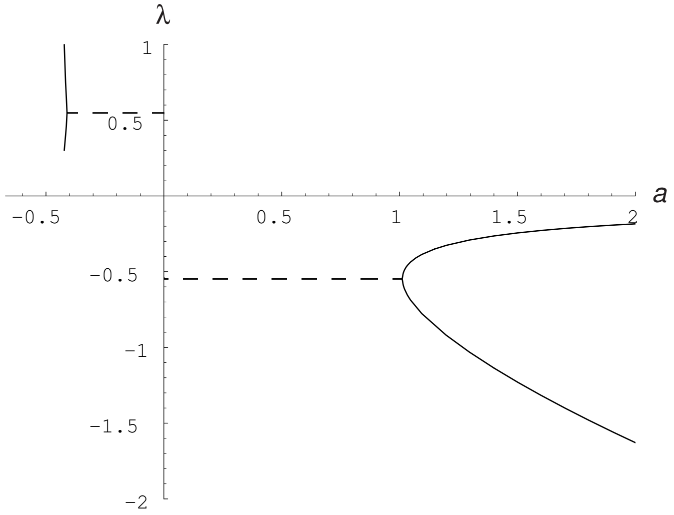

Figure 29.8.5: Eigenvalues λ of R_h^*, when $b = -.3$ and $q_f = q_f^+$, as a function of a. Note the small "line" of positive real eigenvalues for $a < 0$. Its endpoints coincide with the edges of the gap in the curve shown in Figure 8.3.

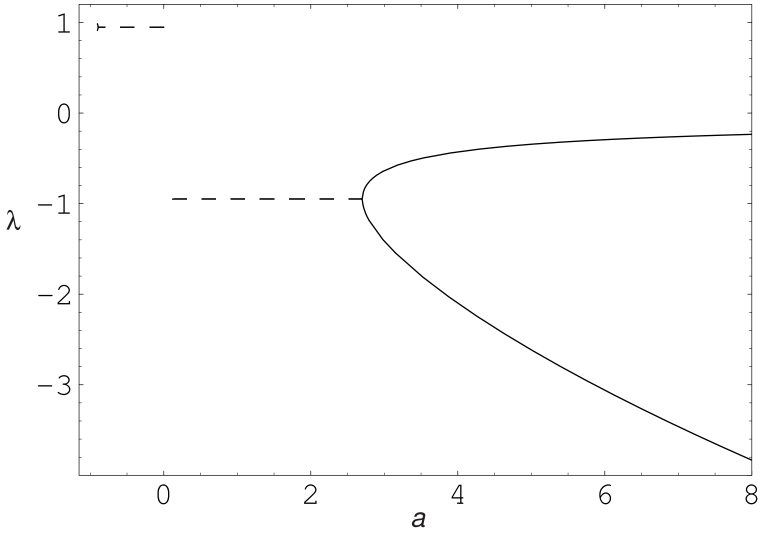

Figure 29.8.6: Eigenvalues λ of R_h^*, when $b = -.9$ and $q_f = q_f^+$, as a function of a. Note the barely visible line of positive real eigenvalues for $a < 0$. Its endpoints coincide with the edges of the tiny gap in the curve shown in Figure 8.4.

By construction $\mathcal{M}_{ffq}^{tr}$ sends the origin into itself. Let L be the Jacobian matrix (linear part) of $\mathcal{M}_{ffq}^{tr}$ about the origin. Evidently L is a diagonal matrix with diagonal entries r and u,

$$L = \begin{pmatrix} r & 0 \\ 0 & u \end{pmatrix}. \tag{29.8.24}$$

It follows that there are the relations

$$\operatorname{tr} L = r + u, \tag{29.8.25}$$

$$\det L = ru. \tag{29.8.26}$$

The map $\mathcal{M}_h^*$ given by (8.9) also sends the origin into itself, and according to (8.10) its linear part R_h^* about the origin satisfies the relations

$$\operatorname{tr} R_h^* = -2aq_f, \tag{29.8.27}$$

$$\det R_h^* = -b. \tag{29.8.28}$$

Since the maps $\mathcal{M}_h^*$ and $\mathcal{M}_{ffq}^{tr}$ are related by a linear change of variables, the matrices R_h^* and L must be related by a similarity transformation. Consequently there must be the equalities

$$\operatorname{tr} R_h^* = \operatorname{tr} L, \tag{29.8.29}$$

$$\det R_h^* = \det L. \tag{29.8.30}$$

It follows that there are the relations

$$r + u = -2aq_f, \tag{29.8.31}$$

$$ru = -b. \tag{29.8.32}$$

Note that (8.23), when employed in (8.31), implies that

$$-b > 0. \tag{29.8.33}$$

Consequently $\mathcal{M}_{ffq}^{tr}$ will be orientation preserving, and the origin will be an attracting, repelling, or hyperbolic fixed point depending on the values given to r and u.

Inspection of Figures 8.5 and 8.6, and reference to (8.18), show that, when r, u lie in the interval $(-b, 1)$, we should set $q_f = q_f^+$ so that (8.31) takes the form

$$r + u = -2aq_f^+ = (1-b) - [(1-b)^2 + 4a]^{1/2}. \tag{29.8.34}$$

Here we have used (8.15). Solving (8.34) for a gives the result

$$a = [(r+u)^2 - 2(r+u)(1+ru)]/4. \tag{29.8.35}$$

For other values of r, u we should set $q_f = q_f^-$. See Figures 8.3 and 8.4. Then (8.31) takes the form

$$r + u = -2aq_f^- = (1-b) + [(1-b)^2 + 4a]^{1/2}. \tag{29.8.36}$$

Solving (8.36) for a again gives the result (8.35). Therefore the only thing we have to remember is that $\mathcal{M}^{tr}_{ffq}$ as given by (8.22) is a form of the general Hénon map $\mathcal{M}^*_h$ about the *second* fixed point $\{q^+_f, p^+_f\}$ when r, u lie *within* the interval $(-b, 1)$, and (8.22) is a form of the general Hénon map $\mathcal{M}^*_h$ about the *first* fixed point $\{q^-_f, p^-_f\}$ when r, u lie *outside* the interval $(-b, 1)$. For most of our future discussion we will be interested in cases where b is very near -1 so that the length of the interval $(-b, 1)$ is very small. Consequently, r, u will generally lie outside the interval $(-b, 1)$. Correspondingly the origin will generally be a hyperbolic fixed point of $\mathcal{M}^{tr}_{ffq}$. At any rate, we will henceforth refer to the origin as the *first* fixed point of $\mathcal{M}^{tr}_{ffq}$, and its other fixed point (still to be found) as its *second* fixed point.

29.8.2 Lie Factorization About the First (Hyperbolic) Fixed Point

To study $\mathcal{M}^{tr}_{ffq}$ it is instructive to factorize it and then make yet more linear changes of variables. Define linear *scaling* and *damping* maps $\mathcal{S}$ and $\mathcal{D}$ by the relations

$$\mathcal{S} = \exp : \left(\log \sqrt{u/r}\right) qp :, \tag{29.8.37}$$

$$\mathcal{D} = \exp\left[\left(\log \sqrt{ru}\right) \Sigma\right]. \tag{29.8.38}$$

Note that $\mathcal{S}$ and $\mathcal{D}$ commute because of (21.3.9). It is easily verified that their actions on the variables q, p are given by the relations

$$\mathcal{S}q = (\sqrt{r/u})q, \tag{29.8.39}$$

$$\mathcal{S}p = (\sqrt{u/r})p, \tag{29.8.40}$$

$$\mathcal{D}q = (\sqrt{ru})q, \tag{29.8.41}$$

$$\mathcal{D}p = (\sqrt{ru})p. \tag{29.8.42}$$

Consequently, there are the results

$$\mathcal{S}\mathcal{D}q = rq, \tag{29.8.43}$$

$$\mathcal{S}\mathcal{D}p = up. \tag{29.8.44}$$

Next let $\mathcal{N}$ be the nonlinear map

$$\mathcal{N} = \exp : (q-p)^3/3 : . \tag{29.8.45}$$

Simple computation shows that it has the properties

$$\mathcal{N}q = q + (q-p)^2, \tag{29.8.46}$$

$$\mathcal{N}p = p + (q-p)^2. \tag{29.8.47}$$

It follows that the map $\mathcal{M}^{tr}_{ffq}$ given by (8.22) can be written in the factorized form

$$\mathcal{M}^{tr}_{ffq} = [\exp : (q-p)^3/3 :]\mathcal{S}\mathcal{D}. \tag{29.8.48}$$

Finally, let $\mathcal{O}(\theta)$ be the linear transformation (rotation)

$$\mathcal{O}(\theta) = \exp : (-\theta/2)(p^2 + q^2) : . \tag{29.8.49}$$

It is easily verified that $\mathcal{O}(5\pi/4)$ has the properties

$$\mathcal{O}(5\pi/4)q = -(q + p)/\sqrt{2}, \tag{29.8.50}$$

$$\mathcal{O}(5\pi/4)p = (q - p)/\sqrt{2}, \tag{29.8.51}$$

$$\mathcal{O}(5\pi/4)(q - p) = -\sqrt{2}q, \tag{29.8.52}$$

$$\mathcal{O}(5\pi/4)(qp) = (p^2 - q^2)/2. \tag{29.8.53}$$

See (1.2.37) and (1.2.38) and Exercise 5.4.5. Note also that $\mathcal{O}(\theta)$ and $\mathcal{D}$ commute.

Now use $\mathcal{S}$, $\mathcal{D}$, and $\mathcal{O}$ to make linear changes of variables, thereby bringing $\mathcal{M}^{tr}_{ffq}$ to a new form which we will call $\mathcal{M}_{-}$, by writing

$$\mathcal{M}_{-} = \mathcal{O}(5\pi/4)\mathcal{D}^{1/2}\mathcal{S}^{1/2}\mathcal{M}^{tr}_{ffq}\mathcal{S}^{-1/2}\mathcal{D}^{-1/2}\mathcal{O}^{-1}(5\pi/4). \tag{29.8.54}$$

Here $\mathcal{S}^{\pm 1/2}$ and $\mathcal{D}^{\pm 1/2}$ are defined by

$$\mathcal{S}^{\pm 1/2} = \exp : (\pm 1/2)(\log \sqrt{u/r})qp :, \tag{29.8.55}$$

$$\mathcal{D}^{\pm 1/2} = \exp[(\pm 1/2)(\log \sqrt{ru})\Sigma]. \tag{29.8.56}$$

From (8.48) and (8.50) through (8.56) we find that $\mathcal{M}_{-}$ has the pleasing factorization

$$\mathcal{M}_{-} = \mathcal{D}^{1/2}\mathcal{H}\exp[(-\sqrt{8}/3) : q^3 :]\mathcal{H}\mathcal{D}^{1/2} \tag{29.8.57}$$

where $\mathcal{H}$ is the linear *hyperbolic* map

$$\mathcal{H} = \exp : (1/4)(\log \sqrt{u/r})(p^2 - q^2) : . \tag{29.8.58}$$

(See Exercise 8.8.) According to our previous discussion, for the most part the origin will be a hyperbolic fixed point of $\mathcal{M}^{tr}_{ffq}$. Correspondingly, since the transformations $\mathcal{O}$, $\mathcal{D}$, and $\mathcal{S}$ involved in (8.54) are linear, the origin will also a hyperbolic fixed point of $\mathcal{M}_{-}$. According to item 1b of Section 18.5, hyperbolic fixed points have index -1. That is why we have used the symbols $\mathcal{M}_{-}$ to denote the map given by (8.54) and (8.57)

To proceed further, we need explicit formulas for the action of $\mathcal{M}_{-}$. Since we want to treat r and u on a similar footing, it is convenient to employ a variable ν defined by writing

$$r = \sqrt{ru}\exp(\nu), \tag{29.8.59}$$

$$u = \sqrt{ru}\exp(-\nu). \tag{29.8.60}$$

Then there are the relations

$$u/r = \exp(-2\nu),\ \sqrt{u/r} = \exp(-\nu), \tag{29.8.61}$$

and $\mathcal{H}$ takes the form

$$\mathcal{H} = \exp : (-\nu/4)(p^2 - q^2) : . \tag{29.8.62}$$

The action of $\mathcal{H}$ may be found from Exercise 5.4.6,

$$\mathcal{H}q = cq + sp\ ,\ \mathcal{H}p = sq + cp, \tag{29.8.63}$$

with

$$c = \cosh(\nu/2)\ ,\ s = \sinh(\nu/2); \tag{29.8.64}$$

and the action of $\mathcal{D}^{1/2}$ follows from (8.41) and (8.42),

$$\mathcal{D}^{1/2}q = (ru)^{1/4}q, \tag{29.8.65}$$

$$\mathcal{D}^{1/2}p = (ru)^{1/4}p. \tag{29.8.66}$$

From these relations we deduce that $\mathcal{M}_-$ takes the form

Action of $\mathcal{M}_-$:

$$\bar{q} = \mathcal{M}_-q = (ru)^{1/2}[q(c^2+s^2) + p(2cs) - s\sqrt{8}(ru)^{1/4}(cq+sp)^2], \tag{29.8.67}$$

$$\bar{p} = \mathcal{M}_-p = (ru)^{1/2}[q(2cs) + p(c^2+s^2) - c\sqrt{8}(ru)^{1/4}(cq+sp)^2]. \tag{29.8.68}$$

To make contact with the parameters a, b of the previous subsection, (8.35) can be solved for a in terms of b and ν using (8.32), (8.59), and (8.60) to give the result

$$a = -(1-b)(\sqrt{-b})\cosh\nu - b\cosh^2\nu. \tag{29.8.69}$$

Figure 8.7 displays a as a function of ν for various values of b. It can be shown that a as given by (8.69) always satisfies the inequality (8.3) provided ν is real. See Exercise 8.10.

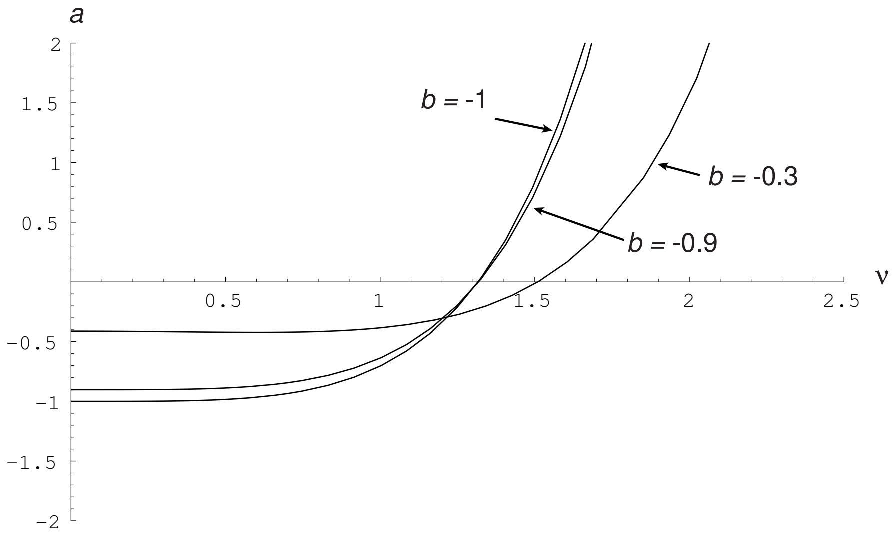

Figure 29.8.7: The parameter a as a function of ν for various values of b.

29.8.3 Location and Nature of Second Fixed Point

We know from the previous discussion, and as is evident from (8.67) and (8.68), that the origin is a fixed point of $\mathcal{M}_-$. What can be said about the *second* fixed point of $\mathcal{M}_-$ as given in the form (8.67) and (8.68)? Its position will depend on the parameters r, u; consequently it will be called the *mobile* fixed point, while the origin will be referred to as the *stationary* fixed point. Somewhat involved calculation shows that the fixed-point equations

$$\bar{q} = q,\ \bar{p} = p \tag{29.8.70}$$

have the second solution

$$q_f = \left(\frac{1}{\sqrt{2}}\right)\left[\frac{\sqrt{u}}{1-u} - \frac{\sqrt{r}}{1-r}\right]\left[\frac{(1-r)(1-u)}{(r-u)}\right]^2, \tag{29.8.71}$$

$$p_f = -\left(\frac{1}{\sqrt{2}}\right)\left[\frac{\sqrt{u}}{1-u} + \frac{\sqrt{r}}{1-r}\right]\left[\frac{(1-r)(1-u)}{r-u}\right]^2. \tag{29.8.72}$$

See Exercise 8.11. We observe that q_f is odd under the interchange of r and u, and p_f is even. According to (8.59) and (8.60), interchanging r and u is equivalent to replacing ν by $-\nu$. Therefore, q_f is an odd function of ν, and p_f is even in ν.

Note also that there is the algebraic identity

$$\frac{\sqrt{u}}{1-u} + \frac{\sqrt{r}}{1-r} = \frac{(\sqrt{u}+\sqrt{r})(1-\sqrt{ru})}{(1-u)(1-r)}. \tag{29.8.73}$$

In the symplectic case there is the relation $ru = 1$, from which it follows, using (8.72) and (8.73), that

$$p_f = 0,\ \text{symplectic case.} \tag{29.8.74}$$

[That is why we chose to bring the general Hénon map to the form given by (8.54) and (8.57).] Moreover, the relation (8.74) will be nearly satisfied if $\mathcal{M}_-$ is nearly symplectic. The expression for q_f also simplifies in the symplectic case. Insertion of (8.74) into (8.67) gives for q_f the result

$$q_f = (1/\sqrt{2})(s/c^2),\ \text{symplectic case.} \tag{29.8.75}$$

Figure 8.8 displays q_f as a function of ν in the symplectic case. Note that in the symplectic case q_f is bounded by the extrema $\pm 1/\sqrt{8}$. We also observe that when $\nu = 0$, the stationary fixed point (the one at the origin) and the mobile fixed point coincide.

To study the location of the mobile fixed point in general, and for future use, it is convenient to introduce a quantity τ defined by the relation

$$\tau = (1-r)(1-u)/(r-u). \tag{29.8.76}$$

Note that τ occurs as a factor in (8.71) and (8.72). From (8.59) through (8.61) we see that it depends on ν and ru in the fashion

$$\tau = [(ru)^{1/2} + (ru)^{-1/2} - 2\cosh\nu]/[2\sinh\nu]. \tag{29.8.77}$$

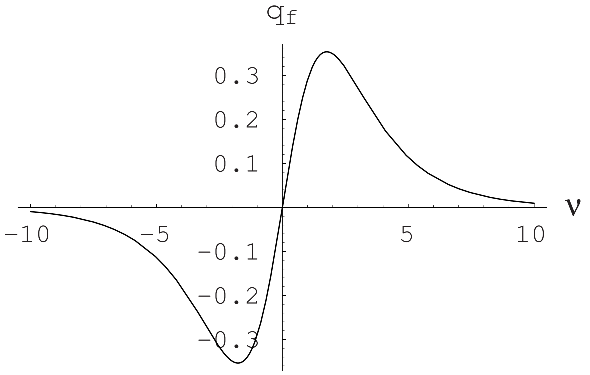

Figure 29.8.8: The quantity q_f for the mobile fixed point as a function of ν in the symplectic case $b = -1$.

It is easily checked that the function f defined by the relation

$$f(x) = x + 1/x \tag{29.8.78}$$

satisfies the inequality

$$f \geq 2 \text{ for } x > 0 \tag{29.8.79}$$

and

$$f = 2 \text{ only when } x = 1. \tag{29.8.80}$$

It follows that τ is singular at $\nu = 0$ except for the symplectic case $ru = 1$, in which case it is regular at $\nu = 0$ and in fact vanishes there. See Figure 8.9.

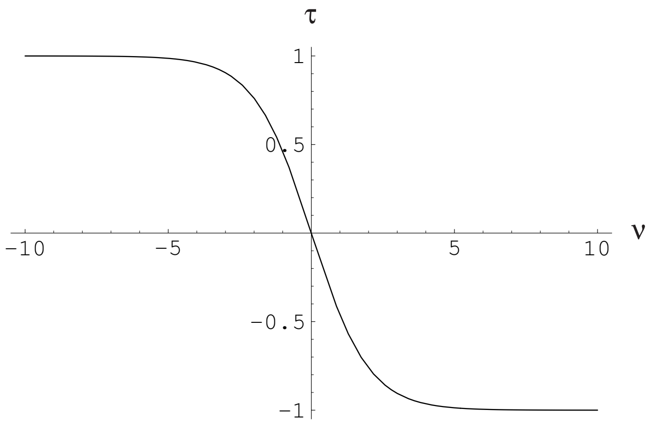

Figure 29.8.9: The quantity τ as a function of ν in the symplectic case $b = -1$.

Let us now look at a numerical example of a nonsymplectic (but orientation preserving) case. Suppose $ru = -b = .3$. Now τ is singular as a function of ν as illustrated in Figure

8.10. Correspondingly, as shown in Figures 8.11 and 8.12, q_f and p_f can also move to infinity. (See Exercise 8.9.) Figure 8.13 shows q_f and p_f simultaneously, and illustrates that now the relation $p_f = 0$ is no longer exactly maintained. Instead the mobile fixed point traces out loops. We also observe that when ν has values such that $\tau = 0$ (see Figure 8.10), then $q_f = p_f = 0$ and the stationary fixed point and the mobile fixed point again coincide. Look at Figures 8.11 through 8.13. As is consistent with the results of Sections 18.4 and 18.5, this happens when $r = 1$ or $u = 1$. See (8.71), (8.72), (8.76), and Exercise 8.10.

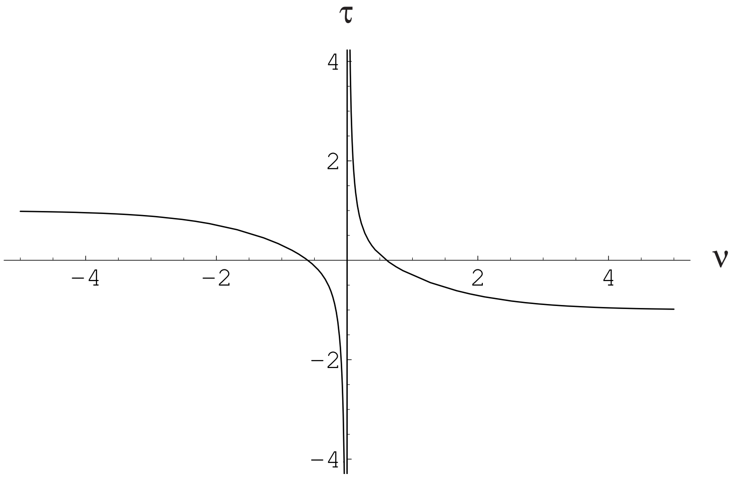

Figure 29.8.10: The quantity τ as a function of ν in the nonsymplectic case $b = -.3$.

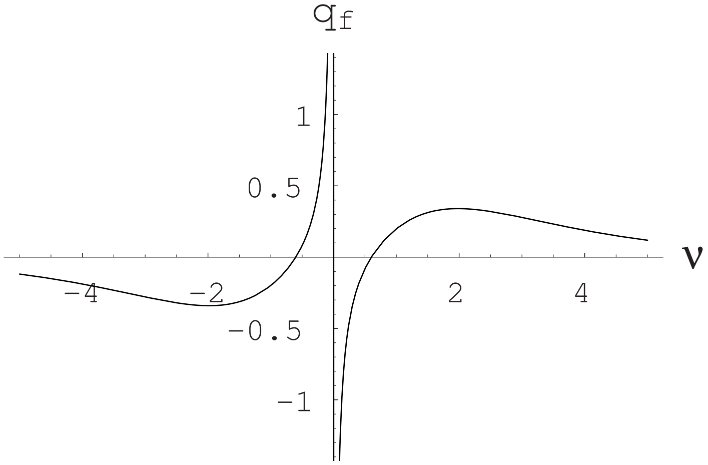

Figure 29.8.11: The quantity q_f for the mobile fixed point as a function of ν in the nonsymplectic case $b = -.3$.

We close this subsection by analyzing the nature of the second (mobile) fixed point. Rather than working with the map $\mathcal{M}_-$ [as given by (8.54), (8.57), (8.67), and (8.68)], it is algebraically simpler to work with the related map $\tilde{\mathcal{M}}$ given by

$$\begin{aligned}\tilde{\mathcal{M}} &= \mathcal{O}^{-1}(5\pi/4)\mathcal{M}_{-}\mathcal{O}(5\pi/4) = \mathcal{D}^{1/2}\mathcal{S}^{1/2}\mathcal{M}^{tr}_{ffq}\mathcal{S}^{-1/2}\mathcal{D}^{-1/2} \\ &= \mathcal{D}^{1/2}\mathcal{S}^{1/2}[\exp:(q-p)^3/3:]\mathcal{S}^{1/2}\mathcal{D}^{1/2}. \qquad (29.8.81)\end{aligned}$$

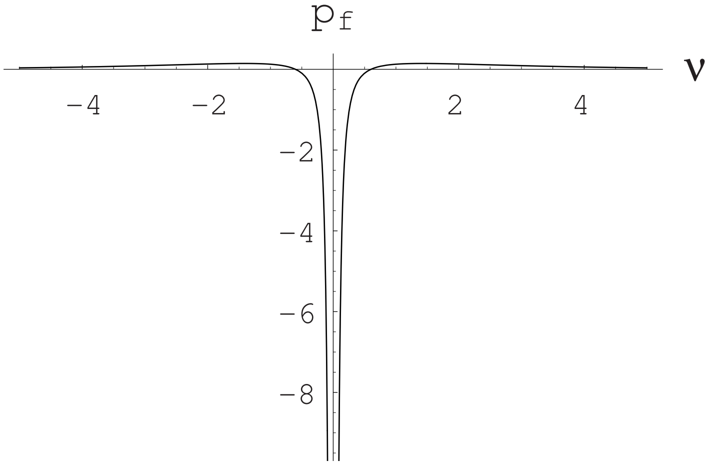

Figure 29.8.12: The quantity p_f for the mobile fixed point as a function of ν in the nonsymplectic case $b = -.3$.

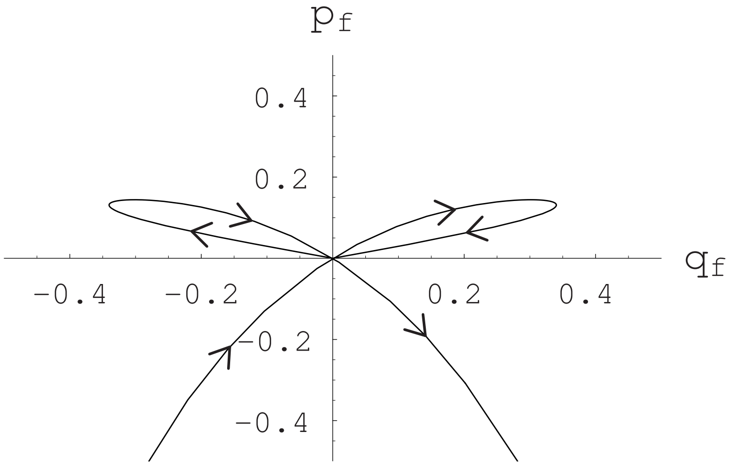

Figure 29.8.13: Location of the mobile fixed point for the nonsymplectic case $b = -.3$ and ν varying over the range $[-20, 20]$.

From (8.39) through (8.47) we find that this map takes the form

Action of $\tilde{\mathcal{M}}$:

$$\bar{q} = \tilde{\mathcal{M}}q = rq + \sqrt{r}(\sqrt{r}q - \sqrt{u}p)^2,$$

$$\bar{p} = \tilde{\mathcal{M}}p = up + \sqrt{u}(\sqrt{r}q - \sqrt{u}p)^2, \qquad (29.8.82)$$

and has the second fixed point

$$\tilde{q}_f = \left(\frac{\sqrt{r}}{1-r}\right)\left[\frac{(1-r)(1-u)}{(r-u)}\right]^2, \tag{29.8.83}$$

$$\tilde{p}_f = \left(\frac{\sqrt{u}}{1-u}\right)\left[\frac{(1-r)(1-u)}{(r-u)}\right]^2. \tag{29.8.84}$$

Since $\mathcal{O}(5\pi/4)$ is simply the r and u independent linear transformation described by the rotation matrix

$$O(5\pi/4) = \begin{pmatrix} -1/\sqrt{2} & -1/\sqrt{2} \\ 1/\sqrt{2} & -1/\sqrt{2} \end{pmatrix}, \tag{29.8.85}$$

the Jacobian matrices (linear parts) of $\mathcal{M}_-$ and $\tilde{\mathcal{M}}$ will be similar (with the matrix O providing the requisite similarity transformation) and therefore will have the *same* spectrum.

At the fixed point $\tilde{q}_f, \tilde{p}_f$ we find the Jacobian matrix of $\tilde{\mathcal{M}}$ as given by (8.82) takes the form

$$\tilde{M}_f = \tilde{M}(\tilde{q}_f, \tilde{p}_f) = L + 2[(1-r)(1-u)/(r-u)]\begin{pmatrix} r & -\sqrt{ru} \\ \sqrt{ru} & -u \end{pmatrix}, \tag{29.8.86}$$

where L denotes the diagonal matrix (8.24). [Note that the factor τ, as given by (8.76), also appears in (8.86).] The nature of this fixed point can be determined by finding the spectrum of $\tilde{M}_f$. We know from (3.42) and (8.28), or find by direct calculation, that

$$\det \tilde{M}_f = ru. \tag{29.8.87}$$

Also, direct calculation gives the result

$$2\sigma = \text{ tr } \tilde{M}_f = 2(1+ru) - (r+u). \tag{29.8.88}$$

Suppose λ_1, λ_2 are the eigenvalues of $\tilde{M}_f$. Then from standard matrix relations we again have the results

$$\lambda_1\lambda_2 = ru \ , \ \lambda_1 + \lambda_2 = 2\sigma. \tag{29.8.89}$$

Define quantities μ_1, μ_2 by the rules

$$\mu_1 = \lambda_1/\sqrt{ru} \ , \ \mu_2 = \lambda_2/\sqrt{ru}. \tag{29.8.90}$$

They evidently satisfy the relations

$$\mu_1\mu_2 = 1 \ , \ \mu_1 + \mu_2 = 2\sigma/\sqrt{ru}. \tag{29.8.91}$$

Equations (8.91) have the immediate solution

$$\mu_\pm = \sigma/\sqrt{ru} \pm \sqrt{\sigma^2/(ru) - 1}. \tag{29.8.92}$$

We see that the μ behave like the eigenvalues of a 2 × 2 symplectic matrix as in Figure 3.4.1. Correspondingly, the λ are given by the relations

$$\lambda_\pm = (\sqrt{ru})\mu_\pm = \sigma \pm \sqrt{\sigma^2 - ru}. \tag{29.8.93}$$

They behave in a similar fashion, but are governed by a circle of radius $\sqrt{ru} = \sqrt{-b}$. According to (8.93), they can potentially come off or on this circle when

$$\sigma^2 = ru, \tag{29.8.94}$$

from which condition we deduce, using (8.88), the relation

$$4r^2u^2 - 4ru(r+u) + r^2 + 6ru + u^2 - 4(r+u) + 4 = 0. \tag{29.8.95}$$

Finally, it is easily verified that -1 becomes an eigenvalue of $\tilde{M}_f$ when r and u satisfy the relation

$$3(1+ru) = (r+u). \tag{29.8.96}$$

See Exercise 8.15.

In terms of the variables ν and ru, the quantity σ is given by the relation

$$\sigma = (ru)^{1/2}[(ru)^{1/2} + (ru)^{-1/2} - \cosh\nu]. \tag{29.8.97}$$

It is also useful to examine the matrix $\tilde{M}_f'$ defined by

$$\tilde{M}_f' = (ru)^{-1/2}\tilde{M}_f. \tag{29.8.98}$$

It is symplectic, and indeed is the symplectic factor in the symplectic polar decomposition of $\tilde{M}_f$. In the case that its eigenvalues lie on the unit circle, it can be brought to the normal form (3.5.61) by a symplectic similarity transformation. See (3.5.53). Moreover, since the trace is preserved by a similarity transformation, we find from (3.5.61), (8.88), (8.97), and (8.98) the result that its phase advance ϕ satisfies the relation

$$\cos\phi = [(ru)^{1/2} + (ru)^{-1/2} - \cosh\nu]. \tag{29.8.99}$$

Now let us look at two numerical examples. In the first example $\tilde{M}_f$ will be symplectic, and thus we set $ru = -b = 1$. Figures 8.14 and 8.15 show $\sigma/\sqrt{ru}$ and the spectrum of $\tilde{M}_f$ as ν is varied. Finally, Figure 8.16 shows the phase advance ϕ for $\tilde{M}_f$ as a function of ν. Note that (8.99) only gives the cosine of the phase advance, and therefore only determines the phase advance up to a sign. The sign of ϕ was determined by bringing $\tilde{M}_f$ to normal form numerically and then examining the 1,2 entry of the normal form. See (3.5.41).

As a second numerical example we consider the nonsymplectic (but orientation preserving) case $ru = -b = .3$. Figures 8.17 and 8.18 show $\sigma/\sqrt{ru}$ and the spectrum of $\tilde{M}_f$ as ν is varied. Figure 8.19 shows the phase advance ϕ for $\tilde{M}_f'$ as a function of ν. The eigenvalues leave the unit circle for $-.839 \leq \nu \leq .839$ and $|\nu| > .886$, and therefore the phase advance is undefined in these ranges. See Exercises 8.18 and 8.19. As is evident from (8.97) and Figure 8.17, σ takes on its maximum value for $\nu = 0$. Consequently, the maximum value of λ_+ as given by (8.93) depends only on the value of the product ru. Figure (8.20) displays this maximum value, $\lambda_+^{\max}$, as a function of ru over the range $0 \leq ru \leq 1$. As the graphic suggests, and computation confirms, $\lambda_+^{\max}$ decreases monotonically from $\lambda_+^{\max} = 2$ for $ru = 0$ to $\lambda_+^{\max} = 1$ for $ru = 1$.

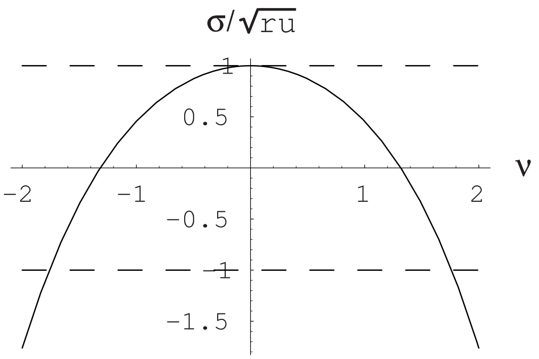

Figure 29.8.14: Value of $\sigma/\sqrt{ru}$ as a function ν in the symplectic case $b = -1$.

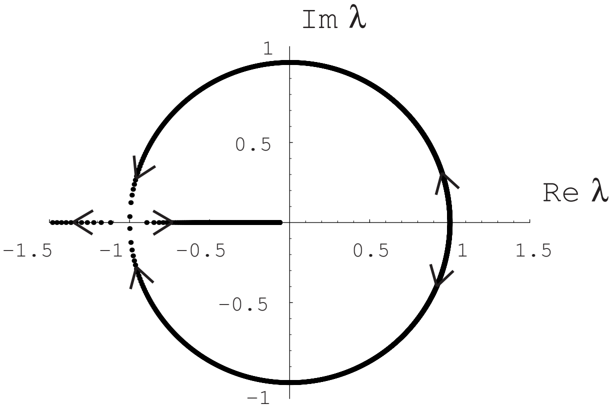

Figure 29.8.15: Spectrum of $\tilde{M}_f$ (and of the linear part of $\mathcal{M}_-$ about its second fixed point) for ν varying over the range $[0, 3]$ in the symplectic case $b = -1$. An identical picture is produced for ν varying in the range $[-3, 0]$ as is evident from (8.97) and Figure 8.14. The eigenvalues leave the unit circle at $\nu = \pm 1.763$ as is also evident from (8.97) and Figure 8.14. See Exercise 8.18.

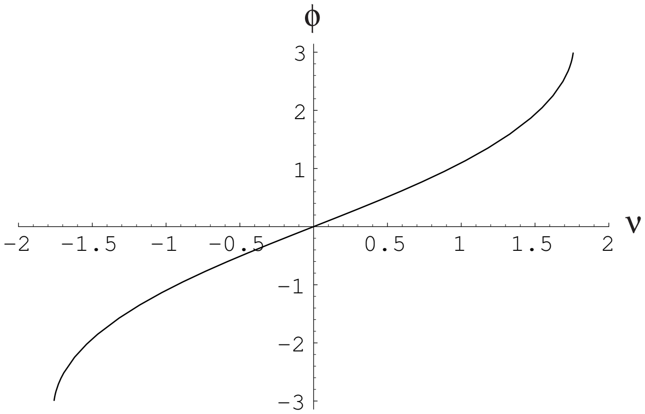

Figure 29.8.16: Phase advance of $\tilde{M}_f$ (and of the linear part of $\mathcal{M}_-$ about its second fixed point) as a function of ν in the symplectic case $b = -1$. Only the range $\nu \in [-1.763, 1.763]$ is shown because the eigenvalues leave the unit circle outside this range.

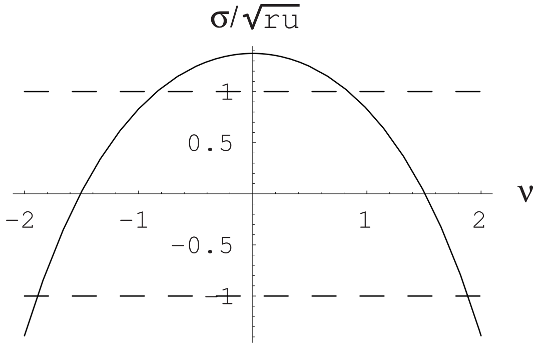

Figure 29.8.17: Value of $\sigma/\sqrt{ru}$ as a function of ν in the nonsymplectic case $b = -.3$.

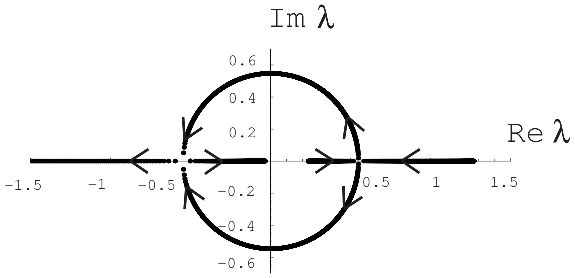

Figure 29.8.18: Spectrum of $\tilde{M}_f$ (and of the linear part of $\mathcal{M}_-$ about its second fixed point) for ν varying over the range $[0, 3]$ in the nonsymplectic case $b = -.3$.

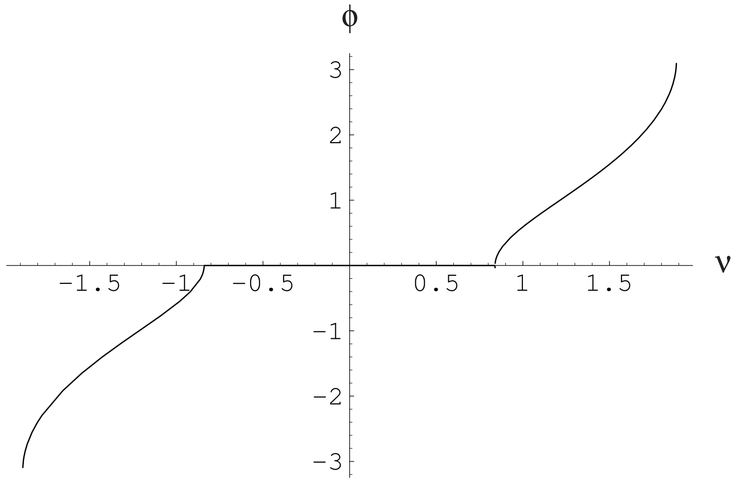

Figure 29.8.19: Phase advance of $\tilde{M}_f'$ as a function of ν in the nonsymplectic case $b = -.3$. Only the ranges $\nu \in [-1.886, -.839]$ and $\nu \in [.839, 1.886]$ are shown because the eigenvalues of $\tilde{M}_f'$ leave the unit circle for ν outside these ranges. See Figure 8.17 and Exercise 8.15.

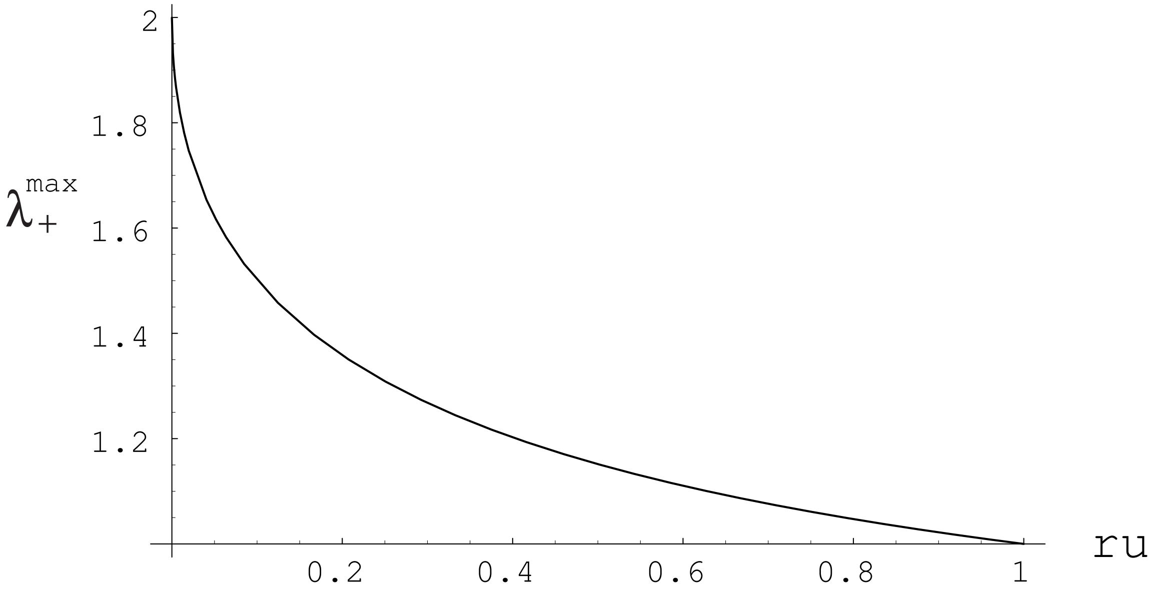

Figure 29.8.20: Maximum value of λ_+ as a function of ru.

29.8.4 Expansion and Lie Factorization About Second Fixed Point

To make contact with earlier work, and for future use, it is also useful to have an expansion and factorization of the Hénon map $\mathcal{M}_-$ about its second fixed point (in which case the second fixed point is placed at the origin and the first fixed point, which was the origin, becomes mobile). We will first expand and factorize $\tilde{\mathcal{M}}$, see (8.81) and (8.82), about its second fixed point $\tilde{q}_f, \tilde{p}_f$; and we will then use the transformation $\mathcal{O}(5\pi/4)$ to obtain an expansion and factorization of $\mathcal{M}_-$ about its second fixed point q_f, p_f.

To expand $\tilde{\mathcal{M}}$ as given by (8.82) about the fixed point $\tilde{q}_f, \tilde{p}_f$, make the change of variables

$$q = Q + \tilde{q}_f,\ p = P + \tilde{p}_f,\ \overline{q} = \overline{Q} + \tilde{q}_f,\ \overline{p} = \overline{P} + \tilde{p}_f, \tag{29.8.100}$$

which amounts to a translation. We will use the notation $\tilde{\mathcal{M}}_f$ to denote the map $\tilde{\mathcal{M}}$ expanded about the fixed point $\tilde{q}_f, \tilde{p}_f$. Inserting (8.100) into (8.82) yields the result

Action of $\tilde{\mathcal{M}}_f$:

$$\begin{aligned}\overline{Q} &= rQ + 2r[(1-r)(1-u)/(r-u)]Q - 2\sqrt{ru}[(1-r)(1-u)/(r-u)]P \\ &\quad + \sqrt{r}(\sqrt{r}Q - \sqrt{u}P)^2,\end{aligned} \tag{29.8.101}$$

$$\begin{aligned}\overline{P} &= 2\sqrt{ru}[(1-r)(1-u)/(r-u)]Q + uP - 2u[(1-r)(1-u)/(r-u)]P \\ &\quad + \sqrt{u}(\sqrt{r}Q - \sqrt{u}P)^2.\end{aligned} \tag{29.8.102}$$

Note that the linear part of $\tilde{\mathcal{M}}_f$ gives a matrix that agrees with (8.86).

We will now seek to Lie factorize $\tilde{\mathcal{M}}_f$. The first step is to show that $\tilde{\mathcal{M}}_f$ can be written as the product of 3 maps. Let $F(\tau)$ be the symplectic matrix

$$F(\tau) = \begin{pmatrix} 1+\tau & -\tau \\ \tau & 1-\tau \end{pmatrix}. \tag{29.8.103}$$

With L given by (8.24), define matrices ${}^1M$ and ${}^2M$ by the rules

$${}^1M = L^{1/2}F = \begin{pmatrix} \sqrt{r}(1+\tau) & -\sqrt{r}\tau \\ \sqrt{u}\tau & \sqrt{u}(1-\tau) \end{pmatrix}, \tag{29.8.104}$$

$${}^2M = FL^{1/2} = \begin{pmatrix} \sqrt{r}(1+\tau) & -\sqrt{u}\tau \\ \sqrt{r}\tau & \sqrt{u}(1-\tau) \end{pmatrix}. \tag{29.8.105}$$

Then it is easily verified that there is the relation

$${}^f\tilde{M} = ({}^1M)\ ({}^2M) \tag{29.8.106}$$

provided τ has the value

$$\tau = [(1-r)(1-u)/(r-u)] = (\sqrt{r}\tilde{q}_f - \sqrt{u}\tilde{p}_f). \tag{29.8.107}$$

Here we have used the symbol ${}^f\tilde{M}$ to replace the symbol $\tilde{M}_f$ since we will soon be adding subscripts to denote specific matrix elements. Note also that (8.107) agrees with (8.76) as the notation is intended to indicate.

Next consider three maps:

$$\bar{Q} = {}^2M_{11}Q + {}^2M_{12}P,\ \bar{P} = {}^2M_{21}Q + {}^2M_{22}P; \tag{29.8.108}$$

$$\bar{\bar{Q}} = \bar{Q} + (\bar{Q} - \bar{P})^2,\ \bar{\bar{P}} = \bar{P} + (\bar{Q} - \bar{P})^2; \tag{29.8.109}$$

$$\bar{\bar{\bar{Q}}} = {}^1M_{11}\ \bar{\bar{Q}} + {}^1M_{12}\ \bar{\bar{P}},\ \bar{\bar{\bar{P}}} = {}^1M_{21}\ \bar{\bar{Q}} + {}^1M_{22}\ \bar{\bar{P}}\ . \tag{29.8.110}$$

Concatenating the first two yields the result

$$\bar{\bar{Q}} = {}^2M_{11}Q + {}^2M_{12}P + ({}^2M_{11}Q + {}^2M_{12}P - {}^2M_{21}Q - {}^2M_{22}P)^2, \tag{29.8.111}$$

$$\bar{\bar{P}} = {}^2M_{21}Q + {}^2M_{22}P + ({}^2M_{11}Q + {}^2M_{12}P - {}^2M_{21}Q - {}^2M_{22}P)^2. \tag{29.8.112}$$

Exploiting the specific form of ${}^2M$ simplifies the common parenthetical term in (8.111) and (8.112) to give the result

$$({}^2M_{11}Q + {}^2M_{12}P - {}^2M_{21}Q - {}^2M_{22}P) = (\sqrt{r}Q - \sqrt{u}P). \tag{29.8.113}$$

Thus the product of the first two maps can also be rewritten in the form

$$\bar{\bar{Q}} = {}^2M_{11}Q + {}^2M_{12}P + (\sqrt{r}Q - \sqrt{u}P)^2, \tag{29.8.114}$$

$$\bar{\bar{P}} = {}^2M_{21}Q + {}^2M_{22}P + (\sqrt{r}Q - \sqrt{u}P)^2. \tag{29.8.115}$$

Now concatenate in the third map by solving (8.110) for $\bar{\bar{\bar{Q}}}$,$\bar{\bar{\bar{P}}}$ to find the result

$$\begin{aligned}\bar{\bar{\bar{Q}}} &= [({}^1M_{11})({}^2M_{11}) + ({}^1M_{12})({}^2M_{21})]Q + [({}^1M_{11})({}^2M_{12}) + ({}^1M_{12})({}^2M_{22})]P \\ &\quad + ({}^1M_{11} + {}^1M_{12})(\sqrt{r}Q - \sqrt{u}P)^2,\end{aligned} \tag{29.8.116}$$

$$\begin{aligned}\bar{\bar{\bar{P}}} &= [({}^1M_{21})({}^2M_{11}) + ({}^1M_{22})({}^2M_{21})]Q + [({}^1M_{21})({}^2M_{12}) + ({}^1M_{22})({}^2M_{22})]P \\ &\quad + ({}^1M_{21} + {}^1M_{22})(\sqrt{r}Q - \sqrt{u}P)^2.\end{aligned} \tag{29.8.117}$$

In view of (8.106) and the explicit form (8.104) of ${}^1M$, this result can be rewritten in the form

$$\bar{\bar{\bar{Q}}} = {}^f\tilde{M}_{11}Q + {}^f\tilde{M}_{12}P + \sqrt{r}(\sqrt{r}Q - \sqrt{u}P)^2, \tag{29.8.118}$$

$$\bar{\bar{\bar{P}}} = {}^f\tilde{M}_{21}Q + {}^f\tilde{M}_{22}P + \sqrt{u}(\sqrt{r}Q - \sqrt{u}P)^2, \tag{29.8.119}$$

which is identical to the map (8.101), (8.102) upon replacing $\bar{\bar{\bar{Q}}}$,$\bar{\bar{\bar{P}}}$ by $\bar{Q}$,$\bar{P}$. Thus $\tilde{\mathcal{M}}_f$ can be written as the product of the 3 maps (8.108) through (8.110)

Lie factorization of $\tilde{\mathcal{M}}_f$ is now straightforward. It is easily verified that the Lie transformation for $F(\tau)$ is given (in q,p variables) by the relation

$$\mathcal{F}(\tau) = \exp : (\tau/2)(q-p)^2 : . \tag{29.8.120}$$

Also, the nonlinear relation (8.109) is produced by the Lie transformation $\exp :(q-p)^3/3:$. Finally, the Lie transformation $\mathcal{L}^{1/2}$ corresponding to $L^{1/2}$ is given by

$$\mathcal{L}^{1/2} = \exp[(1/2)(\log\sqrt{ru}\Sigma]\exp :(1/2)(\log\sqrt{u/r})qp := \mathcal{D}^{1/2}\mathcal{S}^{1/2}. \tag{29.8.121}$$

See (8.37) through (8.44). Consequently, the map $\tilde{\mathcal{M}}_f$ (again in q,p variables) has the factorization

$$\tilde{\mathcal{M}}_f = \mathcal{L}^{1/2}\exp :(\tau/2)(q-p)^2 : \exp :(q-p)^3/3 : \exp :(\tau/2)(q-p)^2 : \mathcal{L}^{1/2}. \tag{29.8.122}$$

Note that in deducing (8.122) it is necessary to recall that Lie transformations act in the opposite order of matrices. See Section 8.3. Note also that the factorization (8.122), like (8.81), has the pleasing feature that the outer linear maps (which depend on r,u) appear in a symmetric way, and the central factor again has a fixed simple form.

As indicated at the beginning of this section, our real aim is to expand $\mathcal{M}_-$ about q_f, p_f. Since the fixed point q_f, p_f is generally elliptic or inversion hyperbolic, it generally has index $+1$. (See Section 18.5). We will therefore call this desired map $\mathcal{M}_+$. Then, in view of (8.81), there is the relation

$$\mathcal{M}_+ = \mathcal{O}(5\pi/4)\tilde{\mathcal{M}}_f\mathcal{O}^{-1}(5\pi/4). \tag{29.8.123}$$

From (8.52) there is the result

$$\mathcal{O}(5\pi/4)\exp :(\tau/2)(q-p)^2 : \mathcal{O}^{-1}(5\pi/4) = \exp :\tau q^2 : . \tag{29.8.124}$$

Also, there are the relations (8.147) and (8.148). See Exercise 8.8. It follows that $\mathcal{M}_+$ has the factorization

$$\mathcal{M}_+ = \mathcal{D}^{1/2}\mathcal{H}\mathcal{B}\mathcal{N}\mathcal{B}\mathcal{H}\mathcal{D}^{1/2} \tag{29.8.125}$$

where $\mathcal{B}$ and $\mathcal{N}$ are defined by

$$\mathcal{B} = \exp :\tau q^2 :, \tag{29.8.126}$$

$$\mathcal{N} = \exp[(-\sqrt{8}/3) : q^3 :]. \tag{29.8.127}$$

Here we have again used the result that $\mathcal{D}$ commutes with $\mathcal{S}$ and $\mathcal{O}(\theta)$.

In the work to follow we will study the properties of the general Hénon map either in the form $\mathcal{M}_-$ given by (8.57) or the form $\mathcal{M}_+$ given by (8.123) or (8.125). However, before doing so, we will demonstrate that in the symplectic case the map $\mathcal{M}_+$ can be brought to the form (1.2.39) provided the eigenvalues of the linear part of $\mathcal{M}_+$ (about the origin) are complex. Starting from (8.125) we write

$$\mathcal{D}^{-1/2}\mathcal{M}_+\mathcal{D}^{-1/2} = \mathcal{H}\mathcal{B}\mathcal{N}\mathcal{B}\mathcal{H}, \tag{29.8.128}$$

$$\mathcal{B}\mathcal{H}\mathcal{D}^{-1/2}\mathcal{M}_+\mathcal{D}^{-1/2}\mathcal{H}^{-1}\mathcal{B}^{-1} = \mathcal{B}\mathcal{H}\mathcal{H}\mathcal{B}\mathcal{N} = \mathcal{C}\mathcal{N} \tag{29.8.129}$$

where $\mathcal{C}$ is the symplectic map

$$\mathcal{C} = \mathcal{B}\mathcal{H}\mathcal{H}\mathcal{B}. \tag{29.8.130}$$

It can be shown that $\mathcal{C}$ has a square root (that is also symplectic) if the eigenvalues of $\tilde{M}_f'$ are complex. Moreover, the eigenvalues of $\mathcal{C}$ and $\mathcal{C}^{1/2}$ will be on the unit circle. See Exercise 8.23. Consequently, in this case, (8.129) may be rewritten in the form

$$\mathcal{C}^{-1/2}\mathcal{B}\mathcal{H}\mathcal{D}^{-1/2}\mathcal{M}_+\mathcal{D}^{-1/2}\mathcal{H}^{-1}\mathcal{B}^{-1}\mathcal{C}^{1/2} = \mathcal{C}^{1/2}\mathcal{N}\mathcal{C}^{1/2}, \tag{29.8.131}$$

or

$$\mathcal{C}^{-1/2}\mathcal{B}\mathcal{H}\mathcal{M}_{+}\mathcal{H}^{-1}\mathcal{B}^{-1}\mathcal{C}^{1/2} = \mathcal{D}^{1/2}\mathcal{C}^{1/2}\mathcal{N}\mathcal{C}^{1/2}\mathcal{D}^{1/2}. \tag{29.8.132}$$

Here we have used the fact that $\mathcal{D}$ also commutes with $\mathcal{B}$, $\mathcal{C}$, and $\mathcal{H}$.

Next, for any $\mathcal{C}$ of the form (8.130), there is a κ such that

$$\exp : \kappa qp : \mathcal{C}^{1/2} \exp : -\kappa qp : = \exp[-(\phi/4) : p^2 + q^2 :] = \mathcal{O}(\phi/2), \tag{29.8.133}$$

where ϕ is the phase advance of M'_f. See Exercise 8.24. Also, we have the relation

$$\hat{\mathcal{N}} \overset{\text{def}}{=} \exp : \kappa qp : \mathcal{N} \exp : -\kappa qp : = \exp : -[\exp(-\kappa)](\sqrt{8}/3)q^3 : . \tag{29.8.134}$$

Let $\mathcal{D}_\lambda$ denote the map defined by the relation

$$\mathcal{D}_\lambda = \exp(\lambda\Sigma). \tag{29.8.135}$$

Then there is a choice of λ such that

$$\mathcal{D}_\lambda \hat{\mathcal{N}} \mathcal{D}_\lambda^{-1} = \exp : -q^3 : . \tag{29.8.136}$$

See Exercise 8.25. Finally, consider the transformation $\mathcal{O}(\pi)$. According to (5.4.19) there are the relations

$$\mathcal{O}(\pi)q = -q \ , \ \mathcal{O}(\pi)p = -p, \tag{29.8.137}$$

from which it follows that

$$\mathcal{O}(\pi)[\exp : -q^3 :]\mathcal{O}^{-1}(\pi) = \exp(: q^3 :). \tag{29.8.138}$$

Now put all this information together. Doing so gives the final result

$$\mathcal{A}\mathcal{M}_{+}\mathcal{A}^{-1} = \mathcal{D}^{1/2}\mathcal{O}(\phi/2)[\exp(: q^3 :)]\mathcal{O}(\phi/2)\mathcal{D}^{1/2} \tag{29.8.139}$$

where $\mathcal{A}$ is the linear map

$$\mathcal{A} = \mathcal{D}_\lambda \mathcal{O}(\pi)[\exp : \kappa qp :]\mathcal{C}^{-1/2}\mathcal{B}\mathcal{H}. \tag{29.8.140}$$

See Exercise 8.26. We observe that, apart from the damping map $\mathcal{D}^{1/2}$, the right sides of (1.2.39) and (8.139) are identical. Thus, under the assumption made about the spectrum of $\tilde{M}'_f$ and in the absence of damping, the map $\mathcal{M}_{+}$ given by (8.125) and the map $\mathcal{M}(\theta)$ given by (1.2.39) are physically equivalent.

Exercises

29.8.1. Verify (8.1) and (8.2). Show that the fixed points $\{q_f^{\pm}, p_f^{\pm}\}$ are real when $a > a_{\min}$. See (8.4). Show that, as illustrated in Figures 8.1 and 8.4, the quantity q_f^{+} has a finite limit as $a \to 0$, and $q_f^{-} \to \infty$ as $a \to 0$. Verify (8.5) and (8.6). Find the asymptotes of $q_f^{\pm}$ as $a \to \infty$.

29.8.2. Verify (8.9).

29.8.3. Show that (8.13) is satisfied for $q_f = q_f^-$ if (8.3) holds, and hence the spectrum in this case is real. Show that at the fixed points $q_f^\pm, p_f^\pm$ given by (8.1) and (8.2) the Jacobian matrices of $\mathcal{M}_h^*$ are given by the relations

$$R_\pm = R_h^*(q_f^\pm, p_f^\pm) = \begin{pmatrix} -2aq_f^\pm & 1 \\ b & 0 \end{pmatrix}. \tag{29.8.141}$$

Show that $R_\pm$ has the trace

$$2\sigma_\pm = \mathrm{tr} R_\pm = (1-b) \mp [(1-b)^2 + 4a]^{1/2}. \tag{29.8.142}$$

Show that the spectrum of R_- is positive, and verify (8.18). Evaluate (8.18) for the cases $b = -.3, -.9$ and compare your results with Figures 8.3 and 8.4.

29.8.4. Review Exercise 8.3. Show that the spectrum of R_+ can be complex, and that the transition from real to complex occurs at the a values given by (8.19) and (8.21). Show that at the value of a given by (8.19) the eigenvalues leave the complex plane and have the value

$$\lambda = -\sqrt{-b}. \tag{29.8.143}$$

Compute, using (8.19), a and λ for the cases $b = -.3$ and $-.9$, and compare these values with those shown in Figures 8.5 and 8.6. Show that at the value of a given by (8.21) the eigenvalues also leave the complex plane and have the value

$$\lambda = +\sqrt{-b}. \tag{29.8.144}$$

Again compute numerical results and compare these results with those shown in Figures 8.5 and 8.6. Show that R_+ has -1 as an eigenvalue when

$$(-1+b) = 2\sigma_+, \tag{29.8.145}$$

and derive the condition (8.20). Assuming that period doubling occurs when R_+ has -1 as an eigenvalue, see Section 18.9, show that (8.20) predicts period doubling for $b = -.3$ when $a = 1.2675$, which is consistent with Figure 7.4. Consider also the cases $b = 0$ and $b = +.3$. Compute the corresponding value of a for each and relate your results to Figures 1.2.10 and 7.1.

29.8.5. Solve (8.34) and (8.36) for a to verify (8.35).

29.8.6. Verify the relations (8.39) through (8.44).

29.8.7. Verify the factorization (8.48).

29.8.8. Verify (8.57) and (8.58) using relations of the form

$$\mathcal{O}\mathcal{S}^{1/2}\mathcal{O}^{-1} = \exp:(1/2)(\log\sqrt{u/r})\mathcal{O}qp: \tag{29.8.146}$$

to show that

$$\mathcal{O}(5\pi/4)\mathcal{S}^{1/2}\mathcal{O}^{-1}(5\pi/4) = \mathcal{H}, \tag{29.8.147}$$

$$\mathcal{O}(5\pi/4)\exp:(q-p)^3/3:\mathcal{O}^{-1}(5\pi/4) = \exp[(-\sqrt{8}/3):q^3:]. \tag{29.8.148}$$

29.8.9. Verify (8.67) and (8.68).

29.8.10. Show from (8.1) and (8.2) that the fixed points q_f^+, p_f^+ and q_f^-, p_f^- coincide when

$$(1-b)^2 + 4a = 0. \tag{29.8.149}$$

Show, using (8.31) and (8.32), that (8.149) implies $r = 1$ or $u = 1$. Verify that (8.69) can be rewritten in the form

$$a = -(1-b)^2/4 + (-b)[\cosh\nu - (1-b)/(2\sqrt{-b})]^2, \tag{29.8.150}$$

thereby demonstrating that a as given by (8.69) always satisfies the inequality (8.3) provided ν is real. Note also that equality, (8.149), is achieved for real ν.

29.8.11. Verify that the map (8.81) has the action (8.82), and has the second (besides the origin) fixed point (8.83) and (8.84). Now use (8.85) to verify that $\mathcal{M}_-$ has the second fixed point (8.71) and (8.72).

29.8.12. Show that the first factor in q_f as given by (8.71) vanishes when $\nu = 0$. Nevertheless, show that the second factor, which is τ^2, is sufficiently divergent at $\nu = 0$ (in the nonsymplectic case) so that q_f is also divergent at $\nu = 0$ in the nonsymplectic case. Verify (8.77).

29.8.13. Verify (8.73) through (8.75).

29.8.14. Verify (8.86).

29.8.15. Verify (8.88).

29.8.16. Verify (8.96) and show that it is equivalent to (8.20).

29.8.17. Verify (8.97)

29.8.18. Verify (8.95). Determine the condition for ϕ, as defined by (8.99), to be real in both the symplectic and nonsymplectic cases. Consider the symplectic case by writing $r = \Lambda$, $u = 1/\Lambda$. Show, using (8.88), that then

$$2\sigma = 4 - \Lambda - 1/\Lambda, \tag{29.8.151}$$

and compare your result with (6.24). Show that in the symplectic case the eigenvalues of $\tilde{M}_f$ leave the unit circle through the point -1 when $\Lambda = 3 \pm \sqrt{8}$.

29.8.19. Correlate the data shown in Figures 8.5 and 8.18.

29.8.20. Problem on Poincaré index: show that index on large circle is zero for Hénon map.

29.8.21. Verify (8.106) using (8.86), (8.103) through (8.105), and (8.107).

29.8.22. Verify that $\mathcal{F}(\tau)$ as given by (8.120) corresponds to $F(\tau)$ as given by (8.103).

29.8.23.

29.8.24.

29.8.25.

29.8.26. Verify (8.139) and (8.140) using (8.131) through (8.134), (8.136), and (8.138). Hint: Recall that $\mathcal{D}$ and $\mathcal{D}_\lambda$ commute with $\mathcal{O}$ and $[\exp : \kappa qp :]$. In the course of your verification use relations of the form

$$\begin{aligned}&[\exp : \kappa qp :]\mathcal{C}^{1/2}\mathcal{N}\mathcal{C}^{1/2}[\exp : -\kappa qp :] =\\ &[\exp : \kappa qp :]\mathcal{C}^{1/2}[\exp : -\kappa qp :][\exp : \kappa qp :]\mathcal{N}[\exp : -\kappa qp :] \times\\ &[\exp : \kappa qp :]\mathcal{C}^{1/2}[\exp : -\kappa qp :] = \mathcal{O}(\phi/2)\hat{\mathcal{N}}\mathcal{O}(\phi/2).\end{aligned} \tag{29.8.152}$$

29.9 Period Doubling and Strange Attractors

With a preliminary study of the general Hénon map $\mathcal{M}_h$ behind us, let us explore the results of iterating $\mathcal{M}_h$. We will first study the behavior of $\mathcal{M}_-$, the form of the general Hénon map with its hyperbolic fixed point translated to the origin as given by (8.57), (8.67), and (8.68). We will examine the stable and unstable manifolds, and the nature of the second fixed point, for various representative values of r and u. Then, to explore the behavior near the the second fixed point in more detail, we will employ $\mathcal{M}_+$, the form of the general Hénon map with its second fixed point translated to the origin as gven by (8.123) or (8.125)

29.9.1 Behavior about Hyperbolic Fixed Point

In analogy with (6.4), let us begin with the case where

$$r = \Lambda, u = 1/\Lambda, \text{with } \Lambda = 3, \tag{29.9.1}$$

and for which

$$b = -ru = -1,\ a = -5/9 = -.555\cdots,\ \nu = 1.098\cdots. \tag{29.9.2}$$

In this case $\mathcal{M}_-$ is symplectic and, according to (8.71) and (8.72), the second fixed point has the location

$$\{q_f, p_f\} = \{\sqrt{3/32}, 0\} = \{.306\cdots, 0\}. \tag{29.9.3}$$

Figure 9.1 shows the stable and unstable manifolds for this case as well as the behavior of points near the second fixed point. The second fixed point is elliptic, in accord with Figure 8.14, and has a tune $T = .1959\cdots$. See Exercise 9.1. Evidently Figure 9.1 is similar to Figure 6.2. The difference consists of a rescaling of the axes and a counterclockwise rotation by $5\pi/4$ radians to achieve symmetry about the q axis. See (8.54) and (8.57). Note that the homoclinic point K now lies on the q axis, and that the whole figure is symmetric about the q axis.

Discussion of period doubling.

29.9.2 Behavior about Second Fixed Point

Discussion of strange attractor.

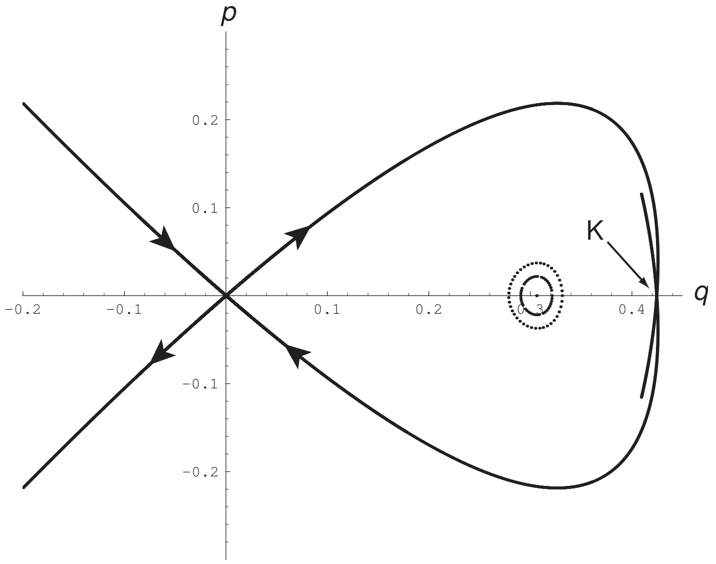

Figure 29.9.1: Stable and unstable manifolds for $\mathcal{M}_{-}$ and behavior of points near the second fixed point for the case $\Lambda = 3$.

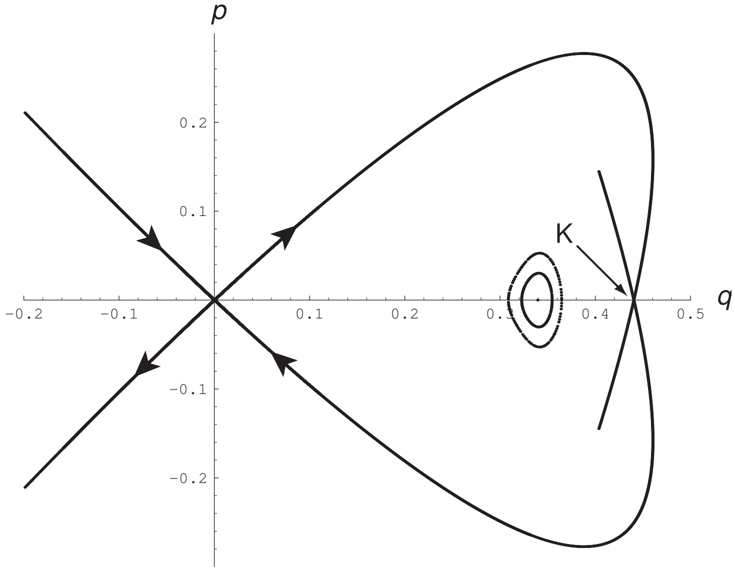

Figure 29.9.2: Stable and unstable manifolds for $\mathcal{M}_{-}$ and behavior of points near the second fixed point for the case $\Lambda = 4$.

Exercises

29.9.1.

29.10 Attempts at Integrals

29.11 Quadratic Maps in Higher Dimensions

This section will discuss Moser's generalization of the quadratic symplectic map to more than 2 dimensions.

29.12 Truncated Taylor Approximations to Stroboscopic Duffing Map

We learned in Section 1.3 that the solutions of ordinary differential equations, under quite general analyticity conditions on their right sides, are analytic in the initial conditions and in whatever parameters that occur. See Theorem 3.3 in Section 1.3. In terms of maps, this means that the maps produced by integrating analytic differential equations will be analytic in the initial conditions and parameters. We may therefore consider approximating such maps by truncated Taylor series in the initial conditions and parameters. Moreover, Section 10.10 described methods for obtaining these truncated Taylor maps.

This section will illustrate, as an example, how the stroboscopic Duffing map can be approximated by truncated Taylor maps, including parameter dependence. At first glance it might appear that the approximation of the stroboscopic Duffing map by a polynomial map, for that is what a truncated Taylor map amounts to, is a foolish enterprise. We know from Chapter 25 that the stroboscopic Duffing map exhibits very complicated properties that almost defy description. Could any polynomial map have similar properties? On the other hand, we have also seen from the logistic and Hénon map examples that polynomial maps can also exhibit complicated behavior. So perhaps there is hope. In fact, we will find that the main features of the stroboscopic Duffing map found in Chapter 25 are reproduced by truncated Taylor maps.

In our actual calculations we will use the quantities Q, σ, and t given by (10.10.103) through (10.10.105). However, for ease of comparison with previous material, when making graphics we will present results in terms of the quantities q, p, and ω of Chapter 25. Finally, for details of how the truncated Taylor maps were computed, see Appendix S.

29.12.1 Saddle-Node Bifurcations

We first explore the possible duplication of saddle-node bifurcations by polynomial maps. This turns out to be the most demanding task and, as we will see, is barely possible for the Duffing map. The reason for the difficulty is that the fixed points move over a considerable region of phase space in the course of a saddle-node bifurcation followed by an inverse saddle-node bifurcation, and a Taylor map may not converge over such a wide domain. See, for example, Figures 25.4.1 and 25.4.2.

To minimize phase-space excursions, let us work with a small value of ϵ, but a value still large enough that saddle-node bifurcations still occur. Figure 12.1 shows the bifurcation diagram for the case $\epsilon = 0.30$. It is this behavior that we wish to reproduce with a Taylor map.

There is another feature of the exact map that is also of interest. Suppose, as in Subsection 10.10.7, we work in terms of the variables z_1 and z_2. Also, let L be the linear part of the stroboscopic map in these variables. Then we may compute the eigenvalues λ of $L(2\pi)$ for each of the fixed points as σ (and therefore also ω) varies. Since $L(2\pi)$ is 2×2, there will be two eigenvalues. These will be the eigenvalues of the linear part of the stroboscopic map (in the variables z_1 and z_2) about any fixed point . Figures 12.2 and 12.3 show (in two perspective views) these eigenvalues plotted as a function of ω over the interval $\omega \in [\omega_{\text{low}}, \omega_{\text{high}}]$ with $\omega_{\text{low}} = 1.27$ and $\omega_{\text{high}} = 1.4$. Notice that we have arranged to have the ordering $\omega_{\text{low}} < \omega_1 < \omega_2 < \omega_{\text{high}}$. The eigenvalues are color coded the same as their corresponding fixed points in Figure 12.1. We would also like to explore to what extent this feature of the exact map can be reproduced by a Taylor map.

The behavior of the eigenvalues shown in these figures can be understood based on the following facts:

1. From (10.10.128) we have the relations

$$\det L(2\pi) = \exp(-4\pi\beta\sigma) = \exp(-4\pi\beta/\omega). \tag{29.12.1}$$

2. For $\omega \in [\omega_{\text{low}}, \omega_{\text{high}}]$, and given that $\beta = .1$, there is the result

$$\det L(2\pi) \in [.37, .41]. \tag{29.12.2}$$

3. Since $L(2\pi)$ is a real matrix, its eigenvalues must be real or complex conjugate. If they are complex conjugate, they must satisfy the relation

$$|\lambda|^2 \in [.37, .41]. \tag{29.12.3}$$

   If they are real, call them λ_1 and λ_2, they must satisfy the relation

$$\lambda_1\lambda_2 \in [.37, .41]. \tag{29.12.4}$$

Armed with these facts, first consider the red curves associated with the eigenvalues of $L(2\pi)$ about the unstable fixed points. These fixed points exist only for ω in the range $\omega \in [\omega_1, \omega_2]$, and hence the red curves appear only in this range. Also, since these fixed points are unstable, for each ω value one of the eigenvalues must satisfy $|\lambda| \geq 1$. In view of (12.3), this fact rules out the possibility of complex conjugate pairs. Thus the eigenvalues for each unstable fixed point must be real, and by (12.4) they must have the same sign. Finally, in the vicinity of the endpoints ω_1 and ω_1, we know that there are two fixed points that are very nearby because that is where two fixed points are born or are annihilated.

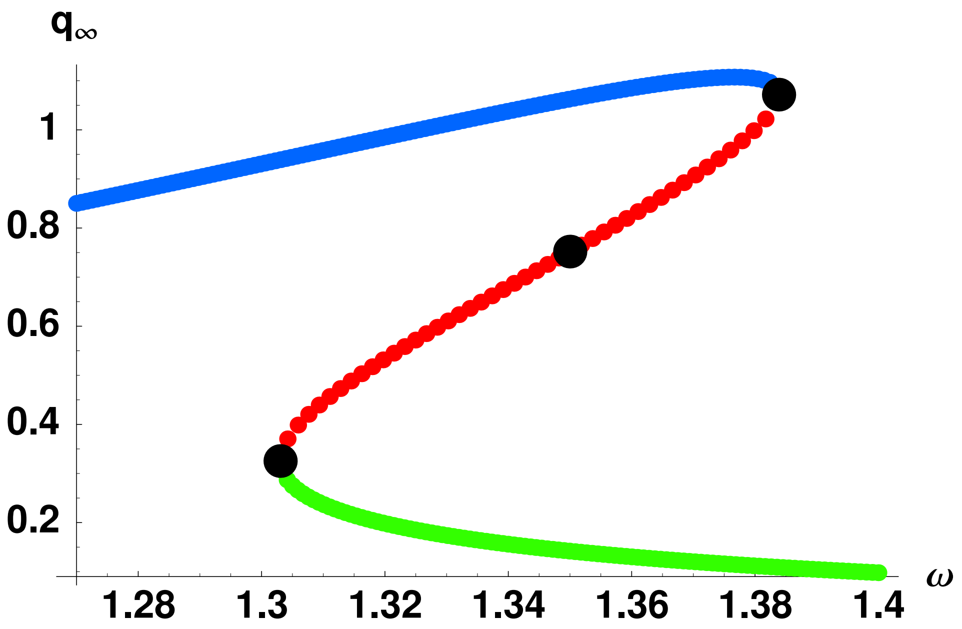

Figure 29.12.1: Bifurcation diagram showing limiting values q_∞ as a function of ω (when $\beta = 0.1$ and $\epsilon = 0.3$) for the stroboscopic Duffing map. The trail of the fixed point that is unique and stable for small values of ω is shown in blue. A pair of fixed points, one stable and one unstable, is born at $\omega = \omega_1 = 1.30305 \cdots$. The trail of the stable fixed point is shown in green and the trail of the unstable fixed point is shown in red. The black dot at the left end of the red trail is the value of $\omega = \omega_1$ at which the pair is born. The blue stable fixed point and the red unstable fixed point annihilate at $\omega = \omega_2 = 1.38386 \cdots$. This point is indicated by the black dot at the right end of the red trail. For larger ω values only the green fixed point remains. The black dot near the center of the red trail marks the expansion point to be used in preparing Figures 12.4 through 12.6.

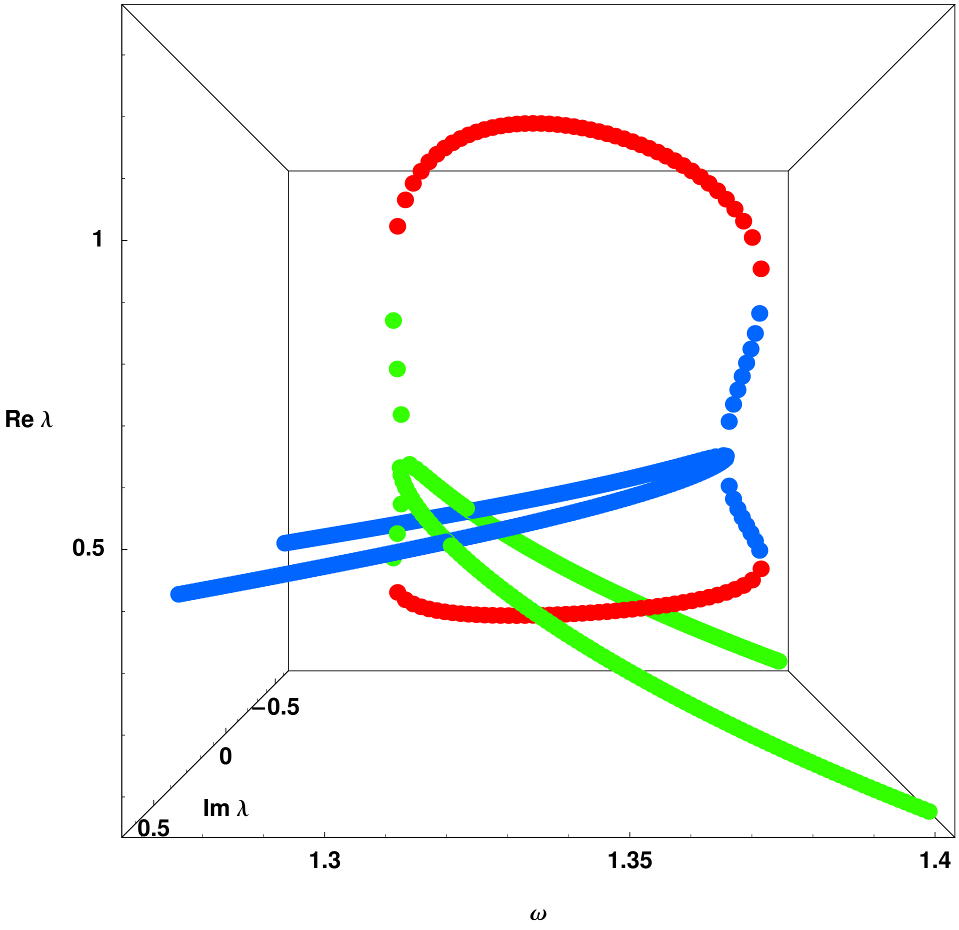

Figure 29.12.2: Eigenvalues of $L(2\pi)$, the linear part of the stroboscopic map (in the variables z_1 and z_2), about the fixed points shown in Figure 12.1. The color coding is that same as in Figure 12.1.

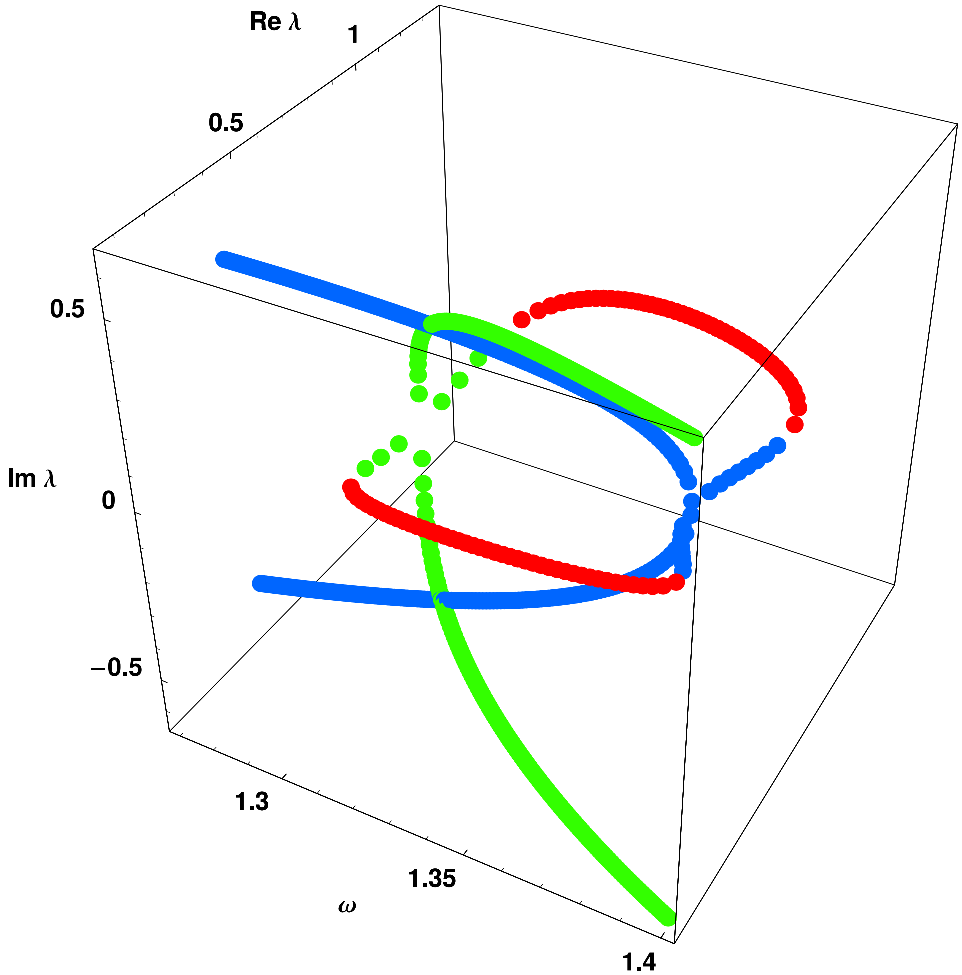

Figure 29.12.3: Eigenvalues of $L(2\pi)$ shown from a different perspective.

Consequently, from the work of Section 4, we know that one eigenvalue, call it λ_1, must be near $+1$. Since the eigenvalues must be real, they cannot change sign without passing through zero, which is forbidden by (12.4). Therefore we conclude that both eigenvalues must be positive. Thus, for the red curves, there must be the relations

$$\lambda_1 = 1 \text{ when } \omega = \omega_1 \text{ or } \omega_2, \tag{29.12.5}$$

$$\lambda_1 > 1, \text{ when } \omega \in (\omega_1, \omega_2), \tag{29.12.6}$$

$$0 < \lambda_2 < 1 \text{ when } \omega \in [\omega_1, \omega_2]. \tag{29.12.7}$$

Examination of the red curves shows that these relations are indeed satisfied.

Consider next the blue curves. They end at $\omega = \omega_2$ because that is the ω value at which the blue and red fixed points mutually annihilate. See Figure 12.1. For ω slightly less than ω_2, we know that the eigenvalues associated with the red fixed points are real and positive. Since the blue fixed points are near the red fixed points for these ω values, it follows that the eigenvalues associated with the blue fixed points must also be real and positive for these ω values. They must also be less than 1 because the blue fixed points are stable. Then, as ω is decreased, the smaller eigenvalue grows and the larger eigenvalue decreases until they become equal. For still smaller ω they leave the real axis and become complex conjugates. We know this must eventually happen because for small enough ω the Duffing oscillator is out of resonance with the drive, and its behavior is essentially that of an undriven oscillator. In that case the stable fixed point is nearly the origin, and points launched near this fixed point spiral into it due to the free (and damped) oscillations of the oscillator. The eigenvalues must have imaginary parts to produce this free oscillation. All this behavior is consistent with the facts listed above.

Finally, consider the green curves. The discussion of their behavior is similar to that of the blue curves. They begin at $\omega = \omega_1$ because that is the ω value at which the red and and green fixed points are born. See Figure 12.1. For ω slightly larger than ω_1, we know that the eigenvalues associated with the red fixed points are real and positive. Since the green fixed points are near the red fixed points for these ω values, it follows that the eigenvalues associated with the green fixed points must also be real and positive for these ω values. They must also be less than 1 because the green fixed points are stable. Then, as ω is increased, the smaller eigenvalue grows and the larger eigenvalue decreases until they become equal. For still larger ω they leave the real axis and become complex conjugates. We know this must eventually happen because for large enough ω the Duffing oscillator is again out of resonance with the drive, and its behavior is essentially that of an undriven oscillator. In that case the stable fixed point is nearly the origin, and points launched near this fixed point spiral into it due to the free (and damped) oscillations of the oscillator. The eigenvalues must have imaginary parts to produce this free oscillation. Again, all this behavior is consistent with the facts listed above.

We will now try to duplicate with a Taylor map the results shown in Figures 12.1 through 12.3. Let ω_{mid} be a value of ω that is approximately *midway* between ω_1 and ω_2. A convenient value is $\omega_{\text{mid}} = 1.35$. Let $(q^{\text{rf}}(\omega_{\text{mid}});\ p^{\text{rf}}(\omega_{\text{mid}}))$ be the unstable (red) fixed point corresponding to this value of ω. It is shown in Figure 12.1. Suppose the stroboscopic Duffing map is Taylor expanded about this fixed point through eighth order in both phase-space coordinates and parameter value. (Use the equations described in Section 10.10.6 and

Section 10.10.7 and the parameter σ, but subsequently plot results in terms of the original coordinates q, p and the parameter ω.) We will call this map $\mathcal{M}_8$. With this polynomial map in hand, it is easy to extract its linear part (Jacobian matrix) L. Now carry out the following steps:

1. Slowly *increase* ω from its initial value $\omega_{\rm mid}$ and find and plot in red the trail of the unstable fixed point for the polynomial map as ω is increased. Since L is available, the location of this fixed point for each value of ω can be found using Newton's method.

2. At the same time, since L is known, calculate its determinant and eigenvalues. Examine the determinant to see how much it differs from the exact value given by (12.1). Plot the eigenvalues in red. See if one of them is approaching the value $+1$. Continue increasing ω until one eigenvalue, call it λ_1, takes on the value $+1$. Record the ω value at which this occurs, and call it $\omega_2^{\rm approx}$.

3. When L has eigenvalue $+1$, we know that a pair of fixed points should be born or annihilated. Starting with $\omega = \omega_2^{\rm approx}$, slowly *decrease* ω while now looking for two (initially nearby) fixed points. One of them should be on the trail of red (unstable) fixed points, and the other should be on the trail of the blue (stable) fixed points. Plot the blue points.

4. At the same time, find L about each blue fixed point. Then find its determinant and eigenvalues. Plot these eigenvalues in blue.

5. Continue to decrease ω until the determinant computed as described in item 4 above deviates by from from its exact value by some significant amount thereby indicating that the polynomial map is becoming unreliable. In this example we have required that this deviation be less than .1 which, in view of (12.2), amounts to an error of approximately 25% or less.

6. Carry out analogous calculations to find points on the trail of the green (stable) fixed point and to find the eigenvalues associated with these fixed points. That is, again starting with $\omega_{\rm mid}$ and the the associated fixed point $(q^{\rm rf}(\omega_{\rm mid});\ p^{\rm rf}(\omega_{\rm mid}))$, now slowly *decrease* the value of ω while again plotting red points and computing red eigenvalues. Continue until again $\lambda_1 = 1$. Record the ω value at which this occurs, and call it $\omega_1^{\rm approx}$. Now slowly increase ω, again finding pairs of fixed points, one red and one green. For each green fixed point, find the linear part of the polynomial map, compute its determinant, and find and plot its eigenvalues in green.

What is the outcome of carrying out all these steps? First, Figures 12.4 through 12.6 show the analogs of Figures 12.1 through 12.3, but now computed using the Taylor map. Evidently, there is good qualitative agreement. In particular, the saddle-node bifurcations are qualitatively reproduced by the Taylor map, at least in the neighborhood of these bifurcations. Second, we find that $\omega_1^{\rm approx} = 1.30325\cdots$ and $\omega_2^{\rm approx} = 1.38225\cdots$. These values agree well with the exact values given in the caption of Figure 12.1. Also, for the red fixed points in Figure 12.4 corresponding to the end values $\omega_1^{\rm approx}$ and $\omega_2^{\rm approx}$, we find that the determinant of the linear part of the Taylor map deviates from that of the linear part of the the exact stroboscopic Duffing map by approximately .001, and is still smaller for the interior red points. Correspondingly, the trail of unstable fixed points is well reproduced. Finally, for the smallest ω value on the blue trail and the largest ω value on the green trail, the error in the determinant becomes as large as .1, which is why the computation of the green trail is terminated slightly to the right of ω_1^{approx} and the computation of the blue trail is terminated slightly to the left of ω_2^{approx}.

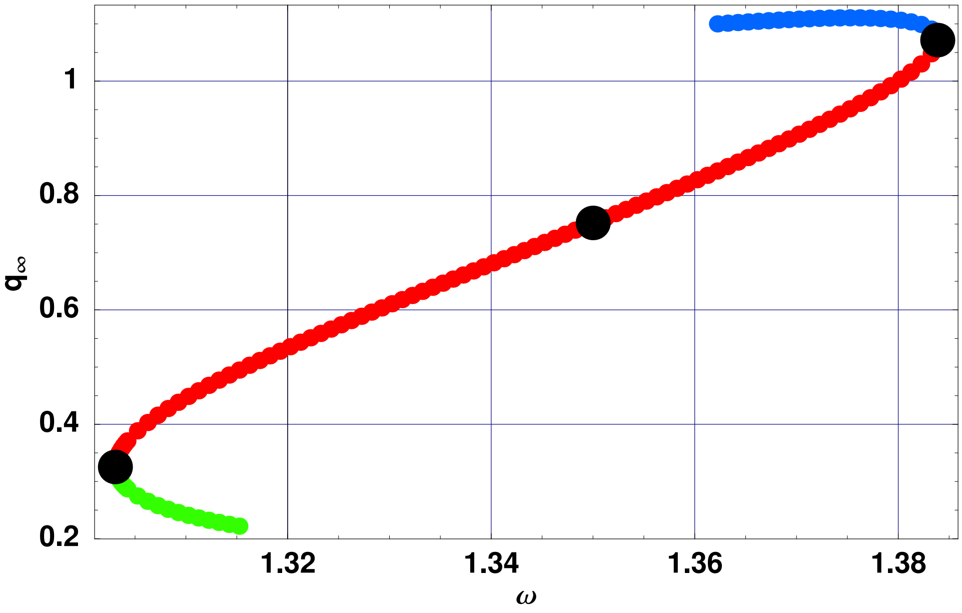

Figure 29.12.4: The analog of Figure 12.1 computed using $\mathcal{M}_8$, an eighth-order approximation to $\mathcal{M}$ including parameter dependence. The black point near the center of the red trail is the point about which the Taylor expansion of the stroboscopic Duffing map is constructed. The black dots near the ends of the red trail are the exact values of the fixed points for the exact values of ω_1 and ω_2.

Having demonstrated that a single map reproduces the saddle-node bifurcations (albeit only over a rather small domain), it is worth exploring if more can be achieved with the use of two or more Taylor maps expanded about different points. The goal would be to cover more of parameter and phase space with overlapping domains associated with multiple maps. We will find that more can indeed be achieved; but, of course, more work is also required.

For simplicity, we will restrict our discussion to the use or two maps. In this case a promising possibility is to choose as expansion points the fixed point in Figure 12.1 where the the red and green trails merge at $\omega = \omega_1$ and the fixed point where the red and blue trails merge at $\omega = \omega_2$. We can then use the Taylor map associated with ω_1 to compute the red and green trails and their associated eigenvalues, and we can use the Taylor map associated with ω_2 to compute the red and blue trails and their associated eigenvalues. As before, we terminate a trail when the determinant of the linear part of the the polynomial-based map differs from its exact value by .1. We expect that it should now be possible to extend the

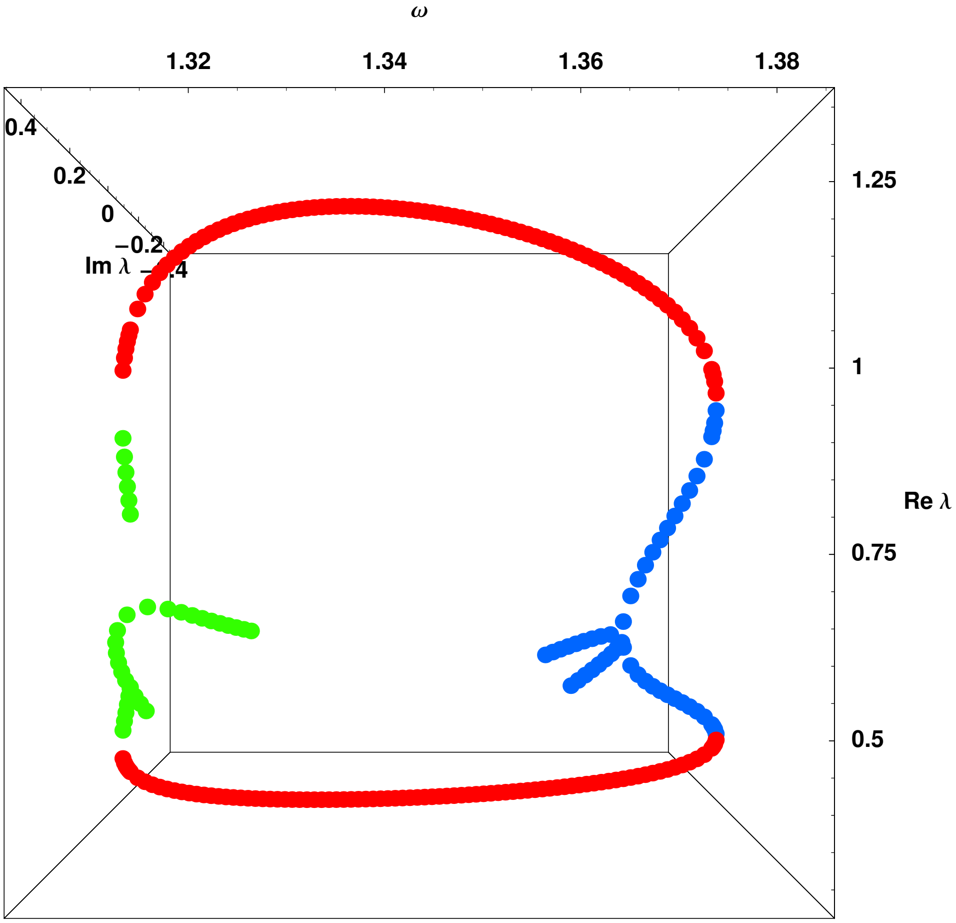

Figure 29.12.5: The analog of Figure 12.2 computed using $\mathcal{M}_8$, an eighth-order approximation to $\mathcal{M}$ including parameter dependence.

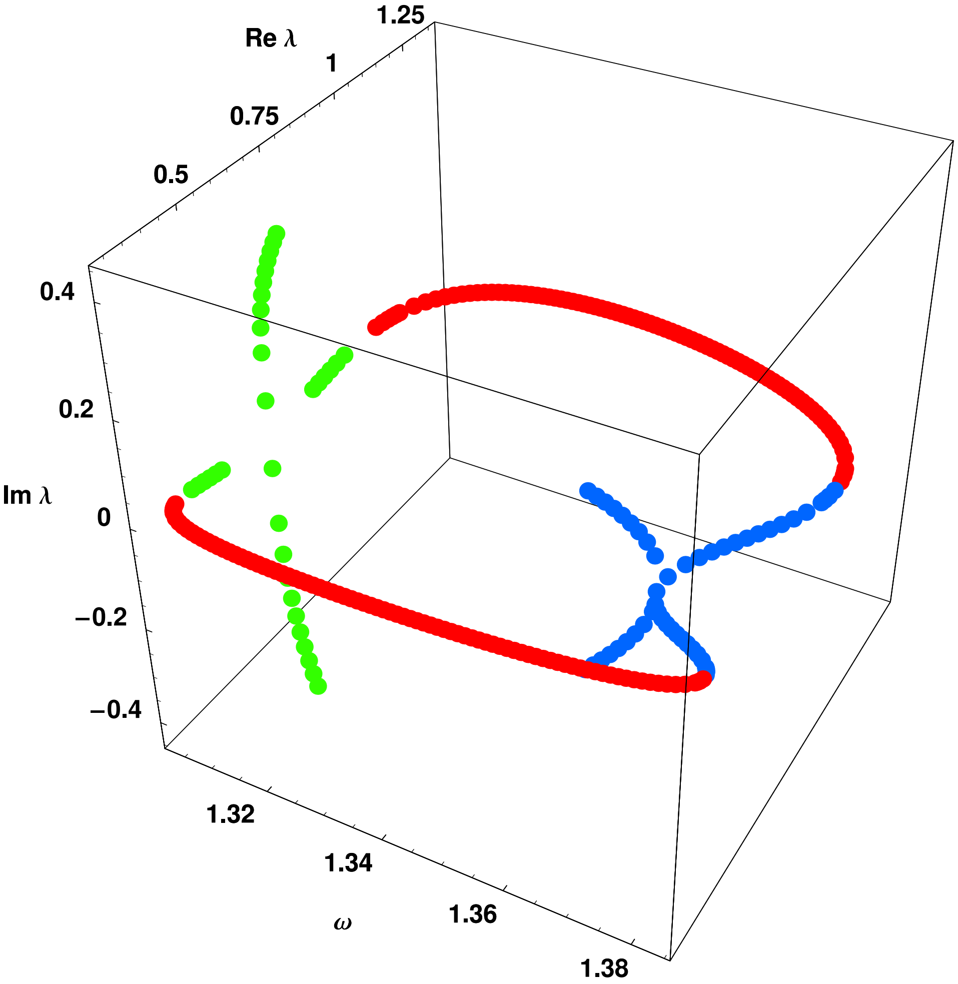

Figure 29.12.6: Data of Figure 12.5 shown from a different perspective.

blue trail farther to the left and the green trail farther to the right. Note that "red" values get computed twice, once for each map, and we can compare them to see how well they agree.

Figures 12.7 through 12.9 show the result of this procedure. Observe that in Figure 12.7 the blue and green trails are indeed extended, and the red points appear to lie almost on a single trail because both Taylor maps give results that nearly agree in this region of parameter and phase space. The red trail computed using the map expanded about ω_1 and its associated fixed point is terminated just to the left of $\omega = \omega_2$, at which point there is an error in the determinant of .009. The green trail is continued on to ω slightly larger than 1.45, at which point the error in the determinant is .1 The red trail computed using the map expanded about ω_2 and its associated fixed point is terminated near $\omega = 1.329$ where the error in the determinant becomes .1. The error in the determinant for the blue branch reaches .1 slightly to the right of $\omega = 1.28$. Observe also that in Figures 12.8 and 12.9 there is some hint of difference in the red-point eigenvalues found using the two different maps, thereby indicating that the computation of the linear-part of a map based on a Taylor expansion can be more demanding than the computation of a fixed point.

We conclude, for the stroboscopic Duffing map, that saddle-node bifurcations can be reproduced by a single polynomial map over a somewhat limited region of parameter and phase space, and that this region can be enlarged by the use of multiple maps.

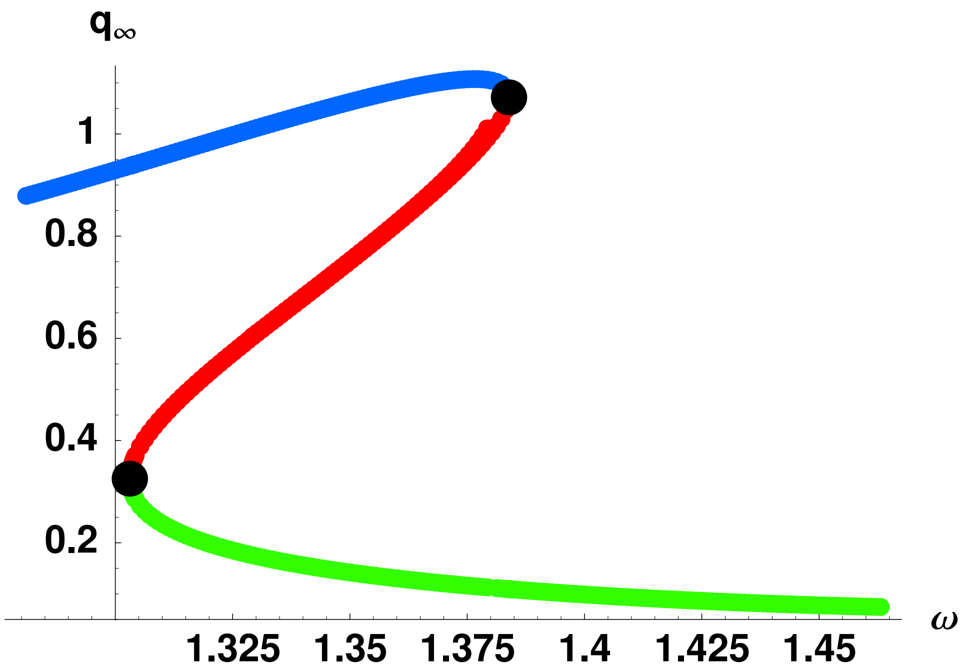

Figure 29.12.7: The analog of Figure 12.1 computed using two eighth-order polynomial maps including parameter dependence. The black dots at the ends of the red trail, located at ω_1 and ω_2, are the points about which the Taylor expansions of the stroboscopic Duffing map are constructed.

Exercises

29.12.1. Look at the green and blue curves in Figures 12.2 and 12.3. For small ω only the blue curves exist, and for large ω only the green curves exist. Somewhere within the interval $[\omega_1, \omega_2]$ there appears to be an ω value for which there are blue-green intersections. For example, in Figure 12.3 the bottom blue and green curves appear to intersect and, at the same ω value, the top blue and green curves also appear to intersect. Prove mathematically that these intersections actually do occur and are not an artifact of the thickness of the lines employed in making the figures.

29.12.2. Exercise on equivariance causing eigenvalues to be the same.

29.12.2 Pitchfork Bifurcations

We have seen that Duffing saddle-node bifurcations can be reproduced by truncated Taylor maps over a limited region of parameter and phase space. Now we will see that pitchfork bifurcations can also be reproduced. Here the problem of domain size is somewhat less pressing because the phase-space excursions associated with a pitchfork bifurcation are generally smaller than those for a saddle-node bifurcation. We will find, for example, that the case $\epsilon = 2.5$ can be handled with the use of a single truncated Taylor map.[3]

Figure 12.10 shows the bifurcation diagram for the Duffing stroboscopic map in the case $\epsilon = 2.5$ (and $\beta = 0.1$) for ω in the vicinity of the first bubble. In this figure the fixed points are shown over the interval $\omega \in [\omega_{\text{low}}, \omega_{\text{high}}]$ with $\omega_{\text{low}} = .76$ and $\omega_{\text{high}} = 1.075$. The trail of the stable fixed point, before the pitchfork bifurcation that occurs at $\omega = \omega_1 = .87076\cdots$ and after the pitchfork merger that occurs at $\omega = \omega_2 = .96639\cdots$, is shown in black. The trails of the two stable fixed points that exist after the pitchfork bifurcation and before the pitchfork merger are shown in blue and green. The trail of the associated unstable fixed point is shown in red.

Also shown in Figures 12.11 and 12.12 are the eigenvalues of the linear parts of the map about the various fixed points. The color coding is the same as in Figure 12.10. The relation (12.1) in this case yields, for $\omega \in [\omega_{\text{low}}, \omega_{\text{high}}]$, the alternatives of complex conjugate eigenvalues with

$$|\lambda|^2 \in [.2361, .2724], \tag{29.12.8}$$

or both eigenvalues real with

$$\lambda_1\lambda_2 \in [.2361, .2724]. \tag{29.12.9}$$

For $\omega \approx \omega_{\text{low}}$ the eigenvalues are complex and (12.8) holds. Then, as ω increases, one of the eigenvalues must approach $+1$ because of the imminent bifurcation. Along the way, as the figure illustrates, the eigenvalues must become real in order to not violate (12.8), and (12.9) then holds, in which case both eigenvalues are positive. At bifurcation, when $\omega = \omega_1$, one of the eigenvalues becomes equal to $+1$.

[3] However, larger ϵ values, such as the value $\epsilon = 5.5$ used in Figures 25.5.2 through 25.5.4, do require the use of multiple maps.

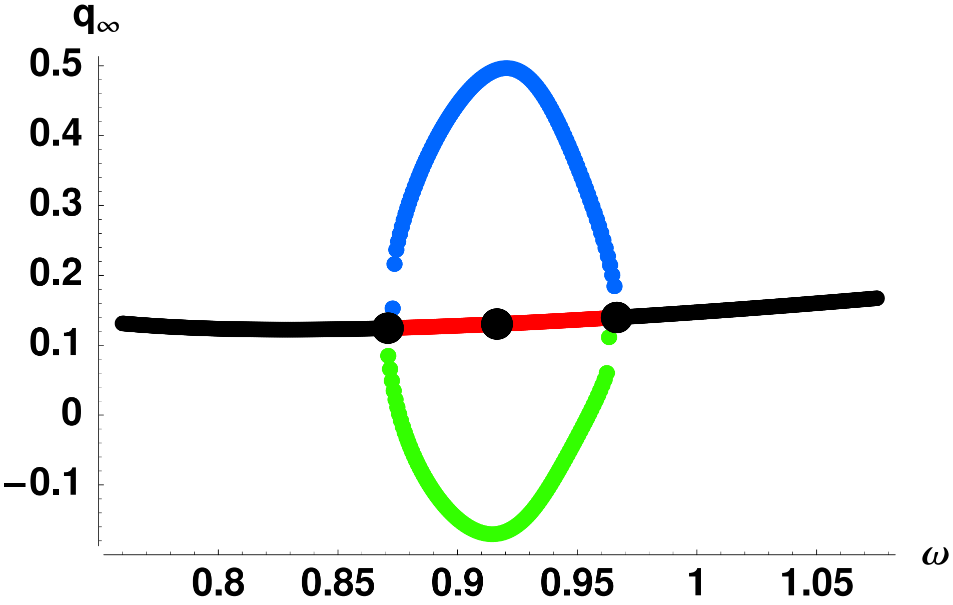

Figure 29.12.10: Bifurcation diagram for the Duffing stroboscopic map in the case $\epsilon = 2.5$ (and $\beta = 0.1$) for ω in the vicinity of the first bubble. The trail of the stable fixed point before the pitchfork bifurcation and after the pitchfork merger is shown in black. The trails of the two stable fixed points that exist after the pitchfork bifurcation and before the pitchfork merger are shown in blue and green. The trail of the associated unstable fixed point is shown in red. The black dot at the left end of the red trail is located at $\omega = \omega_1$. and the black dot at the right end of the red trail is located at $\omega = \omega_2$. The black dot near the middle of the red trail indicates the value $\omega = \omega_{\text{mid}}$ to be used as an expansion point.

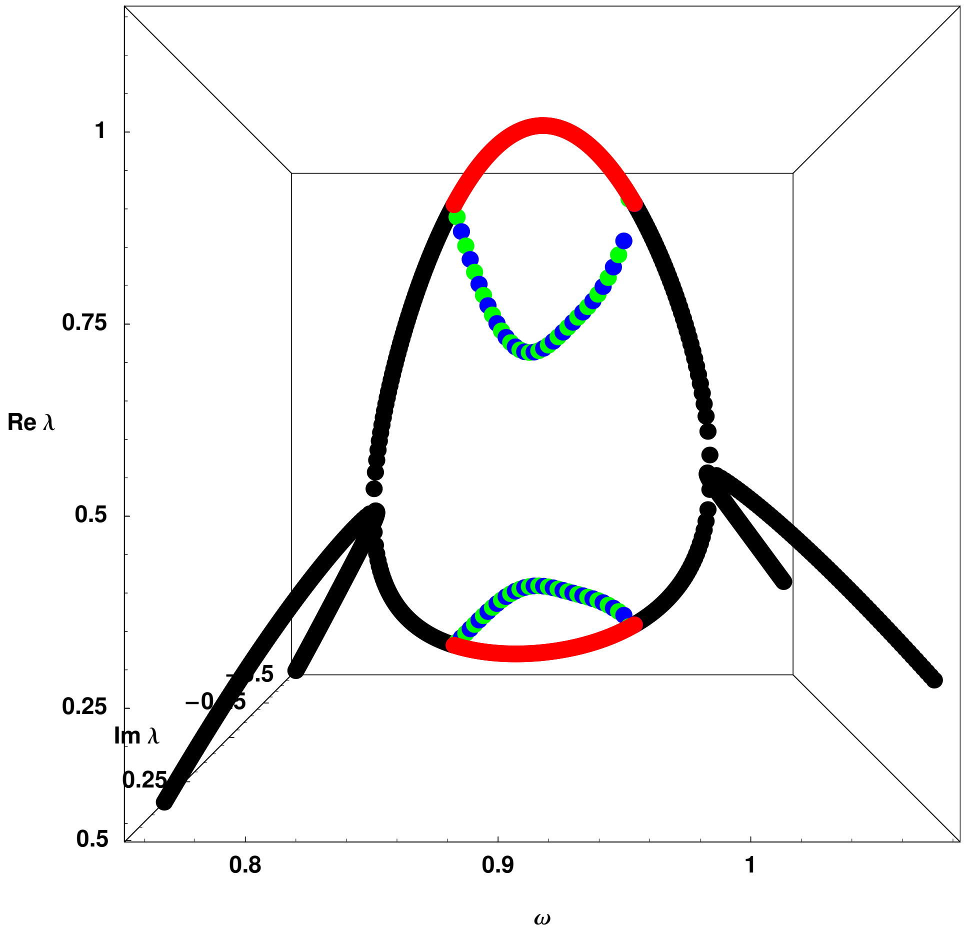

Figure 29.12.11: Eigenvalues of $L(2\pi)$, the linear part of the stroboscopic map (in the variables z_1 and z_2), about the fixed points shown in Figure 12.10. The color coding is that same as in Figure 12.10. Note two of the curves are colored blue-green because, as explained in the text, there is overlap because of equivariance symmetry.

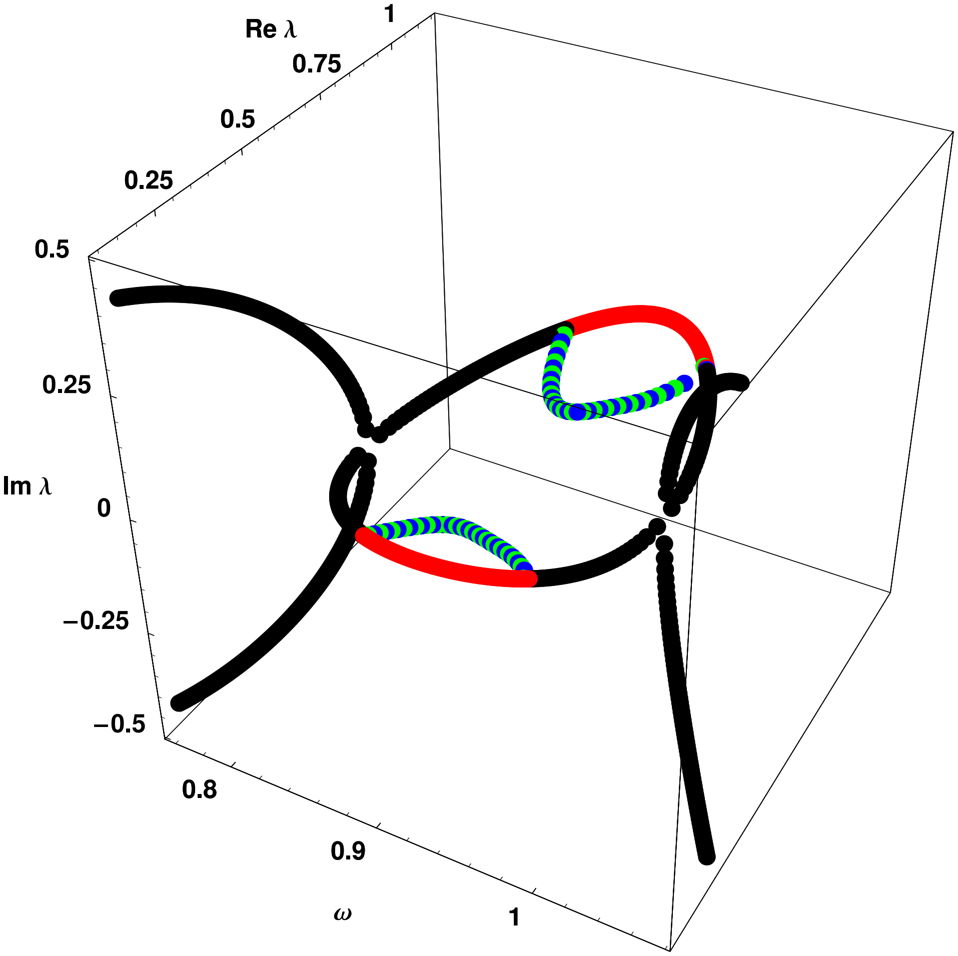

Figure 29.12.12: Data of Figure 12.11 shown from a different perspective.

After bifurcation at ω_1, and within the interval (ω_1, ω_2), we might expect there would be six curves: two red, two blue, and two green. This was the case for the saddle-node bifurcation. Recall Figures 12.2 and 12.3. Inspection of Figures 12.11 and 12.12 shows there is indeed a pair of red curves corresponding to the unstable fixed point trail. However, the blue and green curves overlap in pairs. For this reason, each curve arising from the stable blue and green trails is displayed both in blue and green. It can be shown that this overlap is a consequence of the equivariance relation (25.4.6) that maps the two stable periodic orbits (corresponding to the blue and green stable fixed points) into each other. As a result, for each ω value in (ω_1, ω_2), the linear parts of the map about the blue and green fixed points have the *same* eigenvalues. See Exercise 12.2.

At the inverse bifurcation, when $\omega = \omega_2$, one of the eigenvalues again becomes equal to $+1$. Just beyond the inverse bifurcation there are two real eigenvalues corresponding to the black trail and (12.9) again holds. Eventually these eigenvalues again become complex so that (12.8) then again holds.

It is the behavior shown in Figures 12.10 through 12.12 that we would like to reproduce with a single truncated Taylor map. Figures 12.13 through 12.15 verify that this is indeed possible. Figure 12.13 shows the trails of the fixed points for a single eighth-order map computed by expanding about the black point near the middle of the red trail shown in Figure 12.10 with $\omega_{\text{mid}} = .916349$. Figures 12.14 and 12.15 show the eigenvalues of the linear parts of the eight-order map evaluated at the fixed points on the trails in Figure 12.13. It is found that, over the ω interval displayed, the error in the determinant of the linear part of the map is less than .022. This worst error occurs when $\omega = \omega_{\text{low}}$. To the eye, the truncated Taylor map results appear to be identical to the exact results. A single truncated Taylor map has indeed replicated the pitchfork bifurcation behavior of the exact map.

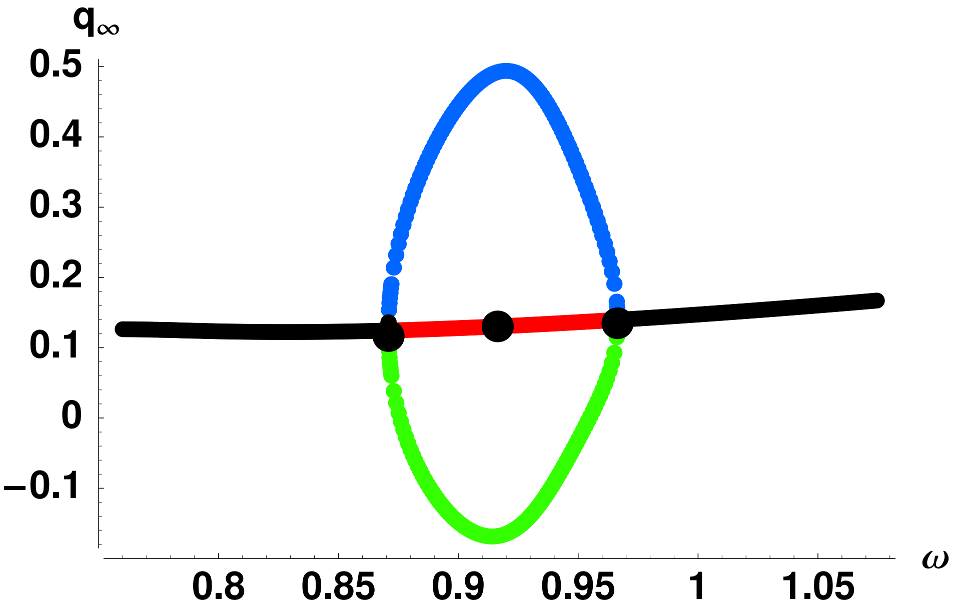

Figure 29.12.13: The analog of Figure 12.10 computed using $\mathcal{M}_8$, an eighth-order approximation to $\mathcal{M}$ including parameter dependence. The black point near the center of the red trail is the point $\omega_{\rm mid} = .916349$ about which the Taylor expansion of the stroboscopic Duffing map was constructed. The other two black points are located at the exact values of ω_1 and ω_2.

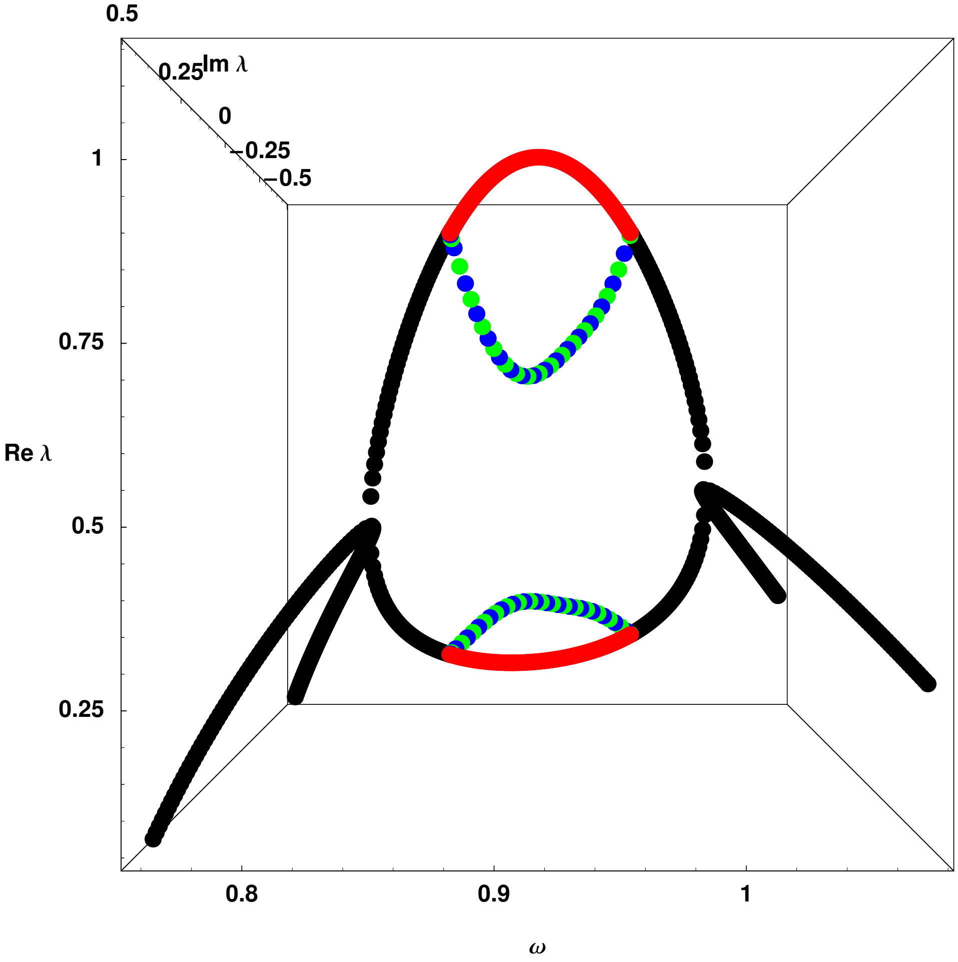

Figure 29.12.14: The analog of Figure 12.11 computed using $\mathcal{M}_8$, an eighth-order approximation to $\mathcal{M}$ including parameter dependence.

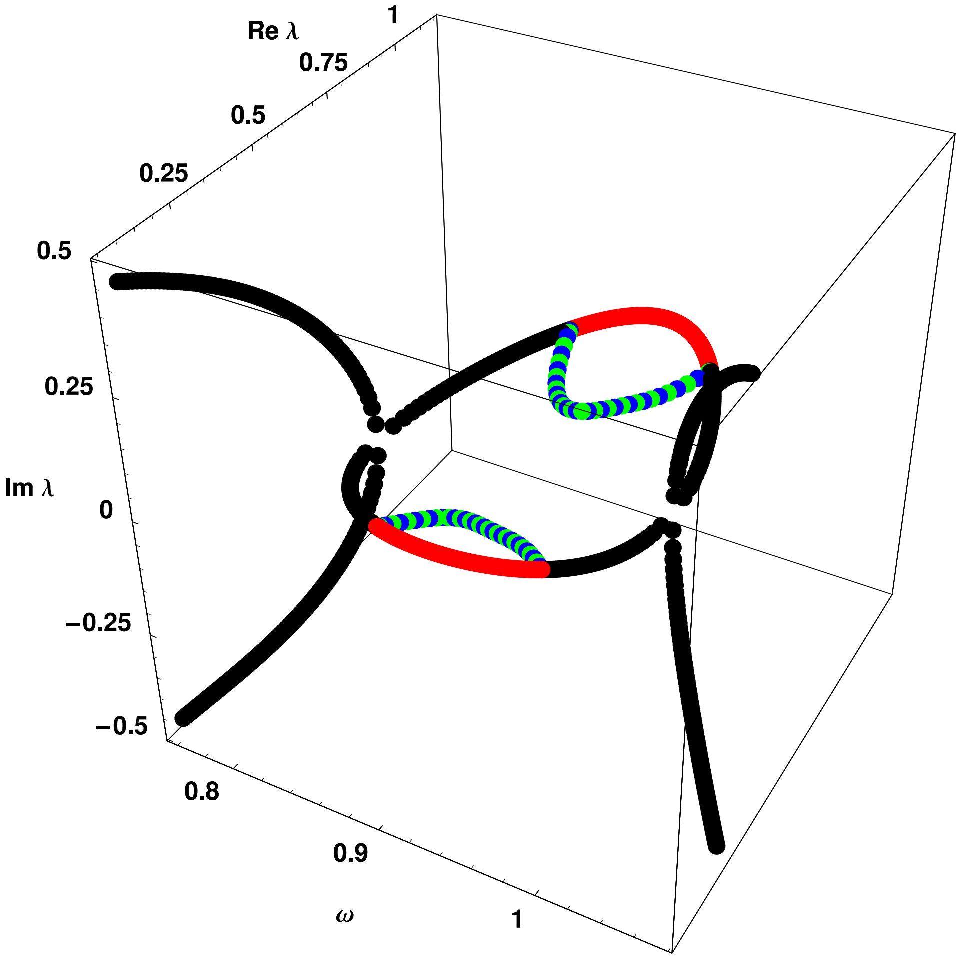

Figure 29.12.15: Data of Figure 12.14 shown from a different perspective.

29.12.3 Infinite Period-Doubling Cascade and Strange Attractor

The main purpose of this subsection is to demonstrate that a single truncated Taylor map can reproduce a Duffing map period doubling cascade and associated strange attractor. However, before doing so, it is instructive to examine the period doubling mechanism. We also verify an earlier conjecture.

Period Doubling Mechanism

Look again at Figure 25.8.6, which shows part of the upper cascade in Figure 25.8.5. Part of it is reproduced below in Figure 12.16 to display the first period doubling bifurcation in more detail. Also, to avoid confusion, the part of the trail of the stable fixed point associated with the second saddle-node bifurcation, and all other high-order fixed points and their bifurcations, are suppressed. Review the discussion of period doubling at the end of Section 9. For ω less than the bifurcation value the stroboscopic Duffing map $\mathcal{M}$ has a single stable fixed point z_f, and its trail is shown in black. After the bifurcation there is still a single fixed point z_f, but now it is unstable and its trail is shown in red. Next consider the map $\mathcal{M}^2$. For each ω value less than the bifurcation value it too has the corresponding point on the black trail as a fixed point, and this fixed point is stable. And for each ω value greater than the bifurcation value it too has the corresponding point on the red trail as a fixed point, and this fixed point is unstable. But, for each ω value greater than the bifurcation value, $\mathcal{M}^2$ has two additional fixed points, and these fixed points are shown in blue and green. These fixed points of $\mathcal{M}^2$ are *not* fixed points of $\mathcal{M}$. Let $z_{\rm blue}$ be a blue fixed point of $\mathcal{M}^2$ corresponding to some value of ω, and let $z_{\rm green}$ be the green fixed point of $\mathcal{M}^2$ for the same value of ω. Then we know there are the relations

$$\mathcal{M}z_{\rm blue} = z_{\rm green}, \tag{29.12.10}$$

$$\mathcal{M}z_{\rm green} = z_{\rm blue}. \tag{29.12.11}$$

Also we know that the linear parts of $\mathcal{M}^2$ about the corresponding fixed points $z_{\rm blue}$ and $z_{\rm green}$ must have the same eigenvalues. Finally, we know that the blue and green fixed points must be (initially) stable. See the discussion at the end of Section 9.

We expect that at the period doubling bifurcation one of the eigenvalues of the linear part of $\mathcal{M}$ will take on the value -1. This is indeed the case. Figures 12.17 and 12.18 show these eigenvalues before, at, and after period doubling. They are colored black while z_f is stable, and red after z_f becomes unstable. Note that for the smaller values of ω the eigenvalues are complex. Then, as ω is increased, they leave the complex plane to become real and negative, but still have magnitude less than 1. Then, as ω is further increased, one of them takes on the value -1, at which point z_f becomes unstable. It remains unstable as ω is increased still further.

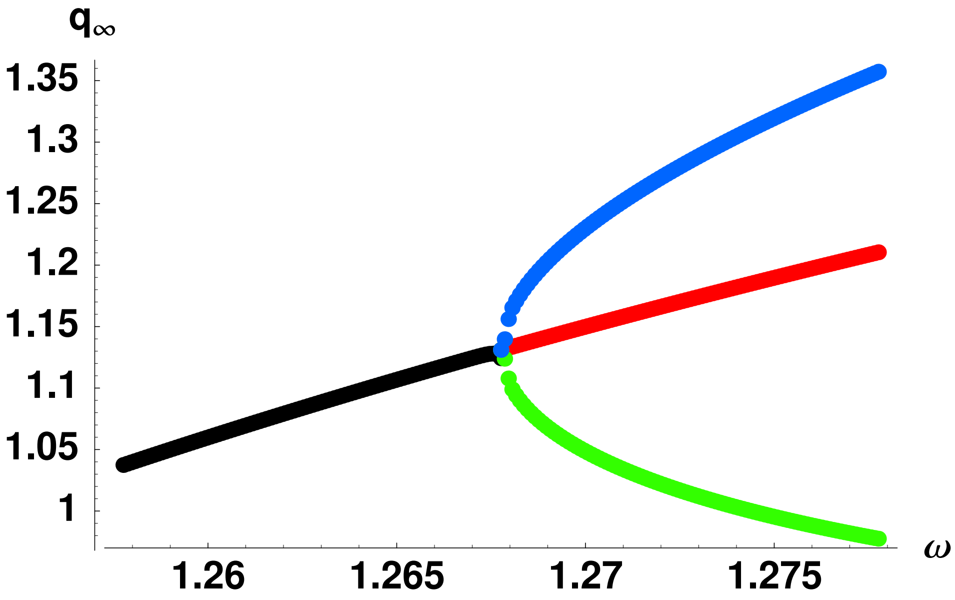

Figure 29.12.16: Detail of part of the period doubling bifurcation shown in Figure 25.8.6. The map $\mathcal{M}$ has one fixed point z_f before period doubling, it is stable, and its trail is shown in black. After period doubling $\mathcal{M}$ still has one fixed point z_f, it is unstable, and its trail is shown in red. These fixed points are, of course, also fixed points of $\mathcal{M}^2$. After period doubling, $\mathcal{M}^2$ has two additional fixed points whose trails are shown in blue and green. These period-two fixed points are not fixed points of $\mathcal{M}$. Instead, they are sent into each other under the action of $\mathcal{M}$.

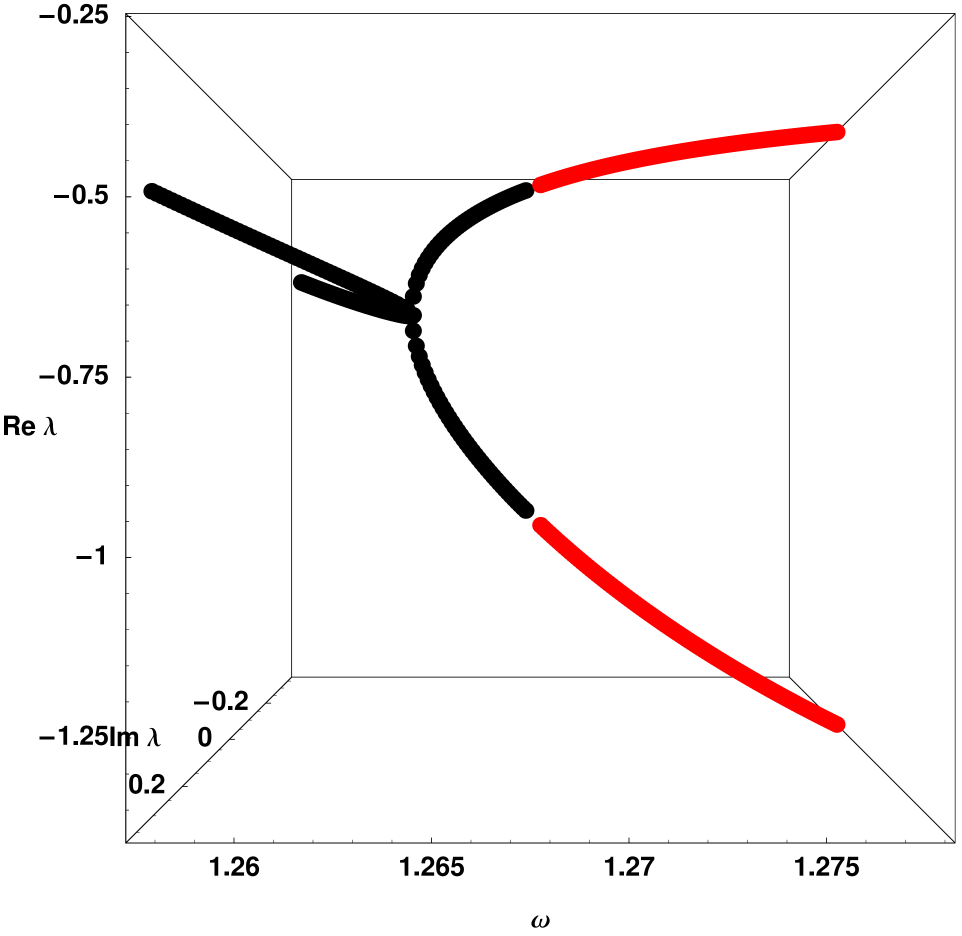

Figure 29.12.17: Eigenvalues of the linear part of $\mathcal{M}$ in the vicinity of its period-doubling bifurcation.

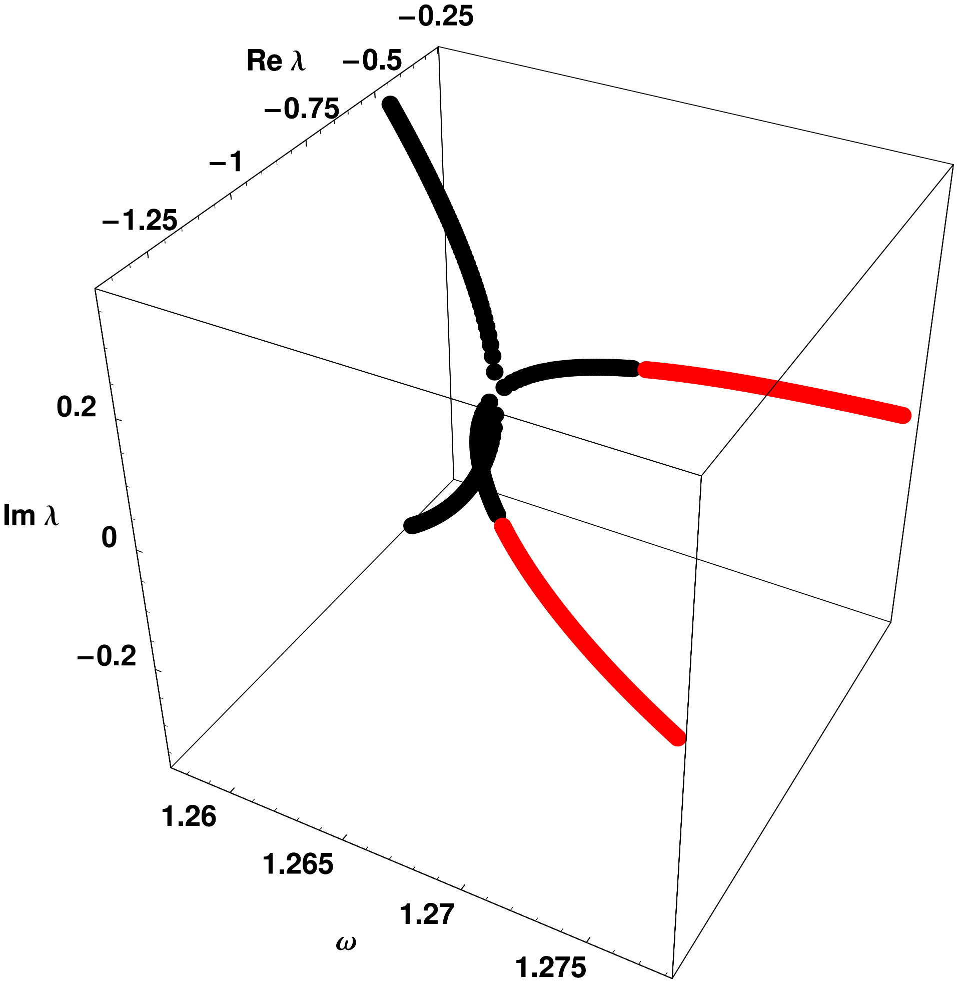

Figure 29.12.18: Different perspective of the eigenvalues of the linear part of $\mathcal{M}$ in the vicinity of its period-doubling bifurcation.

We should also examine the eigenvalues of the linear parts $\mathcal{M}^2$ about its fixed points. They are shown in Figures 12.19 and 12.20. The curves associated with z_f are shown in black before the period doubling bifurcation, and in red afterward. Observe, that as expected, that these eigenvalues are the squares of the eigenvalues of the linear parts of $\mathcal{M}$. The curves associated with $z_{\rm blue}$ and $z_{\rm green}$ are displayed in both blue and green because of their agreement. By continuity, the eigenvalues of the linear parts of $\mathcal{M}^2$ for the period-two fixed points $z_{\rm blue}$ and $z_{\rm green}$ are initially real and positive and, right after birth, have magnitude less than one. Thus $z_{\rm blue}$ and $z_{\rm green}$ are stable. However, as ω is further increased, their eigenvalues eventually become complex while still having magnitude less than one. Moreover, as ω is increased still further, these eigenvalues "circle" through the complex plane until they reach the negative real axis and then again become real. Finally, one of them reaches the value -1. At the corresponding ω value period doubling again occurs so that now $\mathcal{M}^2$ has two period-two fixed points and, correspondingly, $\mathcal{M}$ has four period-four fixed points. This is the mechanism by which continual period doubling can occur to produce a period doubling cascade.

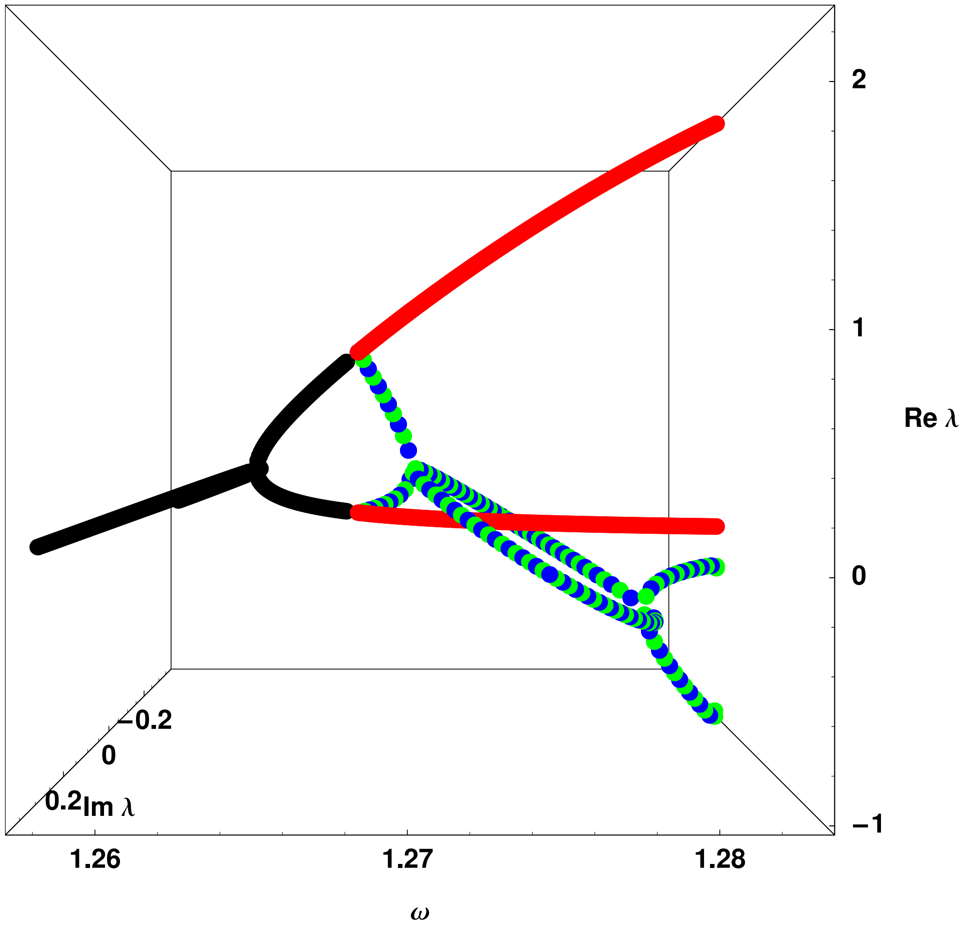

Figure 29.12.19: Eigenvalues of the linear part of $\mathcal{M}^2$ in the vicinity of the period doubling bifurcation of $\mathcal{M}$.

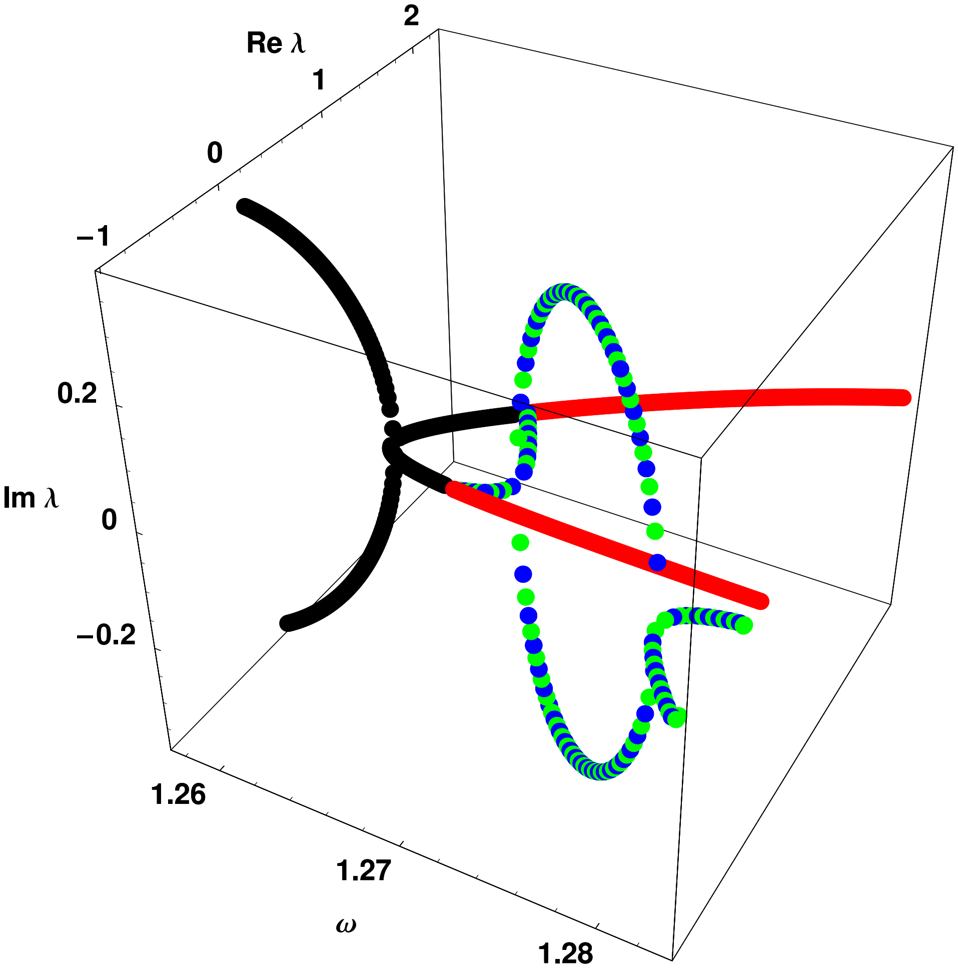

Figure 29.12.20: Different perspective of the eigenvalues of the linear part of $\mathcal{M}^2$ in the vicinity of the period doubling bifurcation of $\mathcal{M}$.

Verification of a Conjecture

Recall the conjecture, made in Exercise 1.2.3, that to find the leading behavior in the case of period doubling it sufficient to know the map through third order. To test this conjecture, let $\mathcal{M}_3$ be the third-order (including parameter dependence) truncated Taylor map expansion of the Dufing stroboscopic map $\mathcal{M}$ about the period-doubling bifurcation point shown in Figures 25.8.6 and 12.16. Figure 12.21 shows its bifurcation diagram. Evidently there is a close resemblance between Figures 12.16 and 12.21. As a further test, we can examine the eigenvalues of $(\mathcal{M}_3)^2$. They are shown in Figures 12.22 and 12.23. Comparison of Figures 12.22 and 12.23 with Figures 12.18 and 12.19 shows there is good quantitative agreement in the vicinity of the bifurcation point, and similar qualitative behavior farther away from the bifurcation point. Indeed, over the ω range displayed, the determinant of the linear part of $(\mathcal{M}_3)^2$ differs from the determinant of the linear part of $\mathcal{M}^2$ by at most .06. Moreover, the *second* period doubling (period quadrupling) for the map $\mathcal{M}_3$ occurs at $\omega = 1.28094\cdots$ while that for the exact map $\mathcal{M}$ occurs at $\omega = 1.28307\cdots$.

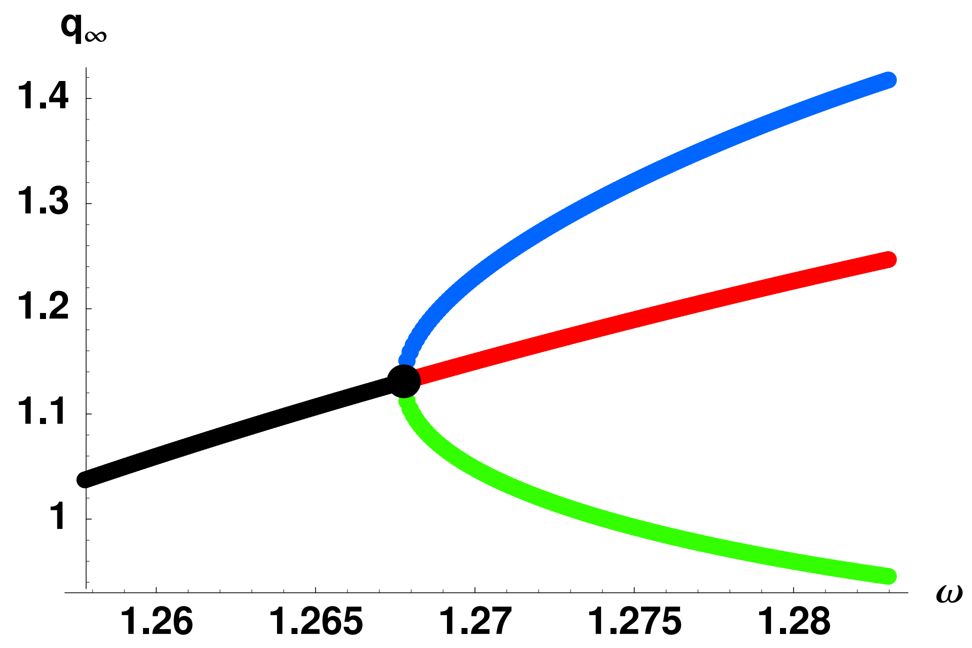

Figure 29.12.21: Bifurcation diagram for the map $\mathcal{M}_3$, the third-order polynomial approximation to $\mathcal{M}$ (including parameter dependence) expanded about the period-doubling bifurcation point shown in black. The polynomial map has one fixed point z_f before period doubling. It is stable and its trail is shown in black. After period doubling $\mathcal{M}_3$ still has one fixed point z_f. It is unstable and its trail is shown in red. These fixed points are, of course, also fixed points of $(\mathcal{M}_3)^2$. After period doubling, $(\mathcal{M}_3)^2$ has two additional fixed points whose trails are shown in blue and green. These period-two fixed points are not fixed points of $\mathcal{M}_3$. Instead, they are sent into each other under the action of $\mathcal{M}_3$.

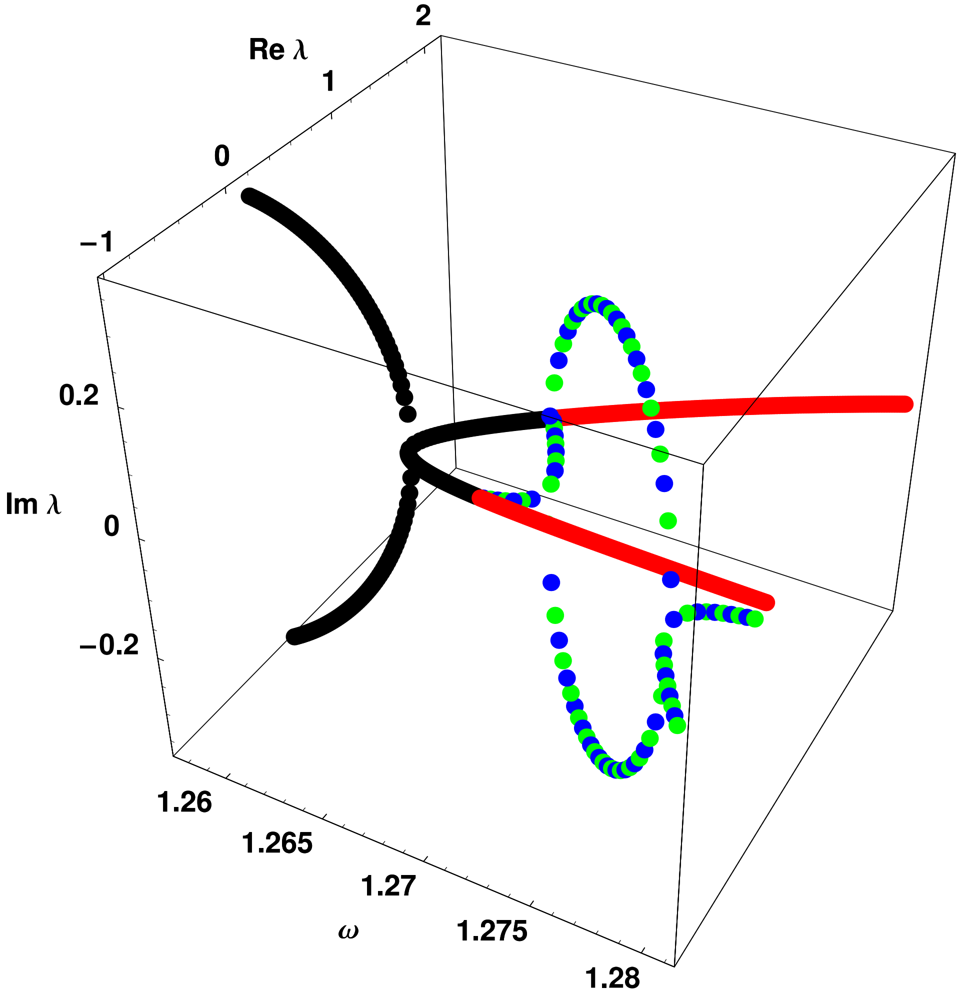

Figure 29.12.23: Different perspective of the eigenvalues of the linear part of $(\mathcal{M}_3)^2$ in the vicinity of the period doubling bifurcation of $\mathcal{M}_3$.

Infinite Period-Doubling Cascade

We now return to the main purpose of this subsection, namely to demonstrate that a single truncated Taylor map can reproduce a Duffing map infinite period-doubling cascade and associated strange attractor. In particular we will try to replicate, using a polynomial map with parameter dependence, the behavior illustrated in Figures 25.8.6, 25.9.1, and 25.9.2.

Figure 12.24 shows a partial Feigenbaum diagram for the map we will call $\mathcal{M}_8$. This is the 8^{th}-order polynomial approximation to the map $\mathcal{M}$. The black dot, situated at $\omega = 1.285\cdots$, is the fixed point z_f of $\mathcal{M}$ for this ω value, and it is used as the expansion point. It lies on a continuation of what is the red trail in Figure 12.21 and has the coordinates

$$z_f = (1.26082\cdots\ ;\ 2.05452\cdots) \text{ and } \omega = 1.285. \tag{29.12.12}$$

Figure 12.25 shows the associated full Feigenbaum diagram. Observe that the points on the full Feigenbaum diagram appear to be very nearly confined to a surface. Therefore, although we are dealing with a map in two dimensions, its behavior is very similar to a map in one dimension. Correspondingly, many aspects of Figure 12.24 are very similar to those of Figure 1.2.4, the Feigenbaum diagram for the logistic map, the simplest map in one dimension.

Comparison of Figures 25.8.6 and 12.24 reveals a striking resemblance.[4] Remarkably, an 8^{th}-order polynomial map approximation fully reproduces the complete period doubling cascade exhibited by the stroboscopic Duffing map. There is good quantitative agreement in the vicinity of the expansion point, and good qualitative agreement over the full cascade. Note that even some of the cascades associated with higher-period fixed points are captured.

[4] Similar color schemes are employed in both figures. They have no dynamical significance save to aid the eye in following successive bifurcations.

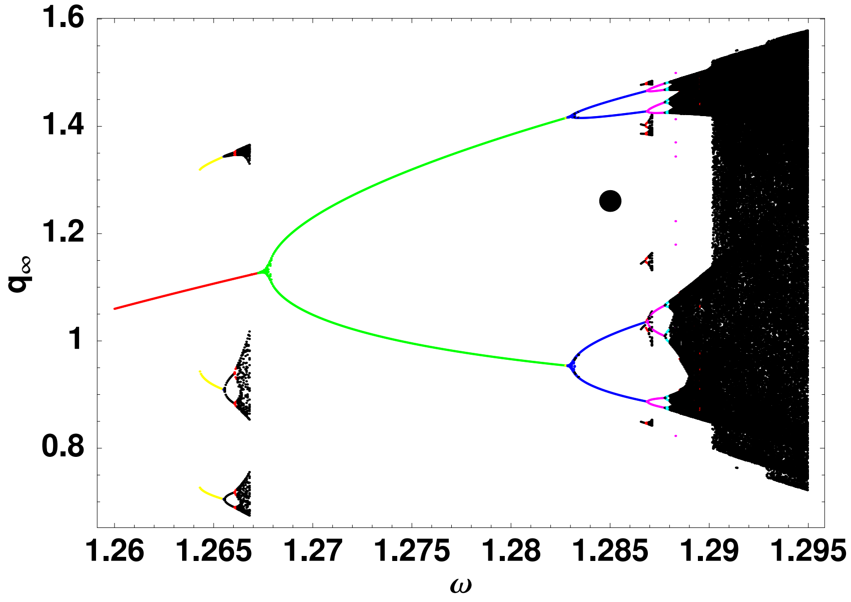

Figure 29.12.24: Partial Feigenbaum diagram for the map $\mathcal{M}_8$. The black dot marks the point about which $\mathcal{M}$ is expanded to yield $\mathcal{M}_8$

.

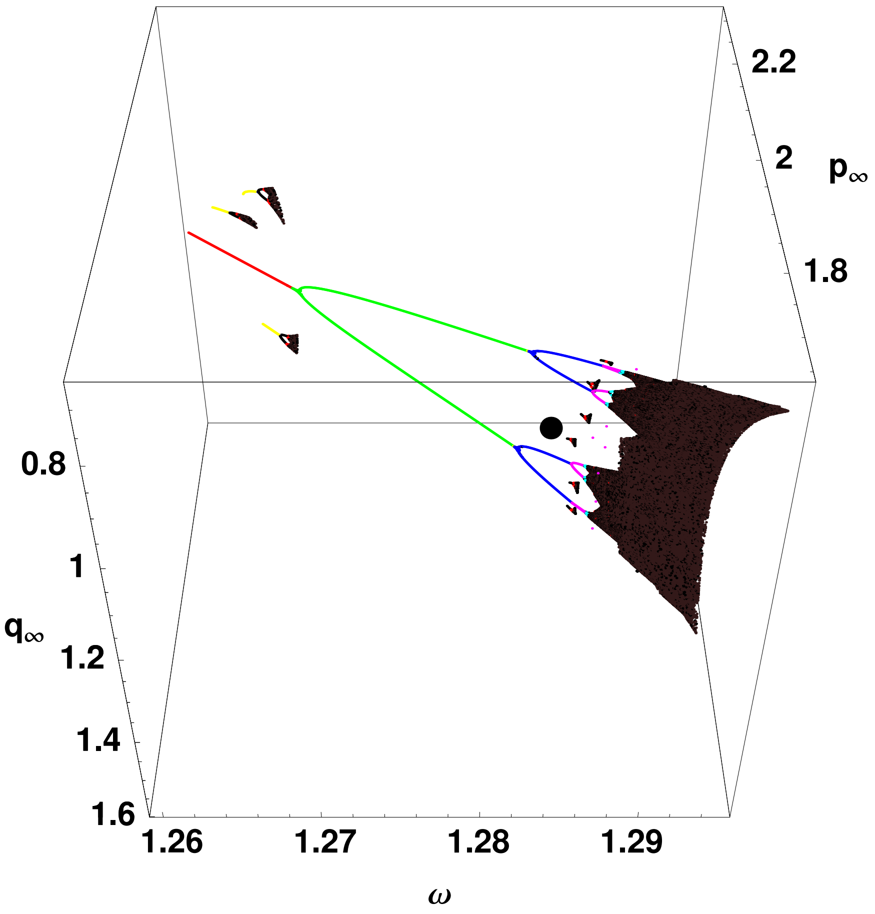

Figure 29.12.25: Full Feigenbaum diagram for the map $\mathcal{M}_8$. The black dot again marks the expansion point.

Strange Attractor

What about the strange attractor that is expected to appear after the completion of the infinite period doubling cascade? Figures 12.26 through 12.29 show the strange attractor for $\mathcal{M}_8$, and magnifications of selected portions, when $\omega = 1.2902$. Comparison of Figures 12.26 and 12.27 with Figures 25.9.1 and 25.9.2 illustrates that the strange attractor is remarkably well reproduced by the polynomial map. Moreover, Figures 12.28 and 12.29 show further successive magnifications, thereby illustrating the continued fractal structure. The exact stroboscopic Duffing map counterparts of these figures would be difficult to produce because of the extensive numerical integration required. However, these magnifications are readily obtained for the polynomial map since it is easily iterated.

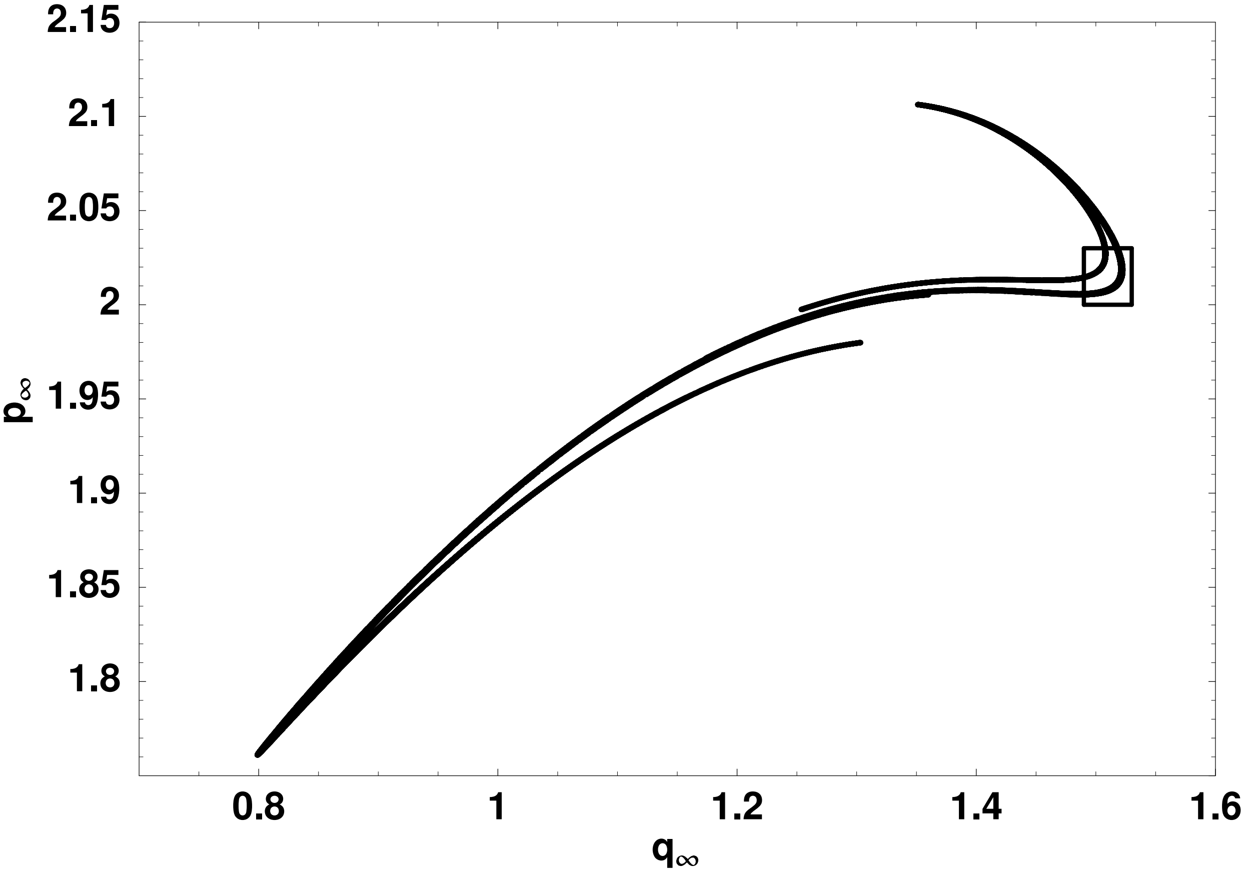

Figure 29.12.26: Limiting values of q_∞, p_∞ for the map $\mathcal{M}_8$ when $\omega = 1.2902$. They appear to lie on a strange attractor.

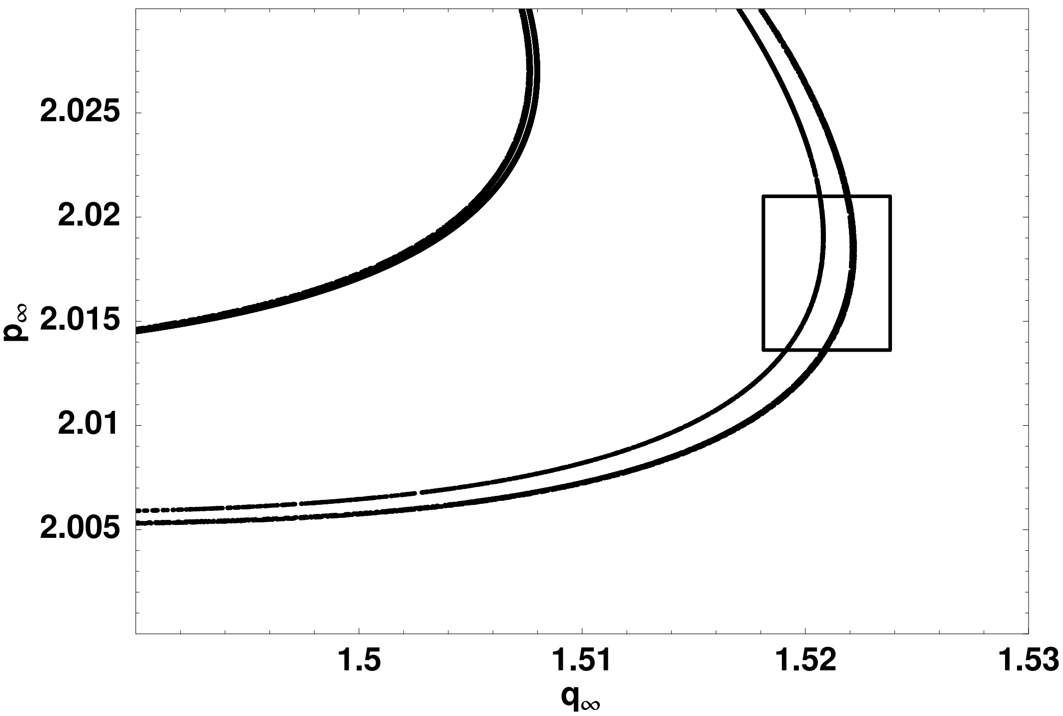

Figure 29.12.27: Enlargement of boxed portion of Figure 12.26 illustrating the beginning of self-similar fractal structure.

29.12.4 Undoing a Cascade by Successive Mergings

According to Figure 25.8.4, the period doubling cascade in Figure 25.8.6 undoes itself by successive mergings as ω becomes sufficiently large. Can this behavior also be reproduced, at least qualitatively, by a polynomial map? The answer is *yes* provided the expansion point is suitably chosen. Figure 12.30 shows the partial Feigenbaum diagram for $\mathcal{M}_8$ when the black dot, located at

$$z_f = (1.59406\cdots\ ;\ 0.565464\cdots), \tag{29.12.13}$$

is used as the expansion point. It is an unstable period-one fixed point when $\omega = 1.4$, and lies on the continuation to smaller ω values of the red fixed-point trail shown on the right side of the figure. Figure 12.31 shows the associated full Feigenbaum diagram. We remark that we were unable to reproduce the full cascade followed by successive merging if the expansion point was chosen to lie on the *left* side of the cascade. Presumably this is because the phase-space and ω excursions associated with the full cascade followed by successive mergings are quite large, and therefore the expansion point has to be sufficiently "centered" in order for the associated Taylor series to have an adequate domain of convergence.[5]

Note that within the q, p range displayed in Figures 12.30 and 12.31 there appears to be for $\mathcal{M}_8$ a gap around $\omega \approx 1.33$ for which there are no stable fixed points nor any attracting set. To the left and right of this gap there are chaotic regions, but there seems to be nothing

[5] In all the examples presented, the expansion point has been chosen to be a fixed point of $\mathcal{M}$ for some value of ω. This is not necessary, and was merely done so that the Taylor map would have the simplifying property of having no constant terms.

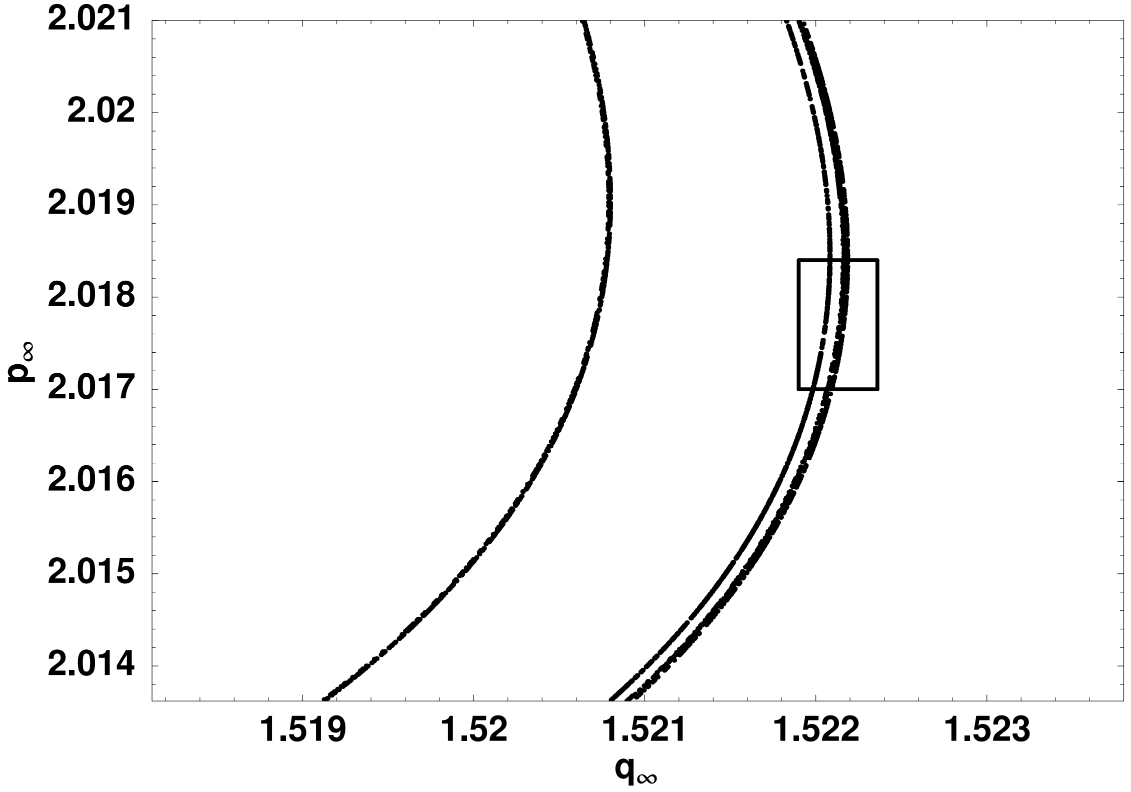

Figure 29.12.28: Enlargement of boxed portion of Figure 12.27 illustrating the continuation of self-similar fractal structure.

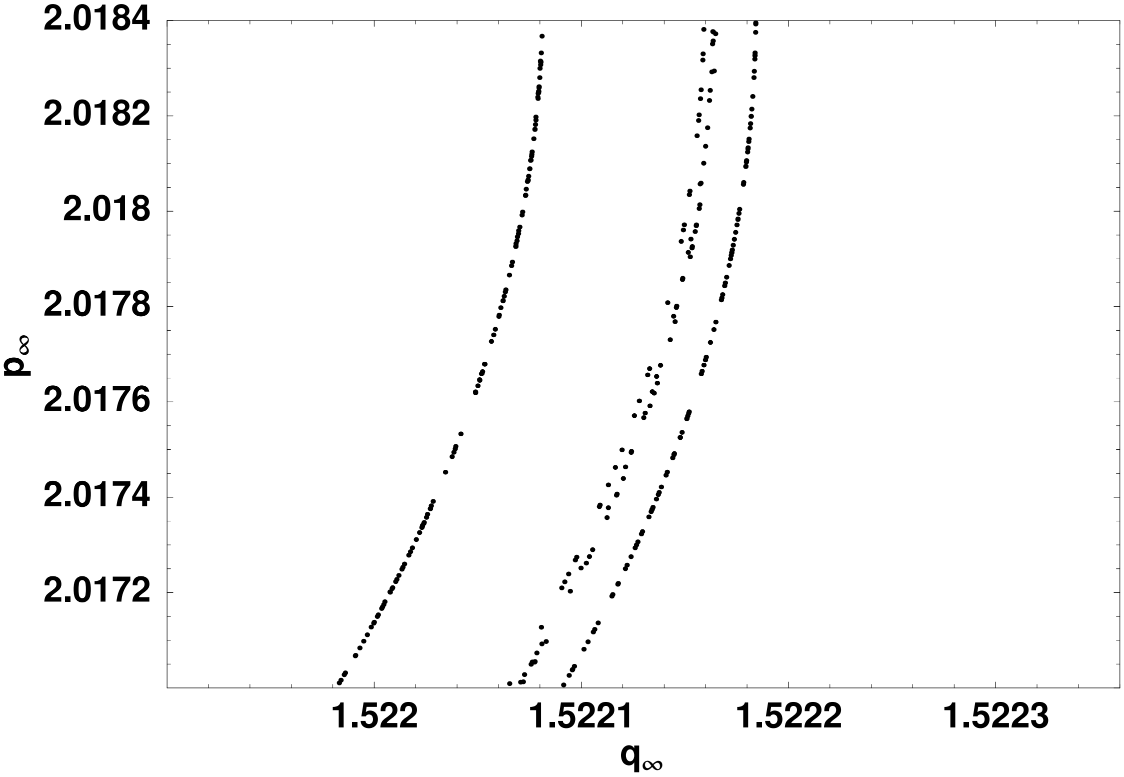

Figure 29.12.29: Enlargement of boxed portion of Figure 12.28 illustrating the further continuation of self-similar fractal structure.

in the gap. Let us examine the behavior of the exact stroboscopic Duffing map $\mathcal{M}$ in this ω range. Figure 25.8.4 provides a partial Feigenbaum diagram and Figure 12.32 provides a full diagram for $\mathcal{M}$.

For ω within the gap and sufficiently large ($\omega \geq 1.335$), Figure 12.32 displays that there are three yellow trails. They correspond to a single stable period-three orbit. That is, there are three stable fixed points of $\mathcal{M}^3$, and these three points are cyclically permuted among themselves under the action of $\mathcal{M}$. The behavior is completely analogous to that of the period-three orbit for the complex logistic map Douady rabbit described by the relations (1.2.33) through (1.2.38). See Section 1.2.2.

Now suppose ω is decreased. Then it happens that *each* of these fixed points of $\mathcal{M}^3$ undergoes a *pitchfork* bifurcation to produce a *triplet* of fixed points of $\mathcal{M}^3$. Thus, there are now three triplets of fixed points of $\mathcal{M}^3$. (Recall that the period does not change at either a saddle-node or pitchfork bifurcaton.) In accord with the pattern for a pitchfork bifurcation, within each triplet two of the fixed points of $\mathcal{M}^3$ are stable, and one is unstable. Consequently, only two points of each triplet will be visible in a Feigenbaum diagram, and there will appear to be three *pairs* of fixed points of $\mathcal{M}^3$ for ω in this range. Correspondingly, there will be *two* period-three stable orbits of $\mathcal{M}$ in this ω range. That is also what Figure 12.32 displays. For ω within the gap and sufficiently large, there are three yellow trails. And, as ω is decreased, each yellow trail splits into two yellow trails so that there are then six yellow trails corresponding to two period-three stable orbits of $\mathcal{M}$. We conclude that the gap is essentially a period-three window.[6]

Finally, we observe that all the stable fixed points in this window have q_∞, p_∞ values that lie outside the q, p range displayed in Figures 12.30 and 12.31, and outside the range for which the Taylor map $\mathcal{M}_8$ well approximates the exact map $\mathcal{M}$. We conclude that $\mathcal{M}_8$ correctly describes the state of affairs for the q, p, ω range depicted in Figure 12.31.

[6] Closer inspection, on a scale finer than that shown in Figure 12.32, reveals that at $\omega = 1.315\cdots$ a *period doubling* occurs so that there are then twelve trails corresponding to two stable period-six orbits. At $\omega = 1.312\cdots$ there is a second period doubling so that now there are twenty-four trails corresponding to two stable period-twelve orbits. The net result is that there appears, on a very fine scale, to be an infinite cascade of period doublings that ultimately merges with the chaotic region to the left of the gap.

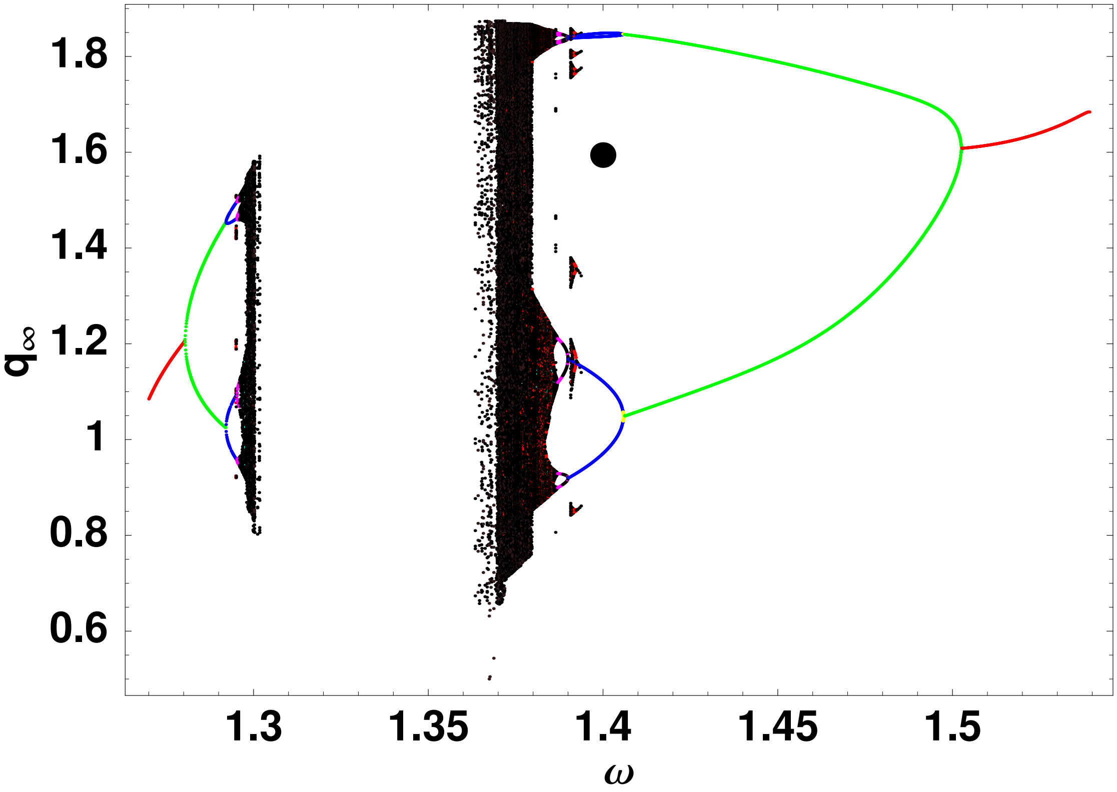

Figure 29.12.30: Partial Feigenbaum diagram for the map $\mathcal{M}_8$ showing a full cascade followed by successive mergings. The black dot marks the point about which $\mathcal{M}$ is now expanded to yield $\mathcal{M}_8$.

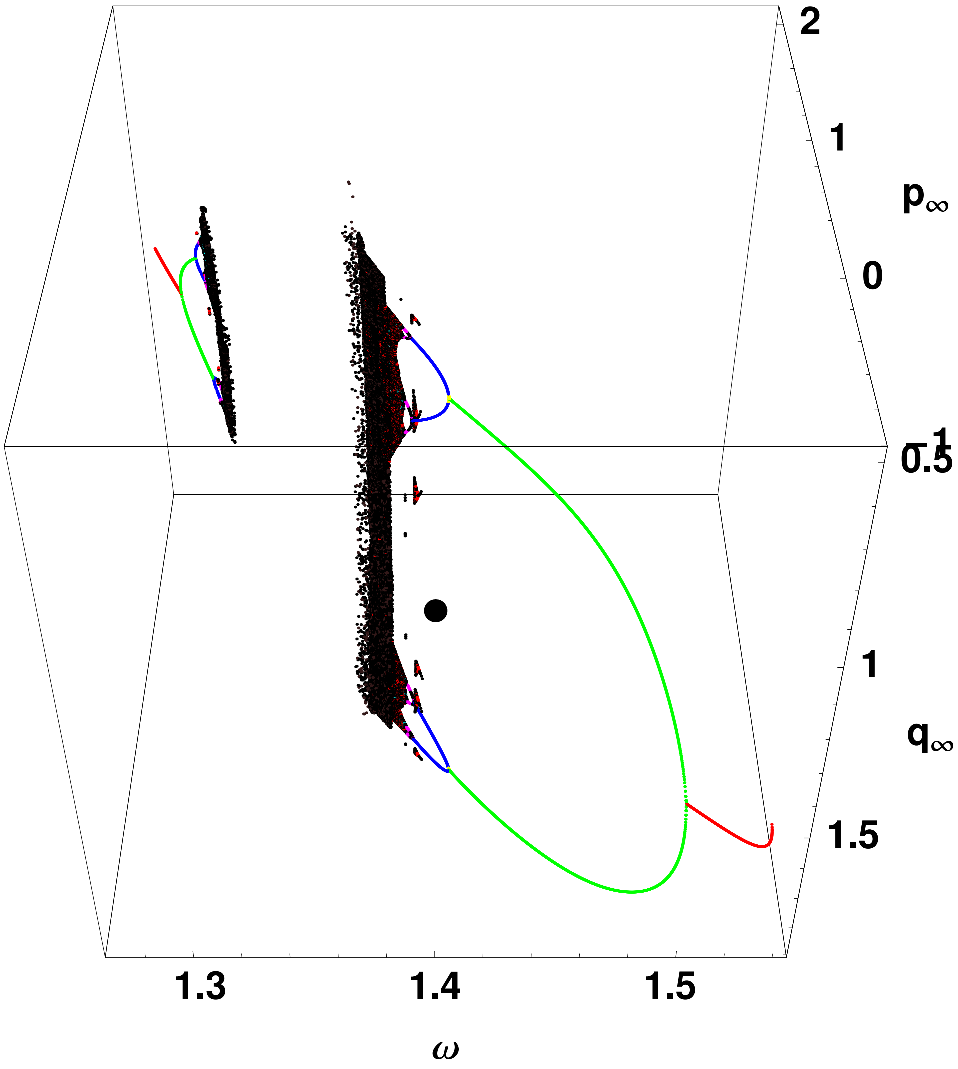

Figure 29.12.31: Full Feigenbaum diagram for the map $\mathcal{M}_8$ showing a full cascade followed by successive mergings. The black dot again marks the point about which $\mathcal{M}$ is expanded to yield $\mathcal{M}_8$.

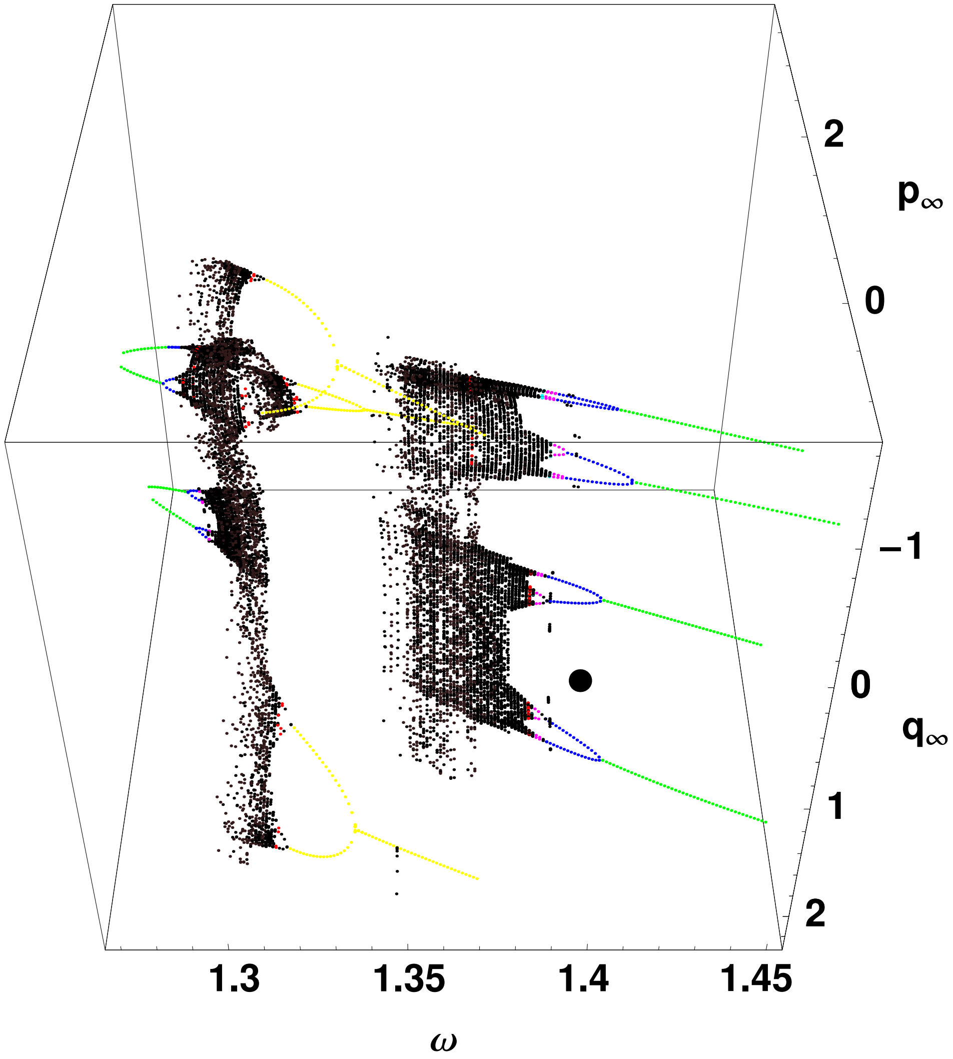

Figure 29.12.32: Full Feigenbaum diagram for the exact map $\mathcal{M}$. See Figure 25.8.4 for a related partial Feigenbaum diagram. The black dot again marks the expansion point used in Figures 12.30 and 12.31. There appears to be a gap around $\omega \approx 1.33$ separating two chaotic regions. Within the right side of the gap (to the right of $\omega \approx 1.335$) there are three yellow trails corresponding to a period-three stable orbit. As ω is decreased, there are pitchfork bifurcations so that each yellow trail splits into two yellow trails. There are then six yellow trails corresponding to two period-three stable orbits. Thus the gap, on the scale shown, is essentially a period-three window.

29.12.5 Convergence of Taylor Maps: Performance of Lower-Order Polynomial Approximations

We close this section with illustrations of the performances of $\mathcal{M}_3$ and $\mathcal{M}_5$, third and fifth-order polynomial approximations (including parameter dependence) to the exact map $\mathcal{M}$. All expansions are made about the point (12.12). Comparison of these performances gives some feeling for the convergence properties of the Taylor approximation to $\mathcal{M}$.

Performance of $\mathcal{M}_3$

Figure 12.33 shows the $\mathcal{M}_3$ counterpart to Figure 12.24 produced using $\mathcal{M}_8$. Evidently the qualitative features of the period doubling cascade are the same. Also, we have found that there is not qualitative agreement if $\mathcal{M}_2$ is used. We conjecture that generically third-order information is necessary and sufficient to obtain qualitative agreement for a period doubling cascade arising from what once was a period-one fixed point.

Note also that $\mathcal{M}_3$ does not reproduce the three features near $\omega = 1.265$ seen in Figure 25.8.6 for the exact $\mathcal{M}$ and in Figure 12.24 for $\mathcal{M}_8$. We have found that these features first appear for $\mathcal{M}_n$ when $n = 5$. They belong to what was initially a period-three fixed point for $\mathcal{M}$.

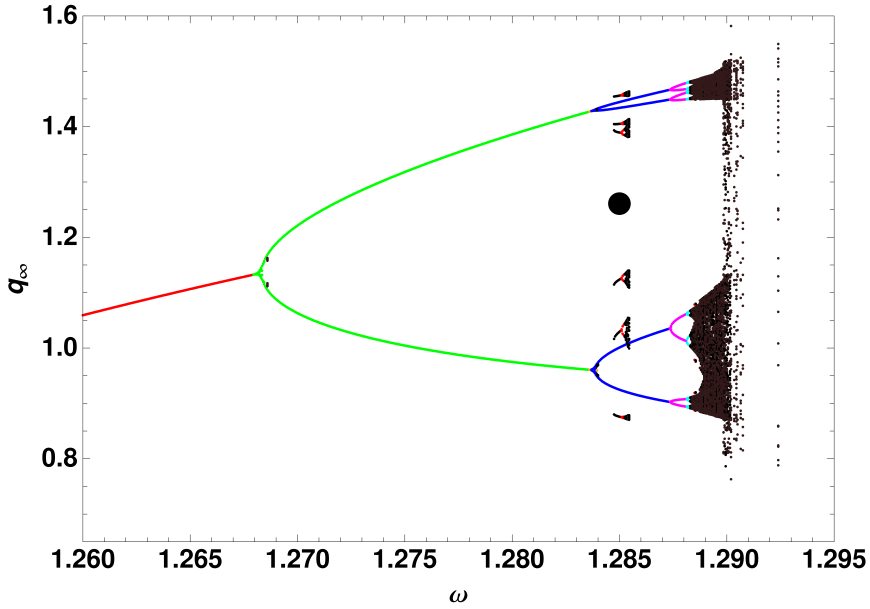

Figure 29.12.33: Partial Feigenbaum diagram for the map $\mathcal{M}_3$. The black dot marks the point about which $\mathcal{M}$ is expanded to yield $\mathcal{M}_3$

.

Figures 12.34 and 12.35 show the $\mathcal{M}_3$ counterparts to Figures 12.26 and 12.27 produced using $\mathcal{M}_8$. Evidently there is qualitative agreement. The attractors in Figures 12.34 and 12.26 look similar. And, when enlarged, both show evidence of fractal structure. Compare Figures 12.35 and 12.27.

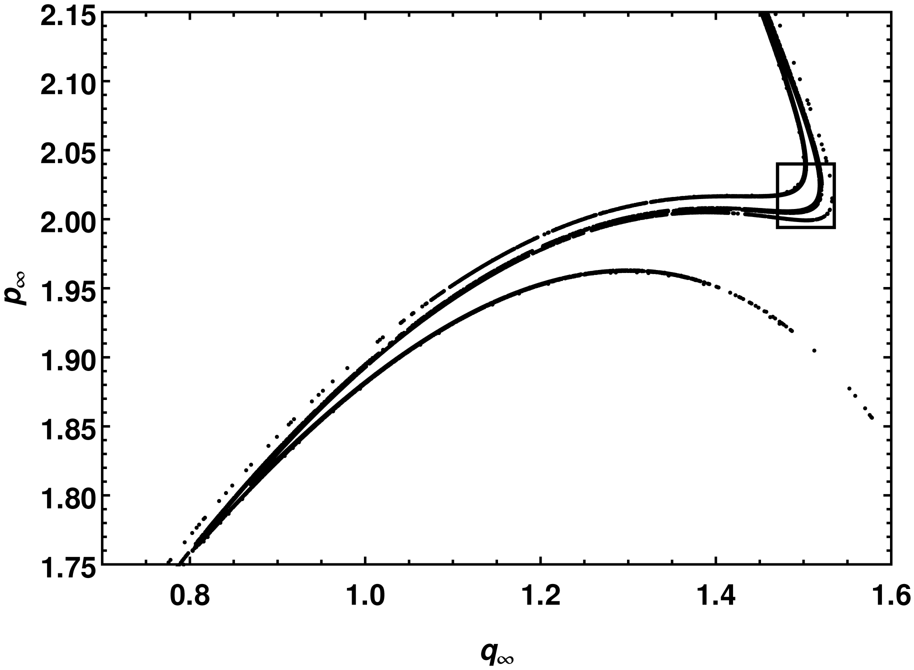

Figure 29.12.34: Limiting values of q_∞, p_∞ for the map $\mathcal{M}_3$ when $\omega = 1.2902$. They appear to lie on a strange attractor.

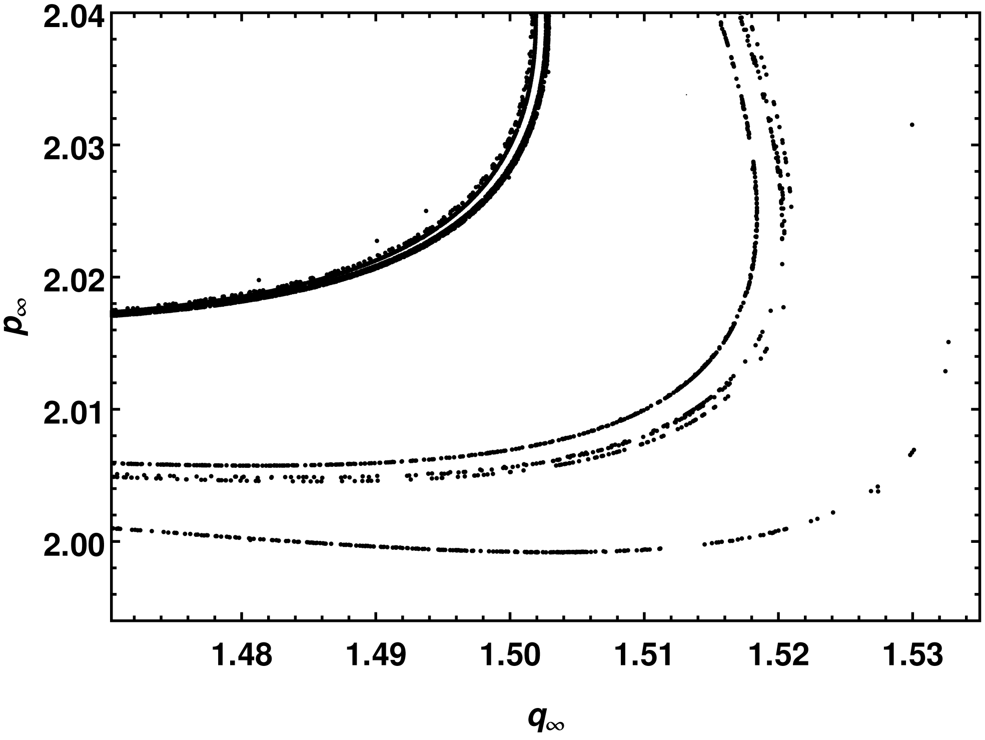

Figure 29.12.35: Enlargement of boxed portion of Figure 12.34 illustrating the beginning of self-similar fractal structure.

Performance of $\mathcal{M}_5$

Figure 12.36 shows the $\mathcal{M}_5$ counterpart to Figure 12.24 produced using $\mathcal{M}_8$. Now there is improved quantitative agreement as well as qualitative agreement. Also, there are now three features near $\omega = 1.265$ that resemble those seen in Figures 25.8.6 and 12.24.

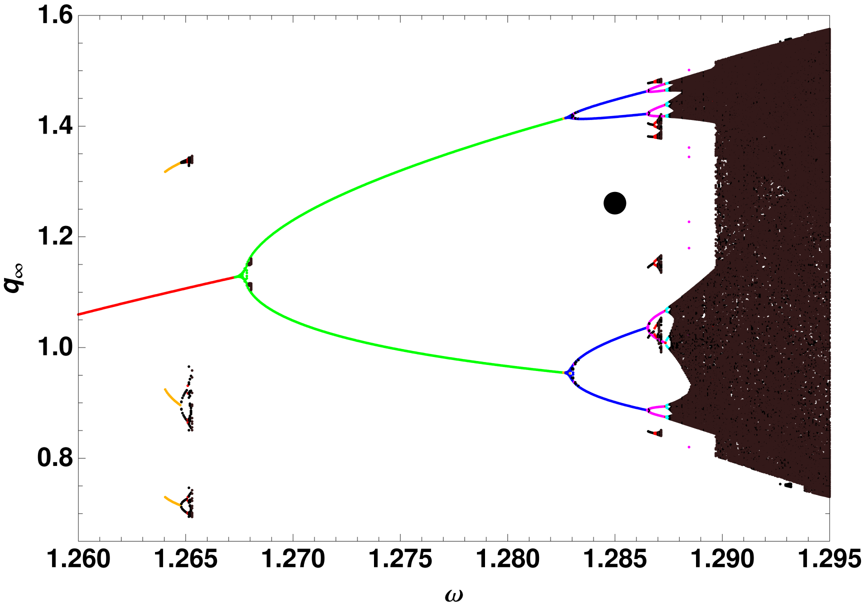

Figure 29.12.36: Partial Feigenbaum diagram for the map $\mathcal{M}_5$. The black dot marks the point about which $\mathcal{M}$ is expanded to yield $\mathcal{M}_5$

.

Figures 12.37 and 12.38 show the $\mathcal{M}_5$ counterparts to Figures 12.26 and 12.27 produced using $\mathcal{M}_8$. Again there is improved quantitative agreement. We surmise that, for the region of phase space and ω range displayed, convergence appears to be well underway.

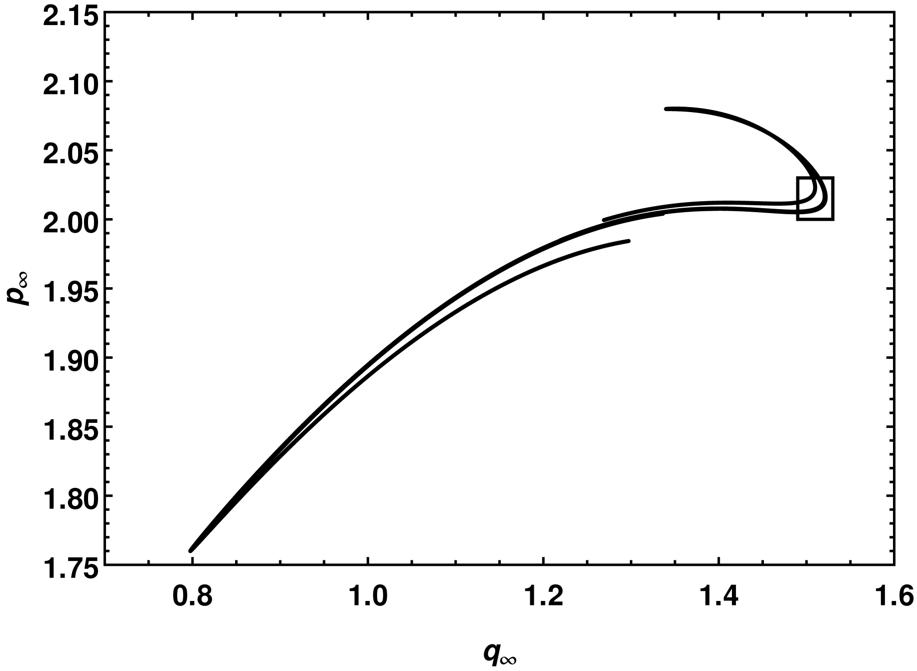

Figure 29.12.37: Limiting values of q_∞, p_∞ for the map $\mathcal{M}_5$ when $\omega = 1.2902$. They appear to lie on a strange attractor.

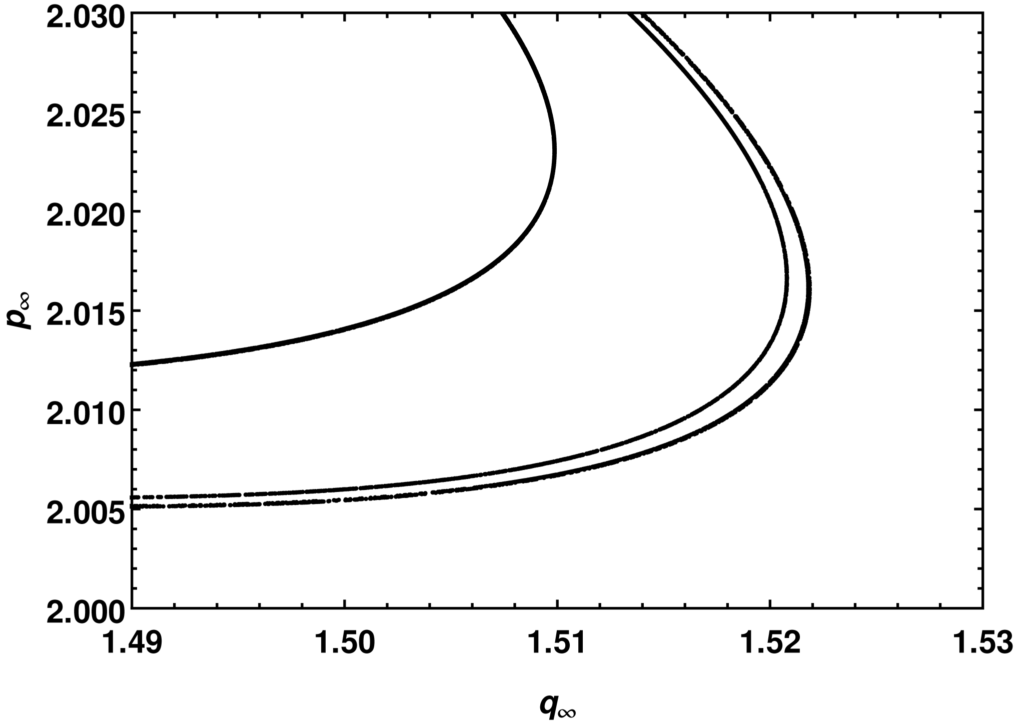

Figure 29.12.38: Enlargement of boxed portion of Figure 12.37 illustrating the beginning of self-similar fractal structure.

29.12.6 Concluding Summary and Discussion

Poincaré analyticity (and its generalization to include parameter dependence) implies that transfer maps $\mathcal{M}$ arising from ordinary differential equations can be expanded as Taylor series in the initial conditions and also in whatever parameters may be present. Section 10.10 described the complete variational equations, and described how the determination of these expansions is equivalent to solving the complete variational equations. Chapter 25 provided an overview of the properties of the stroboscopic transfer map $\mathcal{M}$ for the Duffing equation. The present section described examples of how n^{th} degree approximations $\mathcal{M}_n$ to $\mathcal{M}$ (including parameter dependence) could reproduce various features of the exact $\mathcal{M}$. In particular it illustrated, remarkably, that $\mathcal{M}_8$ produced an infinite period doubling cascade and apparent strange attractor that closely resembled those of the exact map. It also illustrated how the accuracy of $\mathcal{M}_n$ improves with increasing n.

We have seen that there are situations in which a truncated Taylor map well reproduces results obtained by the integration of differential equations. This is comforting since the behavior of polynomial maps, because such maps can easily be evaluated repeatedly, is often studied in detail with the hope that the behavior of such maps is illustrative of what can be expected for maps in general, including the maps that arise from integrating differential equations.

In view of this success, one might wonder if there are situations in which the use of truncated Taylor maps could replace or at least complement direct numerical integration. There is, of course, the question of convergence for Taylor series, and the convergence domain is related to the (generally unknown) singularity structure of the solution to the differential equation in the complex domain. See Section 35.3. However, if satisfactory approximation can be illustrated by the comparison of numerical integration results with truncated Taylor results for representative solutions in some domain, then the use of truncated Taylor maps to find additional results may be faster than continued numerical integration.

For example, in the case of the Duffing equation, although the determination of the relevant $h_a^r(t)$ of Section 10.10 requires the simultaneous numerical integration of a large number of differential equations, these equations need be integrated over only one drive period. Once the truncated Taylor series stroboscopic map has been found, its evaluation for any phase-space point and any parameter value is essentially free. All that is required is the evaluation of two n-degree polynomials (one for ζ_1^f and one for ζ_2^f, the deviation variables associated with q^f and p^f, respectively) in three variables (ζ_1^i, ζ_2^i, and ζ_3^i). (Again see Section 10.10 for notation.) By contrast, the direct construction of a Feigenbaum diagram requires the integration of the Duffing equation for a large number of drive periods and a large number of parameter values. And, determination of the strange attractor associated with the Duffing equation requires the integration of the Duffing equation over thousands of drive periods.

Suppose T_2 is the time required to integrate two equations over a drive period. In our example, it is the time required to integrate the Duffing pair of differential equations (1.4.32) over one drive period. Suppose T_{N_e} is the time required to integrate N_e equations over one drive period. Let $L(m, n)$ be the number of monomials of degree 0 through n in m variables.

It is given by the binomial coefficient

$$L(m,n) = \binom{m+n}{n}. \tag{29.12.14}$$

See Section 7.10. When working with m variables through terms of degree n, the number N_e of differential equations to be integrated to determine the relevant functions $h_a^r(t)$ is given by the relation

$$N_e = mL(m,n), \tag{29.12.15}$$

which amounts to

$$N_e = 3L(3,8) = 3 \times 165 = 495 \tag{29.12.16}$$

in the case of $\mathcal{M}_8$ for the Duffing equation including parameter dependence. We have found in our numerical studies that there is the approximate scaling relation

$$T_{N_e} \simeq (N_e/2)T_2 \tag{29.12.17}$$

for $n \leq 9$. That is, the computation time scales with the number of equations to be integrated. We conclude that in this example the use of $\mathcal{M}_8$ becomes advantageous once the number of drive periods times the number of parameter values exceeds $495/2 \simeq 250$.

With regard to providing complementary information, it is common practice to integrate the first degree variational equations in order to establish the *linear* stability of solutions. Integration of the higher degree variational equations, including possible parameter dependence, provides information about *nonlinear* behavior/stability. As examples, such information is required for the control of orbits in accelerators and the understanding and control of aberrations in optical systems.

In conclusion, there are applications for which use of the higher degree variational equations is advantageous, and the whole subject of the usefulness of truncated Taylor maps merits continued study.

29.13 Analytic Properties of Fixed Points and Eigenvalues

As described in the beginning of Section 12, integrating analytic differential equations can be expected to yield analytic maps. For these maps we can compute fixed points and the eigenvalues of the linear parts of these maps about their fixed points. What can be said about the parameter dependence of these fixed points and eigenvalues?

Consider first the behavior of eigenvalues. They are roots of the characteristic polynomial (3.4.1) when M is the linear part of the map. The coefficients of this polynomial depend on the matrix elements of M in an analytic way. See Exercise 3.7.14. Moreover, since M is determined by integrating the variational equations, we may expect these matrix elements to depend analytically on any parameter. Thus, we may expect that the coefficients of the characteristic polynomial will have analytic parameter dependence.

However, it does not follow that the roots will necessarily have analytic parameter dependence. Think, for example, of the roots of a quadratic equation. The solution of such an equation involves square roots of quantities formed from its coefficients. In such a case we expect that there could be branch points where the arguments of these square roots vanish. Generally we may expect continuity, but not analyticity.

Observe, for example, the behavior of the eigenvalues shown in Figures 12.2 and 12.3. For ω values sufficiently large the green eigenvalues have both real and imaginary parts. But as ω is decreased, there comes an ω value below which the green eigenvalues have only real parts. This means that the green eigenvalues are not analytic functions of ω at this threshold ω value. Similarly, for ω values sufficiently small, the blue eigenvalues have both real and imaginary parts. But as ω is increased, there comes an ω value above which the blue eigenvalues have only real parts. This means that the blue eigenvalues are not analytic functions of ω at this threshold ω value. See Exercise 13.1.

Consider next the case of fixed points. They too may be regarded as the roots of some equations with coefficients that have analytic parameter dependence. We may expect that the fixed points will depend analytically on the parameter as long as no eigenvalue of the linear part of the map about this fixed point has eigenvalue +1. See (4.37). However, as we have learned, fixed points are generally born or annihilated when an eigenvalue becomes equal to +1. Actually, for an analytic map, they are not created or destroyed, but only become invisible by becoming complex. Thus we may again expect the existence of branch points and an associated lack of analyticity at these parameter values. Moreover, if period doubling is to occur, we expect that the linear part of $\mathcal{M}^2$ will have +1 as an eigenvalue; so we also expect lack of analyticity for period-two fixed points as they are born. For a simple one-dimensional example, see Exercise 1.2.2. Finally, at parameter values for which the location of a fixed point fails to be analytic, we may also anticipate failure of analyticity for the associated eigenvalues of the linear part of the map about this fixed point.

Exercises

29.13.1. Suppose $f(z)$ is an analytic function of the complex variable $z = x + iy$. Let z_0 be a point on the real axis and suppose that $f(z)$ is real when z is real and $x < z_0$. Suppose also that f is analytic at z_0. Show that then $f(z)$ is also real for z real and $x > z_0$. Thus, if $f(z)$ is to have an imaginary part for z real and $x > z_0$, then f cannot be analytic at z_0.

29.13.2. Suppose S is a symmetric 2×2 matrix whose entries depend analytically on a parameter λ, and suppose these entries are real when λ is real. Show that in this case the eigenvalues of S are also analytic functions of λ.

Chapter 30

Normal Forms for Symplectic Maps and Their Applications

30.1 Equivalence Relations

Def. 1.1: Let X be some (possibly abstract) set, and let $\sim$ be some relation (something that can be true or false) among pairs of elements in X. The relation $\sim$ is said to be an *equivalence* relation if it satisfies three properties:

i. $x \sim x$ for all x in X (reflexive property).

ii. $x_1 \sim x_2$ implies $x_2 \sim x_1$ for all x_1, x_2 in X (symmetric property) .

iii. $x_1 \sim x_2$ and $x_2 \sim x_3$ implies $x_1 \sim x_3$ for all x_1, x_2, x_3 in X (transitive property).

Def. 1.2: The set of all elements in X that are equivalent (under some given equivalence relation $\sim$) to a given x in X is called the *equivalence class* of x, and is denoted by the symbol $\{x\}$.

Thrm. 1.1: We have the logical relation

$$x_1 \sim x_2 \Leftrightarrow \{x_1\} = \{x_2\}. \tag{30.1.1}$$

Thrm. 1.2: Given an equivalence relation $\sim$ on some set X, show that each x in X belongs to one and only one equivalence class. Thus, under an equivalence relation, a set decomposes in a natural way into disjoint subsets: the equivalence classes produced by the equivalence relation.

Def. 1.3: Let X be some set and x some element in X. Then, given an equivalence relation $\sim$, x belongs to the equivalence class $\{x\}$. A *normal form* x_n for x is an element of $\{x\}$ that has some desired attribute such as “simplicity”. See Figure 1.1.

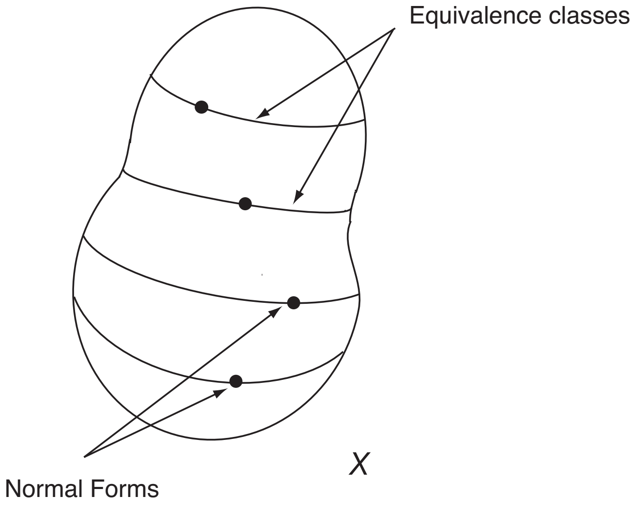

Figure 30.1.1: Decomposition of a set X into disjoint equivalence classes, with a normal form element representative for each equivalence class.

30.2 Symplectic Conjugacy of Symplectic Maps

Def. 2.1: Suppose $\mathcal{M}_1$ and $\mathcal{M}_2$ are two symplectic maps. These maps are said to be (symplectically) *conjugate* if there exists a third (symplectic) map $\mathcal{A}$ such that

$$\mathcal{M}_2 = \mathcal{A}\mathcal{M}_1\mathcal{A}^{-1}. \tag{30.2.1}$$

Def. 2.2: The map $\mathcal{A}$ is called the *conjugating* map.

Thrm. 2.1: Conjugacy and symplectic conjugacy are equivalence relations and therefore determine equivalence classes called *conjugacy classes.* Two maps $\mathcal{M}_1$ and $\mathcal{M}_2$ are equivalent (belong to the same conjugacy class) if a conjugating map $\mathcal{A}$ can be found such that (2.1) holds.

30.3 Normal Forms for Maps

Def. 3.1: A map *normal form* is a representative of an equivalence class (in this case a conjugacy class) selected for its maximal simplicity: Given any map $\mathcal{M}_1$, consider maps $\mathcal{N}_1$ of the form

$$\mathcal{N}_1 = \mathcal{A}_1\mathcal{M}_1\mathcal{A}_1^{-1}. \tag{30.3.1}$$

Select the map $\mathcal{A}_1$, and thereby also the map $\mathcal{N}_1$, in such a way that $\mathcal{N}_1$ is as *simple* as possible. The map $\mathcal{N}_1$ is called the normal form of $\mathcal{M}_1$, and the conjugating map $\mathcal{A}_1$ is called the *normalizing* map. Note that, by construction, we have the relations

$$\mathcal{N}_1 \sim \mathcal{M}_1 \text{ and } \{\mathcal{N}_1\} = \{\mathcal{M}_1\} \tag{30.3.2}$$

so that $\mathcal{N}_1$ is indeed a representative of the conjugacy class of $\mathcal{M}_1$

Thrm. 3.1: Given suitable specifications concerning the set of allowed conjugating maps, there is a *unique* normal form element for each conjugacy class. In other words, the normal form is unique in the sense that if $\mathcal{M}_2$ and $\mathcal{M}_1$ belong to the same conjugacy class,

$$\mathcal{M}_2 \sim \mathcal{M}_1 \text{ and } \{\mathcal{M}_2\} = \{\mathcal{M}_1\}, \tag{30.3.3}$$

then they have the same normal form,

$$\mathcal{N}_2 = \mathcal{N}_1. \tag{30.3.4}$$

Conversely, if two maps $\mathcal{M}_2$ and $\mathcal{M}_1$ have the same normal form, i.e. (3.4) holds, then they are conjugate and (3.4) holds. Thus, we have the logical relation

$$\mathcal{N}_2 = \mathcal{N}_1 \Leftrightarrow \mathcal{M}_2 \sim \mathcal{M}_1 \text{ and } \{\mathcal{M}_2\} = \{\mathcal{M}_1\}. \tag{30.3.5}$$

Proof: Stating that $\mathcal{M}_1$ and $\mathcal{M}_2$ have the normal forms $\mathcal{N}_1$ and $\mathcal{N}_2$ means that there exist normalizing maps $\mathcal{A}_1$ and $\mathcal{A}_2$ such that

$$\mathcal{N}_1 = \mathcal{A}_1\mathcal{M}_1\mathcal{A}_1^{-1}, \tag{30.3.6}$$

$$\mathcal{N}_2 = \mathcal{A}_2\mathcal{M}_2\mathcal{A}_2^{-1}, \tag{30.3.7}$$

and both $\mathcal{N}_1$ and $\mathcal{N}_2$ have maximal simplicity. Now suppose that the left equality in (3.5) holds. This supposition, when combined with (3.6) and (3.7), gives the relation

$$\mathcal{A}_1\mathcal{M}_1\mathcal{A}_1^{-1} = \mathcal{A}_2\mathcal{M}_2\mathcal{A}_2^{-1}, \tag{30.3.8}$$

which can be rewritten in the form

$$\mathcal{M}_1 = (\mathcal{A}_1^{-1}\mathcal{A}_2)\mathcal{M}_2(\mathcal{A}_1^{-1}\mathcal{A}_2)^{-1}. \tag{30.3.9}$$

We conclude that $\mathcal{M}_2$ and $\mathcal{M}_1$ are conjugate,

$$\mathcal{M}_2 \sim \mathcal{M}_1 \text{ and } \{\mathcal{M}_2\} = \{\mathcal{M}_1\}. \tag{30.3.10}$$

Conversely, suppose that $\mathcal{M}_2$ and $\mathcal{M}_1$ are in the same conjugacy class. Then there exists a conjugating map $\mathcal{A}$ such that (2.1) holds. From the relations (2.1), (3.6), and (3.7) we deduce the results

$$\mathcal{N}_1 = \mathcal{A}_1\mathcal{M}_1\mathcal{A}_1^{-1} = \mathcal{A}_1\mathcal{A}^{-1}\mathcal{A}\mathcal{M}_1\mathcal{A}^{-1}\mathcal{A}\mathcal{A}_1^{-1} = (\mathcal{A}_1\mathcal{A}^{-1})\mathcal{M}_2(\mathcal{A}_1\mathcal{A}^{-1})^{-1}, \tag{30.3.11}$$

$$\mathcal{N}_2 = \mathcal{A}_2\mathcal{M}_2\mathcal{A}_2^{-1} = \mathcal{A}_2\mathcal{A}\mathcal{A}^{-1}\mathcal{M}_2\mathcal{A}\mathcal{A}^{-1}\mathcal{A}_2^{-1} = (\mathcal{A}_2\mathcal{A})\mathcal{M}_1(\mathcal{A}_2\mathcal{A})^{-1}. \tag{30.3.12}$$

We see that $\mathcal{M}_2$ has the normal form $\mathcal{N}_1$ when $(\mathcal{A}_1\mathcal{A}^{-1})$ is used as a normalizing map, and $\mathcal{M}_1$ has the normal form $\mathcal{N}_2$ when $(\mathcal{A}_2\mathcal{A})$ is used as a normalizing map. Next, conjugate both sides of (3.6) with the map $(\mathcal{A}_2\mathcal{A}\mathcal{A}_1^{-1})$. Doing so gives the result

$$\begin{aligned}(\mathcal{A}_2\mathcal{A}\mathcal{A}_1^{-1})\mathcal{N}_1(\mathcal{A}_2\mathcal{A}\mathcal{A}_1^{-1})^{-1} &= (\mathcal{A}_2\mathcal{A}\mathcal{A}_1^{-1})\mathcal{A}_1\mathcal{M}_1\mathcal{A}_1^{-1}(\mathcal{A}_2\mathcal{A}\mathcal{A}_1^{-1})^{-1}\\ &= \mathcal{A}_2\mathcal{A}\mathcal{M}_1\mathcal{A}^{-1}\mathcal{A}_2^{-1}\\ &= \mathcal{A}_2\mathcal{M}_2\mathcal{A}_2^{-1} = \mathcal{N}_2.\end{aligned} \tag{30.3.13}$$

Similarly, conjugating both sides of (3.7) with the map $(\mathcal{A}_1\mathcal{A}^{-1}\mathcal{A}_2^{-1})$ gives the result

$$\begin{aligned}(\mathcal{A}_1\mathcal{A}^{-1}\mathcal{A}_2^{-1})\mathcal{N}_2(\mathcal{A}_1\mathcal{A}^{-1}\mathcal{A}_2^{-1})^{-1} &= (\mathcal{A}_1\mathcal{A}^{-1}\mathcal{A}_2^{-1})\mathcal{A}_2\mathcal{M}_2\mathcal{A}_2^{-1}(\mathcal{A}_1\mathcal{A}^{-1}\mathcal{A}_2^{-1})^{-1}\\ &= \mathcal{A}_1\mathcal{A}^{-1}\mathcal{M}_2\mathcal{A}\mathcal{A}_1^{-1}\\ &= \mathcal{A}_1\mathcal{M}_1\mathcal{A}_1^{-1} = \mathcal{N}_1. \qquad (30.3.14)\end{aligned}$$

We have learned that $\mathcal{M}_2$, under the assumption that it is conjugate to $\mathcal{M}_1$, can be normalized to *both* the normal forms $\mathcal{N}_1$ and $\mathcal{N}_2$. Similarly, under the same assumption, $\mathcal{M}_1$ can be normalized to both the normal forms $\mathcal{N}_1$ and $\mathcal{N}_2$. By assumption, the $\mathcal{A}_1$ used in (3.6) and the $\mathcal{A}_2$ used in (3.7) are supposed to make $\mathcal{N}_1$ and $\mathcal{N}_2$ as simple as possible. Moreover, $\mathcal{N}_1$ and $\mathcal{N}_2$ are equally simple. For if $\mathcal{N}_2$ were simpler than $\mathcal{N}_1$, then (3.12) and (3.13) show that the map $(\mathcal{A}_2\mathcal{A})$ normalizes $\mathcal{M}_1$ to the simpler form $\mathcal{N}_2$, which is contrary to the assumption that $\mathcal{A}_1$ has been properly choosen in (3.6) to make $\mathcal{N}_1$ as simple as possible. Similarly, (3.11) and (3.14) show that $\mathcal{N}_1$ cannot be simpler than $\mathcal{N}_2$. We conclude that they must be the same,

$$\mathcal{N}_1 = \mathcal{N}_2. \qquad (30.3.15)$$

Rmk. 3.1: We have seen that the normal form $\mathcal{N}_1$ of a map $\mathcal{M}_1$ is unique. However we remark that, without further requirements, the normalizing map $\mathcal{A}_1$ is not unique. Suppose $\mathcal{B}_1$ is any invertible map that commutes with $\mathcal{N}_1$,

$$\mathcal{N}_1\mathcal{B}_1 = \mathcal{B}_1\mathcal{N}_1. \qquad (30.3.16)$$

Use $\mathcal{B}_1$ to conjugate both sides of (3.6). Doing so and making use of (3.16) gives the result

$$\mathcal{N}_1 = \mathcal{B}_1\mathcal{N}_1\mathcal{B}_1^{-1} = \mathcal{B}_1\mathcal{A}_1\mathcal{M}_1(\mathcal{B}_1\mathcal{A}_1)^{-1}. \qquad (30.3.17)$$

We see that the map $(\mathcal{B}_1\mathcal{A}_1)$ also is a normalizing map that normalizes $\mathcal{M}_1$ to $\mathcal{N}_1$.

Thrm. 3.2: Conversely, suppose $\mathcal{A}_1$ and $\tilde{\mathcal{A}}_1$ are both normalizing maps for $\mathcal{M}_1$,

$$\mathcal{N}_1 = \mathcal{A}_1\mathcal{M}_1\mathcal{A}_1^{-1} = \tilde{\mathcal{A}}_1\mathcal{M}_1\tilde{\mathcal{A}}_1^{-1}. \qquad (30.3.18)$$

Then $\tilde{\mathcal{A}}_1$ and $\mathcal{A}_1$ are related by the equation

$$\tilde{\mathcal{A}}_1 = \mathcal{B}_1\mathcal{A}_1 \qquad (30.3.19)$$

with

$$\mathcal{B}_1 = \tilde{\mathcal{A}}_1\mathcal{A}_1^{-1}, \qquad (30.3.20)$$

where $\mathcal{B}_1$ commutes with $\mathcal{N}_1$.

30.4 Sample Normal Forms

We now describe what normal forms can be achieved in various cases when we are working in the setting of a 6-dimensional phase space with the variables x, y, τ, p_x, p_y, p_τ. As illustrated in Figure 4.1, there are four broad possibilities for general maps $\mathcal{M}$: dynamic (τ-dependent) maps with or without translation factors (characterized by the presence or absence of f_1 terms); static (τ-independent) maps with or without translation factors. These cases are listed below, and will be discussed in subsequent sections.

i. Dynamic map with an f_1 translation factor

ii. Dynamic map without an f_1 translation factor

iii. Static map with an f_1 translation factor

iv. Static map without an f_1 translation factor

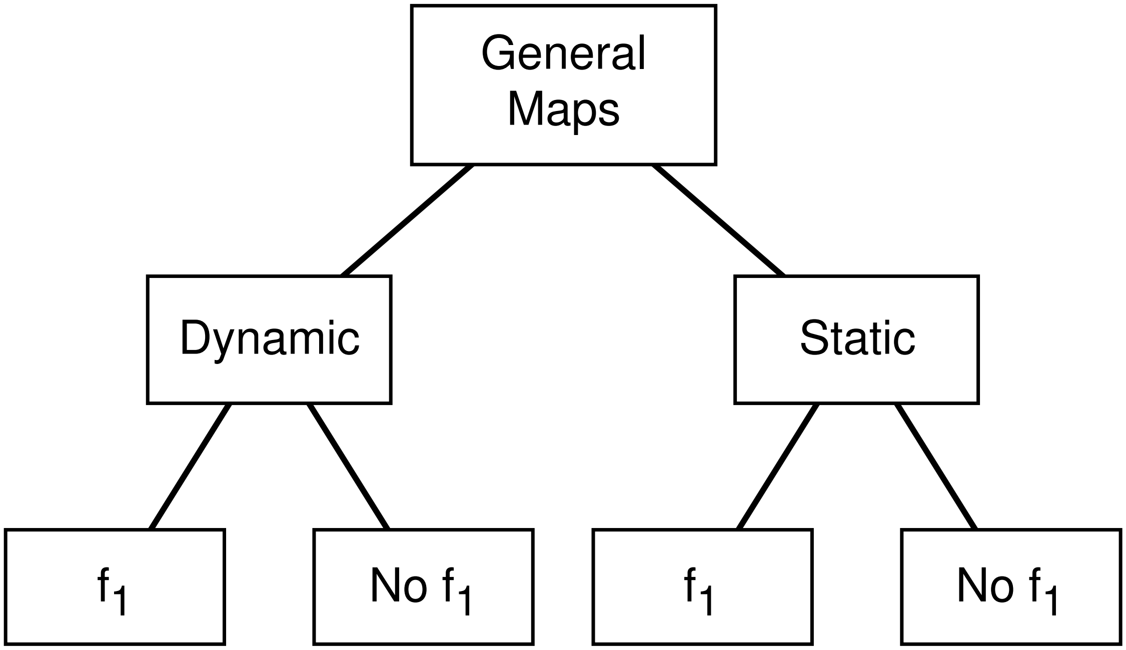

Figure 30.4.1: Four broad possibilities for general maps.

30.5 Dynamic Maps Without Translation Factor

Strangely enough, the easiest case to discuss is dynamic maps without f_1 translation factors. We will therefore treat it first.

30.6 Dynamic Maps With Translation Factor

30.7 Static Maps Without Translation Factor

30.7.1 Preparatory Steps

For the purposes of this section it is convenient to order the phase-space variables as

$$z = (x, p_x; y, p_y; \tau, p_\tau). \tag{30.7.1}$$

According to Section 3.2, J then takes the form (3.2.10) which, in the 6×6 case, is

$$J = \begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & -1 & 0 \end{pmatrix}. \tag{30.7.2}$$

Suppose $\mathcal{M}$ is an origin preserving symplectic map so that it has the Lie factorization

$$\mathcal{M} = \mathcal{R} \exp(: f_3 :) \exp(: f_4 :) \cdots . \tag{30.7.3}$$

Next assume the $\mathcal{M}$ and also has the property

$$\mathcal{M} p_\tau = p_\tau. \tag{30.7.4}$$

For reasons to become evident shortly, we will call such an $\mathcal{M}$ a *static* map. Upon using the representation (5.2) in (5.3) and equating terms of like degree, it follows that there are the relations

$$\mathcal{R} p_\tau = p_\tau. \tag{30.7.5}$$

$$0 =: f_m : p_\tau = [f_m, p_\tau] = \partial f_m / \partial \tau \text{ for } m \geq 3, \tag{30.7.6}$$

The relation (5.6) says that the generators f_m are τ independent (hence static) for $m \geq 3$, and we will see that (5.5) and the symplectic condition imply that the matrix R associated with $\mathcal{R}$ has a very special form.

To explore the properties of R, let us begin by writing it out in full using standard matrix notation,

$$R = \begin{pmatrix} R_{11} & R_{12} & R_{13} & R_{14} & R_{15} & R_{16} \\ R_{21} & R_{22} & R_{23} & R_{24} & R_{25} & R_{26} \\ R_{31} & R_{32} & R_{33} & R_{34} & R_{35} & R_{36} \\ R_{41} & R_{42} & R_{43} & R_{44} & R_{45} & R_{46} \\ R_{51} & R_{52} & R_{53} & R_{54} & R_{55} & R_{56} \\ R_{61} & R_{62} & R_{63} & R_{64} & R_{65} & R_{66} \end{pmatrix}. \tag{30.7.7}$$

Now require that $\mathcal{R}$ be a symplectic map that satisfies (5.5). From (3.1.10) we know that the symplectic condition requires the relation

$$RJR^T = J. \tag{30.7.8}$$

When written in terms of components, this relation takes the form

$$\sum_{bc} R_{ab} J_{bc} R_{dc} = J_{ad}. \tag{30.7.9}$$

As a result of these two requirements (5.5) and (5.8) we will see that many matrix elements of R are 0 or 1, and others are related.

Define the quantities Δ_1 through Δ_4 by the rules

$$\Delta_1 = R_{52}, \tag{30.7.10}$$

$$\Delta_2 = -R_{51}, \tag{30.7.11}$$

$$\Delta_3 = R_{54}, \tag{30.7.12}$$

$$\Delta_4 = -R_{53}, \tag{30.7.13}$$

and view them as the components of a vector Δ. Also define a matrix $\hat{R}$ by the rule

$$\hat{R} = \begin{pmatrix} R_{11} & R_{12} & R_{13} & R_{14} & 0 & 0 \\ R_{21} & R_{22} & R_{23} & R_{24} & 0 & 0 \\ R_{31} & R_{32} & R_{33} & R_{34} & 0 & 0 \\ R_{41} & R_{42} & R_{43} & R_{44} & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}, \tag{30.7.14}$$

and write (5.14) in the more compact form

$$\hat{R} = \begin{pmatrix} \check{R} & 0 \\ 0 & I \end{pmatrix} \tag{30.7.15}$$

where $\check{R}$ is the 4×4 matrix

$$\check{R} = \begin{pmatrix} R_{11} & R_{12} & R_{13} & R_{14} \\ R_{21} & R_{22} & R_{23} & R_{24} \\ R_{31} & R_{32} & R_{33} & R_{34} \\ R_{41} & R_{42} & R_{43} & R_{44} \end{pmatrix}. \tag{30.7.16}$$

Finally, let $\check{J}$ be the the 4×4 version of J,

$$\check{J} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix}. \tag{30.7.17}$$

Then, it is the case that R must be of the more specific form

$$R = \begin{pmatrix} R_{11} & R_{12} & R_{13} & R_{14} & 0 & (\check{R}\Delta)_1 \\ R_{21} & R_{22} & R_{23} & R_{24} & 0 & (\check{R}\Delta)_2 \\ R_{31} & R_{32} & R_{33} & R_{34} & 0 & (\check{R}\Delta)_3 \\ R_{41} & R_{42} & R_{43} & R_{44} & 0 & (\check{R}\Delta)_4 \\ -\Delta_2 & \Delta_1 & -\Delta_4 & \Delta_3 & 1 & R_{56} \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{30.7.18}$$

Also, the entries in the upper left 4×4 block of R, the entries in $\check{R}$, must obey the "reduced" symplectic relations

$$\check{R}\check{J}\check{R}^T = \check{J}. \tag{30.7.19}$$

Observe that the entries R_{16}, R_{26}, R_{36}, and R_{46} in R describe dispersive effects. That is, they describe how the transverse coordinates and momenta depend on p_τ. By contrast, the entries R_{51}, R_{52}, R_{53}, and R_{54} in R describe how the time of flight depends on the transverse initial conditions. From (5.18) we see that dispersive effects and time of flight effects are related by the symplectic condition! They are opposite sides of the same coin. This is an example of what we call *symplectic reciprocity*: seemingly unrelated quantities are in fact related by the symplectic condition.

We will prove this result in stages: We recall that the matrix R associated with $\mathcal{R}$ is given by the relation

$$\mathcal{R}z_a = \sum_b R_{ab} z_b. \tag{30.7.20}$$

As a result of (5.20), the condition (5.5) requires that R have the more specific form

$$R = \begin{pmatrix} R_{11} & R_{12} & R_{13} & R_{14} & R_{15} & R_{16} \\ R_{21} & R_{22} & R_{23} & R_{24} & R_{25} & R_{26} \\ R_{31} & R_{32} & R_{33} & R_{34} & R_{35} & R_{36} \\ R_{41} & R_{42} & R_{43} & R_{44} & R_{45} & R_{46} \\ R_{51} & R_{52} & R_{53} & R_{54} & R_{55} & R_{56} \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{30.7.21}$$

Next, impose the symplectic condition (5.8) for R of the form (5.21). Set $a = 6$ in the relation (5.9) to get the result

$$\sum_{bc} R_{6b} J_{bc} R_{dc} = J_{6d}. \tag{30.7.22}$$

But, from (5.21), we know that

$$R_{6b} = \delta_{6b}. \tag{30.7.23}$$

Therefore the sum (5.22) becomes

$$\sum_c J_{6c} R_{dc} = J_{6d}. \tag{30.7.24}$$

Also, we see from (5.2) that

$$J_{6c} = -\delta_{5c}. \tag{30.7.25}$$

Therefore the sum (5.24) reduces to the result

$$-R_{d5} = J_{6d} \tag{30.7.26}$$

from which we conclude that

$$R_{d5} = 0 \text{ for } d = 1 \text{ to } 4, \tag{30.7.27}$$

$$R_{55} = 1. \tag{30.7.28}$$

Consequently, R must have the yet more specific form

$$R = \begin{pmatrix} R_{11} & R_{12} & R_{13} & R_{14} & 0 & R_{16} \\ R_{21} & R_{22} & R_{23} & R_{24} & 0 & R_{26} \\ R_{31} & R_{32} & R_{33} & R_{34} & 0 & R_{36} \\ R_{41} & R_{42} & R_{43} & R_{44} & 0 & R_{46} \\ R_{51} & R_{52} & R_{53} & R_{54} & 1 & R_{56} \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{30.7.29}$$

Define the quantity ξ by the rule

$$\xi = R_{56}, \tag{30.7.30}$$

and associate with ξ and Δ the matrices $C(\xi)$ and $D(\Delta)$ by the rules

$$C(\xi) = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & \xi \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & R_{56} \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}, \tag{30.7.31}$$

$$D(\Delta) = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & \Delta_1 \\ 0 & 1 & 0 & 0 & 0 & \Delta_2 \\ 0 & 0 & 1 & 0 & 0 & \Delta_3 \\ 0 & 0 & 0 & 1 & 0 & \Delta_4 \\ -\Delta_2 & \Delta_1 & -\Delta_4 & \Delta_3 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{30.7.32}$$

It is easily verified that the matrices $C(\xi)$ and $D(\Delta)$ are symplectic and have the inverses

$$C^{-1}(\xi) = C(-\xi), \tag{30.7.33}$$

$$D^{-1}(\Delta) = D(-\Delta). \tag{30.7.34}$$

Indeed, $C(\xi)$ and $D(\Delta)$ are the matrices associated with the linear symplectic maps $\mathcal{C}(\xi)$ and $\mathcal{D}(\Delta)$ given by the relations

$$\mathcal{C} = \exp(:-\xi p_\tau^2/2:), \tag{30.7.35}$$

$$\mathcal{D} = \exp(: p_\tau g_1 :), \tag{30.7.36}$$

where

$$g_1(\Delta) = \Delta_2 x - \Delta_1 p_x + \Delta_4 y - \Delta_3 p_y. \tag{30.7.37}$$

Note, for future use, that the matrix C commutes with both the matrices D and $\hat{R}$.

We now assert that R has the factorization

$$R = \hat{R}CD \tag{30.7.38}$$

or, equivalently,

$$\hat{R} = RD^{-1}C^{-1}. \tag{30.7.39}$$

The proof of this assertion involves matrix multiplication and invoking the symplectic condition for R. Define a matrix $\hat{R}'$ by the rule

$$\hat{R}' = RD^{-1}C^{-1}. \tag{30.7.40}$$

Carrying out the indicated multiplications gives the result

$$\hat{R}' = \begin{pmatrix} R_{11} & R_{12} & R_{13} & R_{14} & 0 & \epsilon_1 \\ R_{21} & R_{22} & R_{23} & R_{24} & 0 & \epsilon_2 \\ R_{31} & R_{32} & R_{33} & R_{34} & 0 & \epsilon_3 \\ R_{41} & R_{42} & R_{43} & R_{44} & 0 & \epsilon_4 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix} \tag{30.7.41}$$

where

$$\begin{aligned} \epsilon_1 &= R_{16} - [R_{11}R_{52} + R_{12}(-R_{51}) + R_{13}R_{54} + R_{14}(-R_{53})] \\ &= R_{16} - (\check{R}\Delta)_1, \end{aligned} \tag{30.7.42}$$

$$\begin{aligned} \epsilon_2 &= R_{26} - [R_{21}R_{32} + R_{22}(-R_{52}) + R_{23}R_{54} + R_{24}(-R_{53})] \\ &= R_{26} - (\check{R}\Delta)_2, \end{aligned} \tag{30.7.43}$$

$$\begin{aligned} \epsilon_3 &= R_{36} - [R_{31}R_{52} + R_{32}(-R_{51}) + R_{33}R_{54} + R_{34}(-R_{53})] \\ &= R_{36} - (\check{R}\Delta)_3, \end{aligned} \tag{30.7.44}$$

$$\begin{aligned} \epsilon_4 &= R_{46} - [R_{41}R_{52} + R_{42}(-R_{51}) + R_{43}R_{54} + R_{44}(-R_{53})] \\ &= R_{46} - (\check{R}\Delta)_4. \end{aligned} \tag{30.7.45}$$

Next, because R, C^{-1}, and D^{-1} are symplectic matrices, $\hat{R}'$ must a symplectic matrix. In analogy with (5.9), the symplectic condition for $\hat{R}'$ can be written in the form

$$\sum_{bc} \hat{R}'_{ab} J_{bc} \hat{R}'_{dc} = J_{ad}. \tag{30.7.46}$$

Now put $a = 5$ in (5.46) and make use of the special forms of J and $\hat{R}'$ as given by (5.2) and (5.41). Doing so gives the result

$$\sum_{bc} \hat{R}'_{5b} J_{bc} \hat{R}'_{dc} = J_{5d}, \tag{30.7.47}$$

which yields the relations

$$\hat{R}'_{d6} = J_{5d}. \tag{30.7.48}$$

From (5.2), (5.41), and (5.48), we conclude that

$$\epsilon_d = 0 \text{ for } d = 1 \text{ to } 4. \tag{30.7.49}$$

Therefore there is the relation

$$\hat{R}' = \hat{R}, \tag{30.7.50}$$

and (3.39) is correct.

Moreover, in view of (5.42) through (5.45) and (5.49), we have found the relations

$$R_{a6} = (\check{R}\Delta)_a \text{ for } a = 1 \text{ to } 4 \tag{30.7.51}$$

with Δ given by (5.10) through (5.13). Thus, (5.18) is correct. To reiterate, what we have learned from the symplectic condition is that in (5.29) the matrix elements R_{a6} for $a = 1$ to 4 are not independent of the matrix elements R_{5a} for $a = 1$ to 4, but instead are related by the conditions (5.10) through (5.13) and (5.51). Finally, because of (5.15), the remaining relations demanded by (5.46) yield the matrix relation (5.19).

We close this section by noting that the matrix relation (5.38) implies a related factorization for the map $\mathcal{R}$. Let $\hat{\mathcal{R}}$ be the symplectic map associated with $\hat{R}$. Then (5.38) is equivalent to the map factorization relation

$$\mathcal{R} = \mathcal{D}\mathcal{C}\hat{\mathcal{R}} = \mathcal{C}\mathcal{D}\hat{\mathcal{R}}. \tag{30.7.52}$$

Here we have used the fact that C and D commute.

Exercises

30.7.1. Verify that the maps $\mathcal{C}$ and $\mathcal{D}$ given by (5.35) and (5.36) are equivalent to the matrices C and D given by (5.31) and (5.32).

30.7.2. Starting with (5.40), verify that carrying out the indicated multiplications yields the results (5.41) through (5.45).

Chapter 31

Lattice Functions

Chapter 32

Solved and Unsolved Polynomial Orbit Problems: Invariant Theory

32.1 Introduction

As in (8.5.2), let $\mathcal{R}$ be any linear symplectic map [a map corresponding to an $Sp(2n)$ transformation] written in the general form

$$\mathcal{R} = \exp(: f_2^c :) \exp(: f_2^a :). \tag{32.1.1}$$

Suppose $\mathcal{R}$ acts on any homogeneous polynomial g_m in $\mathcal{P}_m$. Then, in view of (21.5.6), the result is a *transformed* polynomial $g_m^{\rm tr}$ that is also in $\mathcal{P}_m$,

$$g_m^{\rm tr}(z) = \mathcal{R} g_m(z) = g_m(\mathcal{R} z) = g_m(Rz). \tag{32.1.2}$$

Here we have also used (8.4.15). Indeed, we know from the work of Chapter 21 that in the two-variable case the $\mathcal{P}_m$ carry the irreducible representation $\Gamma(m)$ of $Sp(2)$; in the four-variable case the $\mathcal{P}_m$ carry the irreducible representation $\Gamma(m,0)$ of $Sp(4)$; in the six-variable case the $\mathcal{P}_m$ carry the irreducible representation $\Gamma(m,0,0)$ of $Sp(6)$; etc.

The set of polynomials $g_m^{\rm tr}$ that can be obtained from any given g_m and arbitrary $\mathcal{R}$ of the form (1.1) is called the *orbit* of g_m under the action of $Sp(2n)$. Now suppose that h_m is any other polynomial in $\mathcal{P}_m$. We will say that h_m is *equivalent* to g_m if there is some $\mathcal{R}$ of the form (1.1) that sends g_m to h_m,

$$h_m \sim g_m \Leftrightarrow h_m = \mathcal{R} g_m \text{ for some } \mathcal{R}. \tag{32.1.3}$$

It is easy to check that (1.3) is indeed an equivalence relation, and we may say that two polynomials in $\mathcal{P}_m$ are equivalent if they lie on the same orbit.

Finally, suppose we are given some polynomial g_m. Then the equivalence class of g_m, which we will denote by $\{g_m\}$, consists of all the $g_m^{\rm tr}$ given by (1.2) for all choices of $\mathcal{R}$. (Thus, the equivalence class $\{g_m\}$ is the orbit of g_m.) Among the $g_m^{\rm tr}$ produced in this fashion there will be one that has some particularly desirable form or property. Various possibilities come to mind: For example, we may attempt to drive to zero as many coefficients in $g_m^{\rm tr}$ as possible by a particular choice of $\mathcal{R}$. Or, if g_m happens to be on the orbit of some monomial, we might like to discover which monomial and determine its coefficient. Or, we might like to find a g_m^{tr} on the oribit of g_m that has the smallest length in the sense of minimizing the scalar product $\langle g_m^{\text{tr}}, g_m^{\text{tr}}\rangle$ as defined in Section 7.3. A or the g_m^{tr} that has some such desirable form or property, or perhaps some other property yet to be discovered, will be called the *normal form* of g_m and will be denoted by the symbols g_m^N. (We remark that in some literature a normal form is called a *canonical* form, and homogeneous polynomials or ratios of homogeneous polynomials are called *quantics*.) Put another way, a normal form of g_m is a particularly simple or pleasing point on the orbit of g_m. Exactly what a normal form for g_m should be is partly a matter of investigation, and partly a matter of choice. Given a g_m, one must first examine all the members of the equivalence class $\{g_m\}$. Then, with their properties clearly in mind, one selects a particularly pleasing g_m^{tr} and calls it g_m^N. Ideally one would like to have an algorithm that takes g_m as an input and provides as outputs g_m^N and the *normalizing* $\mathcal{R}$ that transforms g_m into g_m^N.

Three facts are now obvious practically as a matter of definition. First, $Sp(2n)$ acts transitively on each equivalence class. Second, we may label the equivalence class of g_m by specifying g_m^N. That is. we have the relation

$$\{g_m\} = \{g_m^N\}. \tag{32.1.4}$$

Third, suppose two polynomials g_m and h_m are known or can be shown to have the same normal form,

$$g_m^N = h_m^N. \tag{32.1.5}$$

Then, they are in the same equivalence class and there is an $\mathcal{R}$ that sends one into the other as in (1.3).

There is another terminology that is sometimes used for the situation we have been describing. In this terminology each equivalence class (orbit) is called a *leaf*, and the decomposition of $\mathcal{P}_m$ into equivalence classes is called a *foliation*.

Evidently a general homogeneous polynomial g_m is specified by giving its coefficients. It can be shown (and we will see examples) that there exist polynomial functions of these coefficients that remain unchanged under the transformation (1.2). These functions are called *invariants*. Thus if h_m and g_m are equivalent as in (1.3), each invariant function must have the same value for the coefficients of h_m and the coefficients of g_m.

Why, apart from curiosity, should one care about orbits of g_m in $\mathcal{P}_m$, normal forms g_m^N, and invariants? We will see in Chapter 33 that a knowledge of normal forms for g_2 and invariants for g_m is useful for characterising beams. In Chapter 34 we will see that normal forms for g_3, g_4, $\cdots$ might, if we knew them, be useful in the approximate but exactly symplectic numerical evaluation of the effect of a general map $\mathcal{M}$ on a general phase-space point z as in (7.6.2).

Exercises

32.1.1. Show that (1.3) defines an equivalence relation. See Exercise (5.12.7).

32.2 Solved Polynomial Orbit Problems

In this section we will describe briefly some of what is known about the orbits of g_m under the action of $Sp(2n)$ or, to be more precise, $Sp(2n, \mathbb{R})$. Our results will be fairly complete for the cases $m = 1$ and $m = 2$, and therefore these cases can be characterized as being *solved*. The cases $m > 2$ are much more difficult, and will be characterized largely in terms of what is not known. They are treated in the next section.

First, to dispell a possible false expectation, recall the action of the rotation group on ordinary 3-dimensional Euclidean space. If x, y, z are the usual Cartesian coordinates in Euclidean 3-space, we know that the group $SO(3)$ of rotations about the origin *preserves* the polynomial $(x^2 + y^2 + z^2)$ and any function of this polynomial. Does something analogous happen for the action of $Sp(2n)$ on phase space? The answer is *no.* Suppose that some g_m is preserved,

$$g_m^{\rm tr} = g_m. \tag{32.2.1}$$

Then, from (1.2), we find the result

$$g_m(Rz) = g_m(z) \tag{32.2.2}$$

for all R in $Sp(2n)$. But, from Sections 3.6.5 and 7.2, we know that $Sp(2n)$ acts transitively on phase space. Therefore, any g_m that satisfies (2.2) for all R must have the same value everywhere in phase space, and the only such polynomial is g_0.

There is another instructive way to reach the same conclusion. From (1.1), (1.2), and (2.2) one sees that to be preserved g_m must satisfy the relation

$$\exp(:\epsilon f_2:)g_m = g_m \text{ for all } f_2. \tag{32.2.3}$$

The infinitesimal version of (2.3) is the relation

$$:f_2:g_m = 0 \text{ for all } f_2. \tag{32.2.4}$$

But, say for $sp(6)$, we know that any g_m belongs to the *irreducible* representation $\Gamma(m, 0, 0)$. See Section 1.8. Therefore, the only way that (2.4) can be satisfied is to have $m = 0$.

32.2.1 First-Order Polynomials

We have seen that there is no nontrivial preserved g_m. Thus, $Sp(2n)$ must have some genuine action on each $\mathcal{P}_m$. Let us begin with the case of $\mathcal{P}_1$. Any g_1 in $\mathcal{P}_1$ can be written in the form

$$g_1(a; z) = \sum_j a_j z_j = (a, z). \tag{32.2.5}$$

In this case use of (1.2) gives the result

$$g_1^{\rm tr}(a; z) = (a, Rz) = (R^T a, z) = g_1(R^T a; z) = g_1(a^{\rm tr}; z). \tag{32.2.6}$$

Here we have introduced the notation

$$a^{\rm tr} = R^T a. \tag{32.2.7}$$

We know that R^T is symplectic if R is symplectic; and we again recall that $Sp(2n)$ acts transitively. It follows that if a is any nonzero $2n$-vector, there is a symplectic R such that a^{tr} is any desired vector. Therefore, $\mathcal{P}_1$ decomposes into two equivalence classes: the identically zero polynomial and all the rest. If we ignore the trivial case of the identically zero polynomial, we may say that $\mathcal{P}_1$ consists of only one equivalence class and correspondingly, a single orbit. A convenient normal form is the monomial q_1 with unit coefficient,

$$g_1^N = q_1. \tag{32.2.8}$$

32.2.2 Second-Order Polynomials

Next consider $\mathcal{P}_2$. Here the situation is more complicated. Any g_2 in $\mathcal{P}_2$ can be written in the form

$$g_2(S;z) = \sum_{jk} S_{jk} z_j z_k = (z, Sz) \tag{32.2.9}$$

where S is any symmetric matrix. In this case use of (1.2) gives the result

$$g_2^{\text{tr}}(S;z) = (Rz, SRz) = (z, R^T SRz) = g_2(S^{\text{tr}}; z) \tag{32.2.10}$$

where

$$S^{\text{tr}} = R^T SR. \tag{32.2.11}$$

It is easily checked that S^{tr} is symmetric if S is.

The analysis of the relation (2.11) is facilitated by a trick. Let B denote the *Hamiltonian* matrix gotten from S by the rule

$$B = JS. \tag{32.2.12}$$

Since J is invertible, one can always find S given B, and vice versa. See Section 3.7. Next we define B^{tr} by the rule

$$B^{\text{tr}} = JS^{\text{tr}}. \tag{32.2.13}$$

With the aid of these definitions the relation (2.11) takes the form

$$B^{\text{tr}} = JS^{\text{tr}} = JR^T SR = JR^T J^{-1} JSR = R^{-1} BR. \tag{32.2.14}$$

Here we have used (3.1.9). With the aid of J we have turned a symplectic congruency relation (2.11) into a symplectic conjugacy (similarity) relation (2.14). What we learn from (2.14) is that the problem of finding orbits in $\mathcal{P}_2$ is equivalent to finding orbits in the space of $2n \times 2n$ real Hamiltonian matrices under the action of real symplectic similarity transformations. We know that eigenvalues are unchanged by similarity transformations, and therefore expect that eigenvalues and functions constructed from eigenvalues will play an important role.

Suppose we were allowed to make arbitrary (including complex and nonsymplectic) similarity transformations. Then we know that B, if it has distinct eigenvalues, can be diagonalized. And if the eigenvalues are not distinct, B might still be diagonalizable or, in the worst case, it could still be brought to Jordan normal form. We might define the diagonal or Jordan form for B to be B^{tr}, and then try to form S^{tr} and $g_2^N = g_2^{\text{tr}}$ accordingly. However, we are only allowed to use real symplectic similarity transformations, and we must see to what extent something analogous can be done using only such transformations.

32.2.2.1 Two-Dimensional Phase-Space Case

We will come to the general $2n \times 2n$ case eventually. As a warm-up exercise, consider first the 2×2 case for 2-dimensional phase space.. Then g_2 has the general form

$$g_2 = \beta p^2 + 2\alpha pq + \gamma q^2 \tag{32.2.15}$$

where α, β, γ are arbitrary constants. Correspondingly, the matrices S and B take the forms

$$S = \begin{pmatrix} \gamma & \alpha \\ \alpha & \beta \end{pmatrix}, \tag{32.2.16}$$

$$B = \begin{pmatrix} \alpha & \beta \\ -\gamma & -\alpha \end{pmatrix}. \tag{32.2.17}$$

Evidently the transformation (2.14) cannot change the determinant of B which we will call δ,

$$\delta = \det B = \beta\gamma - \alpha^2. \tag{32.2.18}$$

That is, δ is an *invariant* constructed from the coefficients of g_2. [Note that δ is just the negative of the discriminant. See (8.7.30).] However, as will be seen, we can change α, β, γ while maintaining the condition (2.18). Note that the matrix B has the characteristic polynomial

$$P(\lambda) = \det(B - \lambda I) = \lambda^2 + \beta\gamma - \alpha^2 = \lambda^2 + \delta, \tag{32.2.19}$$

and therefore has the eigenvalues

$$\lambda_\pm = \pm(\alpha^2 - \beta\gamma)^{1/2} = \pm(-\delta)^{1/2}. \tag{32.2.20}$$

It is convenient to consider separately the six cases listed below:

i. $\beta > 0$

ii. $\beta < 0$

iii. $\gamma > 0$

iv. $\gamma < 0$

v. $\beta = \gamma = 0$

vi. $\alpha = \beta = \gamma = 0$

In the next few paragraphs we will treat them one by one.

Case *i*, $\beta > 0$

Let us begin with case i by supposing $\beta > 0$. Let M be the symplectic matrix defined by the equation

$$M = \begin{pmatrix} \sqrt{\beta} & 0 \\ -\alpha/\sqrt{\beta} & 1/\sqrt{\beta} \end{pmatrix}. \tag{32.2.21}$$

Then use of (2.11) with $R = M$ gives a transformed S that we will call S',

$$S' = M^T S M = \begin{pmatrix} \delta & 0 \\ 0 & 1 \end{pmatrix}. \tag{32.2.22}$$

Next suppose that $\delta > 0$. In this case we conclude from (2.18) that $\gamma > 0$ and from (2.20) that the eigenvalues $\lambda_\pm$ are pure imaginary. Let N be the symplectic matrix

$$N = \begin{pmatrix} \delta^{-1/4} & 0 \\ 0 & \delta^{1/4} \end{pmatrix}. \tag{32.2.23}$$

Use of N to transform S' to $S^{\rm tr}$ gives the result

$$S^{\rm tr} = N^T S' N = \begin{pmatrix} \delta^{-1/4} & 0 \\ 0 & \delta^{1/4} \end{pmatrix} \begin{pmatrix} \delta & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \delta^{-1/4} & 0 \\ 0 & \delta^{1/4} \end{pmatrix} = \begin{pmatrix} \delta^{1/2} & 0 \\ 0 & \delta^{1/2} \end{pmatrix}. \tag{32.2.24}$$

Correspondingly $g_2^{\rm tr}$ is given by the relation

$$g_2^{\rm tr} = (z, S^{\rm tr} z) = \delta^{1/2}(p^2 + q^2). \tag{32.2.25}$$

Suppose instead that $\delta = 0$. Now we conclude from (2.18) that $\gamma \geq 0$ and from (2.20) that the eigenvalues $\lambda_\pm$ both vanish. In this case S' as given by (2.22) can be used directly to give the result

$$g_2^{\rm tr} = (z, S' z) = p^2. \tag{32.2.26}$$

It is easily verified that p^2 and q^2 are equivalent,

$$p^2 \sim q^2. \tag{32.2.27}$$

See Exercise 2.1. Therefore, if desired, we can find and employ an R such that

$$g_2^{\rm tr} = q^2. \tag{32.2.28}$$

Finally suppose that $\delta < 0$ (in which case $\beta\gamma < \alpha^2$ and the eigenvalues $\lambda_\pm$ are real). Let N be the symplectic matrix

$$N = \begin{pmatrix} (-\delta)^{-1/4} & 0 \\ 0 & (-\delta)^{1/4} \end{pmatrix}. \tag{32.2.29}$$

Use of N to transform S' to $S^{\rm tr}$ gives the result

$$\begin{aligned} S^{\rm tr} = N^T S' N &= \begin{pmatrix} (-\delta)^{-1/4} & 0 \\ 0 & (-\delta)^{1/4} \end{pmatrix} \begin{pmatrix} \delta & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} (-\delta)^{-1/4} & 0 \\ 0 & (-\delta)^{1/4} \end{pmatrix} \\ &= (-\delta)^{1/2} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \end{aligned} \tag{32.2.30}$$

Correspondingly $g_2^{\rm tr}$ is given by the relation

$$g_2^{\rm tr} = (z, S^{\rm tr} z) = (-\delta)^{1/2}(q^2 - p^2). \tag{32.2.31}$$

Case *ii*, $\beta < 0$

To consider case *ii*, suppose $\beta < 0$. Let M be the symplectic matrix defined by the equation

$$M = \begin{pmatrix} \sqrt{-\beta} & 0 \\ \alpha/\sqrt{-\beta} & 1/\sqrt{-\beta} \end{pmatrix}. \tag{32.2.32}$$

Then use of (2.11) with $R = M$ gives a transformed S which we again call S',

$$S' = M^T S M = \begin{pmatrix} -\delta & 0 \\ 0 & -1 \end{pmatrix}. \tag{32.2.33}$$

Next suppose $\delta > 0$. In this case we conclude from (2.18) that $\gamma < 0$ and from (2.20) that the eigenvalues $\lambda_\pm$ are pure imaginary. Again let N be the symplectic matrix (2.23). Then we find for $S^{\rm tr}$ the result

$$S^{\rm tr} = N^T S' N = -\delta^{1/2} I. \tag{32.2.34}$$

Correspondingly $g_2^{\rm tr}$ is given by the relation

$$g_2^{\rm tr} = -\delta^{1/2}(p^2 + q^2). \tag{32.2.35}$$

Suppose instead that $\delta = 0$. Now we conclude from (2.18) that $\gamma \le 0$ and from (2.20) that the eigenvalues $\lambda_\pm$ both vanish. In this case use of S' directly gives the result

$$g_2^{\rm tr} = -p^2. \tag{32.2.36}$$

Alternatively, in view of (2.27), we can find an R such that

$$g_2^{\rm tr} = -q^2. \tag{32.2.37}$$

Finally suppose $\delta < 0$. Then use of (2.33) and N given by (2.29), and calling the result S'', give the relation

$$S'' = -\begin{pmatrix} (-\delta)^{1/2} & 0 \\ 0 & -(-\delta)^{1/2} \end{pmatrix} = -(-\delta)^{1/2}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{32.2.38}$$

Also, it is easily verified that in this case use of the symplectic matrix J gives the relation

$$S^{\rm tr} = J^T S'' J = -S'' = (-\delta)^{1/2}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{32.2.39}$$

It follows that we may take for $g_2^{\rm tr}$ the polynomial

$$g_2^{\rm tr} = (-\delta)^{1/2}(q^2 - p^2). \tag{32.2.40}$$

Cases *iii* and *iv*, $\gamma > 0$ or $\gamma < 0$

We have covered cases *i* and *ii*. Exercise 2.2 shows that cases *iii* and *iv* give results identical to those for cases *i* and *ii*, respectively. In particular, we still find the results (2.25), (2.26), (2.28), (2.31), (2.35), (2.36), (2.37), and (2.40) [which is identical to (2.31)].

Case *v*, $\beta = \gamma = 0$

For case v we immediately have the result

$$S = \begin{pmatrix} 0 & \alpha \\ \alpha & 0 \end{pmatrix} = (-\delta)^{1/2} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \tag{32.2.41}$$

and g_2 takes the form

$$g_2 = 2(-\delta)^{1/2} qp. \tag{32.2.42}$$

Let O be the symplectic matrix

$$O = (1/\sqrt{2}) \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}. \tag{32.2.43}$$

Use of O to transform S gives the result

$$S^{\rm tr} = O^T S O = (-\delta)^{1/2} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{32.2.44}$$

Correspondingly, we find for $g_2^{\rm tr}$ the identical result (2.40). Note that comparison of (2.41) and (2.44) reveals that there are the equivalence relations

$$+(-\delta)^{1/2}(q^2 - p^2) \sim -(-\delta)^{1/2}(q^2 - p^2) \sim -2(-\delta)^{-1/2} qp \sim +2(-\delta)^{1/2} qp. \tag{32.2.45}$$

Case *vi*, $\alpha = \beta = \gamma = 0$

Finally, case vi gives the zero polynomial.

Normal Forms

Evidently, we may take the various g_2^{tr} discovered for cases i through vi to be normal forms. We see that, for the most part, the normal form is labeled by the value of the invariant δ with additional qualifications for the sign of β or γ in the cases $\delta \geq 0$. Therefore, as mentioned before, a necessary condition for $h_2 \sim g_2$ is that they have the *same* invariant. All these results are summarized in Figure 2.1 below.

$\delta < 0$	$\delta = 0$	$\delta > 0$
$(-\delta)^{1/2}(q^2 - p^2)$	q^2 or p^2 if β or $\gamma > 0$	$(\delta)^{1/2}(p^2 + q^2)$ if β or $\gamma > 0$
or	$-\,q^2$ or $-\,p^2$ if β or $\gamma < 0$	$-\,(\delta)^{1/2}(p^2 + q^2)$ if β or $\gamma < 0$
$2(-\delta)^{1/2}pq$		

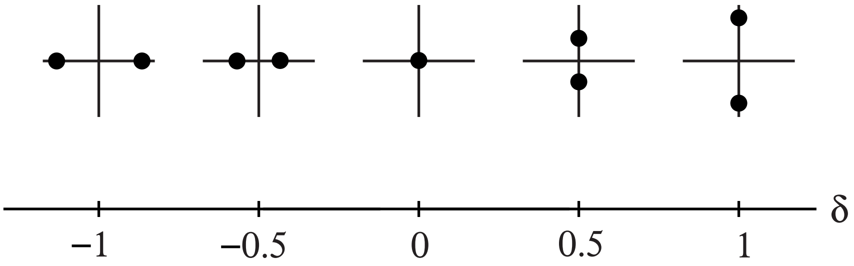

Figure 32.2.1: Normal forms g_2^N and eigenvalue spectrum of associated Hamiltonian matrices in the case of 2-dimensional phase space. The normal forms given in the three columns above are for the cases $\delta < 0$, $\delta = 0$, and $\delta > 0$, respectively.

Geometrical Description

It is also instructive to examine the surfaces $\beta\gamma - \alpha^2 = \delta$ for various values of δ. We will see that each such surface is an orbit. To do so, it is convenient to perform a 45° rotation in the β, γ plane, and to scale α, by introducing new variables ξ, η, ζ by the definitions

$$\beta = (1/\sqrt{2})(\xi - \eta), \tag{32.2.46}$$

$$\gamma = (1/\sqrt{2})(\xi + \eta), \tag{32.2.47}$$

$$\alpha = (1/\sqrt{2})\zeta. \tag{32.2.48}$$

In terms of these variables the relation (2.18) becomes

$$\xi^2 - \eta^2 - \zeta^2 = 2\delta. \tag{32.2.49}$$

Also, use of the scalar product of Section 7.3 and (2.15) gives the result

$$\langle g_2, g_2 \rangle = 2\beta^2 + 4\alpha^2 + 2\gamma^2 = 2(\xi^2 + \eta^2 + \zeta^2). \tag{32.2.50}$$

Thus, polynomials of any given norm are *spheres* in ξ, η, ζ space.

In the case that $\delta \leq 0$, the relation (2.49) can be rewritten in the form

$$\eta^2 + \zeta^2 - \xi^2 = -2\delta. \tag{32.2.51}$$

For $\delta < 0$ this equation yields hyperboloids of one sheet with symmetry axis ξ. See Figure 2.2a below. Evidently for $\delta < 0$ the points on a given hyperboloid that are closest to the origin lie on the plane $\xi = 0$, in which case (2.51) becomes the circle

$$\eta^2 + \zeta^2 = -2\delta. \tag{32.2.52}$$

According to (2.50) all polynomials on this circle have the same squared norm, namely -4δ. The normal form (2.31) lies on this circle and has the coordinates

$$\xi = 0,\ \eta = (-2\delta)^{1/2},\ \zeta = 0, \tag{32.2.53}$$

or, equivalently,

$$-\beta = \gamma = (-\delta)^{1/2},\ \alpha = 0. \tag{32.2.54}$$

Here use has been made of (2.46) through (2.48). Evidently all points on the hyperboloid corresponding to a given value of $\delta < 0$ lie on the same orbit. That is, there is one equivalence class for each value of $\delta < 0$.

The case $\delta = 0$ produces two cones with a common vertex at the origin. Again see Figure 2.2a. Shortly we will discuss it more.

For $\delta > 0$ the equation (2.49) yields a hyperboloid of two sheets with symmetry axis ξ. See Figure 2.2b. On the upper sheet $\xi > 0$, and on the lower sheet $\xi < 0$. Also from (2.49) we conclude that

$$\xi^2 - \eta^2 = \zeta^2 + 2\delta > 0 \text{ when } \delta > 0. \tag{32.2.55}$$

It follows from (2.46) and (2.47) that $\beta, \gamma > 0$ on the upper sheet and $\beta, \gamma < 0$ on the lower sheet. Also, on the upper sheet and for a given value of $\delta > 0$, there is a single point closest to the origin; from (2.49) it has the coordinates

$$\eta = \zeta = 0,\ \xi = (2\delta)^{1/2}, \tag{32.2.56}$$

or, equivalently,

$$\beta = \gamma = \delta^{1/2},\ \alpha = 0. \tag{32.2.57}$$

This point corresponds to the normal form given by (2.25). Similarly, on the corresponding lower sheet, there is also a single point closest to the origin with the coordinates

$$\eta = \zeta = 0,\ \xi = -(2\delta)^{1/2}, \tag{32.2.58}$$

or, equivalently,

$$\beta = \gamma = -\delta^{1/2},\ \alpha = 0. \tag{32.2.59}$$

This point corresponds to the normal form given by (2.35). Evidently, for a fixed value of $\delta > 0$, all points on the upper sheet lie on the same orbit, and those on the lower sheet lie on a second distinct orbit. Consequently, there are two equivalence classes for each positive value of δ. The upper sheet gives the case $\beta, \gamma > 0$, and the lower sheet gives the case $\beta, \gamma < 0$.

There remains the case $\delta = 0$ for which, as already mentioned, the relation (2.49) yields two cones. These cones have no point in common save the origin which corresponds to the single-element equivalence class $g_2 = 0$. Moreover, points on the upper and lower cones belong to separate equivalence classes. It is easy to check that β or $\gamma > 0$ on the upper cone and β or $\gamma < 0$ on the lower cone. (Here the origin is to be excluded.) The monomial $+q^2$ given by (2.28) provides a normal form for polynomials corresponding to points on the upper cone. Its coordinates are given by the relations

$$\xi = \eta = 1/\sqrt{2},\ \zeta = 0, \tag{32.2.60}$$

or, equivalently,

$$\alpha = \beta = 0,\ \gamma = 1. \tag{32.2.61}$$

The monomial $-q^2$ given by (2.37) provides a normal form for polynomials corresponding to points on the lower cone. Its coordinates are given by the relations

$$\xi = \eta = -1/\sqrt{2},\ \zeta = 0, \tag{32.2.62}$$

or, equivalently,

$$\alpha = \beta = 0,\ \gamma = -1. \tag{32.2.63}$$

It follows that each cone is a separate orbit.

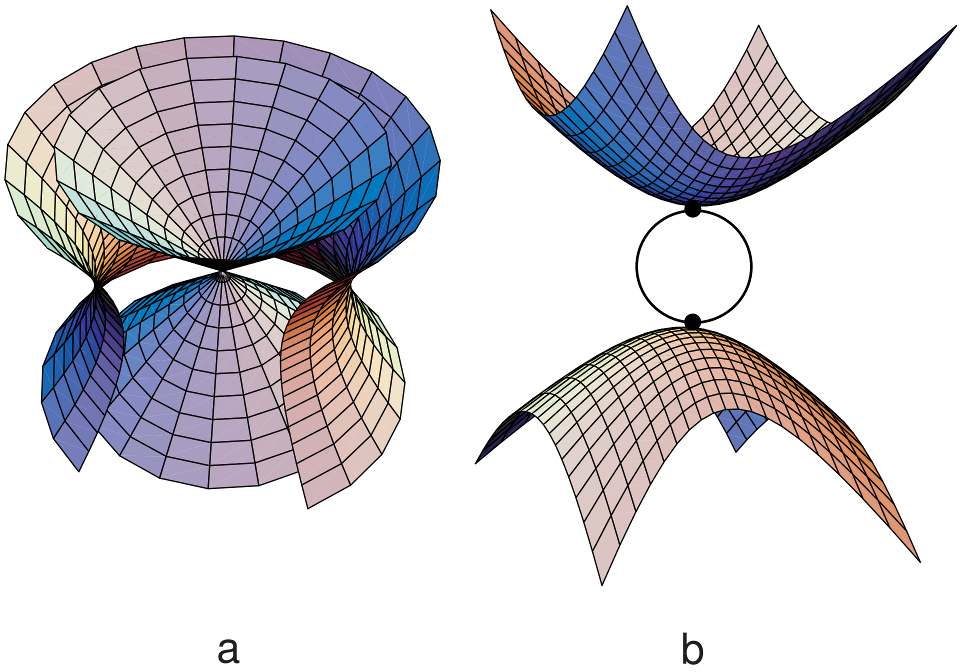

Figure 32.2.2: Equivalence classes (orbits/leaves) for the space $\mathcal{P}_2$ of second-order polynomials in two variables. They are displayed in terms of the variables ξ, η, ζ. In this figure the ξ axis points upward, the η axis points out of the page, and the ζ axis points to the right. Case a, for which $\delta < 0$, shows a typical one-sheeted hyperboloid. The point on the equator given by (2.53) and (2.54) corresponds to the normal form $(-\delta)^{1/2}(q^2 - p^2)$ for that value of δ. Also shown on this diagram are the two cones for $\delta = 0$. The point on the front of the top cone given by ((2.60) and (2.61) corresponds to the normal form $+q^2$ and the point on the rear of the bottom cone given (2.62) and (2.63) by corresponds to the normal form $-q^2$. The origin where the cones meet is the single-element equivalence class $g_2 = 0$. Case b, for which $\delta > 0$, shows a typical two-sheeted hyperboloid. Also shown is the sphere (2.50) that just kisses the hyperboloid. The two kissing points (the points on the upper and lower sheets that are closest to the origin) correspond to the normal forms $\pm\delta^{1/2}(p^2 + q^2)$. For simplicity, cases a and b are shown separately. They should actually be superimposed along with many other such hyperboloids to show all the one-sheeted and two-sheeted hyperboloids for all values of δ.

Observations

Note that generically each equivalence class is two dimensional. However, the origin is zero dimensional. There are four other observations to be drawn from the simple 2-dimensional phase-space example we have been studying.

First, we know that exponentiating Hamiltonian matrices produces symplectic matrices. Therefore the normal form problem for quadratic polynommials is related to the normal form problem for symplectic matrices. For example, exponentiating Hamiltonian matrices corresponding to the quadratic polynomials associated with points on a one-sheeted hyperboloid such as that shown in Figure 2.2a for $\delta < 0$ produces symplectic matrices whose spectrum corresponds to that shown in case 1 of Figure 3.4.1. Also, exponentiating Hamiltonian matrices corresponding to the quadratic polynomials associated with points on either sheet of the two-sheeted hyperboloid such as that shown in Figure 2.2b for $\delta > 0$ produces symplectic matrices whose spectrum corresponds to that shown in case 3 of Figure 3.4.1. In particular, exponentiating the Hamiltonian matrix corresponding to a normal form g_2^N for $\delta > 0$ produces symplectic matrices of the form (3.5.58). Finally, exponentiating Hamiltonian matrices corresponding to the quadratic polynomials associated with points on either cone as shown in Figure 2.2a for $\delta = 0$ produces symplectic matrices whose spectrum corresponds to that shown in case 4 of Figure 3.4.1. Because of the relation between quadratic polynomial and symplectic matrix normal forms, the normal form references cited at the end of Chapter 3 are also relevant to the polynomial case. However, as learned in Section 8.7.2, not every symplectic matrix can be written in single exponential form. Therefore, the classification of symplectic matrices is more complicated than the classification of quadratic polynomials (Hamiltonian matrices).

The second observation is that all quadratic polynomials associated with points on the upper-sheet of the two-sheeted hyperboloid for $\delta > 0$, see Figure 2.2b, are *positive definite.* That is, such polynomials obey $g_2(z) > 0$ for any nonzero z. From this perspective, (2.25) is the normal form for positive-definite quadratic polynomials. Correspondingly, all quadratic polynomials associated with points on the lower sheet of the two-sheeted hyperboloid are *negative definite.* They obey $g_2(z) < 0$ for any nonzero z. Their normal form is given by (2.35).

The third observation is that the normal form problem for quadratic polynomials is identical to that of classifying quadratic Hamiltonians: Given two quadratic Hamiltonians, is there a linear canonical transformation that will send one into the other? Given a quadratic Hamiltonian, how "simple" can it be made by applying a suitable linear canonical transformation? Given a quadratic Hamiltonian, what will be the nature of the motion it generates? For the case of a 2-dimensional phase space we have learned that all quadratic Hamiltonians with $\delta < 0$ can be brought to the form (2.31), and they generate *exponentially unbounded* motion. All nonzero Hamiltonians with $\delta = 0$ can be brought to one of the forms (2.26), (2.36), and they generate *linearly unbounded* motion. All Hamiltonians with $\delta > 0$ can be brought to one of the forms (2.25), (2.35), and they generate *bounded* motion. See Exercise 2.4.

The fourth observation is that we may view the g_2 as elements of the Lie algebra $sp(2)$. From this perspective, we have been studying what elements in the Lie algebra $sp(2)$ can be transformed into each other under the action of the group $Sp(2)$. In the case of a $2n$-dimensional phase space we may view the g_2 as elements of the Lie algebra $sp(2n)$, and studying the action of $Sp(2n)$ on the g_2 is equivalent to studying the action of $Sp(2n)$ on $sp(2n)$. See Exercise 2.6 for a preliminary effort in this direction, mostly devoted to $sp(4)$.

32.2.2.2 Case of Four-Dimensional Phase Space

Having mastered the case of 2-dimensional phase space, we consider the next more complicated case, namely 4-dimensional phase space. Now S takes the general form

$$S = \begin{pmatrix} a & b & c & d \\ b & e & r & s \\ c & r & t & u \\ d & s & u & v \end{pmatrix}. \tag{32.2.64}$$

Invariants

The Hamiltonian matrix $B = JS$ has the characteristic polynomial

$$P(\lambda) = \det(B - \lambda I) = \lambda^4 + C\lambda^2 + D \tag{32.2.65}$$

where

$$C = -b^2 + ae - 2dr + 2cs - u^2 + tv, \tag{32.2.66}$$

$$\begin{aligned} D &= d^2r^2 - 2cdrs + c^2s^2 - d^2et + 2bdst - as^2t \\ &+ 2cdeu - 2bdru - 2bcsu + 2arsu + b^2u^2 \\ &- aeu^2 - c^2ev + 2bcrv - ar^2v - b^2tv + aetv. \end{aligned} \tag{32.2.67}$$

Here we have used the form (3.2.10) for J. Note that $P(\lambda)$ has only even powers of λ as expected for the characteristic polynomial of a Hamiltonian matrix. See Exercise 3.7.14.

It is well known that the coefficients of the characteristic polynomial are invariant under similarity transformations; and, according to (2.14), it is similarity transformations that are being made. Therefore C and D are invariants.

Do they have any interpretation? From (2.65) we have the relation

$$D = \det(B) = \det(JS) = [\det(J)][\det(S)] = \det(S). \tag{32.2.68}$$

Here we have used (3.1.4). It follows that D (modulo sign conventions) is the *discriminant* of the quadratic form g_2. From this perspective the invariance of D follows directly from taking the determinant of both sides of (2.11) and using (3.1.8). Also see Exercise 2.5.

The interpretation of C is a bit more complicated. Since B is traceless (see Exercise 3.7.10), use of (3.7.136), and (3.7.137), and (3.7.143) gives the result

$$C = -(1/2)\ \text{tr}(B^2) = -(1/2)(B, B)_F. \tag{32.2.69}$$

Here we have also used (21.11.15) and employed the subscript F to denote the *fundamental* representation. Since C is constructed from the invariant metric, and the quadratic Casimir operator is also constructed from this metric, by mental association C (as a function of the coefficients in S) is sometimes called the *Casimir* polynomial. From this perspective, the invariance of C is a special case of (21.11.25).

We have seen that there are two invariants for the case of 4-dimensional phase space, namely C and D. Since the set of all symmetric 4×4 matrices S is 10 dimensional, it follows that the orbit space (each equivalence class) is generically 8 dimensional. However, at certain points it has smaller dimension. See Exercise 2.6. In various regions it may also be expected to be multi-sheeted.

Eigenvalues

The eigenvalues of B [the roots of $P(\lambda) = 0$] are of the form

$$\lambda = \pm\sqrt{w} \tag{32.2.70}$$

where w is a root of the equadratic equation

$$w^2 + Cw + D = 0. \tag{32.2.71}$$

That is, w is given by the relation

$$w = [-C \pm (C^2 - 4D)^{1/2}]/2. \tag{32.2.72}$$

Figure 2.3 below shows possible eigenvalue configurations for 4 × 4 real Hamiltonian matrices depending on the values of C and D. Evidently, there are nine cases to be considered:

i. Complex quartet of eigenvalues of the form $\pm\alpha \pm i\beta$.

ii. Two pairs of pure imaginary eigenvalues $\pm i\alpha$ and $\pm i\beta$.

iii. Two pairs of real eigenvalues $\pm\alpha$ and $\pm\beta$.

iv. One pair of real eigenvalues $\pm\alpha$ and one pair of pure imaginary eigenvalues $\pm i\beta$.

v. A pair of repeated real eigenvalues $\pm\alpha$.

vi. A pair of repeated pure imaginary eigenvalues $\pm i\beta$.

vii. A pair of real eigenvalues $\pm\alpha$ and repeated zero eigenvalues $0, 0$.

viii. A pair of imaginary eigenvalues $\pm i\alpha$ and repeated zero eigenvalues $0, 0$.

ix. A quartet of zero eigenvalues $0, 0, 0, 0$.

Cases i through iv are generic, and cases v through ix are degenerate. As usual, transitions between generic configurations can only occur by passage through a degenerate configuration. Note that the results we have found are in accord with those of Exercise 3.7.14. Finally, It is instructive to compare the pair of figures 27.2.1, 3.4.3, the pair of figures 27.2.3, 3.4.4, and the pair of figures 27.2.4, 3.5.1. The first figure in each pair displays the spectrum (eigenvalues) of elements in the Lie algebra $sp(2n, \mathbb{R})$, and the second displays the spectrum of elements in the associated Lie group $Sp(2n, \mathbb{R})$. See also Figures 3.4.1 and 3.4.2.

Normal Forms

For each of the cases i through ix there is a corresponding normal form. They are listed below. Note that cases i, v, vi, and ix are special in that the two degrees of freedom cannot be uncoupled by a suitable choice of coordinates. In all other cases the normal form (when viewed as a Hamiltonian) is a sum of two terms involving different degrees of freedom, and therefore the two terms are in involution. But here is an amazing thing: In each of the

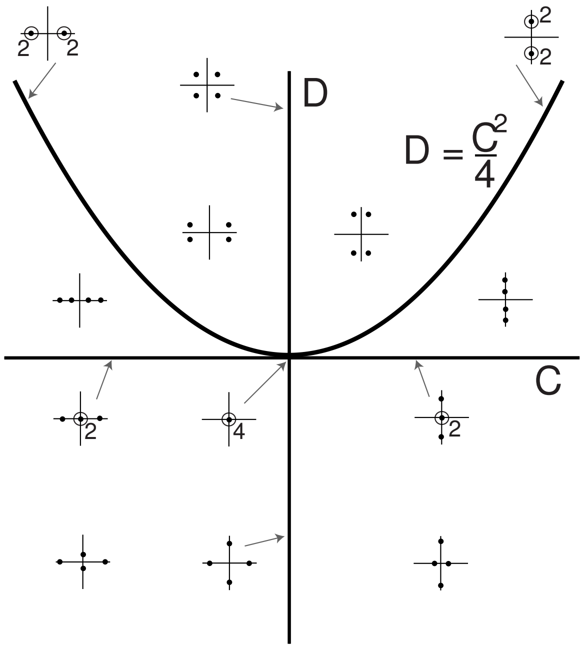

Figure 32.2.3: Eigenvalues of a 4×4 real Hamiltonian matrix as a function of the coefficients C and D in its characteristic polynomial.

coupled cases i, v, vi, and ix the normal form g_2^N is also the sum of two terms, and it can be verified in each case that the two terms are also in involution.

Case i:

$$\begin{aligned}&\lambda = \pm\alpha \pm i\beta, \text{ all signs taken independently, with } \alpha, \beta > 0,\\ &C = -2\alpha^2 + 2\beta^2,\\ &D = (\alpha^2 + \beta^2)^2,\\ &g_2^N = 2\alpha(q_1p_1 + q_2p_2) + 2\beta(q_1p_2 - q_2p_1).\end{aligned} \tag{32.2.73}$$

Case ii:

$$\begin{aligned}&\lambda = \pm i\alpha \text{ and } \pm i\beta, \text{ all signs taken independently, with } \alpha, \beta > 0,\\ &C = \alpha^2 + \beta^2,\\ &D = \alpha^2\beta^2,\\ &g_2^N = \pm\alpha(p_1^2 + q_1^2) \pm \beta(p_2^2 + q_2^2), \text{ all signs taken independently.}\end{aligned} \tag{32.2.74}$$

Case iii:

$$\begin{aligned}&\lambda = \pm\alpha \text{ and } \pm \beta, \text{ all signs taken independently, with } \alpha, \beta > 0,\\ &C = -\alpha^2 - \beta^2,\\ &D = \alpha^2\beta^2,\\ &g_2^N = 2\alpha q_1p_1 + 2\beta q_2p_2.\end{aligned} \tag{32.2.75}$$

Case *iv*:

$$\begin{aligned}&\lambda = \pm\alpha \text{ and } \pm i\beta, \text{ all signs taken independently, with } \alpha, \beta > 0,\\ &C = -\alpha^2 + \beta^2,\\ &D = -\alpha^2\beta^2,\\ &g_2^N = 2\alpha p_1 q_1 \pm \beta(p_2^2 + q_2^2).\end{aligned} \tag{32.2.76}$$

Case *v*:

$$\begin{aligned}&\lambda = \text{ repeated pair } \pm\alpha \text{ with } \alpha > 0,\\ &C = -2\alpha^2,\\ &D = \alpha^4,\\ &g_2^N = 2\alpha(q_1p_1 + q_2p_2) + 2q_1p_2 \text{ or case } iii \text{ with } \alpha = \beta.\end{aligned} \tag{32.2.77}$$

Case *vi*:

$$\begin{aligned}&\lambda = \text{ repeated pair } \pm i\beta \text{ with } \beta > 0,\\ &C = 2\beta^2,\\ &D = \beta^4,\\ &g_2^N = 2\beta(q_1p_2 - q_2p_1) \pm (q_1^2 + q_2^2) \text{ or case } ii \text{ with } \alpha = \beta.\end{aligned} \tag{32.2.78}$$

Case *vii*:

$$\begin{aligned}&\lambda = \pm\alpha \text{ and } 0, 0 \text{ with } \alpha > 0,\\ &C = -\alpha^2,\\ &D = 0,\\ &g_2^N = 2\alpha q_1p_1 \pm q_2^2 \text{ or case } iii \text{ with } \beta = 0.\end{aligned} \tag{32.2.79}$$

Case *viii*:

$$\begin{aligned}&\lambda = \pm i\alpha \text{ and } 0, 0 \text{ with } \alpha > 0,\\ &C = \alpha^2,\\ &D = 0,\\ &g_2^N = \pm\alpha(q_1^2 + p_1^2) \pm q_2^2 \text{ or case } ii \text{ with } \beta = 0.\end{aligned} \tag{32.2.80}$$

Case *ix*:

$$\begin{aligned}&\lambda = 0, 0, 0, 0,\\ &C = 0,\\ &D = 0,\end{aligned}$$

$$g_2^N = 2q_1p_2 \pm q_2^2, \text{ or} \tag{32.2.81}$$

$$g_2^N = 2q_1p_2, \text{ or} \tag{32.2.82}$$

$$g_2^N = \pm q_1^2 \pm q_2^2, \text{ all signs taken independently, or} \tag{32.2.83}$$

$$g_2^N = \pm q_1^2. \tag{32.2.84}$$

Observations

We are ready for four more observations. The first is that, up to ± signs and degeneracy complications that depend on the Jordan block structure of B, the normal form depends primarily on the eigenvalue spectrum. And, since the spectrum depends only on the invariants C and D, it follows that the normal form depends primarily on the values of C and D. Thus, as before, a necessary condition for $h_2 \sim g_2$ is that they have the same invariants.

The second observation is that, unlike the 2-dimensional case, we have not exhibited the transformation $\mathcal{R}$ that brings a g_2 to its normal form g_2^N. In general this must be done numerically, and enough is known about the problem to write computer programs for this purpose. Exercise 2.7 treats an interesting example where some of the required mathematical concepts are illustrated.

The third observation is that we have not exhibited the geometric nature of the various equivalence classes and their representative normal forms in analogy to Figure 2.2. To do so is difficult because, as already described earlier, we need to study 8-dimensional surfaces embedded in a 10-dimensional Euclidean space. See Exercise 2.6. Also, as indicted by the ± signs in cases *ii*, *iv*, and *vi* through *ix*, there is a multi-sheeted structure in parts of the space. However, in the generic situation when the eigenvalues are distinct (no degeneracy), there is one attribute of the normal forms that we can verify without too much effort. As Figure 2.2 illustrates, in the 2-dimensional generic case there is no point on a given orbit that is closer to the origin then the normal form. We may guess that the same is true in the $2n$-dimensional case. What we can easily check is that a g_2^N is at least a local minimum of $\langle g_2^{\rm tr}, g_2^{\rm tr}\rangle$.

Consider elements $g_2^{\rm tr}$ of the form

$$g_2^{\rm tr} = \mathcal{R} g_2^N \tag{32.2.85}$$

with $\mathcal{R}$ given by (1.1). These are just the elements of the equivalence class $\{g_2^N\}$. From (7.3.29) we know that transformations of the form $\exp(: f_2^c :)$ do not change the distance of an element from the origin. Therefore, we may restrict our attention to transformations of the form

$$\mathcal{R}_\epsilon = \exp(\epsilon : f_2^a :) \tag{32.2.86}$$

where, for convenience, we have explicitly included a scaling parameter ϵ. Let us define elements g_2^ϵ by the relation

$$g_2^\epsilon = \mathcal{R}_\epsilon g_2^N. \tag{32.2.87}$$

Then we find the results

$$\begin{aligned}\langle g_2^\epsilon, g_2^\epsilon\rangle &= \langle \mathcal{R}_\epsilon g_2^N, \mathcal{R}_\epsilon g_2^N\rangle = \langle g_2^N, \mathcal{R}_\epsilon^\dagger \mathcal{R}_\epsilon g_2^N\rangle = \langle g_2^N, \mathcal{R}_\epsilon^2 g_2^N\rangle = \langle g_2^N, \exp(2\epsilon : f_2^a :) g_2^N\rangle \\ &= \langle g_2^N, g_2^N\rangle + 2\epsilon\langle g_2^N, : f_2^a : g_2^N\rangle + (4\epsilon^2/2!)\langle g_2^N, : f_2^a :^2 g_2^N\rangle + O(\epsilon^3).\end{aligned} \tag{32.2.88}$$

Here we have used (7.3.30), which states that $: f_2^a :$ is Hermitian. Because $: f_2^a :$ is Hermitian, we may also write

$$\langle g_2^N, : f_2^a :^2 g_2^N\rangle = \langle : f_2^a : g_2^N, : f_2^a : g_2^N\rangle \geq 0. \tag{32.2.89}$$

It follows from (2.88) that g_2^N is at least a local minimum if we have the relation

$$\langle g_2^N, : f_2^a : g_2^N\rangle = 0. \tag{32.2.90}$$

It can be verified by explicit calculation that (2.90) holds for all the normal forms in the generic cases *i* through *iv*. Consider, for example, case *i*. Then, using (2.73) and the notation of Section 5.5.7, we may write

$$g_2^N = -2\alpha f^2 - 2\beta b^2, \tag{32.2.91}$$

$$f_2^a = \phi_1 f^1 + \phi_2 f^2 + \phi_3 f^3 + \gamma_1 g^1 + \gamma_2 g^2 + \gamma_3 g^3. \tag{32.2.92}$$

Here the ϕ_j and γ_j are arbitrary parameters. See (5.7.4) and (5.7.31). From the Poisson bracket rules (5.7.32) through (5.7.37) we find the result

$$\begin{aligned} : f_2^a : g_2^N &= [f_2^a, g_2^N] = -[g_2^N, f_2^a] \\ &= 4\beta\phi_1 f^3 - 4\beta\phi_3 f^1 + 4\beta\gamma_1 g^3 - 4\beta\gamma_3 g^1 \\ &- 4\alpha\phi_1 b^3 + 4\alpha\phi_3 b^1 + 4\alpha\gamma_2 b^0. \end{aligned} \tag{32.2.93}$$

Finally, all the terms on the right of (2.91) are orthogonal to all the terms on the right of (2.93). See Exercise 7.3.8. It follows that (2.90) is true, and therefore g_2^N is indeed at least a local minimum.

32.2.2.3 Case of General $2n$-Dimensional Phase Space

For the general case of $2n$ dimensional phase space normal-form results are also fully known, but considerably more complicated. However, based on our experience with the two and four dimensional cases, we are prepared for some statements about the general $2n$-dimensional case. The first is that nothing new, beyond what has already been seen for the 4-dimensional case, happens in the general case providing all the eigenvalues are distinct (as is generically true). When the eigenvalues are distinct (no degeneracy), the normal form g_2^N can always be taken to be a sum of terms of the form (2.73) through (2.76). Also, if zero occurs only as a doubly repeated eigenvalue, then the normal form g_2^N can be taken to be a sum of terms of the form (2.73) through (2.76) possibly augmented by a term of the form $\pm q_j^2$, as occurs for example in (2.79) and (2.80).

The second observation is that, as is already clear in the 4-dimensional case, repeated (degenerate) eigenvalues can cause complications. When the eigenvalues are degenerate there is the possibility of having the Hamiltonian analog of Jordan blocks. Fortunately, these complications are completely understood in the general case, and detailed results can be found in the literature. Moreover, it is important to note that there are two common cases where degeneracy causes no problems. In the first case, suppose we are working with a Hamiltonian that can be written in the form $h_2 = T_2(p) + V_2(q)$ where the kinetic energy term T_2 is known to be positive definite. Then standard normal mode theory shows that the Hamiltonian can always be diagonalized by a linear canonical transformation [$Sp(2n)$ element] even if some or all eigenvalue pairs are degenerate. Second, suppose that g_2 is known to be positive definite. Then g_2^N can always be taken to be a sum of harmonic oscillators, for example as in (2.74), with all signs positive even if some or all eigenvalue pairs are degenerate. This result will be proved and used in Chapter 33.

Exercises

32.2.1. Verify the equivalence relation (2.27). Find an $\mathcal{R}$ such that $\mathcal{R}q = p$ and $\mathcal{R}p = -q$.

32.2.2. Study cases *iii* and *iv* for 2-dimensional phase space and show that your results are identical to those obtained for cases *i* and *ii*. In particular, exhibit transforming matrices M analogous to (2.21) and (2.32). For example, show that for $\gamma > 0$ one may use the matrix

$$M = \begin{pmatrix} 1/\sqrt{\gamma} & -\alpha/\sqrt{\gamma} \\ 0 & \sqrt{\gamma} \end{pmatrix}. \tag{32.2.94}$$

32.2.3. Verify (2.50).

32.2.4. Solve Hamilton's equations of motion using the normal forms (2.25), (2.35), (2.26), (2.36), and (2.31) as Hamiltonians.

32.2.5. Equation (2.69) shows that the invariant C can be expressed in terms of the Lie element B and various manifestly invariant trace operations. What can be said about the discriminant invariants δ and D?

Use (3.7.115) to show that

$$\delta = \det(B) = -(1/2)\ \mathrm{tr}(B^2) = -(1/2)(B, B)_F \tag{32.2.95}$$

in the 2×2 case. (Recall that B is traceless.) Observe that *stability* is determined by the value of $(B, B)_F$. Show, by examining Figure 2.1, that stability occurs when $(B, B)_F < 0$.

Use (3.7.117) to show that

$$D = \det(B) = (1/8)[\mathrm{tr}(B^2)]^2 - (1/4)\ \mathrm{tr}(B^4) = (1/2)C^2 - (1/4)\ \mathrm{tr}(B^4) \tag{32.2.96}$$

in the 4×4 case. Show, by employing (2.69) and examining Figure 2.3, that, unlike the 2×2 case, knowledge of more that $(B, B)_F$ is required to determine stability.

In view of the ingredients of (2.95) and (2.96), δ and D could also be called Casimir polynomials.

32.2.6. This Exercise studies the dimensionality of the orbits $\{g_2^N\}$ for various normal forms g_2^N. Suppose g_2^N is some normal form. Then the orbit of g_2^N consists of all elements of the form

$$g_2^{\mathrm{tr}} = \mathcal{R} g_2^N. \tag{32.2.97}$$

Since $\mathcal{R}$ is a continuous and invertible mapping (a homeomorphism) of $\mathcal{P}_2$ into itself, the dimensionality of $\{g_2^N\}$ will be the same at every point on the orbit, and it suffices to determine the dimensionality in the vicinity of g_2^N. In this case we may take $\mathcal{R}$ to be near the identity, which means that it can be written in the form

$$\mathcal{R} = \exp(\epsilon : f_2 :) \tag{32.2.98}$$

for some small, but finite, ϵ. Correspondingly we may rewrite (2.94) in the form

$$g_2^{\mathrm{tr}} = \exp(\epsilon : f_2 :) g_2^N = g_2^N + \epsilon : f_2 : g_2^N + O(\epsilon^2). \tag{32.2.99}$$

Thus, infinitesimally, the dimensionality of $\{g_2^N\}$ is given by the number of linearly independent elements produced by terms of the form $:f_2:g_2^N$ for arbitrary choices of f_2. Note that there is the relation

$$:f_2:g_2^N=[f_2,g_2^N]=-[g_2^N,f_2]=-:g_2^N:f_2. \tag{32.2.100}$$

All terms of the form $(:g_2^N:f_2)$ for arbitrary f_2 comprise what is called the *range* (in $\mathcal{P}_2$) of the operator $:g_2^N:$. It is easy to check that the range of a linear operator is a linear vector space. (Check it!) Consequently, we may also say that the dimensionality of $\{g_2^N\}$ as a manifold is equal to the linear vector space dimensionality of the range of $:g_2^N:$.

Now carry out the calculations described below:

a) Suppose g_2^N is given by (2.73) as in case i. We are going to study the range of this $:g_2^N:$ in $\mathcal{P}_2$. Let λ^j be the eigenvalues for this case labeled by the scheme

$$\lambda^1=\alpha+i\beta, \tag{32.2.101}$$

$$\lambda^2=-\alpha+i\beta, \tag{32.2.102}$$

$$\lambda^3=-\alpha-i\beta, \tag{32.2.103}$$

$$\lambda^4=\alpha-i\beta. \tag{32.2.104}$$

Let g_1^j be the first-order polynomials defined by the relations

$$g_1^1=p_1-ip_2, \tag{32.2.105}$$

$$g_1^2=q_1-iq_2, \tag{32.2.106}$$

$$g_1^3=q_1+iq_2, \tag{32.2.107}$$

$$g_1^4=p_1+ip_2. \tag{32.2.108}$$

Evidently they are linearly independent. Verify the eigen relations

$$:g_2^N:g_1^j=2\lambda^j g_1^j. \tag{32.2.109}$$

Next let g_2^{jk} be the second-order polynomials defined by the relations

$$g_2^{jk}=g_1^j g_1^k. \tag{32.2.110}$$

Show that there are 10 such polynomials (since there is symmetry in the j,k indices), and that they are all linearly independent. They consequently form a basis for $\mathcal{P}_2$ [and, therefore, also for $sp(4)$] in the case of a four-dimensional phase space. Show that these polynomials satisfy the eigen relations

$$:g_2^N:g_2^{jk}=2(\lambda^j+\lambda^k)g_2^{jk}. \tag{32.2.111}$$

Thus, $:g_2^N:$ is diagonal in this basis. Verify that g_2^{13} and g_2^{24} are eigenvectors with eigenvalue zero, and verify that all the other eight eigenvectors have nonzero eigenvalues.

The g_2^{jk} form a complex basis for $\mathcal{P}_2$. Verify that a real basis is provided by the elements

$$g_2^1 = \operatorname{Re}(g_2^{11}) = \operatorname{Re}(g_2^{44}) = p_1^2 - p_2^2, \tag{32.2.112}$$

$$g_2^2 = \operatorname{Im}(g_2^{11}) = -\operatorname{Im}(g_2^{44}) = -2p_1p_2, \tag{32.2.113}$$

$$g_2^3 = \operatorname{Re}(g_2^{12}) = \operatorname{Re}(g_2^{34}) = q_1p_1 - q_2p_2, \tag{32.2.114}$$

$$g_2^4 = \operatorname{Im}(g_2^{12}) = -\operatorname{Im}(g_2^{34}) = -q_1p_2 - q_2p_1, \tag{32.2.115}$$

$$g_2^5 = \operatorname{Re}(g_2^{13}) = \operatorname{Re}(g_2^{24}) = q_1p_1 + q_2p_2, \tag{32.2.116}$$

$$g_2^6 = \operatorname{Im}(g_2^{13}) = -\operatorname{Im}(g_2^{24}) = q_2p_1 - q_1p_2, \tag{32.2.117}$$

$$g_2^7 = g_2^{14} = p_1^2 + p_2^2, \tag{32.2.118}$$

$$g_2^8 = \operatorname{Re}(g_2^{22}) = \operatorname{Re}(g_2^{33}) = q_1^2 - q_2^2, \tag{32.2.119}$$

$$g_2^9 = \operatorname{Im}(g_2^{22}) = -\operatorname{Im}(g_2^{33}) = -2q_1q_2, \tag{32.2.120}$$

$$g_2^{10} = g_2^{23} = q_1^2 + q_2^2. \tag{32.2.121}$$

Indeed, verify that these elements are mutually orthogonal for the inner product of Section 7.3.

Using this basis, write an arbitrary f_2 in the form

$$f_2 = \sum_{j=1}^{10} a_j g_2^j \tag{32.2.122}$$

where the a_j are arbitrary coefficients. Verify the relation

$$\begin{aligned} :g_2^N: f_2 &= 4(\alpha a_1 + \beta a_2)g_2^1 + 4(-\beta a_1 + \alpha a_2)g_2^2 + 4\beta a_4 g_2^3 - 4\beta a_3 g_2^4 \\ &+ 4\alpha a_7 g_2^7 + 4(-\alpha a_8 + \beta a_9)g_2^8 + 4(-\beta a_8 - \alpha a_9)g_2^9 \\ &- 4\alpha a_{10} g_2^{10}. \end{aligned} \tag{32.2.123}$$

Observe that all the g_2^j except g_2^5 and g_2^6 appear on the right side of (2.123). Therefore, the range of $:g_2^N:$ is potentially 8 dimensional. To be sure we must show that any linear combination of g_2^1, g_2^2, g_2^3, g_2^4, and g_2^7, g_2^8, g_2^9, g_2^{10} can be obtained on the right side of (2.123) for a suitable choice of the a_j in (2.122). Evidently there are no problems with g_2^3, g_2^4, g_2^7, and g_2^{10} since their coefficients are simply $4\beta a_4$, $-4\beta a_3$, $4\alpha a_7$, and $-4\alpha a_{10}$, respectively, and a_3, a_4, a_7, and a_{10} appear nowhere else on the right side of (2.123). For the coefficients of g_2^1 and g_2^2 we may write the matrix relation

$$\begin{pmatrix} \alpha & \beta \\ -\beta & \alpha \end{pmatrix} \begin{pmatrix} a_1 \\ a_2 \end{pmatrix} = \begin{pmatrix} \alpha a_1 + \beta a_2 \\ -\beta a_1 + \alpha a_2 \end{pmatrix}. \tag{32.2.124}$$

The determinant of the matrix appearing on the left side of (2.124) has the value $(\alpha^2 + \beta^2)$. Therefore the matrix is always invertible, and we can achieve any desired combination of g_2^1 and g_2^2 on the right side of (2.123). Show that a similar argument holds for the coefficients of g_2^8 and g_2^9. We conclude that the range of $:g_2^N:$ is indeed 8 dimensional. Correspondingly, $\{g_2^N\}$ is 8 dimensional.

For any g_2^N, consider the set of all polynomials h_2^0 such that

$$: g_2^N : h_2^0 = 0. \tag{32.2.125}$$

They comprise what is called the *null space* or *kernel* (in $\mathcal{P}_2$) of $: g_2^N :$. Show that these polynomials form a Lie subalgebra with the Poisson bracket as a Lie product. (Hint: use the Jacobi identity.) Show, for the g_2^N given by (2.73), that this Lie algebra is two dimensional and is spanned by the elements $(q_1p_1 + q_2p_2)$ and $(q_1p_2 - q_2p_1)$, which are the real and imaginary parts of g_2^{13} and g_2^{24}. [Hint: Write h_2^0 in the form (2.122) and use (2.123).] Verify that g_2^N is constructed from them and that they are in involution.

Let H be the corresponding subgroup of $Sp(4)$ generated by the $: h_2^0 :$ and consider the coset space $Sp(4)/H$. Show that in some finite neighborhood of the identity any element in $\mathcal{R}$ can be written in the factored form

$$\mathcal{R} = \exp(: h_2^R :) \exp(: h_2^0 :) \tag{32.2.126}$$

where h_2^R is in the range of $: g_2^N :$ and h_2^0 is in the null space of $: g_2^N :$. The factor $\exp(: h_2^0 :)$ corresponds to an element in H, and the factor $\exp(: h_2^R :)$ corresponds to some element in the coset $Sp(4)/H$. From the relation

$$: h_2^0 : g_2^N = [h_2^0, g_2^N] = -[g_2^N, h_2^0] = - : g_2^N : h_2^0 = 0 \tag{32.2.127}$$

show that

$$\exp(: h_2^0 :) g_2^N = g_2^N \tag{32.2.128}$$

and

$$g_2^{\rm tr} = \mathcal{R} g_2^N = \exp(: h_2^R :) g_2^N. \tag{32.2.129}$$

This construction goes beyond the infinitesimal, and shows that the orbit $\{g_2^N\}$ may be identified with the coset space $Sp(4)/H$. Evidently, an analogous result holds for any phase space dimension. In the terminology of Section 5.12, $\{g_2^N\}$ is a homogeneous space and H is the stability group for g_2^N.

b) Carry out similar calculations for the remaining generic cases *ii* through *iv*. You should find that $\{g_2^N\}$ is 8 dimensional in each case.

c) As an example of a degenerate case, consider the specific subcase of case *ix* for which g_2^N is given by the relation

$$g_2^N = q_1^2. \tag{32.2.130}$$

Following the notation of (2.64), let us write an arbitrary f_2 in the form

$$\begin{aligned} f_2 &= aq_1^2 + 2bq_1p_1 + 2cq_1q_2 + 2dq_1p_2 + ep_1^2 \\ &+ 2rp_1q_2 + 2sp_1p_2 + tq_2^2 + 2uq_2p_2 + vp_2^2. \end{aligned} \tag{32.2.131}$$

Show that

$$: g_2^N : f_2 = 4bq_1^2 + 4eq_1p_1 + 4rq_1q_2 + 4sq_1p_2. \tag{32.2.132}$$

Since all the monomials on the right of (2.132) are linearly independent, inspection indicates that the range of $: g_2^N :$ is 4 dimensional. Corresponding, $\{g_2^N\}$ is 4 dimensional. Since $\mathcal{P}_2$ is 10 dimensional, in this case there must be 4 more invariants in addition to C and D.

Show that the condition $: g_2^N : h_2 = 0$, with h_2 written in the form (2.131), requires that $b = e = r = s = 0$. Therefore, the null space of $: g_2^N :$ is 6 dimensional. Verify, as expected, that the null space is a Lie subalgebra.

Show that

$$: g_2^N :^2 z_a = 0, \tag{32.2.133}$$

which implies that

$$B^2 = 0. \tag{32.2.134}$$

We say that B is *nilpotent*. Correspondingly, $\{g_2^N\}$ in this case is called a nilpotent orbit. Show that if g_2^{tr} is any element lying on a nilpotent orbit, it must satisfy the relation

$$: g_2^{\text{tr}} :^2 z_a = 0, \tag{32.2.135}$$

and conversely.

Show that the other normal forms of case *ix* also produce nilpotent orbits, and find their dimensions.

Show that each of the ladder elements $\tilde{r}(\boldsymbol{\mu})$ given by (21.5.11) through (21.5.18) lies on a nilpotent orbit. Show that any linear combination of ladder elements of the form $[a_\alpha \tilde{r}(\boldsymbol{\alpha}) + a_\beta \tilde{r}(\boldsymbol{\beta}) + a_\gamma \tilde{r}(\boldsymbol{\gamma})]$ lies on a nilpotent orbit. Are there other linear combinations of ladder operators that lie on nilpotent orbits? Represent a general element g_2 in $sp(4)$ as a linear combination of the basis elements given by (21.5.9) through (21.5.18). What are the necessary and sufficient conditions on the expansion coefficients for g_2 to lie on a nilpotent orbit?

d) Determine the dimension of $\{g_2^N\}$ for some of the other normal forms in cases *v* through *viii*. For example, show for

$$g_2^N = 2\alpha q_1 p_1 \tag{32.2.136}$$

that $\{g_2^N\}$ is 6 dimensional, and that the null space of $: g_2^N :$ has dimension 4. Is this $\{g_2^N\}$ nilpotent?

32.2.7. Consider the motion of a nonrelativistic particle of rest mass m and charge q in a uniform magnetic field $\boldsymbol{B}$ with

$$\boldsymbol{B} = \tilde{B}\boldsymbol{e}_z. \tag{32.2.137}$$

Show that this field can be generated by the vector potential

$$\boldsymbol{A} = -(1/2)(\boldsymbol{r} \times \boldsymbol{B}) = (\tilde{B}/2)(x\boldsymbol{e}_y - y\boldsymbol{e}_x). \tag{32.2.138}$$

[This choice of vector potential for $\boldsymbol{B}$ is sometimes called the *symmetric* gauge. In view of the facts that $\nabla \cdot \boldsymbol{A} = 0$ and $\boldsymbol{r} \cdot \boldsymbol{A} = 0$, this choice can also be called the Poincaré-Coulomb gauge. See Section 15.2.4 and (16.1.14).] Show that motion in this field is governed by the Hamiltonian

$$\begin{aligned} H &= (p_x + q\tilde{B}y/2)^2/(2m) + (p_y - q\tilde{B}x/2)^2/(2m) + p_z^2/(2m) \\ &= (p_x^2 + p_y^2)/(2m) + [q^2\tilde{B}^2/(8m)](x^2 + y^2) - [q\tilde{B}/(2m)](xp_y - yp_x) + p_z^2/(2m) \\ &= (p_x^2 + p_y^2)/(2m) + [q^2\tilde{B}^2/(8m)](x^2 + y^2) - [q\tilde{B}/(2m)]L_z + p_z^2/(2m). \end{aligned} \tag{32.2.139}$$

Here $L_z = xp_y - yp_x$ is the z component of the canonical angular momentum. Verify that L_z is an integral of motion.

Evidently the motion in the z direction is uncoupled from the motion in the x, y plane, and we can devote our attention to the latter. Show that this motion is governed by the Hamiltonian

$$H_{xy} = (z, Sz) \tag{32.2.140}$$

where the symbol z now stands for the phase-space variables $z = (x, p_x, y, p_y)$ and S is the symmetric matrix

$$S = \begin{pmatrix} q^2\tilde{B}^2/(8m) & 0 & 0 & -q\tilde{B}/(4m) \\ 0 & 1/(2m) & q\tilde{B}/(4m) & 0 \\ 0 & q\tilde{B}/(4m) & q^2\tilde{B}^2/(8m) & 0 \\ -q\tilde{B}/(4m) & 0 & 0 & 1/(2m) \end{pmatrix}. \tag{32.2.141}$$

Show that the corresponding Hamiltonian matrix $B = JS$ is given by the relation

$$B = \begin{pmatrix} 0 & 1/(2m) & q\tilde{B}/(4m) & 0 \\ -q^2\tilde{B}^2/(8m) & 0 & 0 & q\tilde{B}/(4m) \\ -q\tilde{B}/(4m) & 0 & 0 & 1/(2m) \\ 0 & -q\tilde{B}/(4m) & -q^2\tilde{B}^2/(8m) & 0 \end{pmatrix}. \tag{32.2.142}$$

Show that for this B the invariants C and D have the values

$$C = [q\tilde{B}/(2m)]^2 \ , \ D = 0. \tag{32.2.143}$$

Show that these invariant values correspond to case *viii* or case *ii* with $\beta = 0$, and that the eigenvalues of B are

$$\lambda = \pm iq\tilde{B}/(2m) \ , \ 0 \ , \ 0. \tag{32.2.144}$$

We now want to find the transformation $\mathcal{R}$ that brings H_{xy} to its normal form.

Introduce the notation

$$\lambda_\pm = \pm iq\tilde{B}/(2m). \tag{32.2.145}$$

Show that the vectors $w_\pm$ given by

$$w_\pm = \begin{pmatrix} 1 \\ \pm iq\tilde{B}/2 \\ \pm i \\ -q\tilde{B}/2 \end{pmatrix} \tag{32.2.146}$$

satisfy the relations

$$w_{\mp} = \overline{w}_{\pm}, \tag{32.2.147}$$

and are eigenvectors of B with eigenvalues $\lambda_{\pm}$,

$$Bw_{\pm} = \lambda_{\pm} w_{\pm}. \tag{32.2.148}$$

Show that the vectors r and s given by

$$r = \begin{pmatrix} 0 \\ -q\tilde{B}/2 \\ 1 \\ 0 \end{pmatrix}, \tag{32.2.149}$$

$$s = \begin{pmatrix} 1 \\ 0 \\ 0 \\ q\tilde{B}/2 \end{pmatrix}, \tag{32.2.150}$$

are eigenvectors of B with eigenvalue 0,

$$Br = 0\ ,\ Bs = 0. \tag{32.2.151}$$

Define scaled vectors $\hat{u}$, $\hat{v}$, $\hat{r}$, $\hat{s}$ by the relation

$$\hat{u} = (q\tilde{B})^{-1/2}\ \text{Re}(w_+) = \begin{pmatrix} (q\tilde{B})^{-1/2} \\ 0 \\ 0 \\ -(q\tilde{B})^{1/2}/2 \end{pmatrix}, \tag{32.2.152}$$

$$\hat{v} = (q\tilde{B})^{-1/2}\ \text{Im}(w_+) = \begin{pmatrix} 0 \\ (q\tilde{B})^{1/2}/2 \\ (q\tilde{B})^{-1/2} \\ 0 \end{pmatrix}, \tag{32.2.153}$$

$$\hat{r} = (q\tilde{B})^{-1/2} r = \begin{pmatrix} 0 \\ -(q\tilde{B})^{1/2}/2 \\ (q\tilde{B})^{-1/2} \\ 0 \end{pmatrix}, \tag{32.2.154}$$

$$\hat{s} = (q\tilde{B})^{-1/2} s = \begin{pmatrix} (q\tilde{B})^{-1/2} \\ 0 \\ 0 \\ (q\tilde{B})^{1/2}/2 \end{pmatrix}. \tag{32.2.155}$$

Show that these vectors obey the “symplectic” orthonormality conditions

$$(\hat{u}, J\hat{v}) = 1, \tag{32.2.156}$$

$$(\hat{r}, J\hat{s}) = 1, \tag{32.2.157}$$

$$(\hat{u}, J\hat{r}) = (\hat{v}, J\hat{r}) = (\hat{u}, J\hat{s}) = (\hat{v}, J\hat{s}) = 0. \tag{32.2.158}$$

See Sections 3.5 and 4.6 for similar constructions.

Let R be the matrix defined by the relation

$$R = (\hat{u}, \hat{v}, \hat{r}, \hat{s}) = \begin{pmatrix} (q\tilde{B})^{-1/2} & 0 & 0 & (q\tilde{B})^{-1/2} \\ 0 & (q\tilde{B})^{1/2}/2 & -(q\tilde{B})^{1/2}/2 & 0 \\ 0 & (q\tilde{B})^{-1/2} & (q\tilde{B})^{-1/2} & 0 \\ -(q\tilde{B})^{1/2}/2 & 0 & 0 & (q\tilde{B})^{1/2}/2 \end{pmatrix}. \tag{32.2.159}$$

Here each vector $\hat{u}$, $\hat{v}$, $\hat{r}$, $\hat{s}$ is to be viewed as a column vector so that the collection (2.159) forms a real 4×4 matrix. Show that R, as a consequence of (2.156) through (2.158), is a symplectic matrix. Verify the relations

$$B(\hat{u} \pm i\hat{v}) = \pm i[q\tilde{B}/(2m)](\hat{u} \pm i\hat{v}), \tag{32.2.160}$$

$$B\hat{u} = -[q\tilde{B}/(2m)]\hat{v}, \tag{32.2.161}$$

$$B\hat{v} = [q\tilde{B}/(2m)]\hat{u}. \tag{32.2.162}$$

Show that

$$\begin{aligned} BR &= (B\hat{u}, B\hat{v}, B\hat{r}, B\hat{s}) = (-[q\tilde{B}/(2m)]\hat{v}, [q\tilde{B}/(2m)]\hat{u}, 0, 0) \\ &= \begin{pmatrix} 0 & (q\tilde{B})^{1/2}/(2m) & 0 & 0 \\ -(q\tilde{B})^{3/2}/(4m) & 0 & 0 & 0 \\ -(q\tilde{B})^{1/2}/(2m) & 0 & 0 & 0 \\ 0 & -(q\tilde{B})^{3/2}/(4m) & 0 & 0 \end{pmatrix} \\ &= R \begin{pmatrix} 0 & q\tilde{B}/(2m) & 0 & 0 \\ -q\tilde{B}/(2m) & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \\ &= RJ \begin{pmatrix} q\tilde{B}/(2m) & 0 & 0 & 0 \\ 0 & q\tilde{B}/(2m) & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \end{aligned} \tag{32.2.163}$$

Show that

$$B^{\text{tr}} = R^{-1}BR = \begin{pmatrix} 0 & q\tilde{B}/(2m) & 0 & 0 \\ -q\tilde{B}/(2m) & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \tag{32.2.164}$$

and

$$S^{\text{tr}} = J^{-1}B^{\text{tr}} = R^T SR = \begin{pmatrix} q\tilde{B}/(2m) & 0 & 0 & 0 \\ 0 & q\tilde{B}/(2m) & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{32.2.165}$$

It follows that H_{xy} belongs to case *ii* with $\beta = 0$, and has the normal form

$$H_{xy}^N = (\omega/2)(p_1^2 + q_1^2) \tag{32.2.166}$$

where ω is the *cyclotron* frequency,

$$\omega = (q\tilde{B}/m). \tag{32.2.167}$$

Note that H_{xy}^N does not depend on q_2, p_2 at all!

Let q_1^i, p_1^i, q_2^i, p_2^i be *initial* conditions at $t = 0$. For these initial conditions show that the Hamiltonian H_{yt}^N generates the trajectory

$$q_1(t) = q_1^i \cos(\omega t) + p_1^i \sin(\omega t), \tag{32.2.168}$$

$$p_1(t) = -q_1^i \sin(\omega t) + p_1^i \cos(\omega t), \tag{32.2.169}$$

$$q_2(t) = q_2^i, \tag{32.2.170}$$

$$p_2(t) = p_2^i. \tag{32.2.171}$$

Show that the old and new variables are related by the equation

$$\begin{pmatrix} x \\ p_x \\ y \\ p_y \end{pmatrix} = R \begin{pmatrix} q_1 \\ p_1 \\ q_2 \\ p_2 \end{pmatrix}, \tag{32.2.172}$$

and therefore the trajectory in the original phase-space variables is given by the equations

$$\begin{aligned} x(t) &= (q\tilde{B})^{-1/2}[q_1(t) + p_2(t)] \\ &= (q\tilde{B})^{-1/2}[q_1^i \cos(\omega t) + p_1^i \sin(\omega t) + p_2^i], \end{aligned} \tag{32.2.173}$$

$$\begin{aligned} p_x(t) &= [(q\tilde{B})^{1/2}/2][p_1(t) - q_2(t)] \\ &= [(q\tilde{B})^{1/2}/2][-q_1^i \sin(\omega t) + p_1^i \cos(\omega t) - q_2^i], \end{aligned} \tag{32.2.174}$$

$$\begin{aligned} y(t) &= (q\tilde{B})^{-1/2}[p_1(t) + q_2(t)] \\ &= (q\tilde{B})^{-1/2}[-q_1^i \sin(\omega t) + p_1^i \cos(\omega t) + q_2^i], \end{aligned} \tag{32.2.175}$$

$$\begin{aligned} p_y(t) &= [(q\tilde{B})^{1/2}/2][-q_1(t) + p_2(t)] \\ &= [(q\tilde{B})^{1/2}/2][-q_1^i \cos(\omega t) - p_1^i \sin(\omega t) + p_2^i]. \end{aligned} \tag{32.2.176}$$

Show that the orbit in the x, y plane is a circle with a radius ρ given by the relation

$$\rho^2 = [(q_1^i)^2 + (p_1^i)^2]/(q\tilde{B}), \tag{32.2.177}$$

and that the *center* of the circle has coordinates x_c, y_c given by the relations

$$x_c = (q\tilde{B})^{-1/2} p_2^i, \tag{32.2.178}$$

$$y_c = (q\tilde{B})^{-1/2} q_2^i. \tag{32.2.179}$$

Note the curious fact that x_c and y_c do *not* "commute". Evaluate the Poisson bracket $[x_c, y_c]$.

What modifications are required if the particle is relativistic?

32.2.8. Verify that (2.90) holds for all the generic normal forms.

32.2.9. This is an exercise on Krein collisions. Our aim is to study a simple example for which Krein collisions are avoided (as expected) when phase advances have the same sign, and can be seen to occur when phase advances have opposite signs. Consider the Hamiltonian

$$H = (\omega_1/2)(p_1^2 + q_1^2) + (\omega_2/2)(p_2^2 + q_2^2) + \epsilon q_1 q_2 \tag{32.2.180}$$

and the associated map $\mathcal{R}$ given by

$$\mathcal{R} = \exp(- : H :). \tag{32.2.181}$$

Since $\mathcal{R}$ is a linear map, its action on phase space is described by a matrix R. Following the discussion surrounding (10.4.24), show that this Hamiltonian can be written in the form

$$H = (1/2)(z, Sz) \tag{32.2.182}$$

where the symbol z now stands for the phase-space variables $z = (q_1, p_1, q_2, p_2)$ and S is the symmetric matrix

$$S = \begin{pmatrix} \omega_1 & 0 & \epsilon & 0 \\ 0 & \omega_1 & 0 & 0 \\ \epsilon & 0 & \omega_2 & 0 \\ 0 & 0 & 0 & \omega_2 \end{pmatrix}. \tag{32.2.183}$$

Show that the corresponding Hamiltonian matrix $B = JS$ is given by the relation

$$B = \begin{pmatrix} 0 & \omega_1 & 0 & 0 \\ -\omega_1 & 0 & -\epsilon & 0 \\ 0 & 0 & 0 & \omega_2 \\ -\epsilon & 0 & -\omega_2 & 0 \end{pmatrix}. \tag{32.2.184}$$

According to (10.4.8) there is the relation

$$R = \exp(B). \tag{32.2.185}$$

Show that, when $\epsilon = 0$, R is the matrix

$$R = \begin{pmatrix} \cos(\omega_1) & \sin(\omega_1) & 0 & 0 \\ -\sin(\omega_1) & \cos(\omega_1) & 0 & 0 \\ 0 & 0 & \cos(\omega_2) & \sin(\omega_2) \\ 0 & 0 & -\sin(\omega_2) & \cos(\omega_2) \end{pmatrix}. \tag{32.2.186}$$

Therefore, when there is no perturbation, the eigenvalues of R are $\exp(\pm i\omega_1)$ and $\exp(\pm i\omega_2)$, and the phase advances of R are ω_1 and ω_2. See Example 5.1 in Section 3.5.

What concerns us are the eigenvalues of B. Once we know them, we will also know the eigenvalues of R. In particular, if the eigenvalues of B are pure imaginary, then the eigenvalues of R will lie on the unit circle. Moreover if, under perturbation, the eigenvalues of B leave the imaginary axis to become a complex quartet, then the eigenvalues of R will leave the unit circle to form a Krein quartet as in Figure 3.5.1.

Show that for this B the invariants C and D have the values

$$C = (\omega_1^2 + \omega_2^2), \tag{32.2.187}$$

$$D = \omega_1\omega_2(\omega_1\omega_2 - \epsilon^2). \tag{32.2.188}$$

Evidently, for finite values of ω_1, ω_2 and ϵ sufficiently small, both C and D are positive. Thus, our attention should be turned to the upper right quadrant of Figure 2.3; and we are concerned with cases i and ii and the transition between them.

With (2.72) and Figure 2.3 in mind, show that

$$C^2 - 4D = (\omega_1^2 - \omega_2^2)^2 + 4\epsilon^2\omega_1\omega_2. \tag{32.2.189}$$

Show that, when $\epsilon = 0$, the eigenvalues of B are given by

$$\lambda = \pm i\omega_1,\ \pm i\omega_2. \tag{32.2.190}$$

Evidently they are pure imaginary, and they are distinct unless $\omega_1 = \omega_2$ or $\omega_1 = -\omega_2$. Suppose that ω_1 and ω_2 have the same sign. Show that in this case

$$C^2 - 4D \geq 0 \tag{32.2.191}$$

no matter what the value of ϵ. Prove, consequently, that if ω_1, ω_2 are finite and of the same sign, then the eigenvalues remain pure imaginary for sufficiently small ϵ.[1] Indeed, suppose that

$$\omega_1 = \omega_2 = \Omega. \tag{32.2.192}$$

Show that in this case that

$$\lambda = \pm i\Omega[1 \pm \epsilon/\Omega]^{1/2} \tag{32.2.193}$$

where all ± signs are to be taken independently. Thus, in this case, the eigenvalues remain pure imaginary under perturbation ($\epsilon \neq 0$ but sufficiently small) if ω_1, ω_2 are finite and of the same sign. Correspondingly, there is no Krein collision of the eigenvalues of R. Suppose, instead, that

$$\omega_1 = -\omega_2 = \Omega. \tag{32.2.194}$$

Show that in this case that

$$\lambda = \pm i\Omega[1 \pm i\epsilon/\Omega]^{1/2} \tag{32.2.195}$$

where all ± signs are to be taken independently. Now, under perturbation, the eigenvalues leave the imaginary axis to become a complex quartet. Correspondingly, the eigenvalues of R leave the unit circle to become a Krein quartet.

Suppose that ω_1 and ω_2 are opposite in sign, but not exactly equal in magnitude. What happens then under perturbation? Show that the eigenvalues of B leave the imaginary axis to become a complex quartet when

$$\epsilon \geq (1/2)|\omega_1^2 - \omega_2^2|/(|\omega_1\omega_2|)^{1/2} \tag{32.2.196}$$

[1] For sufficiently large ϵ they can be driven to the situation depicted in the lower right quadrant of Figure 2.3.

or

$$\epsilon \leq -(1/2)|\omega_1^2 - \omega_2^2|/(|\omega_1\omega_2|)^{1/2}. \tag{32.2.197}$$

We conclude from this example that, as might be expected, Krein collisions are imminent when phase advances are of opposite sign and nearly equal (even if not exactly equal) in magnitude.

Consider the case, corresponding to tunes of approximately ±1/4, for which

$$\omega_1 = 1.5,\ \omega_2 = -1.6. \tag{32.2.198}$$

Figure 2.4 displays the eigenvalues λ of B as a function of ϵ for this case. When $\epsilon = 0$, the eigenvalues have values of $\pm 1.5i$, $\pm\, 1.6i$ with all signs taken independently. As ϵ is increased, they merge in pairs and then leave the imaginary axis. Verify analytically that they merge and then leave the imaginary axis when $\epsilon \approx \pm .10$. See Figure 2.4 and the upper-right quadrant of Figure 2.3.

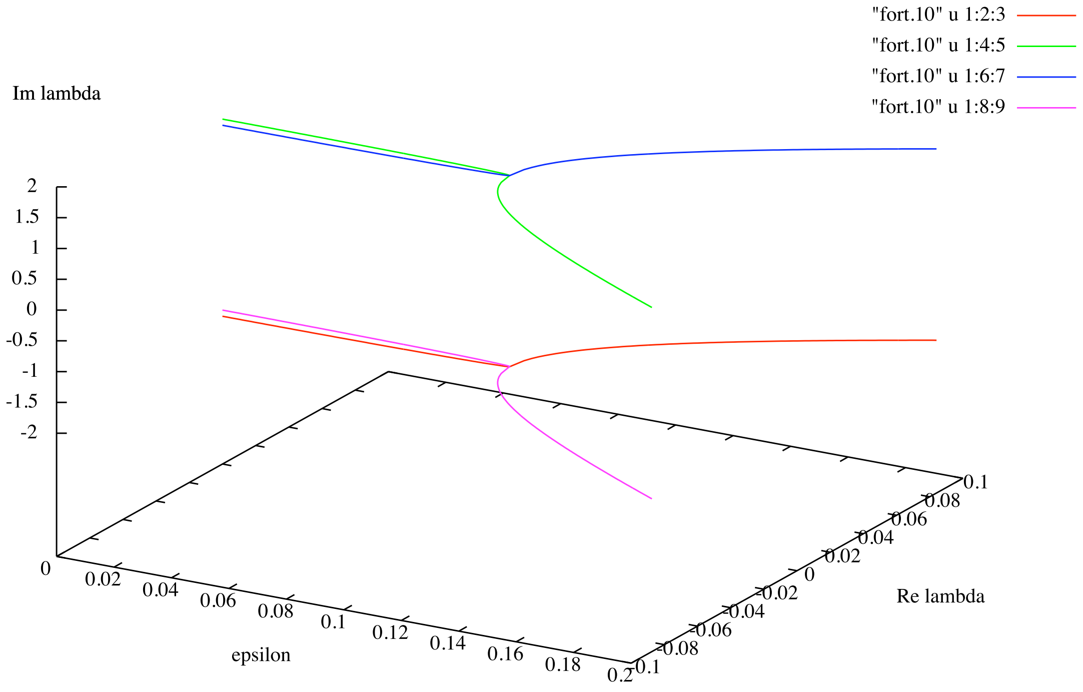

Figure 32.2.4: Eigenvalues of B as a function of ϵ when $\omega_1 = 1.5$ and $\omega_2 = -1.6$.

32.2.10. Consider quadratic polynomials in the phase-space variables for the case of a 4-dimensional phase space. For each of the normal-form cases i through ix, find the Hamiltonian matrix B associated with the specified g_2^N, verify that the invariants C and D have the indicated values, and that the eigenvalues λ have the indicated values.

32.2.11. Consider quadratic polynomials in the phase-space variables for the case of a 4-dimensional phase space. In each of the coupled cases i, v, vi, and ix the normal form g_2^N is the sum of two terms. Verify, in each case, that the two terms are in involution.

32.2.12. Consider quadratic polynomials in the phase-space variables for the case of a 4-dimensional phase space. For each of the cases i through ix, consider the motion generated by g_2^N. Do this by studying the behavior of $z'(t)$ defined by

$$z'_a(t) = \exp(-t : g_2^N :)z_a. \tag{32.2.199}$$

Show that the motion is unbounded (the origin is an unstable equilibrium point) for large $|t|$ in all cases except ii.

32.2.13. Review Exercise 2.12 above. A matrix with distinct eigenvalues can always be diagonalized by a similarity transformation. When the eigenvalues are not distinct, there are matrices for which the best that can be done by a similarity transformation is to bring them to Jordan normal form. In the 2×2 case the eigenvalues for the symplectic matrix

$$M = \begin{pmatrix} 1 & \ell \\ 0 & 1 \end{pmatrix} \tag{32.2.200}$$

are not distinct (they are both $+1$), and moreover M cannot be brought to diagonal form when $\ell \neq 0$.

When an eigenvalue collision occurs on the unit circle in the 4×4 symplectic case as in Figure 3.5.1, the eigenvalues are not distinct. Are there real 4×4 symplectic matrices for which the eigenvalues are complex, lie on the unit circle but are not distinct, and which cannot be diagonalized? What happens at the moment of collision for the two cases of $\omega_1 \simeq \omega_2$ and $\omega_1 \simeq -\omega_2$ in Exercise 2.9 above? Is R diagonalizable?

32.3 Mostly Unsolved Polynomial Orbit Problems

In this section we will describe briefly the case of orbits in $\mathcal{P}_m$ with $m > 2$. Now the situation is far more complicated because we do not have the matrix trick simplification that led to (2.14), and only limited results are available. Some results are known for 2-dimensional phase space. Much less is known for higher-dimensional phase spaces. Even the 2-dimensional case is very difficult for large m.

For the case of 4 and higher dimensional phase space no normal forms seem to be known even for g_3. However, some few invariants are known for any $\mathcal{P}_m$ and any phase-space dimension. They are sufficiently complicated that it requires several pages to write out any one of them explicitly. It is also known that in principle there are many such invariants, and an empirical estimation of their number is available. Finally, for any $\mathcal{P}_m$ and any phase-space dimension, it is known that all invariants can be computed in terms of the monomial coefficients and (when viewed as a tensor) the entries of J.

The previous section described equivalence classes and normal forms, under the action of $Sp(2n, \mathbb{R})$, for the cases of $\mathcal{P}_1$ and $\mathcal{P}_2$. The next few paragraphs provide a sample of some known results for $\mathcal{P}_3$ and $\mathcal{P}_4$.

32.3.1 Cubic Polynomials

For the case of $\mathcal{P}_3$ and 2-dimensional phase space we may write the most general g_3 in the form

$$g_3 = a_0 q^3 + 3a_1 q^2 p + 3a_2 q p^2 + a_3 p^3 \tag{32.3.1}$$

where the a_j are arbitrary coefficients. Note, as in often convenient, we have multiplied the coefficients of q^3, q^2p, qp^2, p^3 by the factors 1, 3, 3, 1. These factors are the binomial coefficients in the expansion of $(q+p)^3$. [We remark that homogeneous polynomials in two variables are called *binary forms* in the Mathematics literature. Thus, (3.1) is called a *cubic* binary form.] It can be shown in this case that there is the invariant D, called the *discriminant* of the cubic form, given by the relation

$$D = a_0^2 a_3^2 - 6a_0 a_1 a_2 a_3 + 4a_0 a_2^3 + 4a_1^3 a_3 - 3a_1^2 a_2^2. \tag{32.3.2}$$

(The *discriminant* of a binary form g_m is an invariant with the special property that its vanishing indicates that the equation $g_m = 0$ has at least one repeated root.) Associated with g_3 is a quadratic form H, called the *Hessian* of g_3, defined by the equation

$$\begin{aligned} H &= (1/36)\det(\partial^2 g_3/\partial z_i \partial z_j) \\ &= (a_0 a_2 - a_1^2)q^2 + (a_0 a_3 - a_1 a_2)qp + (a_1 a_3 - a_2^2)p^2. \end{aligned} \tag{32.3.3}$$

Here we have used our customary notation $z = (q, p)$.

With this background in mind, it can be shown for the case $D > 0$ that g_3 has the normal form

$$g_3^N = D^{1/4}(q^3 + p^3) \text{ for } D > 0. \tag{32.3.4}$$

And, if $D < 0$, g_3 has the normal form

$$g_3^N = (-D/4)^{1/4}(q^3 - 3qp^2) \text{ for } D < 0. \tag{32.3.5}$$

If the discriminant vanishes but the coefficients of the Hessian are not all zero, g_3 has the normal form

$$g_3^N = qp^2 \text{ for } D = 0 \text{ and } H \neq 0. \tag{32.3.6}$$

Finally, if both the discriminant and all coefficients in the Hessian vanish, g_3 has the normal form

$$g_3^N = q^3 \text{ for } D = 0 \text{ and } H = 0. \tag{32.3.7}$$

Evidently cases (3.4) and (3.5) are generic while cases (3.6) and (3.7) are increasingly specific. It is interesting to note that the generic normal forms (3.4) and (3.5) minimize $\langle g_3^{\text{tr}}, g_3^{\text{tr}} \rangle$. See Exercise 3.1. Note also that, under the canonical transformation $q \to p$ and $p \to -q$, (3.5) takes monkey-saddle form. See Exercise 22.5.4.

32.3.2 Quartic Polynomials

For the case of $\mathcal{P}_4$ and 2-dimensional phase space we may write the most general g_4 in the form

$$g_4 = a_0 q^4 + 4a_1 q^3 p + 6a_2 q^2 p^2 + 4a_3 q p^3 + a_4 p^4. \tag{32.3.8}$$

It can be shown that in this case there are two functionally independent invariants S and T,

$$S = a_0a_4 - 4a_1a_3 + 3a_2^2, \tag{32.3.9}$$

$$T = a_0a_2a_4 + 2a_1a_2a_3 - a_0a_3^2 - a_1^2a_4 - a_2^3. \tag{32.3.10}$$

For even degree forms there is always an invariant (with some algebraic/geometrical significance that need not concern us here) given the wonderful name *catalecticant.* In this case T is the catalecticant of g_4. The discriminant D of g_4 is functionally dependent on S and T and is given by the relation

$$D = S^3 - 27T^2. \tag{32.3.11}$$

In the case that D is positive g_4 has the normal form

$$g_4^N = \pm a(q^4 + p^4) + 6bq^2p^2 \text{ for } D > 0 \tag{32.3.12}$$

with

$$a > 0, \tag{32.3.13}$$

$$S = a^2 + 3b^2, \tag{32.3.14}$$

$$T = a^2b - b^3, \tag{32.3.15}$$

$$D = a^2(a^2 - 9b^2)^2. \tag{32.3.16}$$

In the case that D is negative g_4 has the normal form

$$g_4^N = a(q^4 - p^4) + 6bq^2p^2 \text{ for } D < 0 \tag{32.3.17}$$

with

$$a > 0, \tag{32.3.18}$$

$$S = -a^2 + 3b^2, \tag{32.3.19}$$

$$T = -a^2b - b^3, \tag{32.3.20}$$

$$D = -a^2(a^2 - 9b^2)^2. \tag{32.3.21}$$

These are the generic cases. Like g_3, there are also several specific cases for which $D = 0$, and each such case has its own normal form. We will not record them here, but results are available in the literature.

Exercises

32.3.1. Exercise on minimization.

32.4 Application to Analytic Properties

Let $\mathcal{N}$ be the two-dimensional nonlinear map defined by the relation

$$\mathcal{N} = \exp(:g_3:) \tag{32.4.1}$$

with g_3 given by (3.1). It has the action

$$Z(z) = \exp(:g_3:)z. \tag{32.4.2}$$

As usual, we write $z = (q;p)$ and $Z = (Q;P)$. What we wish to determine in this section are the analytic properties $\mathcal{N}$. That is, we wish to study the analytic properties of the quantities $Q(q,p)$ and $P(q,p)$ as functions of the variables q and p. We will see that the answer to this question depends on the normal form of g_3.

Let $\mathcal{R}$ be a linear symplectic map, and consider transformed maps of the form

$$\mathcal{N}^{\text{tr}} = \mathcal{R}\mathcal{N}\mathcal{R}^{-1} = \mathcal{R}\exp(:g_3:)\mathcal{R}^{-1} = \exp(:\mathcal{R}g_3:) = \exp(:g_3^{\text{tr}}:). \tag{32.4.3}$$

We see that a study of the analytic properties of $\mathcal{N}$ is equivalent to studying the analytic properties of $\exp(:g_3^{\text{tr}}:)$ where g_3^{tr} is any of the normal form polynomials given by (3.4) through (3.7).

Consider these cases one at a time and in order of increasing complexity. The simplest case is (3.7), for which we find that

$$\bar{q} = \exp(:q^3:)q = q, \tag{32.4.4}$$

$$\bar{p} = \exp(:q^3:)p = p + 3q^2. \tag{32.4.5}$$

Evidently $\mathcal{N}^{\text{tr}}$ in this case has no singularities save at infinity, and therefore is entire. Correspondingly, all maps in its equivalence class are also entire.

The next simplest case is (3.6), for which we find that

$$\bar{q} = \exp(:qp^2:)q = q(1-p)^2, \tag{32.4.6}$$

$$\bar{p} = \exp(:qp^2:)p = p/(1-p). \tag{32.4.7}$$

Here we have used results from Section 1.4.2. In this case $\mathcal{N}^{\text{tr}}$ has a pole on the surface $p = 1$. Correspondingly, maps in its equivalence class also have pole singularities.

The case (3.4) is next in order of increasing difficulty. Now we have

$$g_3^{\text{tr}} = \lambda(q^3 + p^3) \text{ with } \lambda = D^{1/4} \tag{32.4.8}$$

so that

$$\mathcal{N}^{\text{tr}} = \exp(\lambda :q^3 + p^3:). \tag{32.4.9}$$

Define a parameter dependent map $\mathcal{N}^{\text{tr}}(t)$ by the relation

$$\mathcal{N}^{\text{tr}}(t) = \exp(t:g_3^{\text{tr}}:) = \exp(t\lambda :q^3 + p^3:) \tag{32.4.10}$$

and write

$$\bar{q}(t) = \mathcal{N}^{\text{tr}}(t)q = \exp(t\lambda :q^3 + p^3:)q, \tag{32.4.11}$$

$$\bar{p}(t) = \mathcal{N}^{\rm tr}(t)p = \exp(t\lambda : q^3 + p^3 :)p. \tag{32.4.12}$$

We will show that there is a curve in the real q, p plane such that $\bar{q}(1) = -\infty$ and $\bar{p}(1) = +\infty$. Therefore $\mathcal{N}^{\rm tr} = \mathcal{N}^{\rm tr}(1)$ is singular on this curve.

Differentiate (4.11) and (4.12) with respect to t to obtain the equations of motion

$$\dot{\bar{q}} = \exp(t\lambda : q^3 + p^3 :)\lambda : q^3 + p^3 : q = \exp(t\lambda : q^3 + p^3 :)(-3\lambda p^2) = -3\lambda\bar{p}^2, \tag{32.4.13}$$

$$\dot{\bar{p}} = \exp(t\lambda : q^3 + p^3 :)\lambda : q^3 + p^3 : p = \exp(t\lambda : q^3 + p^3 :)(3\lambda q^2) = 3\lambda\bar{q}^2. \tag{32.4.14}$$

They have the integral

$$-\lambda(\bar{q}^3 + \bar{p}^3) = \Lambda. \tag{32.4.15}$$

Figure 4.1 shows the curves of constant Λ/λ. Also shown as arrows are the directions of the flow that follow from the equations of motion (4.13) and (4.14). Evidently $\bar{q} = \bar{p} = 0$ is the only equilibrium point, and it lies on the curve $\Lambda = 0$. Moreover, all points on the flow line $\bar{p} = -\bar{q}$ and having $\bar{q} > 0$ flow to the origin. All other points flow asymptotically to the point at infinity $\bar{q} = -\infty$, $\bar{p} = +\infty$.

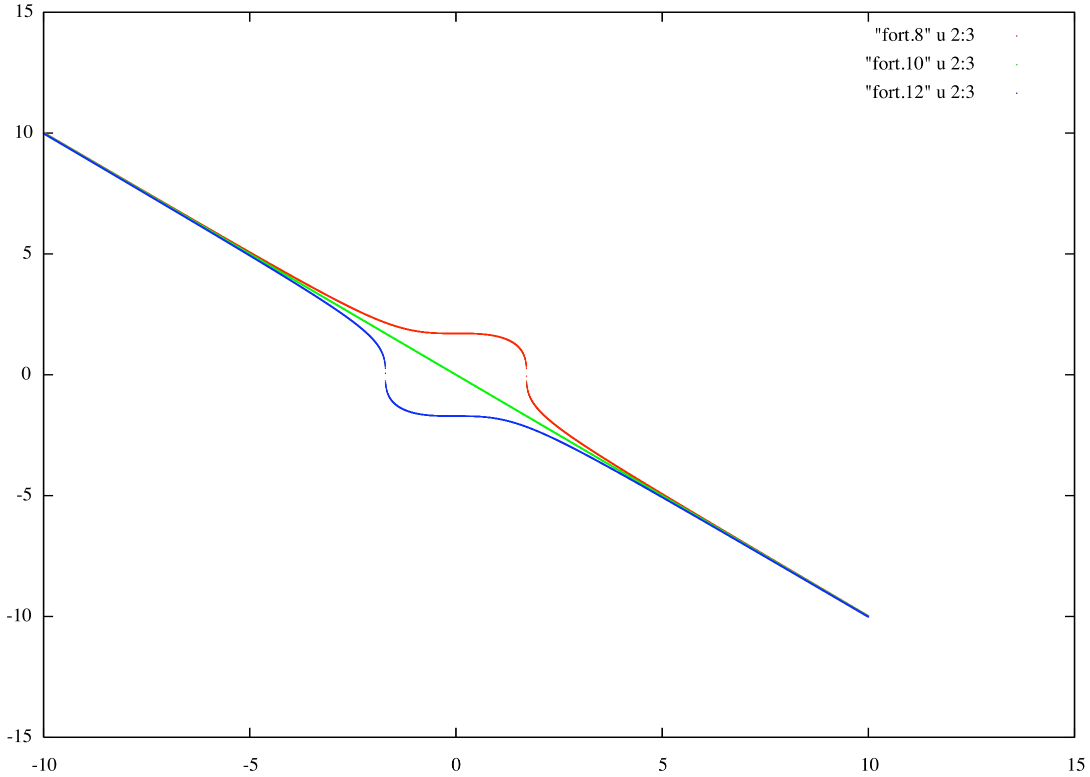

Figure 32.4.1: Curves of constant Λ/λ and flow directions for the equations of motion (4.13) and (4.14). These curves were made with $\lambda = 1$, which simply sets the scale for q and p, and $\Lambda = 0, \pm 5$.

Let us compute the *speed* at which points move along flow lines. The Euclidean distance in the $\bar{q}, \bar{p}$ plane is given by the relation

$$(ds)^2 = (d\bar{q})^2 + (d\bar{p})^2 \tag{32.4.16}$$

and therefore

$$(ds/dt)^2 = (\dot{\bar{q}})^2 + (\dot{\bar{p}})^2 = 9\lambda^2(\bar{q}^4 + \bar{p}^4). \tag{32.4.17}$$

Here we have used the equations of motion (4.13) and (4.14). We see that the speed is always positive save for the equilibrium point at the origin.

Evidently the right sides of the differential equations (4.13) and (4.14) are analytic save at infinity. Therefore, according to Section 1.3, the final conditions will be analytic functions of the initial conditions as long as the intermediate points on the flow are finite. What we wish to compute are the points for which, when regarded as initial conditions at $t = 0$, the flow reaches $\bar{q} = -\infty$, $\bar{p} = +\infty$ when $t = 1$. These points will be the frontier at which $\mathcal{N}^{\rm tr}(1)$ becomes singular.

Consider first the case $\Lambda = 0$ for which

$$\bar{p}(t) = -\bar{q}(t). \tag{32.4.18}$$

As stated earlier, points on the line $\bar{p} = -\bar{q}$ with $\bar{q} > 0$ flow along the line and into the origin; and points on the line with $\bar{q} < 0$ flow along the line to $\bar{q} = -\infty$ and $\bar{p} = +\infty$. What we will show is that on the line there is an initial condition $\bar{q}(0)$, $\bar{p}(0)$ with $\bar{q}(0) < 0$ such that

$$\bar{q}(1) = -\infty \tag{32.4.19}$$

and

$$\bar{p}(1) = +\infty \tag{32.4.20}$$

To do so, employ (4.18) in (4.13) to find the relation

$$\dot{\bar{q}} = -3\lambda\bar{q}^2 \tag{32.4.21}$$

from which it follows that

$$dt = -d\bar{q}/(3\lambda\bar{q}^2). \tag{32.4.22}$$

Integrate both sides of (4.22) to find the result

$$\int_{t^i}^{t^f} dt = -\int_{\bar{q}^i}^{\bar{q}^f} d\bar{q}/(3\lambda\bar{q}^2), \tag{32.4.23}$$

from which it follows that

$$t^f - t^i = [1/(3\lambda)](1/\bar{q})|_{\bar{q}^i}^{\bar{q}^f} = [1/(3\lambda)](1/\bar{q}^f - 1/\bar{q}^i). \tag{32.4.24}$$

Now set

$$t^i = 0,\ t^f = 1,\ \bar{q}^f = -\infty \tag{32.4.25}$$

to obtain the result

$$1 = [1/(3\lambda)](-1/\bar{q}^i) \tag{32.4.26}$$

from which it follows that

$$\bar{q}(0) = \bar{q}^i = -1/(3\lambda) \tag{32.4.27}$$

and

$$\bar{p}(0) = -\bar{q}(0) = 1/(3\lambda). \tag{32.4.28}$$

Next consider the case $\Lambda > 0$. We will again find that there is an initial condition on the curve (4.15) such that (4.19) and (4.20) hold. In this case (4.15) can be solved for $\bar{p}$ to give the result

$$\bar{p} = (-\Lambda/\lambda - \bar{q}^3)^{1/3}. \tag{32.4.29}$$

Here the negative cube root is to be extracted if the quantity $(-\Lambda/\lambda - \bar{q}^3)$ is negative, and the positive square root is to be extracted if the quantity is positive. Thus,

$$\bar{p} = -(\Lambda/\lambda + \bar{q}^3)^{1/3} < 0 \text{ when } \bar{q} > -(\Lambda/\lambda)^{1/3}, \tag{32.4.30}$$

$$\bar{p} = 0 \text{ when } \bar{q} = -(\Lambda/\lambda)^{1/3}, \tag{32.4.31}$$

$$\bar{p} = (-\Lambda/\lambda - \bar{q}^3)^{1/3} > 0 \text{ when } \bar{q} < -(\Lambda/\lambda)^{1/3}. \tag{32.4.32}$$

Observe that $\bar{p}^2$ is always ≥ 0 and is given by the relation

$$\bar{p}^2 = [(\Lambda/\lambda + \bar{q}^3)^2]^{1/3}. \tag{32.4.33}$$

Now the differential equation (4.13) takes the form

$$\dot{\bar{q}} = -3\lambda[(\Lambda/\lambda + \bar{q}^3)^2]^{1/3}, \tag{32.4.34}$$

from which we conclude

$$dt = -[1/(3\lambda)]d\bar{q}/[(\Lambda/\lambda + \bar{q}^3)^2]^{1/3}. \tag{32.4.35}$$

And integrating both sides of (4.35) yields the result

$$\int_{t^i}^{t^f} dt = -\int_{\bar{q}^i}^{\bar{q}^f} [1/(3\lambda)]d\bar{q}/[(\Lambda/\lambda + \bar{q}^3)^2]^{1/3} \tag{32.4.36}$$

from which it follows that

$$1 = -\int_{\bar{q}^i}^{-\infty} [1/(3\lambda)]d\bar{q}/[(\Lambda/\lambda + \bar{q}^3)^2]^{1/3} = \int_{-\infty}^{\bar{q}^i} [1/(3\lambda)]d\bar{q}/[(\Lambda/\lambda + \bar{q}^3)^2]^{1/3}. \tag{32.4.37}$$

Here we have again used (4.25).

What about the case $\Lambda < 0$? Here (4.29) and (4.33) continue to hold. Now we must use

$$\bar{p} = -(\Lambda/\lambda + \bar{q}^3)^{1/3} < 0 \text{ when } \bar{q} > (-\Lambda/\lambda)^{1/3}, \tag{32.4.38}$$

$$\bar{p} = 0 \text{ when } \bar{q} = (-\Lambda/\lambda)^{1/3}, \tag{32.4.39}$$

$$\bar{p} = (-\Lambda/\lambda - \bar{q}^3)^{1/3} > 0 \text{ when } \bar{q} < (-\Lambda/\lambda)^{1/3}. \tag{32.4.40}$$

With this understanding, (4.37) also continues to hold.

Taken together, (4.27) and (4.37) yield $\bar{q}^i$ as a function of Λ. And, when $\bar{q}^i$ is known and Λ is specified, (4.30) through (4.32) and (4.38) through (4.41) give $\bar{p}^i$. This curve, shown in Figure 4.2 superimposed on an enlarged portion of Figure 4.1, provides (in the real $\bar{q}, \bar{p}$ plane) the set of points at which $\mathcal{N}^{\text{tr}}(1)$ becomes singular. The map is well defined and analytic in the initial conditions for initial conditions to the right of this curve. Its status for points to left of this curve is not yet established. To do so would require, among other things some compactification procedure analogous to the Riemann sphere but in four dimensions. At this stage we do not know whether the map has only a pole or poles as was the case for (4.7), or has more complicated singularities, such as branch points that preclude single-valued analytic continuation, or singularities that preclude any analytic continuation at all. Finally we note that this one-dimensional curve is the real intersection of a two-dimensional manifold in the full four-dimensional domain of two complex variables. This manifold is specified by letting Λ be complex in (4.37) and in the relations for $\bar{p}^i$ in terms of $\bar{q}^i$ and Λ.

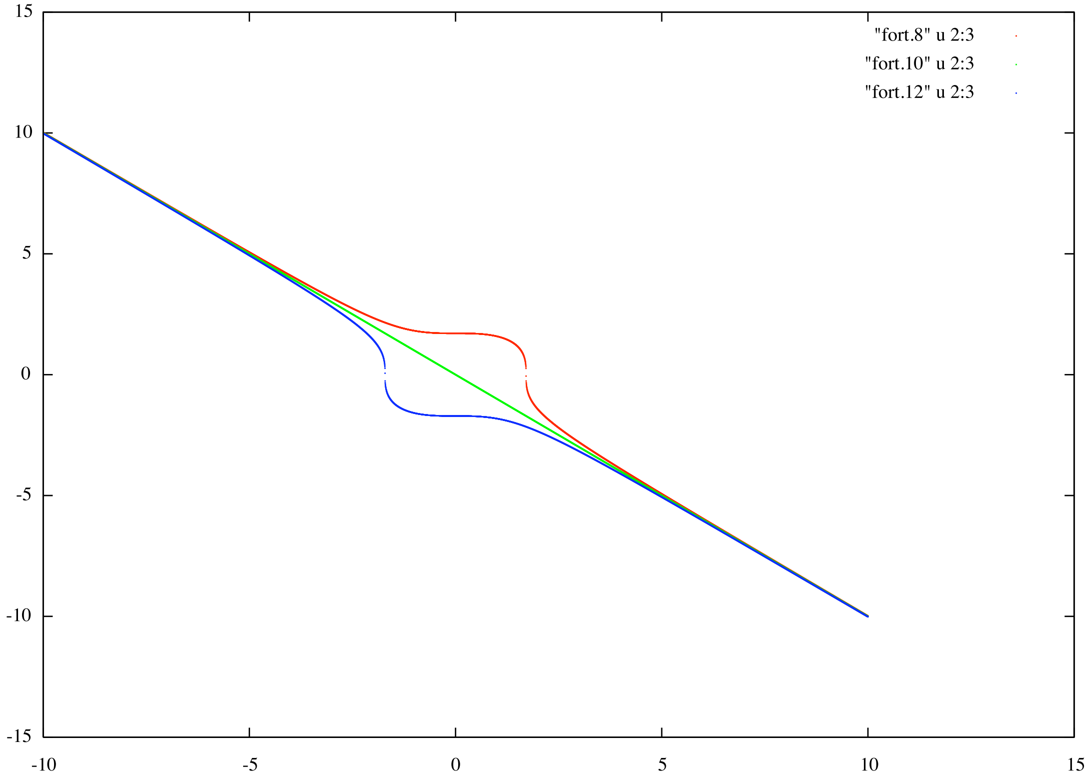

Figure 32.4.2: (Place Holder) Curve on which the map $\mathcal{N}^{\rm tr}(1)$ becomes singular. The map is well defined and analytic for phase-space points to the right of this curve. Points on the curve are sent to infinity. The possible action of the map on points to the left of the curve is unknown.

The last and most difficult case is (3.5). Now we have

$$g_3^{\rm tr} = \lambda(q^3 - 3qp^2) \text{ with } \lambda = (-D)^{1/4} \tag{32.4.41}$$

so that

$$\mathcal{N}^{\rm tr} = \exp(\lambda : q^3 - 3qp^2 :). \tag{32.4.42}$$

Again define a parameter dependent map $\mathcal{N}^{\rm tr}(t)$, now by the relation

$$\mathcal{N}^{\rm tr}(t) = \exp(t : g_3^{\rm tr} :) = \exp(t\lambda : q^3 - 3qp^2 :) \tag{32.4.43}$$

and write

$$\bar{q}(t) = \mathcal{N}^{\rm tr}(t)q = \exp(t\lambda : q^3 - 3qp^2 :)q, \tag{32.4.44}$$

$$\bar{p}(t) = \mathcal{N}^{\rm tr}(t)p = \exp(t\lambda : q^3 - 3qp^2 :)p. \tag{32.4.45}$$

We will again show that there is a curve in the real q, p plane on which $\mathcal{N}^{\rm tr} = \mathcal{N}^{\rm tr}(1)$ is singular.

Differentiate (4.44) and (4.45) with respect to t to obtain the equations of motion

$$\dot{\bar{q}} = \exp(t\lambda : q^3 - 3qp^2 :)\lambda : q^3 - 3qp^2 : q = \exp(t\lambda : q^3 - 3p^2 :)(3\lambda qp) = 3\lambda\bar{q}\bar{p}, \tag{32.4.46}$$

$$\dot{\bar{p}} = \exp(t\lambda : q^3 - 3qp^2 :)\lambda : q^3 - 3qp^2 : p = \exp(t\lambda : q^3 - 3qp^2 :)3\lambda(q^2 - p^2) = 3\lambda(\bar{q}^2 - \bar{p}^2). \tag{32.4.47}$$

They have the integral

$$-\lambda(\bar{q}^3 - 3\bar{q}\bar{p}^2) = \Lambda. \tag{32.4.48}$$

Observe that if we set $\Lambda = 0$ we find the three lines

$$\bar{q} = 0, \tag{32.4.49}$$

$$\bar{q} = (\sqrt{3})\bar{p}, \tag{32.4.50}$$

$$\bar{q} = -(\sqrt{3})\bar{p}. \tag{32.4.51}$$

Figure 4.3 shows these lines and the remaining curves of constant Λ/λ. Also shown as arrows are the directions of the flow that follow from the equations of motion (4.46) and (4.47). For the speed along these flow lines we find the result

$$(ds/dt)^2 = (\dot{\bar{q}})^2 + (\dot{\bar{p}})^2 = 9\lambda^2[(\bar{q}^2 - \bar{p}^2)^2 + (\bar{q}\bar{p})^2]. \tag{32.4.52}$$

Evidently $\bar{q} = \bar{p} = 0$ is the only equilibrium point, and it lies on the intersection of the lines (4.49) through (4.51). Moreover, we can conclude the following:

- All points on the flow line (4.49)with $p > 0$ flow into the origin. All points on that line with $p < 0$ flow to the point at infinity $(\bar{q}, \bar{p}) = (0, -\infty)$.
- All points on the flow line (4.50)with $p < 0$ flow into the origin. All points on that line with $p > 0$ flow to the point at infinity $(\bar{q}, \bar{p}) = (\infty\sqrt{3}, \infty)$.
- All points on the flow line (4.51)with $p < 0$ flow into the origin. All points on that line with $p > 0$ flow to the point at infinity $(\bar{q}, \bar{p}) = (-\infty\sqrt{3}, \infty)$.
- All other points on all other flow lines eventually flow into one of the three points at infinity listed above.

The text below requires further work

Evidently the right sides of the differential equations (3.13) and (3.14) are analytic save at infinity. Therefore, according to Section 1.3, the final conditions will be analytic functions of the initial conditions as long as the intermediate points on the flow are finite. What we wish to compute are the points for which, when regarded as initial conditions at $t = 0$, the

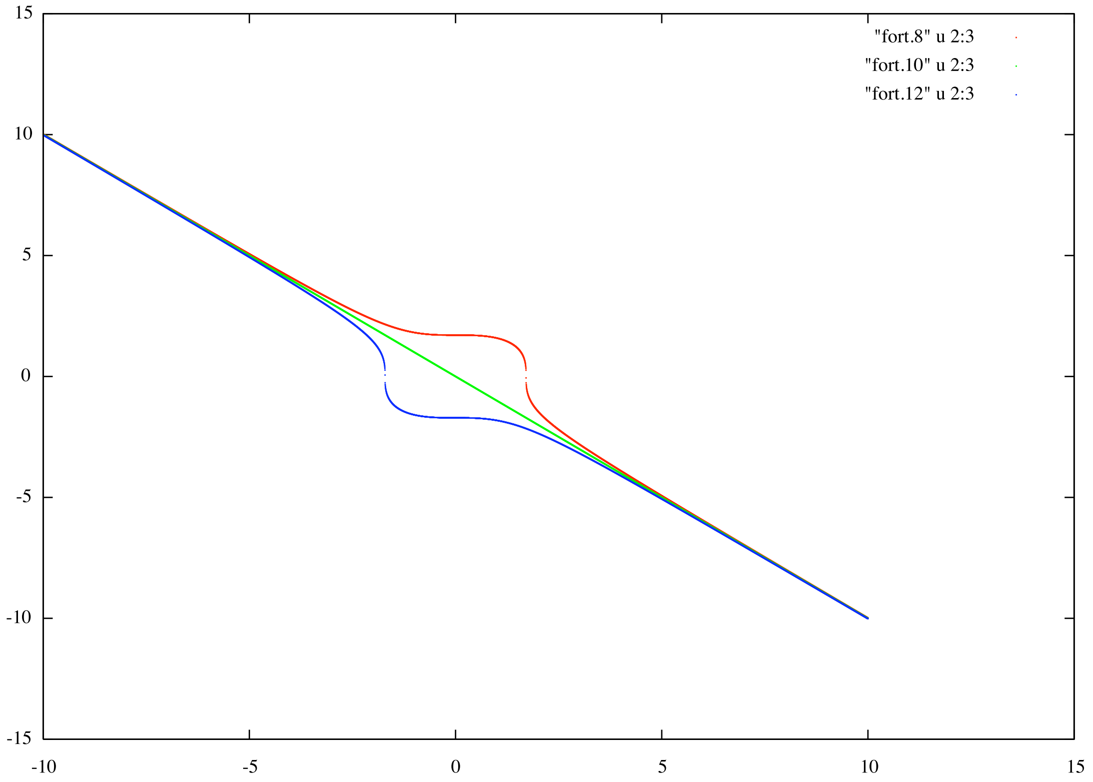

Figure 32.4.3: (Place Holder) Curves of constant Λ/λ and flow directions for the equations of motion (4.44) and (4.45). These curves were made with $\lambda = 1$, which simply sets the scale for q and p, and $\Lambda = 0, \pm 5$.

flow reaches $\bar{q} = -\infty$, $\bar{p} = +\infty$ when $t = 1$. These points will be the frontier at which $\mathcal{N}^{\text{tr}}(1)$ becomes singular.

Consider first the case $\Lambda = 0$ for which

$$\bar{p}(t) = -\bar{q}(t). \tag{32.4.53}$$

As stated earlier, points on the line $\bar{p} = -\bar{q}$ with $\bar{q} > 0$ flow along the line and into the origin; and points on the line with $\bar{q} < 0$ flow along the line to $\bar{q} = -\infty$ and $\bar{p} = +\infty$. What we will show is that on the line there is an initial condition $\bar{q}(0)$, $\bar{p}(0)$ with $\bar{q}(0) < 0$ such that

$$\bar{q}(1) = -\infty \tag{32.4.54}$$

and

$$\bar{p}(1) = +\infty \tag{32.4.55}$$

To do so, employ (3.18) in (3.13) to find the relation

$$\dot{\bar{q}} = -3\lambda\bar{q}^2 \tag{32.4.56}$$

from which it follows that

$$dt = -d\bar{q}/(3\lambda\bar{q}^2). \tag{32.4.57}$$

Integrate both sides of (3.22) to find the result

$$\int_{t^i}^{t^f} dt = -\int_{\bar{q}^i}^{\bar{q}^f} d\bar{q}/(3\lambda\bar{q}^2). \tag{32.4.58}$$

from which it follows that

$$t^f - t^i = [1/(3\lambda)](1/\bar{q})|_{\bar{q}^i}^{\bar{q}^f} = [1/(3\lambda)](1/\bar{q}^f - 1/\bar{q}^i). \tag{32.4.59}$$

Now set

$$t^i = 0,\ t^f = 1,\ \bar{q}^f = -\infty \tag{32.4.60}$$

to obtain the result

$$1 = [1/(3\lambda)](-1/\bar{q}^i) \tag{32.4.61}$$

from which it follows that

$$\bar{q}(0) = \bar{q}^i = -1/(3\lambda) \tag{32.4.62}$$

and

$$\bar{p}(0) = -\bar{q}(0) = 1/(3\lambda). \tag{32.4.63}$$

Next consider the case $\Lambda > 0$. We will again find that there is an initial condition on the curve (3.15) such that (3.19) and (3.20) hold. In this case (3.15) can be solved for $\bar{p}$ to give the result

$$\bar{p} = (-\Lambda/\lambda - \bar{q}^3)^{1/3}. \tag{32.4.64}$$

Here the negative cube root is to be extracted if the quantity $(-\Lambda/\lambda - \bar{q}^3)$ is negative, and the positive square root is to be extracted if the quantity is positive. Thus,

$$\bar{p} = -(\Lambda/\lambda + \bar{q}^3)^{1/3} < 0 \text{ when } \bar{q} > -(\Lambda/\lambda)^{1/3}, \tag{32.4.65}$$

$$\bar{p} = 0 \text{ when } \bar{q} = -(\Lambda/\lambda)^{1/3}, \tag{32.4.66}$$

$$\bar{p} = (-\Lambda/\lambda - \bar{q}^3)^{1/3} > 0 \text{ when } \bar{q} < -(\Lambda/\lambda)^{1/3}. \tag{32.4.67}$$

Observe that $\bar{p}^2$ is always ≥ 0 and is given by the relation

$$\bar{p}^2 = [(\Lambda/\lambda + \bar{q}^3)^2]^{1/3}. \tag{32.4.68}$$

Now the differential equation (3.13) takes the form

$$\dot{\bar{q}} = -3\lambda[(\Lambda/\lambda + \bar{q}^3)^2]^{1/3}, \tag{32.4.69}$$

from which we conclude

$$dt = -[1/(3\lambda)]d\bar{q}/[(\Lambda/\lambda + \bar{q}^3)^2]^{1/3}. \tag{32.4.70}$$

And integrating both sides of (3.35) yields the result

$$\int_{t^i}^{t^f} dt = -\int_{\bar{q}^i}^{\bar{q}^f} [1/(3\lambda)]d\bar{q}/[(\Lambda/\lambda + \bar{q}^3)^2]^{1/3} \tag{32.4.71}$$

from which it follows that

$$1 = -\int_{\bar{q}^i}^{-\infty} [1/(3\lambda)]d\bar{q}/[(\Lambda/\lambda + \bar{q}^3)^2]^{1/3} = \int_{-\infty}^{\bar{q}^i} [1/(3\lambda)]d\bar{q}/[(\Lambda/\lambda + \bar{q}^3)^2]^{1/3} \tag{32.4.72}$$

Here we have again used (3.25).

What about the case $\Lambda < 0$? Here (3.29) and (3.33) continue to hold. Now we must use

$$\bar{p} = -(\Lambda/\lambda + \bar{q}^3)^{1/3} < 0 \text{ when } \bar{q} > (-\Lambda/\lambda)^{1/3}, \tag{32.4.73}$$

$$\bar{p} = 0 \text{ when } \bar{q} = (-\Lambda/\lambda)^{1/3}, \tag{32.4.74}$$

$$\bar{p} = (-\Lambda/\lambda - \bar{q}^3)^{1/3} > 0 \text{ when } \bar{q} < (-\Lambda/\lambda)^{1/3}. \tag{32.4.75}$$

With this understanding, (3.37) also continues to hold.

Taken together, (3.27) and (3.37) yield $\bar{q}^i$ as a function of Λ. And, when $\bar{q}^i$ is known and Λ is specified, (3.30) through (3.32) and (3.38) through (3.41) give $\bar{p}^i$. This curve, shown in Figure 3.2 superimposed on an enlarged portion of Figure 3.1, provides (in the real $\bar{q}, \bar{q}$ plane) the set of points at which $\mathcal{N}^{\text{tr}}(1)$ becomes singular. The map is well defined and analytic in the initial conditions for initial conditions to the right of this curve. Its status for points to left of this curve is not yet established. To do so would require, among other things some compactification procedure analogous to the Riemann sphere but in four dimensions. At this stage we do not know whether the map has only a pole or poles as was the case for (3.7), or has more complicated singularities, such as branch points that preclude single-valued analytic continuation, or singularities that preclude any analytic continuation at all. Finally we note that this one-dimensional curve is the real intersection of a two-dimensional manifold in the full four-dimensional domain of two complex variables. This manifold is specified by letting Λ be complex in (3.37) and in the relations for $\bar{p}^i$ in terms of $\bar{q}^i$ and Λ.

Exercises

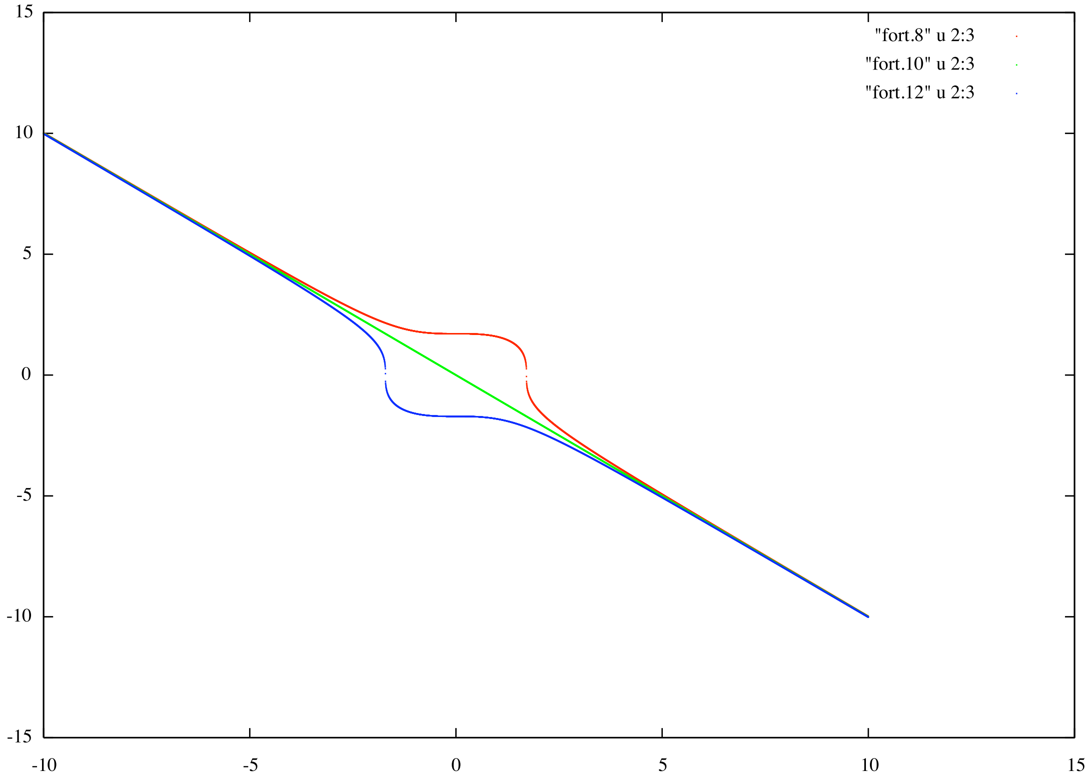

Figure 32.4.4: (Place Holder) Curve on which the map $\mathcal{N}^{\text{tr}}(1)$ becomes singular. The map is well defined and analytic for phase-space points to the right of this curve. Points on the curve are sent to infinity. The possible action of the map on points to the left of the curve is unknown.

Chapter 33

Beam Description and Moment Transport

33.1 Preliminaries

The previous chapters dealt with *single*-particle orbit theory. In this chapter we will treat *many*-particle distributions in the approximation that the particles are *noninteracting.* Under this noninteracting assumption all results about particle distributions are derivable from properties of the single-particle transfer map $\mathcal{M}$. Here we will find it convenient to use the phase-space variable ordering

$$z = (z_1, z_2, \ldots, z_{2n-1}, z_{2n}) = (q_1, p_1, q_2, p_2, \ldots, q_n, p_n). \tag{33.1.1}$$

That is, we will employ the ordering (3.2.20) presented in Exercise 3.2.6, but will omit the prime for notational simplicity. Also, we will use the matrix J' given by (3.2.10) and (3.2.11), but will again omit the prime. See Section 3.2.

Suppose $h(z)$ is some *density* function describing a collection of particles in phase space. That is d^6N, the number of particles in a phase-space volume d^6z, is given by the relation

$$d^6N = h(z)d^6z, \tag{33.1.2}$$

and there is the result

$$N = \int d^6z\ h(z) \tag{33.1.3}$$

where N is the number of particles under consideration.

More specifically, suppose $h^i(z)$ is a function describing some *initial* distribution of particles in phase space. Next suppose the particle distribution is transported through some system described by a map $\mathcal{M}$. Then, by Liouville's theorem, the *final* distribution $h^f(z)$ at the end of the system is given by the relation

$$h^f(z) = h^i(\mathcal{M}^{-1}z). \tag{33.1.4}$$

See Subsection 6.8.1 and Exercise 6.8.2. Also recall that, as sketched in Section 6.8, the problem of determining what distribution can be sent into what under the action of some symplectic map $\mathcal{M}$, which is what (1.4) describes, is deep and only partially understood. See also Chapter 29.

33.2 Moments and Moment Transport

Suppose, as before, that $h^i(z)$ is a function describing some *initial* distribution of particles in phase space. Since $h^i(z)$ is a function, generally an infinite number of parameters are required for its specification. One way to *characterize* $h^i(z)$ is in terms of initial moments $Z^i_{abc\cdots}$ defined by the rule

$$Z^i_{abc\cdots} = \langle z_a z_b z_c \cdots \rangle^i = (1/N) \int d^6z \; h^i(z) z_a z_b z_c \cdots \, . \tag{33.2.1}$$

We use the term *characterize* advisedly rather than *specify* because in general the problem of reconstructing (uniquely determining) a function given its moments is ill posed. Nevertheless, moments may provide some useful information about $h^i(z)$.

How are initial and final moments related? To answer this question it is useful to employ a different notation for moments. Let $P_\alpha(z)$, where α is some running index, denote a complete set of homogeneous polynomials in z through terms of some fixed degree. See Chapter 36. Then one can define initial moments m^i_α by the rule

$$m^i_\alpha = (1/N) \int d^6z \; h^i(z) P_\alpha(z). \tag{33.2.2}$$

Correspondingly, the final moments are given by the relation

$$\begin{aligned} m^f_\alpha &= (1/N) \int d^6z \; h^f(z) P_\alpha(z) = (1/N) \int d^6z \; h^i(\mathcal{M}^{-1}z) P_\alpha(z) \\ &= (1/N) \int d^6\bar{z} \; h^i(\bar{z}) P_\alpha(\mathcal{M}\bar{z}). \end{aligned} \tag{33.2.3}$$

Here we have used (1.4). And, to obtain the last line, we have changed variables of integration by the rule

$$\bar{z} = \mathcal{M}^{-1} z. \tag{33.2.4}$$

Doing so required calculation of the determinant of the Jacobi matrix M associated with $\mathcal{M}$. However, it is a property of symplectic matrices that they all have determinant $+1$. Therefore the determinant of M is $+1$ and need not appear explicitly in (2.3).

Since the P_α are complete, there is an expansion of the form

$$P_\alpha(\mathcal{M}\bar{z}) = \sum_\beta \mathcal{D}_{\alpha\beta}(\mathcal{M}) P_\beta(\bar{z}) \tag{33.2.5}$$

where the $\mathcal{D}_{\alpha\beta}(\mathcal{M})$ are coefficients that can be calculated for any transfer map $\mathcal{M}$. Employing (2.5) in (2.3) gives the intermediate result

$$\begin{aligned} m^f_\alpha &= (1/N) \int d^6\bar{z} \; h^i(\bar{z}) P_\alpha(\mathcal{M}\bar{z}) = (1/N) \int d^6\bar{z} \; h^i(\bar{z}) \sum_\beta \mathcal{D}_{\alpha\beta}(\mathcal{M}) P_\beta(\bar{z}) \\ &= \sum_\beta \mathcal{D}_{\alpha\beta}(\mathcal{M}) (1/N) \int d^6\bar{z} \; h^i(\bar{z}) P_\beta(\bar{z}). \end{aligned} \tag{33.2.6}$$

It follows that moments transform *linearly* according to the rule

$$m^f_\alpha = \sum_\beta D_{\alpha\beta}(\mathcal{M}) m^i_\beta. \tag{33.2.7}$$

Note that by this method one can find the evolution of moments *without* tracking (following orbits of individual particles in) particle distributions.

33.3 Various Beam Distributions and Beam Matching

33.4 Some Properties of First-Order Moments

33.4.1 Transformation Properties

For reasons that will become clear later, see Section 5, in this subsection we will examine the transformation properties of first-order moments under the action of the inhomogeneous symplectic group $ISp(2n)$. Recall Section 9.2 for a discussion of $ISp(2n)$.

Properties under Translations

Let us first find the transformation properties of first-order moments under the action of translations. Let $\mathcal{T}$ be the *translation* map given by

$$\mathcal{T} = \exp : g_1 : \tag{33.4.1}$$

with

$$g_1(z) = -(\delta, Jz). \tag{33.4.2}$$

It has the property that

$$\mathcal{T} z_a = z_a + \delta_a. \tag{33.4.3}$$

See Section 7.7. Conversely, there is the inverse relation

$$\mathcal{T}^{-1} z_a = z_a - \delta_a. \tag{33.4.4}$$

As a special case of the Liouville relation (1.4), under the action of $\mathcal{T}$ the distribution function h becomes a transformed distribution function h' with

$$h'(z) = h(\mathcal{T}^{-1} z). \tag{33.4.5}$$

From the definition (2.1) we see that the transformed moments $\langle z_a \rangle'$ are given by the relation

$$\langle z_a \rangle' = (1/N) \int d^6\ h'(z) z_a = (1/N) \int d^6 z\ h(\mathcal{T}^{-1} z) z_a. \tag{33.4.6}$$

Introduce new variables $\bar{z}$ by the rule

$$z = \mathcal{T} \bar{z} \tag{33.4.7}$$

or, equivalently,

$$\bar{z} = \mathcal{T}^{-1} z. \tag{33.4.8}$$

The relation (4.7) implies the component relations

$$z_a = \bar{z}_a + \delta_a \tag{33.4.9}$$

Also, we see that

$$d^6 z = d^6 \bar{z}. \tag{33.4.10}$$

With these facts in mind, we see that (4.6) can be rewritten in the form

$$\begin{aligned} \langle z_a \rangle' &= (1/N) \int d^6 \bar{z}\ (\bar{z}_a + \delta_a) h(\bar{z}) \\ &= (1/N) \int d^6 \bar{z}\ \bar{z}_a h(\bar{z}) + (1/N) \int d^6 \bar{z}\ \delta_a h(\bar{z}) \\ &= \langle z_a \rangle + \delta_a, \end{aligned} \tag{33.4.11}$$

which has the more compact vector form

$$\langle z \rangle' = \langle z \rangle + \delta. \tag{33.4.12}$$

We may view the first-order moments of a distribution as specifying the *centroid* of a distribution. According to (4.12), under the action of a translation, the centroid transforms like the coordinates of a particle located at the centroid. The centroid is simply translated, as expected. We observe also that the transformation rule is the same for all distributions having the same first-order moments. Finally note that the steps leading from (4.6) to (4.12) are simply (for the translation case and for first-order moments) a more detailed recapitulation of the steps (2.3) through (2.7).

Properties under Linear Symplectic Maps

Next let us find the transformation properties of first-order moments under the action of a linear symplectic map $\mathcal{R}$ described by the symplectic matrix R. Now the Liouville relation (1.4) relating the initial distribution function h and the transformed distribution function h' takes the form

$$h'(z) = h(R^{-1} z). \tag{33.4.13}$$

From the definition (2.1) we see that the transformed moments $\langle z_a \rangle'$ are given by the relation

$$\langle z_a \rangle' = (1/N) \int d^6 z\ h'(z) z_a = (1/N) \int d^6 z\ h(R^{-1} z) z_a. \tag{33.4.14}$$

Introduce new variables $\bar{z}$ by the rule

$$z = R\bar{z} \tag{33.4.15}$$

or, equivalently,

$$\bar{z} = R^{-1} z. \tag{33.4.16}$$

The relation (4.15) implies the component relations

$$z_a = \sum_c R_{ac}\bar{z}_c. \tag{33.4.17}$$

Also, because R is symplectic and therefore must have determinant one, we find that

$$d^6z = [\det(R)]d^6\bar{z} = d^6\bar{z}. \tag{33.4.18}$$

With these facts in mind, we see that (4.14) can be rewritten in the form

$$\begin{aligned}\langle z_a\rangle' &= (1/N)\int d^6\bar{z}\ \sum_c R_{ac}\bar{z}_c h(\bar{z}) \\ &= \sum_c R_{ac}(1/N)\int d^6\bar{z}\ \bar{z}_c h(\bar{z}) \\ &= \sum_c R_{ac}\langle z_c\rangle,\end{aligned} \tag{33.4.19}$$

which has the more compact matrix form

$$\langle z\rangle' = R\langle z\rangle. \tag{33.4.20}$$

Recall that we may view the first-order moments of a distribution as specifying the centroid of a distribution. According to (4.20), under the action of a linear symplectic map, the centroid transforms like the coordinates of a particle located at the centroid. We observe, in particular, that the transformation rule is the same for all distributions having the same first-order moments. Note also that the steps leading from (4.14) to (4.20) are again (for the linear case and for first-order moments) simply a more detailed recapitulation of the steps (2.3) through (2.7).

33.4.2 Normal Form

From the work of Subsection 3.6.5 we know that $Sp(2n)$ acts transitively on phase space. See (3.6.114) through (3.6.116). Therefore, unless $\langle z\rangle = 0$, there is a sympletic matrix R such that

$$\langle z\rangle' = R\langle z\rangle = e^1. \tag{33.4.21}$$

That is, all the components of $\langle z\rangle'$ vanish save for the first, which has the value 1. Alternatively, if $\langle z\rangle$ vanishes, then $\langle z\rangle'$ also vanishes. Thus the set of first-order moments consists, under the action of $Sp(2n)$, of two *equivalence* classes: the elements that are equivalent to e^1 (which is the set all nonzero $\langle z\rangle$) and the zero element $\langle z\rangle = 0$. Correspondingly, we may view the vectors e^1 and 0 as being *normal* forms for the set of all first-order moments.

33.5 Kinematic Moment Invariants

Definition

Let m be a vector with components m_α, and let $D(\mathcal{M})$ be a matrix with entries $D_{\alpha\beta}(\mathcal{M})$. Write (2.7) in the more compact form

$$m^f = D(\mathcal{M})m^i. \tag{33.5.1}$$

A function of moments $I[m]$ is said to be a *kinematic moment invariant* if it obeys the relations

$$I[m^f] = I[m^i], \tag{33.5.2}$$

or

$$I[D(\mathcal{M})m] = I[m], \tag{33.5.3}$$

for *all* symplectic maps $\mathcal{M}$.

Rather little is known about the existence and properties of kinematic moment invariants for the set of all symplectic maps. However, kinematic moment invariants are known to exist and all kinematic moment invariants have been found when the symplectic maps $\mathcal{M}$ are restricted to be those associated with the inhomogeneous symplectic group $ISp(2n)$. Moreover, their existence is a consequence of group theory applied to $ISp(2n)$. We note that, if deviation variables are employed, the full $\mathcal{M}$ is well approximated by translation and linear maps provided excursions about the design orbit are sufficiently small.

First-Order Moments

At this point we can observe that there are no *significant* kinematic invariants in the case of first-order moments. Evidently, by definition, a kinematic invariant has the same value for all moments that belong to the same equivalence class. If only translations $\mathcal{T}$ are considered, (4.12) shows that any set of first-order moments can be transformed to any other, and therefore there is only one equivalence class. Consequently I must have a constant value. And, if only linear symplectic transformations $\mathcal{R}$ are considered, we have seen that for the case of first-order moments there are only two equivalence classes. Consequently, in this case I can have only two possible values.

Second-Order Moments

Of particular interest are kinematic moment invariants that can be constructed from the second-order moments Z_{ab} with

$$Z_{ab} = \langle z_a z_b \rangle = (1/N) \int d^6 z \; h(z) z_a z_b. \tag{33.5.4}$$

For a given particle distribution, let Z be the matrix with entries Z_{ab}. In the case of a 1-degree of freedom system phase space is 2 dimensional, and the matrix Z in this case is 2×2. It is easily verified that in this case a kinematic moment invariant [under the action of $Sp(2)$] is given by the rule

$$I[Z] = \mathrm{tr}[(ZJ_2)^2] = 2[(Z_{12})^2 - Z_{11}Z_{22}] = -2(\langle q^2 \rangle \langle p^2 \rangle - \langle qp \rangle^2). \tag{33.5.5}$$

See Exercise 6.1 where this result is verified and shown to be a consequence of group theory applied to $Sp(2)$. Note that in this case I is proportional to the *mean square emittance* ϵ^2 *defined* by the rule

$$\epsilon^2 = \langle q^2 \rangle \langle p^2 \rangle - \langle qp \rangle^2. \tag{33.5.6}$$

In the case of a 3-degree of freedom system it can be shown that there are 3 such functionally independent invariants given by the rules

$$I^{(n)}[Z] = \mathrm{tr}[(ZJ)^n], \quad n = 2, 4, 6; \tag{33.5.7}$$

and all other invariants constructed from second-order moments are functions of these invariants. See Exercises 6.2 and 6.3.

33.6 Some Properties of Second-Order Moments

In this section we will explore various properties of Z.

33.6.1 Positive Definite Property

We begin by showing that the matrix Z, which is obviously real and symmetric, is also positive definite. Since $h(z)$ is a phase-space density, it is positive or zero for all z,

$$h(z) \geq 0 \text{ for all } z; \tag{33.6.1}$$

and it follows from (6.1) and continuity that there must be some finite phase-space volume for which $h(z) > 0$. Next let u be any real six-dimensional nonzero vector. Form the function $(u, z)^2$. It has the property

$$(u, z)^2 \geq 0 \text{ for all } z. \tag{33.6.2}$$

Moreover, in the volume where $h(z) > 0$, there must be some subvolume where $(u, z)^2 > 0$. It follows that there is the result

$$\begin{aligned}(u, Zu) &= \sum_{ab} u_a Z_{ab} u_b = (1/N) \int d^6z\ h(z) \sum_{ab} u_a z_a u_b z_b \\ &= (1/N) \int d^6z\ h(z)(u, z)^2 > 0. \end{aligned} \tag{33.6.3}$$

33.6.2 Transformation Properties

Properties under Translations

From the definition (2.1) we see that under translations the transformed moments $\langle z_a z_b \rangle'$ are given by the relation

$$\langle z_a z_b \rangle' = (1/N) \int d^6\ h'(z) z_a z_b = (1/N) \int d^6z\ h(\mathcal{T}^{-1} z) z_a z_b. \tag{33.6.4}$$

As in Subsection 4.1, introduce new variables $\bar{z}$ by the rules (4.7) through (4.9) and employ (4.10). So doing reveals that (6.4) can be rewritten in the form

$$\begin{aligned}
\langle z_a z_b\rangle' &= (1/N)\int d^6\bar{z}\ (\bar{z}_a+\delta_a)(\bar{z}_b+\delta_b)h(\bar{z}) \\
&= (1/N)\int d^6\bar{z}\ \bar{z}_a\bar{z}_b h(\bar{z}) + (1/N)\int d^6\bar{z}\ \bar{z}_a\delta_b h(\bar{z}) \\
&\quad +(1/N)\int d^6\bar{z}\ \delta_a\bar{z}_b h(\bar{z}) + (1/N)\int d^6\bar{z}\ \delta_a\delta_b h(\bar{z}) \\
&= \langle z_a z_b\rangle + \langle z_a\rangle\delta_b + \delta_a\langle z_b\rangle + \delta_a\delta_b. \qquad (33.6.5)
\end{aligned}$$

Properties under Linear Symplectic Maps

Let us next find the transformation properties of second-order moments under the action of a linear symplectic map $\mathcal{R}$ described by the symplectic matrix R. From the definition (4.1) and (4.13) we see that the transformed moments $\langle z_a z_b\rangle'$ are given by the relation

$$\langle z_a z_b\rangle' = (1/N)\int d^6z\ h'(z)z_a z_b = (1/N)\int d^6z\ h(R^{-1}z)z_a z_b. \qquad (33.6.6)$$

Again introduce new variables $\bar{z}$ by the rules (4.15) through (4.17) and supplement (4.17) with the relation

$$z_b = \sum_d R_{bd}\bar{z}_d. \qquad (33.6.7)$$

Also employ the relation (4.18). With these tools we see that (6.6) can be rewritten in the form

$$\begin{aligned}
\langle z_a z_b\rangle' &= (1/N)\int d^6\bar{z}\ \sum_{cd} R_{ac}R_{bd}\bar{z}_c\bar{z}_d h(\bar{z}) \\
&= \sum_{cd} R_{ac}R_{bd}(1/N)\int d^6\bar{z}\ \bar{z}_c\bar{z}_d h(\bar{z}) \\
&= \sum_{cd} R_{ac}R_{bd}\langle z_c z_d\rangle. \qquad (33.6.8)
\end{aligned}$$

In terms of the notation employed in (5.4), the relation (6.8) can be rewritten in the component form

$$Z'_{ab} = \sum_{cd} R_{ac}R_{bd}Z_{cd} = \sum_{cd} R_{ac}Z_{cd}(R^T)_{db}, \qquad (33.6.9)$$

which has the more compact matrix form

$$Z' = RZR^T. \qquad (33.6.10)$$

This matrix relation specifies how second-order moments transform under a linear symplectic map. We observe, in particular, that the transformation rule is the same for all distributions having the same second-order moments.

33.6.3 Williamson Normal Form

Even more can be said. Since the matrix Z is real, symmetric, and positive definite, according to a theorem of Williamson there is a symplectic matrix A such that

$$AZA^T = D \tag{33.6.11}$$

where D is the *diagonal* matrix

$$D = \text{diag}\{\lambda_1, \lambda_1, \lambda_2, \lambda_2, \lambda_3, \lambda_3\} \tag{33.6.12}$$

with all $\lambda_j > 0$. The right side of (6.11) is called the *Williamson normal form* of Z.

Two things should be noted about this remarkable result. Define the matrix Z^{norm} by the rule

$$Z^{\text{norm}} = AZA^T = D. \tag{33.6.13}$$

Then, from (6.12 and (6.13), we see that there are the results

$$\langle q_j q_k \rangle^{\text{norm}} = \langle p_j p_k \rangle^{\text{norm}} = 0 \text{ if } j \neq k, \tag{33.6.14}$$

$$\langle q_j^2 \rangle^{\text{norm}} = \langle p_j^2 \rangle^{\text{norm}} = \lambda_j, \tag{33.6.15}$$

$$\langle q_j p_k \rangle^{\text{norm}} = 0. \tag{33.6.16}$$

Also, we observe that (6.11) is of the form (6.10) with $R = A$. Thus, if a beam transport system can be found whose transfer matrix is A, then this transport system will bring the second-order moments to the normal form given by (6.14) through (6.16).

33.6.4 Eigen Emittances

We will next see that two second-order moment matrices Z' and Z have the *same* Williamson normal form if they are connected by a relation of the form (6.10). Indeed, observe that we may write the relation

$$\begin{aligned} AR^{-1}Z'(AR^{-1})^T &= AR^{-1}RZR^T(R^T)^{-1}A^T \\ &= AZA^T = D. \end{aligned} \tag{33.6.17}$$

[Here we have used the result $(R^{-1})^T = (R^T)^{-1}$ which holds for any invertible matrix.] But, by the group property of symplectic matrices, the matrix AR^{-1} is symplectic if the matrices A and R are symplectic. We see from (6.17) that the symplectic matrix AR^{-1} brings Z' to Williamson normal form and, according to (6.13), this normal form is the same as that for Z. The quantities λ_j^2 are called mean-square *eigen* emittances, or simply eigen remittances. It follows that while the entries in Z evolve as a particle distribution propagates through various elements, see (6.10), the eigen emittances remain *unchanged* (in the linear approximation). Thus, given an initial particle distribution, one can compute the initial second moments $\langle z_a z_b \rangle^i$, and from them the eigen emitances. And these eigen emittances will remain unchanged (in the linear approximation) as the particle distribution evolves.

It can be shown that the eigen emittances generalize the 1-degree of freedom mean-square emittance given by (5.6) to the fully coupled case. Indeed, it can be shown that in terms of the λ_j the kinematic invariants $I^{(n)}$ given by (5.7) have the values

$$I^{(n)} = 2(-1)^{n/2}(\lambda_1^n + \lambda_2^n + \lambda_3^n). \tag{33.6.18}$$

See Exercise 6.3.

There are symplectic matrix routines that, given Z, find A and the λ_j. If only the λ_j are required, they can be found from the eigenvalues of JZ. Note that JZ is a Hamiltonian matrix. See Exercise 3.17.14.

To see that the λ_j can be found from the eigenvalues of JZ, suppose both sides of (6.11) are multiplied by J to give the result

$$JAZA^T = JD. \tag{33.6.19}$$

From the symplectic condition for A it follows that there is the relation

$$JA = (A^T)^{-1}J. \tag{33.6.20}$$

Consequently (6.19) can be rewritten in the form

$$(A^T)^{-1}JZA^T = JD, \tag{33.6.21}$$

which reveals that the matrices JZ and JD are related by a *similarity* transformation, and therefore have the same eigenvalues. See Exercise 3.7.16.

What remains is to find the eigenvalues of JD which, according to (3.2.10), (3.2.11), and (6.12) can be written in the block form

$$JD = \begin{pmatrix} \lambda_1 J_2 & & \\ & \lambda_2 J_2 & \\ & & \lambda_3 J_2 \end{pmatrix}. \tag{33.6.22}$$

Let W_2 be the unitary and (complex) symplectic 2×2 matrix

$$W_2 = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix}. \tag{33.6.23}$$

[See (3.9.12).] It has the property

$$W_2^{-1} J_2 W_2 = iK_2 \tag{33.6.24}$$

where K_2 is the matrix

$$K_2 = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}. \tag{33.6.25}$$

From W_2 construct the the 6×6 matrix W given in block form by the rule

$$W = \begin{pmatrix} W_2 & & \\ & W_2 & \\ & & W_2 \end{pmatrix}. \tag{33.6.26}$$

It follows from (6.22) and (6.24) that there is the relation

$$W^{-1}JDW = \begin{pmatrix} i\lambda_1 K_2 & & \\ & i\lambda_2 K_2 & \\ & & i\lambda_3 K_2 \end{pmatrix}. \tag{33.6.27}$$

We see that the eigenvalues of JD, and hence JZ, are pure imaginary and come in the ± pairs

$$\sigma_j = \pm i\lambda_j. \tag{33.6.28}$$

Conversely, if the eigenvalues $\pm\sigma_j$ of JZ are computed, then the eigen emittances are given by the relation

$$\lambda_j = |\sigma_j]. \tag{33.6.29}$$

Suppose we combine the relations (6.21) and (6.27) to find the result

$$W^{-1}(A^T)^{-1}JZA^TW = \begin{pmatrix} i\lambda_1 K_2 & & \\ & i\lambda_2 K_2 & \\ & & i\lambda_3 K_2 \end{pmatrix} = \text{diag}\{-i\lambda_1, i\lambda_1, -i\lambda_2, i\lambda_2, -i\lambda_3, i\lambda_3\}. \tag{33.6.30}$$

Let A' be the matrix defined by the rule

$$A' = A^TW, \;\; (A')^{-1} = W^{-1}(A^T)^{-1}. \tag{33.6.31}$$

It will be symplectic since A (and hence A^T) and W are symplectic. With the aid of A' the relation (6.30) takes the form

$$(A')^{-1}JZA' = \text{diag}\{-i\lambda_1, i\lambda_1, -i\lambda_2, i\lambda_2, -i\lambda_3, i\lambda_3\}. \tag{33.6.32}$$

We observe that since Z is positive definite, JZ is a particular/special kind of Hamiltonian matrix. As a consequence of Williamson's theorem we have seen that it can be diagonalized by a similarity transformation even if its eigenvalues are not distinct; moreover the diagonalizing matrix A' can be chosen to be symplectic. And, as stated earlier, the eigenvalues of JZ are pure imaginary.

Finally, we note that multiplying both sides of (6.10) by J produces the relation

$$JZ' = JRZR^T = (R^T)^{-1}JZR^T. \tag{33.6.33}$$

Here we have used the fact that R is symplectic. We see that with the use of J the evolution rule (6.10) for Z becomes the *similarity* transformation rule (6.33) for JZ. Since eigenvalues are preserved by similarity transformations, we have found an alternative explanation of why the eigen emittances remain unchanged as a particle distribution evolves.

33.6.5 Classical Uncertainty Principle

Statement

The results of the previous subsection can be used to derive a *classical* uncertainty principle. What we will show is that there is the inequality

$$\langle q_i^2\rangle\langle p_i^2\rangle \geq \lambda_{\text{min}}^2, \; i = 1, 2, 3, \tag{33.6.34}$$

where λ_{min} is the minimum of the λ_k. No matter what is done to a beam (ignoring nonlinear and nonsymplectic effects), the products of the mean-square deviations in q_i and p_i for any plane must exceed, or at best equal, λ_{min}^2.

Proof

Begin by rewriting (6.13) in the form

$$Z = A^{-1}Z^{\text{norm}}(A^{-1})^T = N^T Z^{\text{norm}} N = N^T D N \tag{33.6.35}$$

where we have made the definition

$$N = (A^{-1})^T. \tag{33.6.36}$$

We note that N will be symplectic if A is symplectic, and conversely.

Let us compute the $\langle q_i^2\rangle$ and $\langle p_i^2\rangle$. To compute the $\langle q_i^2\rangle$ set

$$a = j \text{ with } j = 1, 3, 5 \text{ when } i = 1, 2, 3. \tag{33.6.37}$$

We then find from (6.35) that

$$\begin{aligned} \langle q_i^2\rangle &= Z_{aa} = (N^T D N)_{aa} = \sum_{cd} (N^T)_{ac} D_{cd} N_{da} \\ &= \sum_c N_{ca} D_{cc} N_{ca} = \sum_c (N_{ca})^2 D_{cc} \\ &\geq \lambda_{\text{min}} \sum_c (N_{ca})^2. \end{aligned} \tag{33.6.38}$$

Similarly, to compute the $\langle p_i^2\rangle$, upon setting

$$b = j + 1, \tag{33.6.39}$$

we find that

$$\begin{aligned} \langle p_i^2\rangle &= Z_{bb} = (N^T D N)_{bb} = \sum_{cd} (N^T)_{bc} D_{cd} N_{db} \\ &= \sum_d N_{db} D_{dd} N_{db} = \sum_d (N_{db})^2 D_{dd} \\ &\geq \lambda_{\text{min}} \sum_d (N_{db})^2. \end{aligned} \tag{33.6.40}$$

It follows that

$$\langle q_i^2\rangle\langle p_i^2\rangle \geq \lambda_{\text{min}}^2 \left[\sum_c (N_{ca})^2\right] \left[\sum_d (N_{db})^2\right]. \tag{33.6.41}$$

To proceed further, let u^a and u^b be vectors with the entries

$$u_c^a = N_{ca}, \tag{33.6.42}$$

$$u_d^b = N_{db}. \tag{33.6.43}$$

Evidently u^a and u^b are the $a^{\rm th}$ and $b^{\rm th}$ columns of N. With these definitions we may write (6.41) in the more compact form

$$\langle q_i^2\rangle\langle p_i^2\rangle \geq \lambda_{\rm min}^2 ||u^a||^2\ ||u^b||^2 \tag{33.6.44}$$

where $|| * ||$ denotes the Euclidean norm. Since N is a symplectic matrix, it follows from the symplectic condition that there is also the relation

$$(u^a, Ju^b) = 1. \tag{33.6.45}$$

See Exercise 3.6.13. It can be shown using the spectral norm for J that (6.45) in turn entails the inequality.

$$||u^a||\ ||u^b|| \geq 1. \tag{33.6.46}$$

See Exercise 3.7.1. Upon combining (6.44) and (6.46) we find the advertised result (6.34).

33.6.6 Minimum Emittance Theorem

Statement

The classical uncertainty principle shows that (in the linear approximation) no matter how a beam is transformed, the product of the spreads in position and the conjugate momentum must satisfy the relation (6.34). There is a related constraint on the mean-square emittances ϵ_i defined by

$$\epsilon_i^2 = \langle q_i^2\rangle\langle p_i^2\rangle - \langle q_i p_i\rangle^2. \tag{33.6.47}$$

What we will show is that (in the linear approximation) no matter how a beam is transformed (symplectically) there is the constraint

$$\epsilon_i^2 \geq \lambda_{\rm min}^2,\ i = 1, 2, 3. \tag{33.6.48}$$

Together the information provided by the classical uncertainty principle and the minimum emittance theorem is useful when designing a beam line to perform emittance manipulations because it sets lower limits on what one can hope to achieve.

Proof

Suppose, in the 6×6 case under consideration, that we partition Z into nine 2×2 blocks by writing

$$Z = \begin{pmatrix} Z^{11} & Z^{12} & Z^{13} \\ Z^{21} & Z^{22} & Z^{23} \\ Z^{31} & Z^{32} & Z^{33} \end{pmatrix}. \tag{33.6.49}$$

Because Z is symmetric, the blocks will satisfy the relations

$$(Z^{ij})^T = Z^{ji}. \tag{33.6.50}$$

Let R be a 6×6 matrix having the block form

$$R = \begin{pmatrix} A & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{pmatrix}. \tag{33.6.51}$$

It will be symplectic if A is symplectic. Its use in (6.10) produces a Z' given by

$$Z' = \begin{pmatrix} A & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{pmatrix} \begin{pmatrix} Z^{11} & Z^{12} & Z^{13} \\ Z^{21} & Z^{22} & Z^{23} \\ Z^{31} & Z^{32} & Z^{33} \end{pmatrix} \begin{pmatrix} A^T & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{pmatrix}. \tag{33.6.52}$$

Carrying out the indicated multiplication gives the result

$$Z' = \begin{pmatrix} AZ^{11}A^T & AZ^{12} & AZ^{13} \\ Z^{21}A^T & Z^{22} & Z^{23} \\ Z^{31}A^T & Z^{32} & Z^{33} \end{pmatrix}. \tag{33.6.53}$$

In particular, we see that

$$(Z')^{11} = AZ^{11}A^T. \tag{33.6.54}$$

We will now seek a symplectic A that brings Z^{11} to Williamson normal form. Define the quantity ϵ_1 by the rules

$$\epsilon_1^2 = Z_{11}^{11}Z_{22}^{11} - (Z_{12}^{11})^2 = \langle q_1^2\rangle\langle p_1^2\rangle - \langle q_1p_1\rangle^2, \tag{33.6.55}$$

$$\epsilon_1 = +\sqrt{\epsilon_1^2}. \tag{33.6.56}$$

It follows from the Schwarz inequality that there is the relation

$$\langle q_1p_1\rangle^2 \le \langle q_1^2\rangle\langle p_1^2\rangle \tag{33.6.57}$$

and therefore the right side of (6.55) can never be negative. See Exercise 6.4. Consequently ϵ_1 is well defined by (6.55) and (6.56), and is positive. Next define "beam" betatron functions α, β, γ by the rules

$$\alpha = -Z_{12}^{11}/\epsilon_1 = -\langle q_1p_1\rangle/\epsilon_1, \tag{33.6.58}$$

$$\beta = Z_{11}^{11}/\epsilon_1 = \langle q_1^2\rangle/\epsilon_1, \tag{33.6.59}$$

$$\gamma = Z_{22}^{11}/\epsilon_1 = \langle p_1^2\rangle/\epsilon_1. \tag{33.6.60}$$

In terms of these definitions, Z^{11} takes the form

$$Z^{11} = \epsilon_1 \begin{pmatrix} \beta & -\alpha \\ -\alpha & \gamma \end{pmatrix}. \tag{33.6.61}$$

From (6.59) and (6.60) there are the inequalities $\beta \ge 0$ and $\gamma \ge 0$. And, from (6.55) through (6.60), there is the relation

$$1 = \beta\gamma - \alpha^2. \tag{33.6.62}$$

Finally, define the matrix A by the rule

$$A = \begin{pmatrix} 1/\sqrt{\beta} & 0 \\ \alpha/\sqrt{\beta} & \sqrt{\beta} \end{pmatrix}. \tag{33.6.63}$$

Since A is 2×2 and evidently has unit determinant, it is symplectic. Correspondingly, the R given by (6.51) is symplectic. And, from the definitions made and executing the matrix multiplications $AZ^{11}A^T$ indicated in (6.54), we find that

$$(Z')^{11} = AZ^{11}A^T = \mathrm{diag}(\epsilon_1, \epsilon_1). \tag{33.6.64}$$

See Exercise 6.5.

We will now exploit these results. From (6.64) we find that

$$\langle q_1^2 \rangle' = (Z')^{11}_{11} = \epsilon_1, \tag{33.6.65}$$

$$\langle p_1^2 \rangle' = (Z')^{11}_{22} = \epsilon_1. \tag{33.6.66}$$

It follows that

$$\langle q_1^2 \rangle' \, \langle p_1^2 \rangle' = \epsilon_1^2. \tag{33.6.67}$$

But we also have the relation (6.34). We conclude that there is the inequality

$$\epsilon_1^2 \geq \lambda_{\min}^2, \tag{33.6.68}$$

in accord with (6.48). Analogous results hold for the other planes.

Sharpening

We close this subsection by noting that the minimum emittance theorem (6.48) sharpens the classical uncertainty principle (6.34). Indeed, combining (6.47) and (6.48) produces the result

$$\langle q_i^2 \rangle \langle p_i^2 \rangle \geq \lambda_{\min}^2 + \langle q_i p_i \rangle^2, \; i = 1, 2, 3. \tag{33.6.69}$$

We see that to minimize $\langle q_i^2 \rangle \langle p_i^2 \rangle$ we must insure that $\langle q_i p_i \rangle$ vanishes.

33.6.7 Nonexistence of Maximum Emittances

The classical uncertainty principle (6.34) and the minimum emittance theorem (6.48) show that the mean square emittances are bounded from below under the action of linear symplectic maps. We will now see that they are *not* bounded from above if the phase space has 4 or more dimensions.

Consider the 4-dimensional case, and suppose initially a particle distribution has all quadratic moments zero save for the moments $\langle q_1^2 \rangle$, $\langle p_1^2 \rangle$, $\langle q_2^2 \rangle$, and $\langle p_2^2 \rangle$. (From the work of Subsection 6.3 we know that there is always a linear symplectic transformation that will bring the quadratic moments to this form.) In this case the mean square emittances ϵ_i^2 are given by the relation

$$\epsilon_i^2 = \langle q_i^2 \rangle \langle p_i^2 \rangle. \tag{33.6.70}$$

Let $\mathcal{R}$ be the linear symplectic map

$$\mathcal{R} = \exp(\nu : q_1 p_2 :). \tag{33.6.71}$$

Here ν is some some real parameter. It is easily verified that this map has the properties

$$\bar{q}_1 = \mathcal{R} q_1 = q_1, \tag{33.6.72}$$

$$\bar{p}_1 = \mathcal{R} p_1 = p_1 + \nu p_2, \tag{33.6.73}$$

$$\bar{q}_2 = \mathcal{R} q_2 = q_2 - \nu q_1, \tag{33.6.74}$$

$$\bar{p}_2 = \mathcal{R} p_2 = p_2. \tag{33.6.75}$$

It is also easily verified that there are the transformed moment relations

$$\langle \bar{q}_1^2 \rangle = \langle q_1^2 \rangle, \tag{33.6.76}$$

$$\langle \bar{p}_1^2 \rangle = \langle (p_1 + \nu p_2)^2 \rangle = \langle p_1^2 \rangle + \nu^2 \langle p_2^2 \rangle, \tag{33.6.77}$$

$$\langle \bar{q}_1 \bar{p}_1 \rangle = 0; \tag{33.6.78}$$

$$\langle \bar{q}_2^2 \rangle = \langle (q_2 - \nu q_1)^2 \rangle = \langle q_2^2 \rangle + \nu^2 \langle q_1^2 \rangle, \tag{33.6.79}$$

$$\langle \bar{p}_2^2 \rangle = \langle p_2^2 \rangle, \tag{33.6.80}$$

$$\langle \bar{q}_2 \bar{p}_2 \rangle = 0. \tag{33.6.81}$$

Correspondingly, the transformed mean square emittance $\bar{\epsilon}_1^2$ satisfies the relation

$$\begin{aligned} \bar{\epsilon}_1^2 &= \langle \bar{q}_1^2 \rangle \langle \bar{p}_1^2 \rangle - \langle \bar{q}_1 \bar{p}_1 \rangle^2 \\ &= \langle q_1^2 \rangle (\langle p_1^2 \rangle + \nu^2 \langle p_2^2 \rangle) \\ &= \epsilon_1^2 + \nu^2 \langle q_1^2 \rangle \langle p_2^2 \rangle. \end{aligned} \tag{33.6.82}$$

Similarly the transformed mean square emittance $\bar{\epsilon}_2^2$ satisfies the relation

$$\bar{\epsilon}_2^2 = \epsilon_2^2 + \nu^2 \langle q_1^2 \rangle \langle p_2^2 \rangle. \tag{33.6.83}$$

We conclude that both $\bar{\epsilon}_1^2$ and $\bar{\epsilon}_2^2$ can be made arbitrarily large by making $|\nu|$ arbitrarily large.

33.6.8 Second-Order Moments about the Beam Centroid

Definition

Define second-order moments *About* the *Beam Centroid*, denoted as Z_{ab}^{ABC}, by the rule

$$Z_{ab}^{\mathrm{ABC}} = \langle (z_a - \langle z_a \rangle)(z_b - \langle z_b \rangle) \rangle = (1/N) \int d^6 z \; h(z)(z_a - \langle z_a \rangle)(z_b - \langle z_b \rangle). \tag{33.6.84}$$

Executing the indicated operations gives the result

$$\begin{aligned} Z_{ab}^{\rm ABC} &= \langle (z_a - \langle z_a \rangle)(z_b - \langle z_b \rangle)\rangle \\ &= \langle z_a z_b \rangle - \langle z_a \langle z_b \rangle\rangle - \langle\langle z_a \rangle z_b\rangle + \langle\langle z_a\rangle\langle z_b\rangle\rangle \\ &= \langle z_a z_b\rangle - \langle z_a\rangle\langle z_b\rangle \\ &= Z_{ab} - Z_{ab}^{\rm OBC}. \end{aligned} \tag{33.6.85}$$

Here $Z_{ab}^{\rm OBC}$ denotes the set of second-order moments *Of* the *Beam Centroid* defined by the rule

$$Z_{ab}^{\rm OBC} = \langle z_a\rangle\langle z_b\rangle. \tag{33.6.86}$$

Intuitively, $Z^{\rm OBC}$ may be viewed as the collection of second-order moments of a beam distribution consisting of a single *macro* particle located at the beam centroid. We also observe, in passing, that (6.85) can be rewritten in the form

$$Z = Z^{\rm ABC} + Z^{\rm OBC}, \tag{33.6.87}$$

which is analogous to the fact that the inertia tensor of a rigid body about some specified origin is the sum of its inertia tensor about its center of mass plus the inertia tensor of its center of mass about the specified origin.

Properties under Translations

What are the transformation properties of $Z^{\rm ABC}$ under the action of a translation $\mathcal{T}$? Starting from the definition (6.83) we find the chain of equalities

$$\begin{aligned} (Z_{ab}^{\rm ABC})' &= (\langle (z_a - \langle z_a\rangle')(z_b - \langle z_b\rangle')\rangle)' \\ &= (1/N)\int d^6z\ h'(z)(z_a - \langle z_a\rangle')(z_b - \langle z_b\rangle') \\ &= (1/N)\int d^6z\ h(\mathcal{T}^{-1}z)(z_a - \langle z_a\rangle')(z_b - \langle z_b\rangle') \\ &= (1/N)\int d^6\bar z\ h(\bar z)(\bar z_a + \delta_a - \langle z_a\rangle')(\bar z_b + \delta_b - \langle z_b\rangle') \\ &= (1/N)\int d^6\bar z\ h(\bar z)(\bar z_a - \langle z_a\rangle)(\bar z_b - \langle z_b\rangle) \\ &= Z_{ab}^{\rm ABC}. \end{aligned} \tag{33.6.88}$$

Here we have used (4.9) and (4.10) to change variables and have used (4.12) to obtain the relation

$$(\bar z_a + \delta_a - \langle z_a\rangle')(\bar z_b + \delta_b - \langle z_b\rangle') = (\bar z_a - \langle z_a\rangle)(\bar z_b - \langle z_b\rangle). \tag{33.6.89}$$

We see that $Z^{\rm ABC}$ is *invariant* under translations. (For an alternate proof of this result, see Exercise 6.6.) The quantity $Z^{\rm ABC}$ describes an *intrinsic* property of the beam distribution in that it does not depend on the location of the beam relative to the design orbit. Note that, according to (6.85) and(6.86), each component $Z_{ab}^{\rm ABC}$ of $Z^{\rm ABC}$ depends on first and second moments. Therefore, each component is a moment invariant under the action of translations.

Properties under Linear Symplectic Maps

What are the transformation properties of $Z^{\rm ABC}$ under the action of a linear symplectic map $\mathcal{R}$? Evidently, according to (6.85), we may write the relation

$$(Z^{\rm ABC})' = Z' - (Z^{\rm OBC})'. \tag{33.6.90}$$

We see from (4.19) that there is the relation

$$(Z^{\rm OBC}_{ab})' = \langle z_a\rangle'\langle z_b\rangle' = \sum_{cd} R_{ac}R_{bd}\langle z_c\rangle\langle z_d\rangle, \tag{33.6.91}$$

which can be written in the more compact form

$$(Z^{\rm OBC})' = RZ^{\rm OBC}R^T. \tag{33.6.92}$$

Recall also the relation (6.10). It follows that there is the result

$$(Z^{\rm ABC})' = RZR^T - RZ^{\rm OBC}R^T = RZ^{\rm ABC}R^T. \tag{33.6.93}$$

We conclude that Z, $Z^{\rm ABC}$, and $Z^{\rm OBC}$ all transform in the same manner.

Positive Definiteness

What about positive definiteness? First consider $Z^{\rm OBC}$. As in Subsection 6.1, u be any real nonzero vector. It follows from (6.86) that there is the result

$$(u, Z^{\rm OBC}u) = \sum_{ab} u_a Z^{\rm OBC}_{ab} u_b = \sum_{ab} u_a\langle z_a\rangle\langle z_b\rangle u_b = (u, \langle z\rangle)^2 \geq 0. \tag{33.6.94}$$

We see that $(u, Z^{\rm OBC}u)$ can never be negative. However if $(u, \langle z\rangle) = 0$, which is certainly possible, then $(u, Z^{\rm OBC}u) = 0$. Therefore $Z^{\rm OBC}$ is *not* positive *definite*.

Even more can be said. Let R be a symplectic matrix that has the property (4.21). Then we see from (6.91) that in this case

$$(Z^{\rm OBC})' = D \tag{33.6.95}$$

where D is a diagonal matrix with all entries zero save for D_{11} which has the value $D_{11} = 1$. Correspondingly, DJ has all entries zero save that $(DJ)_{12} = 1$. Consequently, the eigenvalues of DJ and JD, and hence of $Z^{\rm OBC}J$ and $JZ^{\rm OBC}$, all vanish. Recall Exercises 3.7.18 and 3.7.16. Moreover, there is the relation

$$(DJ)^2 = 0, \tag{33.6.96}$$

from which it follows that

$$(Z^{\rm OBC}J)^2 = 0. \tag{33.6.97}$$

We conclude from (5.7) and (6.97) that for $Z^{\rm OBC}$ there is the result

$$I^{(n)}[Z^{\rm OBC}] = 0. \tag{33.6.98}$$

The second-order moment invariants of a beam distribution consisting of a single macro particle all vanish.

What about second-order moments about the beam centroid, those described by Z^{ABC}? Calculation/insight shows that Z^{ABC} *is* positive definite. See Exercise 6.7. Therefore it has a Williamson normal form and is characterized by eigen emittances. Note that because Z^{ABC} is invariant under translations, these eigen emittances are *invariant* under the action of the *full* group $ISp(2n)$.

We also observe that in general these eigen emittances may differ from those of Z, but they may be of interest if the beam centroid is quite far from the design orbit. See Exercise 6.8. However in practice it is probably desirable, as one of the criteria for beam matching, to arrange to have the beam centroid coincide with the design orbit. This is also natural from an instrumentation perspective since beam position monitors essentially record the spatial coordinates of the beam centroid. Recall Section 3.

33.6.9 Summary of What We Have Learned

The information provided by the classical uncertainty principle and the minimum emittance theorem is useful when designing a beam line to perform emittance manipulations on a beam because it sets lower limits on what one can hope to achieve. It should also be useful in analyzing the results of beam cooling experiments. In this case one can measure all quadratic moments before and after a cooling channel. Next compute the eigen emittances of Z before and Z after. Ideally, one would like to find that all the λ_j^2 have decreased, or at least the minimum of the λ_j^2 has decreased.

We have seen that, in considering what can be achieved under beam transport (in the linear approximation), what counts are the eigen emittances, and these can be viewed as properties of the *initial* particle distribution. Moreover, according to (6.14) through (6.16), the best that can be achieved are the spread relations

$$\langle q_i^2\rangle\langle p_i^2\rangle = \lambda_i^2,\ i = 1, 2, 3 \tag{33.6.99}$$

where the λ_i are the eigen emittances in some order. Thus, in the combined context of both source and beam-line design, the challenge is to produce an initial particle distribution having optimal eigen emittances and to then transform the initial particle distribution in such a way that the optimal spread relations are realized in the desired planes. The next sections will describe various methods for producing initial particle distributions having optimal eigen emittances and how to then transform these distributions in such a way that the optimal spread relations are realized in the desired planes.

Exercises

33.6.1. Verify (5.5). Next suppose that Z' and Z are related by (6.10) and that R is symplectic. Verify that

$$I[Z'] = \mathrm{tr}[(Z'J_2)^2] = \mathrm{tr}[(RZR^TJ_2)^2]. \tag{33.6.100}$$

Next verify that

$$\begin{aligned} \mathrm{tr}[(RZR^TJ_2)^2] &= \mathrm{tr}[RZR^TJ_2RZR^TJ_2] = \mathrm{tr}[RZJ_2ZR^TJ_2] \\ &= \mathrm{tr}[ZJ_2ZR^TJ_2R] = \mathrm{tr}[ZJ_2ZJ_2] \\ &= \mathrm{tr}[(ZJ_2)^2] = I[Z]. \end{aligned} \tag{33.6.101}$$

Here we have used that assumption that R is symplectic and the trace property (3.6.130). Combining (6.100) and (6.101) shows that I is invariant,

$$I[Z'] = I[Z]. \tag{33.6.102}$$

How might we have known that there should be an invariant? Consider the space of all quadratic polynomial functions of the two-dimensional phase-space variables q, p. For present purposes, a convenient basis for these polynomials is given by the monomials

$$c^1 = q^2, \tag{33.6.103}$$

$$c^2 = qp, \tag{33.6.104}$$

$$c^3 = p^2. \tag{33.6.105}$$

According to Section 24.2, these polynomials carry the $sp(2)$ representation $\Gamma(2)$. Also, comparison of (2.5) and (2.7) shows that polynomials P_α and moments m_α have the *same* transformation properties. Therefore, and in particular, second-order moments of the two-dimensional phase-space variables q, p also carry the representation $\Gamma(2)$.

Next we observe that, for $sp(2)$, there is the Clebsch-Gordan series result

$$\Gamma(2) \otimes \Gamma(2) = \Gamma(0) \oplus \Gamma(2) \oplus \Gamma(4). \tag{33.6.106}$$

This is just the $sp(2)$ analog of the familiar statement that spin 1 and spin 1 combine to make spin 0, spin 1, and spin 2. Even more familiar, it is the analog of the statement that two vectors can be combined to make a scalar by use of the dot product, or can be combined to make another vector by use of the cross product, or can be combined to make a tensor by use of the tensor product. By definition, an entity (if is nonzero) that carries the representation $\Gamma(0)$ will be an invariant. Therefore, according to (6.106), there is at least the hope/possibility of constructing an invariant out of quadratic products of second-order moments. Note that the contents of (5.5) are indeed quadratic products of second-order moments.

How can we construct an entity that carries the representation $\Gamma(0)$? We have already seen some such constructions in Section 24.11, which you should review. You will now have the pleasure of making a similar construction for the problem at hand.

Begin by finding the symmetric matrices S^j associated with the c^j by the rule

$$c^j = (z, S^j z). \tag{33.6.107}$$

Show that these matrices are given by the relations

$$S^1 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \tag{33.6.108}$$

$$S^2 = (1/2)\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \tag{33.6.109}$$

$$S^3 = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}. \tag{33.6.110}$$

Next find the associated $sp(2)$ matrices C^j defined by the rule

$$C^j = JS^j. \tag{33.6.111}$$

Show that these matrices are given by the relations

$$C^1 = \begin{pmatrix} 0 & 0 \\ -1 & 0 \end{pmatrix}, \tag{33.6.112}$$

$$C^2 = (1/2)\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \tag{33.6.113}$$

$$C^3 = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}. \tag{33.6.114}$$

From these $sp(2)$ matrices construct the associated down-index metric tensor g by the rule

$$g_{jk} = \mathrm{tr}(C^j C^k). \tag{33.6.115}$$

Show that g has the entries

$$g = \begin{pmatrix} 0 & 0 & -1 \\ 0 & 1/2 & 0 \\ -1 & 0 & 0 \end{pmatrix}. \tag{33.6.116}$$

With g in hand, construct the up-index metric tensor $\hat{g}$ by the rule

$$\hat{g}^{jk} = (g^{-1})_{jk}. \tag{33.6.117}$$

Show that $\hat{g}$ has the entries

$$\hat{g} = \begin{pmatrix} 0 & 0 & -1 \\ 0 & 2 & 0 \\ -1 & 0 & 0 \end{pmatrix}. \tag{33.6.118}$$

Finally, based on arguments provided in Section 24.11, the quantity I defined by

$$I = \sum_{jk} \langle c^j \rangle \hat{g}^{jk} \langle c^k \rangle \tag{33.6.119}$$

should be invariant. Verify that

$$I = \sum_{jk} \langle c^j \rangle \hat{g}^{jk} \langle c^k \rangle = -2\langle c^1 \rangle \langle c^3 \rangle + 2\langle c^2 \rangle^2 = -2(\langle q^2 \rangle \langle p^2 \rangle - \langle qp \rangle^2), \tag{33.6.120}$$

which agrees with (5.6). If we look at (6.120) from a group-theory perspective, we see that the quantities $\hat{g}^{jk}$ are the $Sp(2)$ Clebsch-Gordan coefficients that couple $\Gamma(2)$ and $\Gamma(2)$ down to $\Gamma(0)$.

There is one further proof of the invariance of I as given by (5.5), actually of ϵ^2 as given by (5.6), that historically probably came first. Begin by verifying, in the case of a two-dimensional phase space, that the second-order moment matrix Z has the form

$$Z = \begin{pmatrix} \langle q^2 \rangle & \langle qp \rangle \\ \langle qp \rangle & \langle p^2 \rangle \end{pmatrix}. \tag{33.6.121}$$

Consequently, the determinant of Z has the value

$$\det Z = \langle q^2 \rangle \langle p^2 \rangle - \langle qp \rangle^2 = \epsilon^2. \tag{33.6.122}$$

Next look at the transformation rule (6.10) in the two-dimensional phase space case. Verify that taking the determinant of both sides of (6.10) and recalling Section 3.3.3 give the result

$$\det Z' = \det RZR^T = (\det R)(\det Z)(\det R^T) = \det Z, \tag{33.6.123}$$

thereby demonstrating the invariance of the mean-square emittance in the two-dimensional phase space case.

33.6.2. The aim of this exercise is to show that $I^{(n)}[Z]$ as given by (5.7) is invariant. First, as warmup steps, verify the relations

$$I^{[n]} = 0 \text{ for odd } n, \tag{33.6.124}$$

$$\mathrm{tr}[(ZJ)^n] = \mathrm{tr}[(JZ)^n]. \tag{33.6.125}$$

Deduce from (6.33) that

$$(JZ')^n = [(R^T)^{-1} JZR^T]^n = (R^T)^{-1}(JZ)^n R^T. \tag{33.6.126}$$

Next verify from (6.126) that

$$\mathrm{tr}[(JZ')^n] = \mathrm{tr}[(JZ)^n]. \tag{33.6.127}$$

You have shown that

$$I^{(n)}[Z'] = \mathrm{tr}[(JZ')^n] = \mathrm{tr}[(Jz)^n] = I^{(n)}[Z]. \tag{33.6.128}$$

33.6.3. The aim of this exercise is to prove (6.18) and to remark on one of its consequences. To do so, begin by verifying the following chain of equalities:

$$I^{(n)}[Z] = I^{(n)}[AZA^T] = I^{(n)}[D] = \mathrm{tr}[(DJ)^n] = \mathrm{tr}[(JD)^n]. \tag{33.6.129}$$

Here we have used the invariance of $I^{(n)}$, the relation (6.11), and the relation (6.125). Next use (6.22) to show that

$$(JD)^2 = -\mathrm{diag}\{\lambda_1^2, \lambda_1^2, \lambda_2^2, \lambda_2^2, \lambda_3^2, \lambda_3^2\}, \tag{33.6.130}$$

from which it follows that

$$(JD)^n = (-1)^{n/2}\mathrm{diag}\{\lambda_1^n, \lambda_1^n, \lambda_2^n, \lambda_2^n, \lambda_3^n, \lambda_3^n\}. \tag{33.6.131}$$

Here we assume n is even since the case of odd n has already been covered in (6.124). Finally, verify that

$$\mathrm{tr}[(JD)^n] = 2(-1)^{n/2}(\lambda_1^n + \lambda_2^n + \lambda_2^n) \tag{33.6.132}$$

thereby proving (6.18).

As a parting comment we remark that, if desired, relations of the form (6.18) can be solved for the λ_j in terms of the $I^{[n]}$, and that the solution is given in terms of radicals for the cases where the phase-space dimension is less than or equal to 8. Find explicit results when the phase-space dimension is 2 or 4.

33.6.4. Let $f(z)$ and $g(z)$ be any two real *polynomial* functions. Such functions form a vector space. By using the phase-space density $h(z)$, which is assumed to fall off sufficiently fast at infinity, define a scalar product (f, g) by the rule

$$(f, g) = (1/N) \int d^6z\; h(z)f(z)g(z). \tag{33.6.133}$$

Verify that (6.133) satisfies all the requirements to be a scalar product including the positive-definite conditions

$$(f, f) \geq 0, \tag{33.6.134}$$

$$(f, f) = 0 \Leftrightarrow f = 0. \tag{33.6.135}$$

Note also that, in terms of moment notation, there is the relation

$$(f, g) = \langle fg \rangle. \tag{33.6.136}$$

Prove the Schwarz inequality in this context, and use it to verity the result (6.57). See Exercise 3.7.1.

33.6.5. Verify (6.62). Let I be the 2×2 identity matrix, and let Z^{11} and A be the matrices (6.61) and (6.63), respectively. Verify the matrix multiplication result

$$AZ^{11}A^T = \epsilon_1 I. \tag{33.6.137}$$

33.6.6. The aim of this exercise is to provide an alternate proof of (6.88).

33.6.7. Suppose Z and Z' are two matrices related by (6.10). Under the assumption that R is nonsingular, but not necessarily symplectic, show that Z' is symmetric and positive definite if the same is true for Z.

A further task is to show that Z^{ABC} is positive definite. First provide a proof along the lines of that in Subsection 6.1. Next $\cdots$.

33.6.8. The purpose of this exercise is to illustrate by a simple example that translation can change an emittance. Consider, for simplicity, the case of a two-dimensional phase space, and suppose a beam initially has the moments

$$\langle q^2 \rangle = \langle p^2 \rangle = \lambda, \tag{33.6.138}$$

$$\langle qp \rangle = \langle q \rangle = \langle p \rangle = 0. \tag{33.6.139}$$

Then the initial mean-square emittance ϵ^2 has the value

$$\epsilon^2 = \lambda^2. \tag{33.6.140}$$

Next consider the effect of a translation that simply augments q by an amount δ. Then, to compute the final emittance, we need the quantities

$$\langle q^2\rangle' = \langle (q+\delta)^2\rangle = \langle (q^2 + 2q\delta + \delta^2)\rangle = \langle q^2\rangle + 2\delta\langle q\rangle + \delta^2 = \lambda + \delta^2, \tag{33.6.141}$$

$$\langle p^2\rangle' = \langle p^2\rangle = \lambda \tag{33.6.142}$$

$$\langle qp\rangle' = \langle (q+\delta)p\rangle = \langle qp\rangle + \delta\langle p\rangle = 0. \tag{33.6.143}$$

From these quantities show that the transformed mean-square emittance is given by the relation

$$(\epsilon^2)' = \langle q^2\rangle'\langle p^2\rangle' - (\langle qp\rangle')^2 = (\lambda + \delta^2)\lambda = \lambda^2 + \delta^2\lambda. \tag{33.6.144}$$

Upon comparing (6.140) and (6.144), we see that the mean-square emittance has been *increased* by an amount $\delta^2\lambda$.

33.7 Construction of Initial Distributions with Small/Optimized Eigen Emittances

33.8 Realization of Eigen Emittances as Mean-Square Emittances

Chapter 34

Optimal Evaluation of Symplectic Maps

34.1 Overview of Symplectic Map Approximation

Several previous chapters have been devoted to the subject of describing, computing, manipulating, and analyzing symplectic maps. This chapter is devoted to the subject of *applying* symplectic maps to phase-space data. That is, we are given a symplectic map $\mathcal{M}$ in some some form and a general phase-space point z, and we wish to find the phase-space point $\bar{z}$ given by

$$\bar{z} = \mathcal{M}z. \tag{34.1.1}$$

This task is more difficult and more complicated than one might suppose.

In practice, generally the only symplectic maps we can deal with in an explicit way are *truncated* Taylor series of the form (7.5.5) or (7.6.1) or (7.7.13). These Taylor series will obey the symplectic condition to the order through they have been calculated, i.e. they are symplectic jets.[1] But usually they will fail to obey the symplectic condition exactly because of the missing higher-order terms. Of course, we can always make the Lie factorization (7.7.23) and then truncate the infinite product at some order. So doing will still yield a symplectic map. However, its evaluation will generally involve summing infinite series of the form (5.4.1) and (5.42). When working numerically, at best these series can be evaluated to machine precision. But usually this is impractical because of the great effort involved if this is to be done very often. Usually we must truncate the Lie series, in which case we are again left with a symplectic jet which generally does not satisfy the symplectic condition exactly.

Put another way, suppose the map $\mathcal{M}$ is factored in the form

$$\mathcal{M} = \exp(:f_1:)\mathcal{R}\mathcal{N} \tag{34.1.2}$$

where

$$\mathcal{N} = \exp(:f_3:)\exp(:f_4:)\exp(:f_5:)\cdots . \tag{34.1.3}$$

Then we can evaluate $\exp(:f_1:)$ exactly because it simply produces a translation, and we can evaluate the linear part $\mathcal{R}$ to produce a matrix R that is symplectic to machine precision

[1] See Section 7.5.

using the methods of Chapter 4. However, there is generally no easy way to evaluate the action of the nonlinear part $\mathcal{N}$. In particular, approximating its action as a jet generally violates the symplectic condition.

Failure to satisfy the symplectic condition exactly may not produce serious errors when tracking particles through *single-pass* systems such as beam lines or electron microscopes or spot forming systems or linear accelerators or linear colliders. However, failure to satisfy the symplectic condition is very serious when one tries to model the long-term behavior of particles in *circulating* devices such as synchrotrons or damping rings or storage rings.

As a simple example, consider the two-dimensional symplectic map $\mathcal{M}$ given by the relation

$$\mathcal{M} = \mathcal{R}\mathcal{N} \tag{34.1.4}$$

with linear part

$$\mathcal{R} = \exp(-(\theta/2) : p^2 + q^2 :) \tag{34.1.5}$$

and nonlinear part

$$\mathcal{N} = \exp(: qp^2 :). \tag{34.1.6}$$

The map $\mathcal{R}$ can be evaluated exactly, see (1.2.48) and (1.2.49). And, thanks to its simplicity, so can the map $\mathcal{N}$. There is the result

$$\bar{q} = \mathcal{N}q = q(1-p)^2, \tag{34.1.7}$$

$$\bar{p} = \mathcal{N}p = p/(1-p). \tag{34.1.8}$$

See Section 1.4.2. Therefore $\mathcal{M}$ can also be evaluated exactly.

Figure 1.1 shows the result of applying $\mathcal{M}$ repeatedly to seven initial conditions for the case $\theta/2\pi = 0.22$. That is, seven initial conditions have been selected and their orbits have been found under the repeated action of $\mathcal{M}$. One initial condition is near the origin, and its orbit appears to lie on a closed curve that is nearly elliptical. (It would be nearly circular had the horizontal and vertical scales been equal.) This is to be expected because the effect of the nonlinear part $\mathcal{N}$ is small on such orbits so that such orbits are essentially those of $\mathcal{R}$. By contrast, the other initial conditions are successively farther from the origin where the effect of $\mathcal{N}$ becomes ever more significant. Their orbits appear to lie on closed curves that, the farther they are from the origin, are more and more noticeably distorted from circular by nonlinearities.

Now suppose the nonlinear map $\mathcal{N}$ is *truncated*, to become the map $\mathcal{N}^{\rm tr}$, by retaining only the first two terms in its Taylor expansion,

$$\mathcal{N}^{\rm tr} = \mathcal{I} + : qp^2 : . \tag{34.1.9}$$

The truncated map $\mathcal{N}^{\rm tr}$ has the effect

$$\bar{q} = \mathcal{N}^{\rm tr}q = (\mathcal{I} + : qp^2 :)q = q + [qp^2, q] = q - 2qp, \tag{34.1.10}$$

$$\bar{p} = \mathcal{N}^{\rm tr}p = (\mathcal{I} + : qp^2 :)p = p + [qp^2, p] = p + p^2. \tag{34.1.11}$$

Evidently $\mathcal{N}^{\rm tr}$ is a degree-two symplectic jet map.

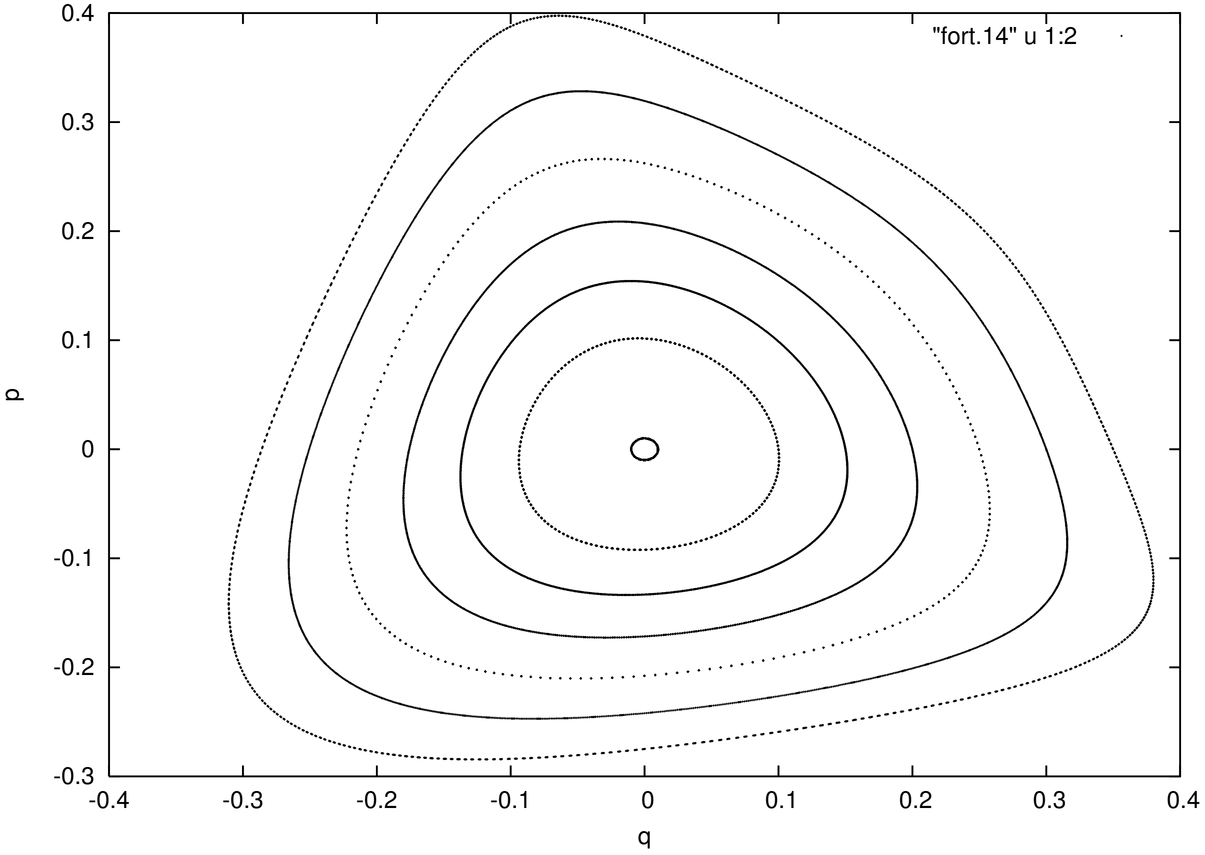

Figure 34.1.1: Phase-space portrait, in the case $\theta/2\pi = 0.22$, resulting from applying the map $\mathcal{M}$ repeatedly (2000 times) to the seven initial conditions $(q,p) = (.01,0)$, $(.1,0)$, $(.15,0)$, $(.2,0)$, $(.25,0)$, $(.3,0)$, and $(.35,0)$ to find their orbits.

Next define a corresponding map $\mathcal{M}^{\rm tr}$ by writing

$$\mathcal{M}^{\rm tr} = \mathcal{R}\mathcal{N}^{\rm tr}. \tag{34.1.12}$$

Figure 1.2 shows the orbits of $\mathcal{M}^{\rm tr}$ for two initial conditions, one near the origin and one quite far away. Inspection of the figure shows that orbits are no longer distorted circles, but instead appear to spiral into the origin. This motion into the origin occurs because $\mathcal{N}^{\rm tr}$, and consequently $\mathcal{M}^{\rm tr}$, is not symplectic. See Exercise 1.1. Indeed, following the discussion of Section 22.1, the map $\mathcal{M}^{\rm tr}$ must have a factorization of the form

$$\begin{aligned}\mathcal{M}^{\rm tr} = \; & \exp(\mathcal{G}_4)\exp(\mathcal{G}_5)\exp(\mathcal{G}_6)\cdots\times \\ & \exp(-(\theta/2) : p^2+q^2 :)\exp(: qp^2 :)\exp(: f_4 :)\exp(: f_5 :)\cdots\end{aligned} \tag{34.1.13}$$

with the non-Hamiltonian vector field $\mathcal{G}_4$ being nonzero.

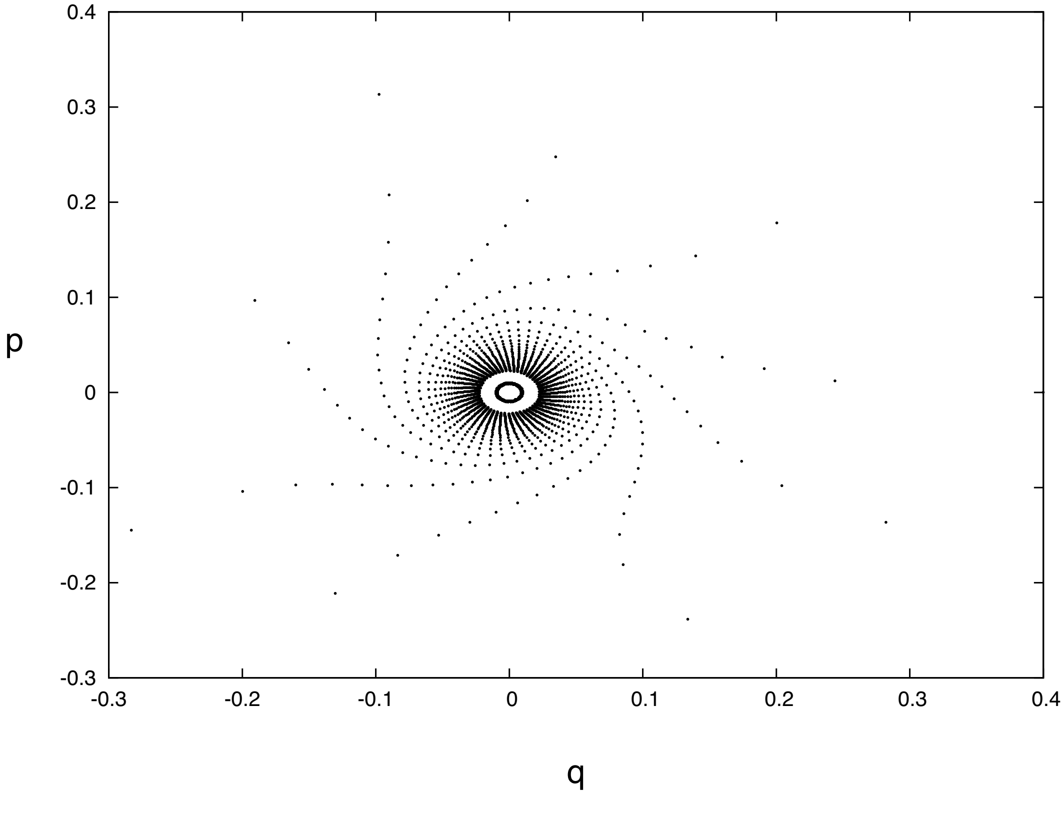

Figure 34.1.2: Phase-space portrait, in the case $\theta/2\pi = 0.22$, resulting from applying the map $\mathcal{M}^{\rm tr}$ repeatedly (2000 times) to the two initial conditions $(q,p) = (.01,0)$ and $(.4,0)$ to find their orbits. The orbits appear to spiral into the origin.

Suppose we also retain the next term in the Lie series for $\exp(: qp^2 :)$ to form the degree-three symplectic jet map

$$\mathcal{N}^{\rm tr3} = \mathcal{I}+ : qp^2 : + : qp^2 :^2 /2. \tag{34.1.14}$$

The truncated map $\mathcal{N}^{\rm tr3}$ has the effect

$$\begin{aligned}\bar{q} &= \mathcal{N}^{\rm tr3}q = (\mathcal{I} + :qp^2: + :qp^2:^2/2)q \\ &= q + [qp^2, q] + [qp^2, [qp^2, q]]/2 = q - 2qp + qp^2, \end{aligned} \tag{34.1.15}$$

$$\begin{aligned}\bar{p} &= \mathcal{N}^{\rm tr3}p = (\mathcal{I} + :qp^2: + :qp^2:^2/2)p \\ &= p + [qp^2, p] + [qp^2, [qp^2, p]]/2 = p + p^2 + p^3. \end{aligned} \tag{34.1.16}$$

Again define a corresponding map $\mathcal{M}^{\rm tr3}$ by writing

$$\mathcal{M}^{\rm tr3} = \mathcal{R}\mathcal{N}^{\rm tr3}. \tag{34.1.17}$$

Figure 1.3 shows the orbits of $\mathcal{M}^{\rm tr3}$ for four initial conditions relatively near the origin. Now orbits move away from the origin. And the farther they are from the origin, the faster they move further away from the origin. Indeed, the orbits of initial conditions somewhat farther from the origin move very far from the origin under 2000 applications of $\mathcal{M}^{\rm tr3}$. This motion away from the origin occurs because $\mathcal{N}^{\rm tr3}$, and consequently $\mathcal{M}^{\rm tr3}$, is again not symplectic, although more nearly symplectic than $\mathcal{N}^{\rm tr}$ because $\mathcal{N}^{\rm tr3}$ is a degree-three symplectic jet whereas $\mathcal{N}^{\rm tr}$ is a degree-two symplectic jet. Now, following the discussion of Section 22.1, the map $\mathcal{M}^{\rm tr3}$ must have a factorization of the form

$$\begin{aligned}\mathcal{M}^{\rm tr3} = \; & \exp(\mathcal{G}_5)\exp(\mathcal{G}_6)\exp(\mathcal{G}_7)\cdots \times \\ & \exp(-(\theta/2):p^2+q^2:)\exp(:qp^2:)\exp(:f_5:)\exp(:f_6:)\cdots \end{aligned} \tag{34.1.18}$$

with the non-Hamiltonian vector field $\mathcal{G}_5$ being nonzero.

We have learned that violation of the symplectic condition can lead both to spurious damping (motion toward the origin) and spurious growth (motion away from the origin).

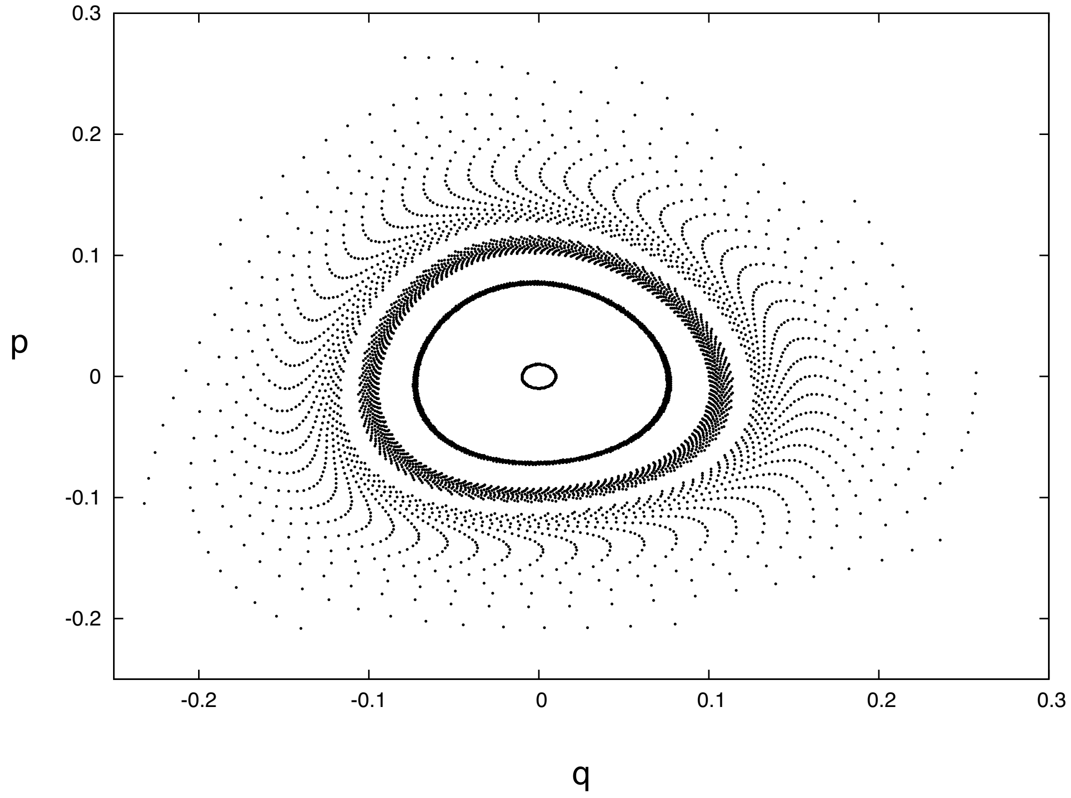

Figure 34.1.3: Phase-space portrait, in the case $\theta/2\pi = 0.22$, resulting from applying the map $\mathcal{M}^{\mathrm{tr3}}$ repeatedly (2000 times) to the four initial conditions $(q,p) = (.01,0)$, $(.075,0)$, $(.1,0)$, and $(.125,0)$ to find their orbits. The orbits appear to move away from origin.

Exercises

34.1.1. Verify that (1.10) and (1.11) are truncated Taylor expansions of (1.7) and (1.8). Show that the map $\mathcal{N}^{\rm tr}$ given by (1.10) and (1.11) satisfies the relation

$$[\bar{q}, \bar{p}] = 1 - 4p^2, \tag{34.1.19}$$

and is therefore a symplectic jet but not a symplectic map.

34.1.2. Find $\mathcal{G}_4$ and f_4 in the factorization (1.13) for the map $\mathcal{M}^{\rm tr}$

34.2.1 Criteria

34.2.2 Monomial Approximation

34.2.3 Generating Function Approximation

34.2.4 Cremona Maps

Kick Approximation

Jolt Approximation

34.3 Connection Between Mixed-Variable Generating Functions and Lie Generators

Sections 6.5 through 6.7 described the parameterization of symplectic maps in terms of mixed-variable generating functions. Chapters 7 through 9 described, among other things, the parameterization of symplectic maps in terms of Lie generators. The purpose of this section is to study the relation between these two parameterizations.

In particular, suppose $\mathcal{N}$ is a *nonlinear* symplectic map of the form

$$\mathcal{N} = \exp(:f_3:)\exp(:f_4:)\exp(:f_5:)\cdots . \tag{34.3.1}$$

Select some Darboux matrix α. Then, generally, there will be some source function $g(u)$ that will produce the same map using (6.7.21). We will see that the source function $g(u)$ has a homogeneous polynomial expansion of the form

$$g = g_2 + g_3 + g_4 + \cdots . \tag{34.3.2}$$

What we wish to do is to find the relation between the f_m and the g_m.

34.3.1 Method of Calculation

The task we have posed is algebraically complicated. As a first step, with the aid of the CBH series, we combine all the exponents appearing in (3.1) into one grand exponent $: e :$. Thus, we may also write

$$\mathcal{N} = \exp(: e :) \tag{34.3.3}$$

with

$$e = e_3 + e_4 + e_5 + \cdots \tag{34.3.4}$$

where

$$\begin{aligned} e_3 &= f_3, \\ e_4 &= f_4, \\ e_5 &= f_5 + [f_3, f_4], \\ e_6 &= f_6 +, \text{ etc.} \end{aligned} \tag{34.3.5}$$

Next define a function h by the rule

$$h = -e = h_3 + h_4 + h_5 + \cdots \tag{34.3.6}$$

so that $\mathcal{N}$ can be written in the form

$$\mathcal{N} = \exp(- : h :). \tag{34.3.7}$$

That is, $\mathcal{N}$ can be viewed as the map generated by integrating from $t = 0$ to $t = 1$ the equations of motion arising from the *time-independent* Hamiltonian h. Our intermediate goal now is to find a relation between the h_m and the g_m.

This goal can be achieved with the aid of the results of Section 6.7.3.2. There we learned that the source function and the Hamiltonian are related by (6.7.131) and (6.7.145). In this instance, we should set $t^i = 0$, $t = 1$, and $H(\zeta, \tau) = h(\zeta)$ to give the result

$$g(u) = g(u, t = 1) = (1/2)(\hat{Z}, \alpha^T S \alpha \hat{Z}) + (1/2)A'(u, t = 1) \tag{34.3.8}$$

with

$$A'(u, t = 1) = \int_0^1 d\tau[(\zeta, J\dot{\zeta}) + 2h(\zeta)]. \tag{34.3.9}$$

It is this result that we will manipulate and evaluate to bring it into usable form.

Let us begin with the first term appearing on the right side of (3.8). For this term we undo (6.7.144) to write

$$(1/2)(\hat{Z}, \alpha^T S \alpha \hat{Z}) = (1/2)(U, u) = (1/2)(u, U) \tag{34.3.10}$$

with

$$U = A^\alpha Z + B^\alpha z. \tag{34.3.11}$$

Now work on $(1/2)A'(u, t = 1)$, the second term on the right side of (3.8). Consider the first term appearing in the integrand of (3.9). We know that $\zeta(\tau)$ is given by the relation

$$\zeta(\tau) = \exp(-\tau : h :)z \tag{34.3.12}$$

and therefore

$$\dot{\zeta} = -\exp(-\tau : h :) : h : z = -\exp(-\tau : h :)[h, z]. \tag{34.3.13}$$

Consequently we find that

$$(\zeta, J\dot{\zeta}) = -(\exp(-\tau : h :)z, J\exp(-\tau : h :)[h, z]) = -\exp(-\tau : h :)(z, J[h, z]). \tag{34.3.14}$$

Let us evaluate $(z, J[h, z])$. In terms of components, and employing the convention of summing over repeated indices, we find that

$$\begin{aligned}(z, J[h, z]) = z_a J_{ab}[h, z_b] &= z_a J_{ab}(\partial h/\partial z_c)J_{cd}(\partial z_b/\partial z_d)\\ &= z_a J_{ab}(\partial h/\partial z_c)J_{cd}\delta_{bd}\\ &= z_a J_{ab}(\partial h/\partial z_c)J_{cb}\\ &= z_a J_{ab}(J^T)_{bc}(\partial h/\partial z_c)\\ &= z_a(JJ^T)_{ac}(\partial h/\partial z_c)\\ &= z_a(\partial h/\partial z_a).\end{aligned} \tag{34.3.15}$$

The right side of (3.15) cries out for Euler's homogeneous function theorem. By this theorem, for each homogeneous component appearing in (3.6), we have the result

$$z_a(\partial h_m/\partial z_a) = m h_m. \tag{34.3.16}$$

Therefore we may also write

$$(z, J[h, z]) = \sum_{m=3}^{\infty} m h_m. \tag{34.3.17}$$

It follows that

$$(\zeta, J\dot{\zeta}) = -(\exp(-\tau : h :)\sum_{m=3}^{\infty} m h_m. \tag{34.3.18}$$

We also note that the second term appearing in the integrand of (3.9) can be rewritten in the form

$$2h(\zeta) = 2h(\exp(-\tau : h :)z) = 2\exp(-\tau : h :)h(z). \tag{34.3.19}$$

Consequently, the full integrand can be rewritten as

$$(\zeta, J\dot{\zeta}) + 2h(\zeta) = \exp(-\tau : h :)\sum_{m=3}^{\infty}(2-m)h_m. \tag{34.3.20}$$

Correspondingly, the integral takes the form

$$A'(u, t = 1) = \int_0^1 d\tau[\exp(-\tau : h :)\sum_{m=3}^{\infty}(2-m)h_m. \tag{34.3.21}$$

Since the τ behavior has been isolated, this integral can be evaluated to give the result

$$A'(u, t = 1) = \mathrm{iex}(- : h :)\sum_{m=3}^{\infty}(2-m)h_m. \tag{34.3.22}$$

We can now put all our results together to obtain the relation

$$g(u) = (1/2)(u, U) + (1/2)\text{iex}(- : h :) \sum_{m=3}^{\infty} (2 - m)h_m. \tag{34.3.23}$$

Recall the relation (6.7.18), which can be rewritten in the form

$$u = C^\alpha Z + D^\alpha z = C^\alpha \mathcal{N} z + D^\alpha z = C^\alpha \exp(- : h :)z + D^\alpha z. \tag{34.3.24}$$

This relation is to solved to give z in terms of u. This $z(u)$ must then be substituted into the right side of (3.23) to yield $g(u)$. Finally, g must be expanded in homogeneous polynomials as in (3.2).

34.3.2 Computing g_2

We begin with the computation g_2. The relation (3.24) has the expansion

$$\begin{aligned} u &= C^\alpha \exp(- : h :)z + D^\alpha z = C^\alpha(\mathcal{I} - : h : + \cdots)z + D^\alpha z \\ &= (C^\alpha + D^\alpha)z + C^\alpha(- : h : + \cdots)z. \end{aligned} \tag{34.3.25}$$

Thus, because the quantity $[(- : h : + \cdots)z]$ consists of terms that are of order 2 and higher, the expansion (3.24) has the inverse expansion

$$z = z^{(1)}(u) + O(u^2) \tag{34.3.26}$$

with

$$z^{(1)}(u) = (C^\alpha + D^\alpha)^{-1}u. \tag{34.3.27}$$

Observe that the second set of terms on the right side of (3.23) is of order 3 and higher in z. It follows that second set of terms contributes only terms of order u^3 and higher. Therefore second degree terms, the ones required for g_2, can only come from the quantity $(1/2)(u, U)$, the first term on the right side of (3.23). We have from (3.11) the expansion

$$\begin{aligned} U &= A^\alpha Z + B^\alpha z = A^\alpha \mathcal{N} z + B^\alpha z \\ &= A^\alpha \exp(- : h :)z + B^\alpha z = A^\alpha(\mathcal{I} - : h : + \cdots)z + B^\alpha z \\ &= (A^\alpha + B^\alpha)z + A^\alpha(- : h : + \cdots)z \\ &= (A^\alpha + B^\alpha)z + O(z^2). \end{aligned} \tag{34.3.28}$$

Next substitute (3.26) and (3.27) into (3.28) to yield the expansion

$$U = (A^\alpha + B^\alpha)(C^\alpha + D^\alpha)^{-1}u + O(u^2). \tag{34.3.29}$$

Also observe that the matrix product appearing in (3.29) can be written in the Möbius transformation form

$$(A^\alpha + B^\alpha)(C^\alpha + D^\alpha)^{-1} = (A^\alpha I + B^\alpha)(C^\alpha I + D^\alpha)^{-1} = T_\alpha(I). \tag{34.3.30}$$

Therefore (3.29) can be rewritten as

$$U = Wu + O(u^2) \tag{34.3.31}$$

with

$$W = T_\alpha(I), \tag{34.3.32}$$

and it follows that

$$(1/2)(u, U) = (1/2)(u, Wu) + O(u^3). \tag{34.3.33}$$

Thus we have the result

$$g_2(u) = (1/2)(u, Wu), \tag{34.3.34}$$

which is what we should have expected. Consult Exercise 6.7.1. We see that W is well defined provided

$$\det(C^\alpha + D^\alpha) \neq 0, \tag{34.3.35}$$

which was also required to write (3.27).

34.3.3 Low Order Results: Computing g_3 and g_4

Let us push on to compute g_3 and g_4. To do so, we will need to retain various higher-order terms in the expressions we have already encountered. We might think that we need to retain higher order terms in (3.25) or (3.26), in (3.28), and in the second term on the right side of (3.23). In fact, this would be one way to proceed. However, at this stage, it is also possible to avoid dealing with (3.28) entirely, thereby achieving a considerable simplification.

Again Euler comes to the rescue. We thought we had to deal with (3.28) because it appeared to be needed to compute the first term on the right side of (3.23), namely $(1/2)(u, U)$. However, using (6.7.14), we may write

$$(u, U) = \sum_a u_a(\partial g/\partial u_a). \tag{34.3.36}$$

Therefore, if we decompose g into homogeneous polynomials as in (3.2) by writing

$$g = \sum_{n=2}^{\infty} g_n, \tag{34.3.37}$$

we find by Euler's theorem the result

$$(1/2)(u, U) = (1/2)\sum_a u_a(\partial g/\partial u_a) = (1/2)\sum_{n=2}^{\infty}\sum_a u_a(\partial g_n/\partial u_a) = (1/2)\sum_{n=2}^{\infty} n g_n. \tag{34.3.38}$$

Moreover, we find that

$$g - (1/2)(u, U) = \sum_{n=2}^{\infty}(1 - n/2)g_n. \tag{34.3.39}$$

Consequently, when (6.7.14) is taken into account, the defining relation (3.23) can also be written in the form

$$\sum_{n=3}^{\infty}(2-n)g_n = \text{iex}(-:h:)\sum_{m=3}^{\infty}(2-m)h_m. \tag{34.3.40}$$

It is this form that we will employ to compute g_3 and g_4.

We must still retain higher-order terms in (3.25). Doing so gives the result

$$\begin{aligned} u &= (C^\alpha + D^\alpha)z + C^\alpha(-:h:+:h:^2/2!+\cdots)z \\ &= (C^\alpha + D^\alpha)z + C^\alpha(-:h_3:+:h_3:^2/2!-:h_4:+\cdots)z \\ &= (C^\alpha + D^\alpha)z + C^\alpha(-[h_3,z]+(1/2)[h_3,[h_3,z]]-[h_4,z]+\cdots). \end{aligned} \tag{34.3.41}$$

Let us rewrite this relation in the implicit form

$$z = (C^\alpha + D^\alpha)^{-1}u - (C^\alpha + D^\alpha)^{-1}C^\alpha\{-[h_3,z]+(1/2)[h_3,[h_3,z]]-[h_4,z]+\cdots\}. \tag{34.3.42}$$

We can now invert the relation by iteration. In lowest order we have the results (3.26) and (3.27). In next order, we find

$$z = z^{(2)}(u) + O(u^3). \tag{34.3.43}$$

with

$$z^{(2)}(u) = (C^\alpha + D^\alpha)^{-1}u - (C^\alpha + D^\alpha)^{-1}C^\alpha\{-[h_3,z]\}|_{z=z^{(1)}}. \tag{34.3.44}$$

Also, we need to expand the right side of (3.40). Through terms of degree 4 we have the result

$$\begin{aligned} \text{iex}(-:h:)\sum_{m=3}^{\infty}(2-m)h_m &= (\mathcal{I}-:h:/2+\cdots)(-h_3-2h_4-\cdots) \\ &= -h_3-2h_4+O(z^5). \end{aligned} \tag{34.3.45}$$

Next we need to express both sides of (3.45) as functions of u using (3.26) and (3.43). Doing so we find the result

$$\{\text{iex}(-:h:)\sum_{m=3}^{\infty}(2-m)h_m\}|_{z=z^{(2)}} = -(h_3)|_{z=z^{(2)}} - 2(h_4)|_{z=z^{(1)}} + O(u^5). \tag{34.3.46}$$

Note that because $z^{(2)}(u)$ contains quadratic terms in u, see (3.44), the first quantity on the right of (3.46) will contribute terms that are both of degree 3 and 4 in u. Let us see what they are. Rewrite (3.44) in the form

$$z^{(2)}(u) = z^{(1)}(u) + \Delta \tag{34.3.47}$$

where

$$\Delta = -(C^\alpha + D^\alpha)^{-1}C^\alpha\{-[h_3,z]\}|_{z=z^{(1)}}. \tag{34.3.48}$$

With this notation, and inspired by Taylor, we find the result

$$(h_3)|_{z=z^{(2)}} = h_3(z^{(1)}+\Delta) = h_3(z^{(1)}) + \sum_a \Delta_a(\partial h_3/\partial z_a)|_{z=z^{(1)}} + O(\Delta^2). \tag{34.3.49}$$

Also, the quantity $[h_3, z]$ appearing in Δ can be evaluated,

$$\begin{aligned} [h_3, z_a] &= \sum_{bc} (\partial h_3/\partial z_b) J_{bc} (\partial z_a/\partial z_c) = \sum_{bc} (\partial h_3/\partial z_b) J_{bc} \delta_{ac} \\ &= \sum_b (\partial h_3/\partial z_b) J_{ba} = -\sum_b J_{ab} (\partial h_3/\partial z_b). \end{aligned} \qquad (34.3.50)$$

This result can be written more compactly in vector notation as

$$[h_3, z] = -J(\partial h_3/\partial z). \qquad (34.3.51)$$

Correspondingly, Δ takes the more compact form

$$\Delta = K(\partial h_3/\partial z) \qquad (34.3.52)$$

where K is the matrix

$$K = -(C^\alpha + D^\alpha)^{-1} C^\alpha J. \qquad (34.3.53)$$

Finally, (3.49) takes the compact form

$$(h_3)|_{z=z^{(2)}} = (h_3)|_{z=z^{(1)}} + ((\partial h_3/\partial z), K(\partial h_3/\partial z))|_{z=z^{(1)}} + O(u^5), \qquad (34.3.54)$$

and (3.46) becomes

$$\begin{aligned} \{\mathrm{iex}(- : h :) \sum_{m=3}^{\infty} (2-m) h_m\}|_{z=z^{(2)}} &= -(h_3)|_{z=z^{(1)}} - ((\partial h_3/\partial z), K(\partial h_3/\partial z))|_{z=z^{(1)}} \\ &\quad -2(h_4)|_{z=z^{(1)}} + O(u^5). \end{aligned} \qquad (34.3.55)$$

Now we are ready to equate terms of like degree in (3.40). Equating terms of degree 3 gives the result

$$-g_3(u) = -h_3(z)|_{z=z^{(1)}}, \qquad (34.3.56)$$

or

$$g_3(u) = h_3(z)|_{z=z^{(1)}}. \qquad (34.3.57)$$

And equating terms of degree 4 gives the result

$$-2g_4(u) = -((\partial h_3/\partial z), K(\partial h_3/\partial z))|_{z=z^{(1)}} - 2h_4(z)|_{z=z^{(1)}} \qquad (34.3.58)$$

or

$$g_4(u) = (1/2)((\partial h_3/\partial z), K(\partial h_3/\partial z))|_{z=z^{(1)}} + h_4(z)|_{z=z^{(1)}} \qquad (34.3.59)$$

In terms of the f_m, these relations can be written in the form

$$g_3(u) = -f_3(z)|_{z=z^{(1)}}, \qquad (34.3.60)$$

$$g_4(u) = (1/2)((\partial f_3/\partial z), K(\partial f_3/\partial z))|_{z=z^{(1)}} - f_4(z)|_{z=z^{(1)}}. \qquad (34.3.61)$$

34.3.4 Two Examples

Eventually we will want to find higher-order results to determine the $g_n(u)$ for, say, $n \leq 8$ and some select Darboux matrices α. Before doing so, let us see what can be said so far for familiar choices of α. If we look at the Darboux α matrices for the generating functions F_1 and F_4, see Table 6.7.1, we observe that the matrices $(C^\alpha + D^\alpha)$ are singular. Hence these Darboux matrices cannot be used for our purposes. By contrast, the matrices $(C^\alpha + D^\alpha)$ for the three Darboux matrices associated with F_2, F_3, and F_+ are invertible. We will study the cases of F_2 and F_+. The case of F_3 is similar to that of F_2.

The Case of F_2

First consider the case of F_2. We find from (6.7.56) that

$$C^\alpha + D^\alpha = I^{2n} \tag{34.3.62}$$

and

$$C^\alpha = \begin{pmatrix} 0 & 0 \\ 0 & I^n \end{pmatrix}. \tag{34.3.63}$$

It follows from (3.27) that

$$z^{(1)}(u) = u. \tag{34.3.64}$$

Also, from (6.7.55) and (3.32), we find that

$$W = \begin{pmatrix} 0 & I^n \\ I^n & 0 \end{pmatrix}. \tag{34.3.65}$$

Finally, from (3.41), (3.47), and (3.63), we find that

$$K = -C^\alpha J = \begin{pmatrix} 0 & 0 \\ I^n & 0 \end{pmatrix}. \tag{34.3.66}$$

We are now ready to compute $g_2(u)$ through $g_4(u)$. As in Exercise 6.7.5, partition u into position-like and momentum-like components by writing

$$u = (v; w). \tag{34.3.67}$$

Then, from (3.42), (3.48), and (3.49) we have for $g_2(u)$ the result

$$g_2(u) = (v, w), \tag{34.3.68}$$

which can also be written in the form

$$g_2(u) = (q, p)|_{z=u}. \tag{34.3.69}$$

Next, from (3.45) and (3.47), we find that

$$g_3(u) = -f_3(u). \tag{34.3.70}$$

Finally, from (3.46), (3.47), and taking into account the form of K given by (3.49), we find the results

$$g_4(u) = -f_4(u) + (1/2)(\partial f_3/\partial q, \partial f_3/\partial p)|_{z=u}. \tag{34.3.71}$$

The Case of F_+

Next consider the case of F_+. We find from (6.7.67) that

$$C^\alpha + D^\alpha = \sqrt{2} I^{2n} \tag{34.3.72}$$

and

$$C^\alpha = (1/\sqrt{2}) I^{2n}. \tag{34.3.73}$$

It follows that in this case

$$z^{(1)}(u) = (1/\sqrt{2})u. \tag{34.3.74}$$

Also, from (6.7.67) and (3.15), we find that

$$W = 0. \tag{34.3.75}$$

Finally, from (3.41), (3.55), and (6.7.67), we find that

$$K = -(1/2)J. \tag{34.3.76}$$

We are again ready to compute $g_2(u)$ through $g_4(u)$. From (3.42) and (3.56) we find that

$$g_2(u) = 0. \tag{34.3.77}$$

Next, from (3.45) and (3.55), we find that

$$g_3(u) = -f_3(u/\sqrt{2}). \tag{34.3.78}$$

Finally we observe from (3.57) that

$$((\partial f_3/\partial z), K(\partial f_3/\partial z)) = -(1/2)((\partial f_3/\partial z), J(\partial f_3/\partial z)) = 0 \tag{34.3.79}$$

since J is an antisymmetric matrix. It follows from (3.46) and (3.60) that in this case g_4 takes the simple form

$$g_4(u) = -f_4(u/\sqrt{2}). \tag{34.3.80}$$

34.3.5 Exploration

Let us explore what maps are produced when the source function consists only of quadratic and cubic terms,

$$g(u) = g_2(u) + g_3(u). \tag{34.3.81}$$

For simplicity, we will explore only the use of F_2 and F_+ generating functions, and work with only a two-dimensional phase space so that $z = (q; p)$ and $Z = (Q; P)$.

Use of F_2

General Discussion

Let us begin with the use of F_2. In that case, we will consider generating functions of the form

$$F_2(q,P) = qP + aq^3 + bq^2P + cqP^2 + dP^3 \tag{34.3.82}$$

with arbitrary coefficients a through d. Then use of (6.7.54) produces the implicit relations

$$p = P + 3aq^2 + 2bqP + cP^2, \tag{34.3.83}$$

$$Q = q + bq^2 + 2cqP + 3dP^2. \tag{34.3.84}$$

Since these equations are quadratic, they can be solved exactly, and we will do so shortly. First, however, let us find the first few terms in the Taylor expansions of $Q(q,p)$ and $P(q,p)$ in powers of q and p. Rewrite (3.64) in the form

$$P = p - 3aq^2 - 2bqP - cP^2. \tag{34.3.85}$$

Now we can expand Q and P in powers of q and p by iteration of (3.65) and (3.66). In lowest approximation, they have the solution

$$Q = q + O(z^2), \tag{34.3.86}$$

$$P = p + O(z^2). \tag{34.3.87}$$

Now substitute (3.67) and (3.68) into (3.65) and (3.66) to get the improved solution

$$Q = q + bq^2 + 2cqp + 3dp^2 + O(z^3), \tag{34.3.88}$$

$$P = p - 3aq^2 - 2bqp - cp^2 + O(z^3) \tag{34.3.89}$$

For our present purposes we will be content with expansions that retain terms through degree three. This can be achieved by substituting (3.69) and (3.70) into (3.65) and (3.66). Doing so gives the results

$$Q = q + bq^2 + 2cqp + 3dp^2 + *q^3 + *q^2p + *qp^2 + *p^3 + O(z^4), \tag{34.3.90}$$

$$P = p - 3aq^2 - 2bqp - cp^2 + *q^3 + *q^2p + *qp^2 + *p^3 + O(z^4). \tag{34.3.91}$$

For comparison, let us evaluate the Taylor series for the transformation

$$Z = \mathcal{N}z \tag{34.3.92}$$

where

$$\mathcal{N} = \exp(:f_3:) \tag{34.3.93}$$

with

$$f_3(z) = -aq^3 - bq^2p - cqp^2 - dp^3. \tag{34.3.94}$$

Then it is easily verified that the Lie transformation

$$Z = \exp(:f_3:)z = \sum_{m=0}^{\infty}(1/m!) :f_3:^m z = z + :f_3: z + (1/2!) :f_3:^2 z + O(z^4) \quad (34.3.95)$$

gives the result

$$Q = q + bq^2 + 2cqp + 3dp^2 + *q^3 + *q^2p + *qp^2 + *p^3 + O(z^4), \quad (34.3.96)$$

$$P = p - 3aq^2 - 2bqp - cp^2 + *q^3 + *q^2p + *qp^2 + *p^3 + O(z^4). \quad (34.3.97)$$

We see that the linear and quadratic terms in (3.71) and (3.72) agree with those in (3.77) and (3.78), respectively. However, the cubic terms do not.

These results are to be expected based on the findings of Subsection 27.3.3. There we saw that g_3 and f_3 should be related by (3.53), and that is what has been done in writing (3.63) and (3.76). Therefore the quadratic terms in in (3.71) and (3.72) should agree with those in (3.77) and (3.78). With regard to cubic terms, in writing (3.62) we have implicitly made the requirement

$$g_n(u) = 0 \text{ for } n \geq 4. \quad (34.3.98)$$

And, in writing (3.74), we have implicitly made the requirement

$$f_n(z) = 0 \text{ for } n \geq 4. \quad (34.3.99)$$

But we see from (3.54) that in general these requirements are incompatible. Therefore we expect differences in the cubic (and higher-order) terms.

As promised, let us now solve the relations (3.65) and (3.66) exactly. We must distinguish two cases:

The Case When $c = 0$

If $c = 0$, (3.66) has the immediate solution

$$P = (p - 3aq^2)/(2bq + 1). \quad (34.3.100)$$

And substituting this result into (3.65) gives the complementary result

$$Q = q + bq^2 + 3d(p - 3aq^2)^2/(2bq + 1)^2. \quad (34.3.101)$$

The Case When $c \neq 0$

When $c \neq 0$, the relation (3.66) is quadratic in P and has the solution

$$P = [1/(2c)]\{-(2bq + 1) + [(2bq + 1)^2 + 4c(p - 3aq^2)]^{1/2}\}. \quad (34.3.102)$$

The implicit relation (3.64) can be solved to give the explicit relation

$$P = [1/(2c)]\{-(1 + 2bq) + [1 + 4bq + cp + 3(b^2 - 4ac)q^2]^{1/2}\}. \quad (34.3.103)$$

And (3.81) can then be substituted into (3.65) to give the complementary explicit relation

$$Q = . \tag{34.3.104}$$

We see that, as functions of q and p, Q and P *generically* have branch points.[2] They occur on the surface

$$1 + 4bq + cp + 3(b^2 - 4ac)q^2 = 0. \tag{34.3.105}$$

By contrast, we know from the work of Section 25.3 that the map given by (3.73) and (3.74) generally has poles.

Case When Only $a \neq 0$

Let us consider some special cases. First suppose that only $a \neq 0$. Then the Lie transformation series (3.76) terminates and gives the exact result

$$Q = q, \tag{34.3.106}$$

$$P = p - 3aq^2. \tag{34.3.107}$$

Also, in this case, solution of the implicit relations (3.64) and (3.65) gives identical results. Thus in this case, which is easily verified to be that of a kick map, the use of F_2 and the exact Lie transformation give the same result. It is an easy calculation to show that the same holds true when only $d \neq 0$.

Jolt Case

Next assume that f_3 is of the form

$$f_3 = (\alpha q - \beta p)^3 \tag{34.3.108}$$

which amounts to setting

$$a = -\alpha^3, \tag{34.3.109}$$

$$b = 3\alpha^2\beta, \tag{34.3.110}$$

$$c = -3\alpha\beta^2, \tag{34.3.111}$$

$$d = \beta^3. \tag{34.3.112}$$

Then it is easily verified that the Lie transformation series (3.76) also terminates and gives the exact result

$$Q = q + 3\beta(\alpha q - \beta p)^2, \tag{34.3.113}$$

$$P = p + 3\alpha(\alpha q - \beta p)^2. \tag{34.3.114}$$

See Section 22.3. In fact, $\mathcal{N}$ in this case is a jolt map. See Exercise *. By contrast, solution of the implicit relations (3.64) and (3.65) in this case gives the results

$$Q =, \tag{34.3.115}$$

[2] However.

$$P = . \qquad (34.3.116)$$

We see that the Q and P given by (3.91) and (3.92) are entire functions of q and p. By contrast, the relations (3.93) and (3.94) show that the map produced by F_2 in this case has branch points. They are located on the surface

$$= . \qquad (34.3.117)$$

Case When Only $c \neq 0$

As another example, suppose f_3 is of the form

$$f_3 = -cqp^2 \qquad (34.3.118)$$

as in (1.6). So doing amounts to assuming that only $c \neq 0$ in (3.75). As already seen, setting $c = -1$ in (3.73) and (3.74) leads to the relation

$$Q = \mathcal{N}q = q(1-p)^2, \qquad (34.3.119)$$

$$P = \mathcal{N}p = p/(1-p). \qquad (34.3.120)$$

By contrast, the implicit equations (3.64) and (3.65) in this case have the explicit solution

$$Q = q(1+4cp)^{1/2}, \qquad (34.3.121)$$

$$P = [1/(2c)][(1+4cp)^{1/2} - 1]. \qquad (34.3.122)$$

We see that in this case the map produced by F_2 has a branch point (when $c = -1$) on the surface $p = 1/4$ while, according to (3.98), the exact Lie transformation map has a pole on the surface $p = 1$.

The last case to be considered in this vein is that of $b \neq 0$ and all other coefficients in (3.63) or (3.75) set to zero. You, dear reader, will have the pleasure of doing so in Exercise *.

F_2 Symplectic Completion of $\mathcal{N}^{\rm tr}$

Let $\mathcal{N}^{\rm sc}$ be the map given by (3.99) and (3.100) when $c = -1$. We may view $\mathcal{N}^{\rm sc}$ as a *symplectic completion* of the degree-two symplectic jet map $\mathcal{N}^{\rm tr}$ given by (1.9). Corespondingly, we define the associated map $\mathcal{M}^{\rm sc}$ by the relation

$$\mathcal{M}^{\rm sc} = \mathcal{R}\mathcal{N}^{\rm sc}. \qquad (34.3.123)$$

Figure 3.1 shows the result of applying $\mathcal{M}^{\rm sc}$ repeatedly to four initial conditions for the case $\theta/2\pi = 0.22$. Note that, unlike the cases of Figures 1.2 and 1.3, points on the orbit no longer spiral into or out of the origin. Moreover, the behavior of the orbits is similar to that shown in Figure 1.1.

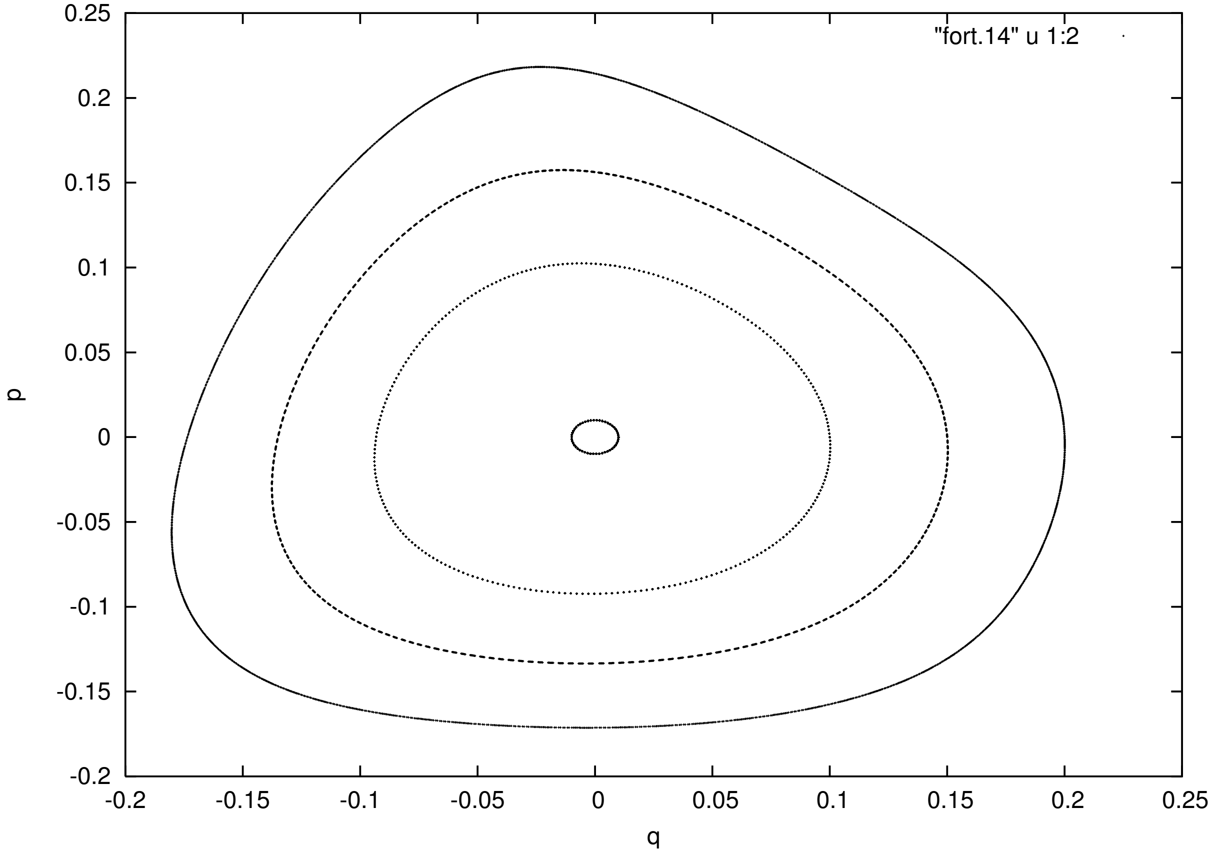

Figure 34.3.1: Phase-space portrait, in the case $\theta/2\pi = 0.22$, resulting from applying the map $\mathcal{M}^{\rm sc}$ repeatedly (2000 times) to the four initial conditions $(q,p) = (.01,0)$, $(.1,0)$, $(.15,0)$, and $(.2,0)$ to find their orbits.

Root Trick

Of course, we know that in this case use of $\mathcal{N}^{\rm sc}$ can at best make sense for $|p| < 1/4$. What can be done for points farther from the origin? For a map of the form (3.3) we can easily extract a square root. In accord with the relation (3.6), we will write

$$\mathcal{N}^{1/2} = \mathcal{N}(1/2). \tag{34.3.124}$$

Also, let $\mathcal{N}^{\rm sc}(1/2)$ denote the map given by (3.99) and (3.100) with $c = -1/2$. We may view $\mathcal{N}^{\rm sc}(1/2)$ as the F_2 symplectification of the degree-two jet map $\mathcal{N}^{\rm tr}(1/2)$. We see, from (3.99) and (3.100) with $c = -1/2$, that the map $\mathcal{N}^{\rm sc}(1/2)$ is well defined for $|p| < 1/2$.

Now watch closely. We know that

$$\mathcal{M} = \mathcal{R}\mathcal{N}^{1/2}\mathcal{N}^{1/2}. \tag{34.3.125}$$

Therefore, it makes sense to consider what we will call the *improved symplectically completed* map $\mathcal{M}^{\rm isc}$ defined by the relation

$$\mathcal{M}^{\rm isc} = \mathcal{R}\mathcal{N}^{\rm sc}(1/2)\mathcal{N}^{\rm sc}(1/2). \tag{34.3.126}$$

This map will be defined over a larger region of phase space and will be a better approximation to $\mathcal{M}$. Figure 3.2 shows the result of applying $\mathcal{M}^{\rm isc}$ repeatedly to seven initial conditions for the case $\theta/2\pi = 0.22$. Again points on the orbits neither spiral into or out of the origin, and the orbits more nearly approximate those of Figure 1.1.

Use of the Poincaré Generating Function F_+

General Discussion

We now repeat much of the work above, but this time for the case where F_+ is used. Now (3.58) holds and, in accord with (3.59), the source function g_3 will have the form

$$g_3(u) = (1/\sqrt{2})^3(av^3 + bv^2w + cvw^2 + dw^3). \tag{34.3.127}$$

In this case use of (6.7.21) with α given by (6.7.67) gives the implicit relations

$$Q = q + (1/4)[b(Q + q)^2 + 2c(Q + q)(P + p) + 3d(P + p)^2], \tag{34.3.128}$$

$$P = p - (1/4)[3a(Q + q)^2 + 2b(Q + q)(P + p) + c(P + p)^2]. \tag{34.3.129}$$

Since these equations are quadratic, they can again be solved exactly. However, the solutions are far too long to record. In section 3.5 we will see they again involve square roots, and therefore the functions $Q(q, p)$ and $P(q, p)$, like the F_2 case, have square root branch-point singularities.

But, again, we can obtain Taylor expansions of Q and P in terms if q and p by iteration. Doing so gives, as first and second passes, the expansions (3.67) through (3.70). And the third pass gives the expansions (3.77) and (3.78). That is, unlike the F_2 case, use of F_+ gives expansions that agree with the exact result through terms of third order.

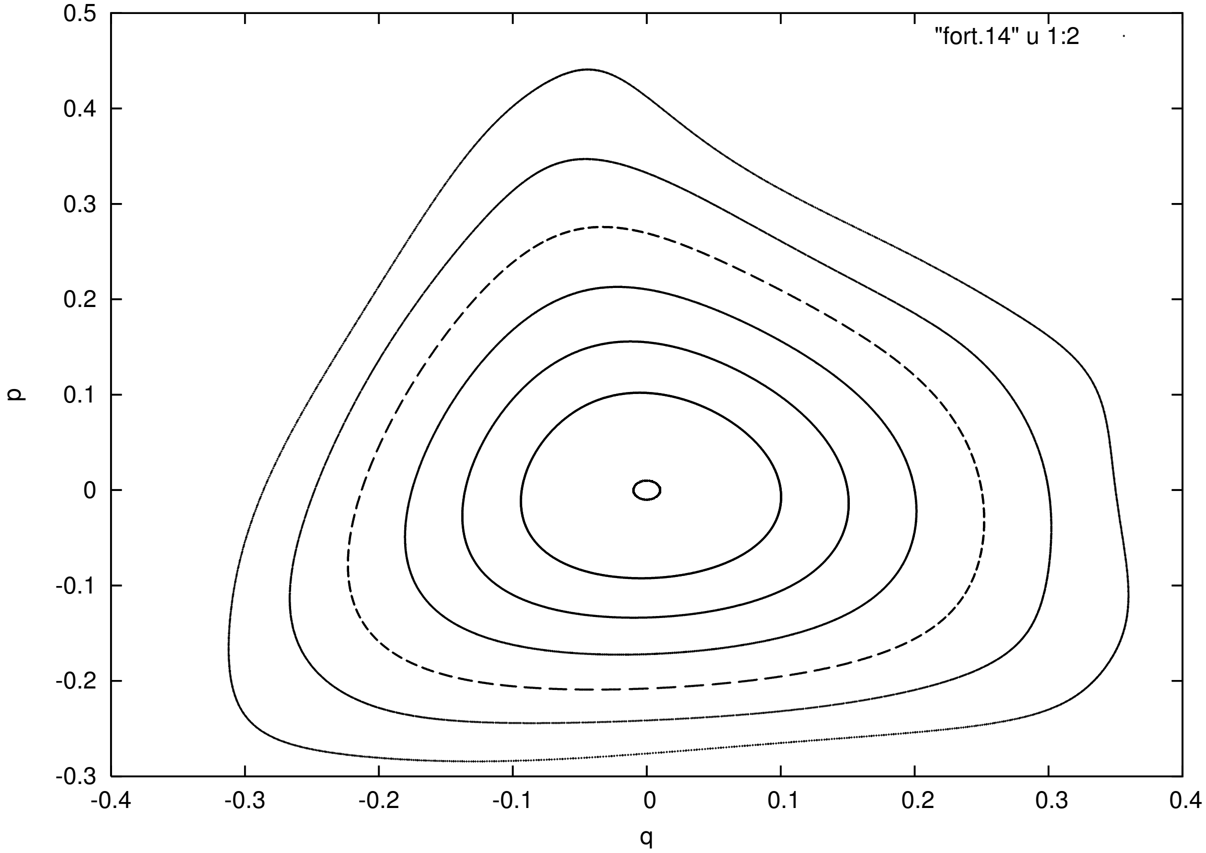

Figure 34.3.2: Phase-space portrait, in the case $\theta/2\pi = 0.22$, resulting from applying the map $\mathcal{M}^{\rm isc}$ repeatedly (2000 times) to the seven initial conditions $(q,p) = (.01,0)$, $(.1,0)$, $(.15,0)$, $(.2,0)$, $(.25,0)$, $(.3,0)$, and $(.35,0)$ to find their orbits.

This accuracy is again to be expected based on the findings of Subsection 27.3.3. There we saw that g_3 and f_3 should be related by (3.59), and that is what has been done in writing (3.105). Therefore the maps produced by the use of F_+ should agree with those produced by the $\mathcal{N}$ given by (3.73) through quadratic terms. With regard to cubic terms, we see from (3.61) that the implicit assumptions (3.79), which are still in effect, imply that f_4 vanishes. Therefore, the cubic terms must also agree. Later we will see that quartic and higher-order terms need not agree.

Cases When Only a or $d \neq 0$

Let us again consider some special cases. First suppose that only $a \neq 0$. Then (3.106) and (3.107) can be solved immediately to give the results (3.84) and (3.85). And if only $d \neq 0$, (3.106) and (3.107) have the solution

$$Q = q + 3dp^2, \tag{34.3.130}$$

$$P = p. \tag{34.3.131}$$

Thus, like F_2, use of F_+ also gives exact results for kick maps.

Jolt Case

Suppose the values of a through d given by (3.114) through (3.117) are employed in (3.106) and (3.107); and that also the quantities Q and P appearing in (3.106) and (3.107) are replaced by the right sides of equations (3.91) and (3.92). Upon doing so one finds that the resulting two equations (which now involve only the quantities α, β, q, and p) are satisfied *identically* for all values of α, β, q, and p. It follows that, unlike the case of F_2, the use of F_+ gives exact results for jolt maps as well. Why this should be so is explained in a subsequent section.

Case When Only $c \neq 0$

If only $c \neq 0$, (3.106) and (3.107) have the solution

$$Q = q(1 + 2cp)^{1/2}/[2 - (1 + 2cp)^{1/2}], \tag{34.3.132}$$

$$P = -[p + (2/c)] + (2/c)(1 + 2cp)^{1/2}. \tag{34.3.133}$$

We see that in this case use of F_+ produces a map that has a branch point on the surface

$$p = -1/(2c). \tag{34.3.134}$$

By contrast, according to (3.100), use of F_2 in this case produces a map that has a branch point on the surface

$$p = -1/(4c). \tag{34.3.135}$$

Therefore the branch-point surface for F_+ is farther from the origin than that of F_2. In particular, for $c = -1$, it is located at $p = 1/2$. But note that it is still closer to the origin than the pole of the exact map which, we have seen, is on the surface $p = 1$.

Again the last case to be considered in this vein is that of only $b \neq 0$. This case is treated in Exercise *.

F_+ Symplectic Completion of $\mathcal{N}^{\mathrm{tr}}$

Let $\mathcal{N}^{\mathrm{psc}}$ be the map given by (3.113) and (3.114) when $c = -1$. We may view $\mathcal{N}^{\mathrm{psc}}$ as the *Poincaré symplectic completion* of the degree-two symplectic jet map $\mathcal{N}^{\mathrm{tr}}$ given by (1.9). Corespondingly, we define the associated map $\mathcal{M}^{\mathrm{psc}}$ by the relation

$$\mathcal{M}^{\mathrm{psc}} = \mathcal{R}\mathcal{N}^{\mathrm{psc}}. \tag{34.3.136}$$

Figure 3.3 shows the result of applying $\mathcal{M}^{\mathrm{psc}}$ repeatedly to seven initial conditions for the case $\theta/2\pi = 0.22$. Again there is no spurious spiraling into or out of the origin. Note also that we have been able to apply this map to a larger region of phase space than we could for $\mathcal{N}^{\mathrm{sc}}$. Compare Figures 3.1 and 3.3.

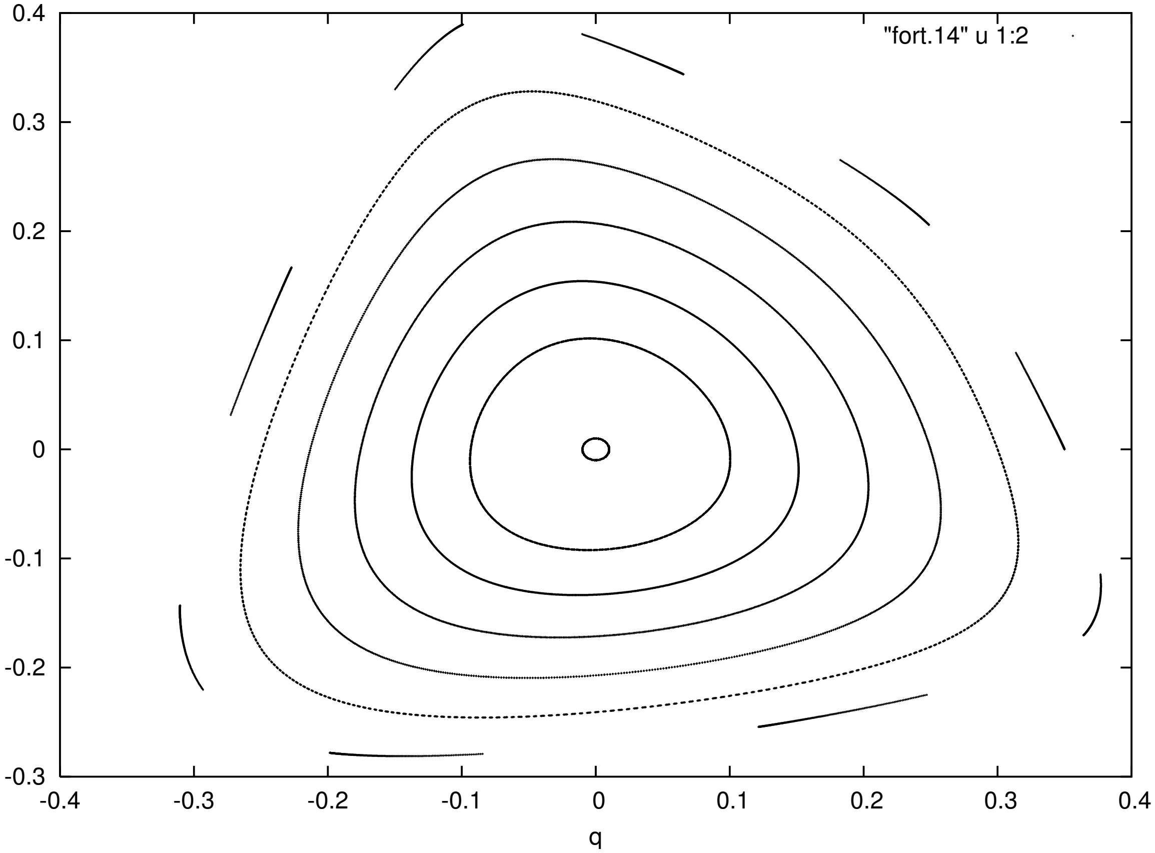

Figure 34.3.3: Phase-space portrait, in the case $\theta/2\pi = 0.22$, resulting from applying the map $\mathcal{M}^{\mathrm{psc}}$ repeatedly (2000 times) to the to the seven initial conditions $(q, p) = (.01, 0)$, $(.1, 0)$, $(.15, 0)$, $(.2, 0)$, $(.25, 0)$, $(.3, 0)$, and $(.35, 0)$ to find their orbits.

Root Trick for F_+

Evidently the root trick can be applied to any symplectification procedure. Here we will explore its use for our example of Poincaré symplectification. Let $\mathcal{N}^{\mathrm{psc}}(1/2)$ denote the map given by (3.113) and (3.114) with $c = -1/2$. We may view $\mathcal{N}^{\mathrm{psc}}(1/2)$ as the F_+

symplectification of the degree-two jet map $\mathcal{N}^{\rm tr}(1/2)$. We see, from (3.115) with $c = -1/2$, that the map $\mathcal{N}^{\rm psc}(1/2)$ has a branch point on the surface $p = 1$, the same surface on which the origin map has a pole. We will now study the behavior of the *improved Poincaré symplectically completed* map $\mathcal{M}^{\rm ipsc}$ defined by the relation

$$\mathcal{M}^{\rm ipsc} = \mathcal{R}\mathcal{N}^{\rm psc}(1/2)\mathcal{N}^{\rm psc}(1/2). \tag{34.3.137}$$

Figure 3.4 shows the result of applying $\mathcal{M}^{\rm ipsc}$ repeatedly to seven initial conditions for the case $\theta/2\pi = 0.22$. We see that now the orbits approximate those of Figure 1.1 remarkably well. Presumably one reason for this improvement is the larger domain of analyticity for $\mathcal{N}^{\rm psc}(1/2)$.

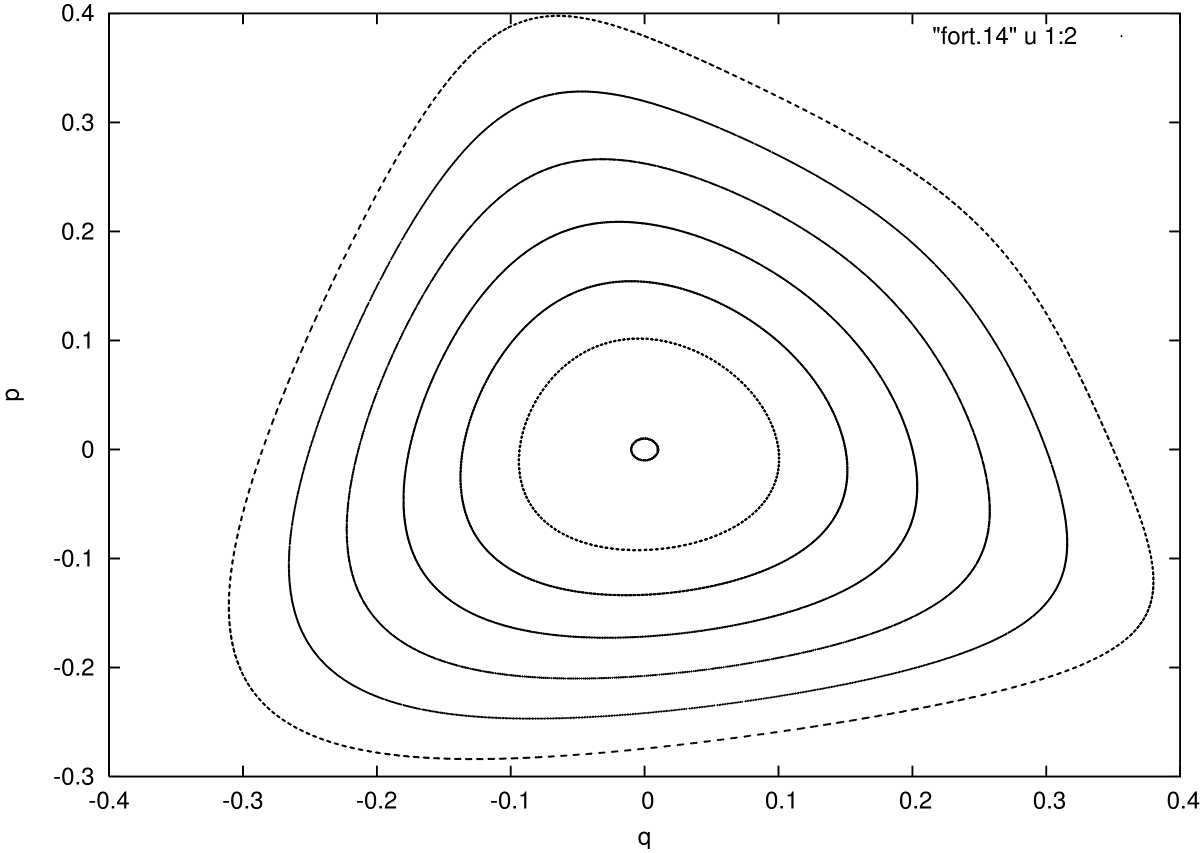

Figure 34.3.4: Phase-space portrait, in the case $\theta/2\pi = 0.22$, resulting from applying the map $\mathcal{M}^{\rm ipsc}$ repeatedly (2000 times) to the seven initial conditions $(q, p) = (.01, 0)$, $(.1, 0)$, $(.15, 0)$, $(.2, 0)$, $(.25, 0)$, $(.3, 0)$, and $(.35, 0)$ to find their orbits.

34.3.6 Comments and Comparisons

At this point some comments and comparisons are in order. Based on our experience so far, we may draw the following (sometimes tentative) conclusions:

1. The symplectification of symplectic jets overcomes the problem of spurious spiraling into or out of the origin.

2. The use of either F_2 or F_+ (Poincaré) generating functions gives exact results for jets that are kick maps. Kick maps are, of course, symplectic, and their symplectification by use of either F_2 or F_+ (Poincaré) generating functions leaves them unchanged.

3. The use of F_+ (Poincaré) generating functions gives exact results for jets that are jolt maps. Such jet maps are also also exactly symplectic, and their Poincaré symplectification also leaves them unchanged. Such is not the case for F_2 symplectification. Given a jolt map, it generally converts this map into some other map. While the result of this conversion is a symplectic map, it is not generally the original jolt map. Put colloquially, Poincaré symplectification has the good sense to leave a good thing alone, but F_2 symplectification generally does not. In fact, in this case F_2 symplectification replaces a map with no singularities by a map with singularities.

4. The root trick enlarges the applicable domain and improves accuracy. It might also appear to require more work because now a symplectified nonlinear map has to be evaluated twice. However, the iterative method employed to solve numerically the implicit equations associated with the use of $\mathcal{N}^{\rm psc}(1/2)$ is expected to converge faster than that for $\mathcal{N}^{\rm psc}(1)$ because $\mathcal{N}^{\rm psc}(1/2)$ is less nonlinear; and this gain in convergence speed is likely to be greater than the loss associated with evaluating $\mathcal{N}^{\rm psc}(1/2)$ twice.

5. Compared to a F_2 symplectified map, a Poincaré symplectified map has a larger domain of applicability.

6. Compared to a F_2 symplectified map, a Poincaré symplectified map has higher-order accuracy.

Let us explore item 5 above in some more detail. In Section 26.2 we listed the normal forms for cubic polynomials in two variables, namely those given by (26.2.4) through (26.2.7). It is instructive to compare F_2 and Poincaré symplectification for each. We have already considered the cases (26.2.6) and (26.2.7). We now consider the two remaining cases.

Case When $a = 1$, $b = -3$, $c = d = 0$

We begin with the case (26.2.5), which is the easier of the two. In this case, by suitable rescaling, there is no loss of generality in taking a and b as the the only nonzero coefficients and giving them the values $a = 1$ and $b = -3$.

For these values use of (3.81) and (3.82) gives the map

$$Q = q - 3q^2, \tag{34.3.138}$$

$$P = (p - 3q^2)/(1 - 6q). \tag{34.3.139}$$

We see that for the F_2 case the map is singular on the surface

$$? = . \tag{34.3.140}$$

For these same values of a and b, the implicit relations (3.106) and (3.107), produced by the use of F_+, take the form

$$Q = q - (3/4)(Q + q)^2, \tag{34.3.141}$$

$$P = p - (1/4)[3(Q+q)^2 - 6(Q+q)(P+p)]. \tag{34.3.142}$$

These implicit relations have the solution

$$Q = (2/3)\{-[1+(3/2)q] + [1+6q]^{1/2}\}, \tag{34.3.143}$$

$$P = . \tag{34.3.144}$$

We see that for the F_+ case the map is singular on the surface

$$? = . \tag{34.3.145}$$

Case When $a = d = 1$, $b = c = 0$

For the remaining case (26.2.4) there is no loss of generality in taking a and d as the only nonzero coefficients and giving them the values $a = d = 1$.

For these values use of (3.81) and (3.82) gives the map

$$Q =, \tag{34.3.146}$$

$$P = . \tag{34.3.147}$$

We see that for the F_2 case the map is singular on the surface

$$? = . \tag{34.3.148}$$

For these same values of a and d, the implicit relations (3.106) and (3.107), produced by the use of F_+, take the form

$$Q = q + (3/4)(P+p)^2, \tag{34.3.149}$$

$$P = p - (3/4)(Q+q)^2. \tag{34.3.150}$$

These implicit relations have the solution

$$Q =, \tag{34.3.151}$$

$$P = . \tag{34.3.152}$$

We see that for the F_+ case the map is singular on the surface

$$? = . \tag{34.3.153}$$

Let us also explore item 6 above in some more detail. To do so it is convenient to make some definitions. First, suppose $\mathcal{N}$ is some nonlinear map. We will define $\mathrm{n}(\mathcal{N}, z)$, the local *nonlinearity* of $\mathcal{N}$, by the rule

$$\mathrm{n}(\mathcal{N}, z) = ||(\mathcal{N} - \mathcal{I})z||/||z||. \tag{34.3.154}$$

Here $||\ ||$ denotes the vector norm of a phase-space vector in the usual Euclidean metric. The quantity $n(\mathcal{N}, z)$ measures how much a phase-space point z moves under the action of $\mathcal{N}$ normalized by its distance from the origin.

It may be the case that $\mathcal{N}$ is a symplectic jet. In that case, it is useful to have some measure of the violation of the symplectic condition associated with the action of $\mathcal{N}$. One possibility is to define $\mathrm{sv}(\mathcal{N}, z)$, the local *symplectic violation*, by the rule

$$\mathrm{sv}(\mathcal{N}, z) = ||([\mathcal{N}z_a, \mathcal{N}z_b] - J_{ab})||. \tag{34.3.155}$$

Here $|| \; ||$ denotes some matrix norm, say the maximum column sum norm.

Given two nonlinear maps $\mathcal{N}_1$ and $\mathcal{N}_2$, we will also want to have some measure of the *difference* between them. One way to do so is to introduce the quantity $\mathrm{d}(\mathcal{N}_1, \mathcal{N}_2, z)$ by the rule

$$\mathrm{d}(\mathcal{N}_1, \mathcal{N}_2, z) = ||\mathcal{N}_1 z - \mathcal{N}_2 z||. \tag{34.3.156}$$

34.4 Use of Poincaré Generating Function

34.4.1 Determination of Poincaré Generating Function in Terms of H

Suppose we are given a time-independent Hamiltonian H. Use it to generate the symplectic map

$$\mathcal{M}(\tau) = \exp(-\tau : H :) \tag{34.4.1}$$

Let $F_+(\Sigma, \tau)$ be the Poincaré generating function associated with $\mathcal{M}(\tau)$. We want to find a formula for F_+ in terms of H. To do so we will seek a Taylor expansion of $F_+(\Sigma, \tau)$ in powers of τ.

We first note that F_+ is odd in τ. From (2.1) we have the relation

$$\mathcal{M}(-\tau) = \exp(+\tau : H :) = \mathcal{M}^{-1}(\tau). \tag{34.4.2}$$

Next we observe that (6.6.45), which can be written in the form

$$Z = z + J\partial_\Sigma F_+|_{\Sigma=(Z+z)/2}, \tag{34.4.3}$$

can be rewritten in the form

$$z = Z - J\partial_\Sigma F_+|_{\Sigma=(Z+z)/2}, \tag{34.4.4}$$

which reveals that if the Poincaré generating function associated with $\mathcal{M}(\tau)$ is $F_+(\Sigma, \tau)$, then the Poincaré generating function associated with $\mathcal{M}^{-1}(\tau)$ is $-F_+(\Sigma, \tau)$. Consequently, we conclude that

$$F_+(\Sigma, -\tau) = -F_+(\Sigma, \tau). \tag{34.4.5}$$

Since F_+ is odd in τ, only odd powers of τ can occur in its Taylor expansion so that we may write

$$F_+(\Sigma, \tau) = F_+^{(1)}(\Sigma)\tau + F_+^{(3)}(\Sigma)\tau^3 + F_+^{(5)}(\Sigma)\tau^5 + \cdots . \tag{34.4.6}$$

The first term in the expansion is H itself,

$$F_+^{(1)}(\Sigma) = H(\Sigma). \tag{34.4.7}$$

Let $\mathcal{S}(H)$ denote the Hessian of H,

$$\mathcal{S}(H)_{ab} = \partial_a \partial_b H. \tag{34.4.8}$$

Then the next term in the expansion is given by the equation

$$F_+^{(3)}(\Sigma) = (1/24)(\partial H, J\mathcal{S}(H)J\partial H). \tag{34.4.9}$$

The successive terms are ever more complicated to state in explicit form. For $F_+^{(5)}$ there is the intermediate result

$$F_+^{(5)}(\Sigma) = \tag{34.4.10}$$

and the final result

$$F_+^{(5)}(\Sigma) = . \tag{34.4.11}$$

34.4.2 Application to Quadratic Hamiltonian

As a preliminary application of these results, let us first consider the simple case where

$$H(z) = h_2(z) = (1/2)(z, Sz). \tag{34.4.12}$$

Then we have the relations

$$\partial_a H = S_{ab} z_b, \tag{34.4.13}$$

$$\mathcal{S}(H) = S. \tag{34.4.14}$$

Correspondingly, we find the results

$$F_+^{(1)}(\Sigma) = H(\Sigma) = (1/2)(\Sigma, S\Sigma), \tag{34.4.15}$$

$$F_+^{(3)}(\Sigma) = (1/24)(\partial_a H J_{ab} \mathcal{S}(H)_{bc} J_{cd} \partial_d H) = (1/24)(\Sigma, SJSJS\Sigma), \tag{34.4.16}$$

$$F_+^{(5)}(\Sigma) = . \tag{34.4.17}$$

The net result is that $F_+(\Sigma, \tau)$ has the expansion

$$F_+(\Sigma,\tau) = (\Sigma, [(1/2)\tau S + (1/24)\tau^3 S(JS)^2 + ()\tau^5 S(JS)^4 + \cdots]\Sigma) \tag{34.4.18}$$

However, thanks to (), we already know that in this case

$$\begin{aligned} F_+(\Sigma,\tau) &= (1/2)(\Sigma, W'\Sigma) = (\Sigma, -J\tanh[\tau JS/2]\Sigma) \\ &= (\Sigma, [-J\tau JS/2 + J(1/3)(\tau JS/2)^3 + J(2/15)(\tau JS/2)^5/3 + \cdots]\Sigma) \\ &= (\Sigma, [(1/2)\tau S + (1/24)\tau^3 S(JS)^2 + (1/240)\tau^5 S(JS)^4 + \cdots]\Sigma). \end{aligned} \tag{34.4.19}$$

Here we have used the series

$$\tanh x = x - (1/3)x^3 + (2/15)x^5 + \cdots . \tag{34.4.20}$$

Evidently the expansions () and () agree.

34.4.3 Application to Symplectic Approximation

As a second application, suppose H has a homogeneous polynomial expansion of the form

$$H = h_3 + h_4 + h_5 + \cdots . \tag{34.4.21}$$

In this case we wish to obtain a homogeneous polynomial expansion for $F_+(\Sigma, \tau)$ of the form

$$F_+(\Sigma, \tau) = F_+^3(\Sigma, \tau) + F_+^4(\Sigma, \tau) + F_+^5(\Sigma, \tau) + \cdots . \tag{34.4.22}$$

We will now find that each $F_+^m(\Sigma, \tau)$ is also polynomial in the variable τ. Therefore, we may set $\tau = 1$, and drop τ from our variable list. Then we will have the relation

$$\mathcal{M} = \exp(- : H :). \tag{34.4.23}$$

For this symplectic map there will be the Poincaré generating function

$$F_+(\Sigma) = F_+^3(\Sigma) + F_+^4(\Sigma) + F_+^5(\Sigma) + \cdots \tag{34.4.24}$$

with

$$F_+^m(\Sigma) = F_+^m(\Sigma, \tau = 1). \tag{34.4.25}$$

Upon equating like powers of Σ on both sides of () and (), we find, through terms of degree 8, the results

$$F_+^3 = h_3, \tag{34.4.26}$$

$$F_+^4 = h_4, \tag{34.4.27}$$

$$F_+^5 = h_5 + (1/24)(\partial h_3, J\mathcal{S}(h_3)J\partial h_3), \tag{34.4.28}$$

$$F_+^6 = h_6 + (1/24)(\partial h_3, J\mathcal{S}(h_4)J\partial h_3) + (1/12)(\partial h_3, J\mathcal{S}(h_3)J\partial h_4), \tag{34.4.29}$$

$$F_+^7 = h_7 + (1/24)(\partial h_4, J\mathcal{S}(h_3)J\partial h_4) + (1/12)(\partial h_3, J\mathcal{S}(h_4)J\partial h_4), \tag{34.4.30}$$

$$F_+^8 = h_8 + (1/24)(\partial h_4, J\mathcal{S}(h_4)J\partial h_4). \tag{34.4.31}$$

Suppose we know h_3 through h_n and wish to 'evaluate'

$$\mathcal{M}^{[n]} = \exp(- : H^{[n]} :) \tag{34.4.32}$$

where

$$H^{[n]} = h_3 + h_4 + \cdots + h_n. \tag{34.4.33}$$

For this purpose, let us use a corresponding Poincaré generating function also truncated beyond terms of degree n. That is, we use the function $F_+^{[n]}$ defined by the rule

$$F_+^{[n]} = F_+^3 + F_+^4 + \cdots + F_+^n \tag{34.4.34}$$

Let $\mathcal{M}_+^{[n]}$ be the symplectic map produced by the use of $F_+^{[n]}$. By construction it will have the single-exponent Lie representation

$$\mathcal{M}_+^{[n]} = \exp(- : h_3 : - : h_4 : - \cdots - : h_n : + : g_{n+1} : + : g_{n+2} : + \cdots). \tag{34.4.35}$$

That is, the exponent of $\mathcal{M}_+^{[n]}$ will agree with that of $\mathcal{M}^{[n]}$ through terms of degree n, but there will generally be additional terms $g_{n+1},\ g_{n+2},\ \cdots$ which reflect the fact that the maps $\mathcal{M}_+^{[n]}$ and $\mathcal{M}$ are generally not identical. We will see that these additional terms depend on the given/known h_m, and that this dependence has three desirable properties.

Suppose, for example, that $n = 4$ so that

$$\mathcal{M}^{[4]} = \exp(- : h_3 : - : h_4 :), \tag{34.4.36}$$

$$F_+^{[4]} = F_+^3 + F_+^4, \tag{34.4.37}$$

and

$$\mathcal{M}_+^{[4]} = \exp(- : h_3 : - : h_4 : + : g_5 : + : g_6 : + \cdots). \tag{34.4.38}$$

Evidently truncating the series (2.34) beyond terms of degree 4 is equivalent to including all terms in the series and requiring that

$$F_+^m = 0 \text{ for all } m > 4. \tag{34.4.39}$$

Inspection of (2.28) through (2.31) shows that the requirement (2.39) produces, through terms of degree 8, the relations

$$-h_5 = (1/24)(\partial h_3, J\mathcal{S}(h_3)J\partial h_3), \tag{34.4.40}$$

$$-h_6 = (1/24)(\partial h_3, J\mathcal{S}(h_4)J\partial h_3) + (1/12)(\partial h_3, J\mathcal{S}(h_3)J\partial h_4), \tag{34.4.41}$$

$$-h_7 = (1/24)(\partial h_4, J\mathcal{S}(h_3)J\partial h_4) + (1/12)(\partial h_3, J\mathcal{S}(h_4)J\partial h_4), \tag{34.4.42}$$

$$-h_8 = (1/24)(\partial h_4, J\mathcal{S}(h_4)J\partial h_4), \tag{34.4.43}$$

and we see that

$$g_m = -h_m \text{ for all } m > 4 \tag{34.4.44}$$

with the h_m for $m > 4$ defined by in terms of h_3 and h_4 by the relations (2.40) through (2.43).

Now we are ready to examine in some detail the properties of the dependence of the $g_{n+1},\ g_{n+2},\ \cdots$ on the $h_3,\ h_4,\ \cdots\ h_n$. To do so, it is useful to introduce a somewhat more elaborate notation. Let us employ, in place of $\mathcal{M}_+^{[n]}$, the symbols $\mathcal{M}_+^{[n]}\{H^{[n]}\}$ to indicate that the map $\mathcal{M}_+^{[n]}$ depends on $h_3,\ h_4,\ \cdots\ h_n$. The first property is this: Suppose all the h_m are replaced by $-h_m$. Then we see, from () through () and () through (), that all the F_+^m and all the g_m are replaced by $-F_+^m$ and $-g_m$, respectively. Consequently, there is the relation

$$\mathcal{M}_+^{[n]}\{-H^{[n]}\} = (\mathcal{M}_+^{[n]}\{H^{[n]}\})^{-1}. \tag{34.4.45}$$

In words, if $\mathcal{M}_+^{[n]}$ is the symplectic approximation to $\mathcal{M}^{[n]}$, then $(\mathcal{M}_+^{[n]})^{-1}$ is the symplectic approximation to $(\mathcal{M}^{[n]})^{-1}$. We may invert and then symplectically approximate, or symplectically approximate and then invert. The result of both procedures is the same. We may say that symplectic approximation by the use of a Poincaré generating function is invariant under the operation of map inversion.

The second property is more subtle. Suppose $\mathcal{R}$ is a linear symplectic map with associated symplectic matrix R. Suppose the h_m are transformed under the action of $\mathcal{R}$ to become the homogeneous polynomials $h_m^{\rm tr}$ by the rule

$$h_m^{\rm tr}(z) = \mathcal{R}h_m(z) = h_m(Rz). \tag{34.4.46}$$

Also, let $g_{n+1}^{\rm tr}(z)$, $g_{n+2}^{\rm tr}(z)$, $\cdots$ be the functions obtained by applying the rules defining the $g_{n+1}(z)$, $g_{n+2}(z)$, $\cdots$ to the $h_m^{\rm tr}$. Then there is also the result

$$\begin{aligned} g_{n+1}^{\rm tr}(z) &= \mathcal{R}g_{n+1}, \\ g_{n+2}^{\rm tr}(z) &= \mathcal{R}g_{n+2}, \text{ etc.} \end{aligned} \tag{34.4.47}$$

Suppose we assume, for the moment, that (2.47) is correct. It follows that there is then the relation

$$\mathcal{M}_+^{[n]}\{\mathcal{R}H^{[n]}\} = \mathcal{R}\mathcal{M}_+^{[n]}\{H^{[n]}\}(\mathcal{R})^{-1}. \tag{34.4.48}$$

Of course, we also have the relation

$$\mathcal{R}\mathcal{M}^{[n]}(\mathcal{R})^{-1} = \exp(- : \mathcal{R}H^{[n]} :). \tag{34.4.49}$$

In words, if we conjugate the map $\mathcal{M}^{[n]}$ with $\mathcal{R}$ and then symplectically approximate the result, the outcome is the same as first symplectically approximating $\mathcal{M}^{[n]}$ and then conjugating with $\mathcal{R}$. We may say that symplectic approximation by the use of a Poincaré generating function is invariant under the operation of conjugation with the linear symplectic map $\mathcal{R}$.

34.5 Use of Other Generating Functions

34.6 Cremona Approximation

Decomposition of the $sp(6, \mathbb{R})$ representation $\Gamma(\ell, 0, 0)$ into representations of $su(3)$.

Chapter 35

Orbit Stability, Long-Term Behavior, and Dynamic Aperture

Chapter 36

Reversal Symmetry

The concept of reversibility, and that reversibility has various implications for charged-particle and light optics (and the study of general dynamical systems), are part of the common lore of those working in these fields, and its role and value are generally understood at least on an intuitive level. The purpose of this chapter is to explore reversal symmetry systematically. Reversal symmetry is defined; it is shown that the transfer maps for most common beam-line elements are reversal symmetric including nonlinear effects; and various linear and nonlinear consequences of reversal symmetry are worked out in some detail.

Section 1 defines the operation of reversal and works out some of its properties. Section 2 describes some of the applications of these properties. In particular it defines what is meant for a transfer map to be reversal symmetric, and shows that the transfer maps for many common beam-line elements are reversal symmetric. Section 3 works out some of the general consequences of reversal symmetry for straight and circular machines, and Section 4 treats some special cases. Section 5 studies the consequences of reversal symmetry for closed orbits in a circular machine, and Section 6 studies the consequences for the *Courant-Snyder* functions in a circular machine. A final section treats various nonlinear consequences of reversal symmetry. It seems remarkable that such a simple concept should be so rich in consequences.

36.1 Reversal Operator

We will work with a coordinate system that is particularly useful for charged-particle optics. We write

$$z = (x, p_x; y, p_y; \tau, p_\tau). \tag{36.1.1}$$

The quantities x and y are transverse deviations from a design trajectory, and p_x and p_y are their conjugate momenta. The quantity τ is the difference (time deviation) between the arrival/departure time of a given particle and a particle on the design trajectory. Finally, p_τ is the *negative* of the energy difference between that of the given particle and that of a particle on the design trajectory. Note that this choice of variables presumes that some *coordinate* (it could be Cartesian or angular or path length along some design trajectory) is taken to play the role of the *independent* (time-like) variable. When this is done, its conjugate momentum does not appear in the associated Hamiltonian, and τ and p_τ are both *dependent* variables. Finally, we note that in accelerator physics it is common to scale the transverse coordinates x and y by some convenient scale length ℓ, to scale the transverse momenta p_x and p_y by some "design" momentum p^0, to scale p_t (which is the negative of the energy) by p^0c (where c is the speed of light), and to scale the time t by ℓ/c. In this chapter we do not do so. In particular, for the purpose of this chapter, p_τ is defined in terms of p_t simply by subtracting off the design value of p_t without any scaling, and τ is defined in terms of t simply by subtracting off the time of flight for the design orbit, again without any scaling factor.

Let z be any point in phase space as specified by (1.1). *Define* a "reversal" operator $\mathcal{R}$ acting on phase space by the rule

$$\mathcal{R}z = z^r \tag{36.1.2}$$

with

$$z^r = (x, -p_x; y, -p_y; -\tau, p_\tau). \tag{36.1.3}$$

The reversal operation is analogous to time reversal, but differs from it in two essential ways. First, recall that the definitions (1.1) through (1.3) presume that some coordinate is playing the role of the independent (time-like) variable, its conjugate momentum is absent, and τ and p_τ are dependent variables. Second, the magnetic field does not change sign. It is for these reasons that, as we will see, a transfer map can violate what we will define as reversal symmetry even though the fundamental laws that govern charged-particle motion, the electromagnetic field, and the electromagnetic interaction are all invariant under time reversal as usually defined.

It is easily verified that, when acting on phase space, the effect of $\mathcal{R}$ can be described by a matrix R with

$$\mathcal{R}z_a = (Rz)_a \tag{36.1.4}$$

where R is the matrix

$$R = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{36.1.5}$$

We note for future reference that J and R have the properties

$$JR = \begin{pmatrix} 0 & -1 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix}, \tag{36.1.6}$$

$$J^2 = -I, \tag{36.1.7}$$

$$R^2 = I, \tag{36.1.8}$$

$$(JR)^2 = I, \tag{36.1.9}$$

$$RJR = -J, \tag{36.1.10}$$

$$RJ = -JR. \tag{36.1.11}$$

Here we use the form (3.2.10) for J. We also remark that since R is a symmetric matrix, $R^T = R$, (1.10) can also be written in the form

$$R^T JR = -J. \tag{36.1.12}$$

Therefore, R is an *antisymplectic* matrix. See Exercise 3.12.8. Correspondingly, we will say that $\mathcal{R}$ is an *antisymplectic* map. We have learned that, in our setting of Classical Mechanics, evolution (with some coordinate playing the role of the independent variable) is described by a symplectic map acting on phase space, and reversal is described by an antisymplectic map. This terminology is analogous to that employed in Quantum Mechanics where time evolution is described by a unitary transformation acting on Hilbert space, and time reversal is described by what is called an *antiunitary* transformation.

We have seen that $\mathcal{R}$ is an antisymplectic map. The same is true of the maps $\mathcal{M}\mathcal{R}$ and $\mathcal{R}\mathcal{M}$ if $\mathcal{M}$ is symplectic. To prove this, let $\mathcal{N}$ be the map given by the product

$$\mathcal{N} = \mathcal{M}\mathcal{R}. \tag{36.1.13}$$

By the chain rule its Jacobian matrix N is given by the relation

$$N = MR, \tag{36.1.14}$$

and we find the result

$$N^T JN = RM^T JMR = RJR = -J. \tag{36.1.15}$$

Similarly, if $\mathcal{N}$ is the map given by the product

$$\mathcal{N} = \mathcal{R}\mathcal{M}, \tag{36.1.16}$$

we find the results

$$N = RM \tag{36.1.17}$$

and

$$N^T JN = M^T RJRM = M^T(-J)M = -J. \tag{36.1.18}$$

We also note the converse conclusion: If $\mathcal{N}$ is an antisymplectic map, then the maps $\mathcal{R}\mathcal{N}$ and $\mathcal{N}\mathcal{R}$ are symplectic. Finally, there is an immediate generalization: The product of a symplectic map and an antisymplectic map is antisymplectic, and the product of two antisymplectic maps is symplectic.

Extend $\mathcal{R}$ to phase-space functions $f(z)$ by the rule

$$\mathcal{R}f = f^r \tag{36.1.19}$$

with

$$f^r(z) = f(z^r). \tag{36.1.20}$$

Evidently $\mathcal{R}$ is a linear operator with the property

$$\mathcal{R}^2 = \mathcal{I} \text{ or } \mathcal{R}^{-1} = \mathcal{R}. \tag{36.1.21}$$

For any two functions g and h there is also the property

$$\mathcal{R}(gh) = (\mathcal{R}g)(\mathcal{R}h). \tag{36.1.22}$$

Finally we note that since the application of $\mathcal{R}$ commutes with the operation of scaling variables, everything we will conclude about reversal properties of maps given in terms of unscaled variables will also hold for maps given in terms of scaled variables.

Let us determine the effect of reversal on Lie operators. We claim that $\mathcal{R}$ has the property

$$\mathcal{R} : f : \mathcal{R} = - : \mathcal{R}f := - : f^r : \tag{36.1.23}$$

for any Lie operator $: f :$. To prove this claim, let $\mathcal{R} : f : \mathcal{R}$ act on any function g. The calculation is a bit delicate, and is best done in stages and pieces. To begin, we have the result

$$\begin{aligned}
\mathcal{R} : f : \mathcal{R}g &= \mathcal{R}[f, \mathcal{R}g] \\
&= \mathcal{R}\{\sum_j (\partial f/\partial q_j)(\partial(\mathcal{R}g)/\partial p_j) - (\partial f/\partial p_j)(\partial(\mathcal{R}g)/\partial q_j)\} \\
&= \sum_j \{\mathcal{R}(\partial f/\partial q_j)\}\{\mathcal{R}(\partial(\mathcal{R}g)/\partial p_j)\} \\
&- \{\mathcal{R}(\partial f/\partial p_j)\}\{\mathcal{R}(\partial(\mathcal{R}g)/\partial q_j)\}.
\end{aligned} \tag{36.1.24}$$

Here we have used (1.22). Next, it follows from (1.2) and (1.3) that there are the operator relations

$$\mathcal{R}(\partial/\partial z_a) = (\partial/\partial z_a)\mathcal{R} \text{ for } a = 1, 3, 6; \tag{36.1.25}$$

$$\mathcal{R}(\partial/\partial z_a) = -(\partial/\partial z_a)\mathcal{R} \text{ for } a = 2, 4, 5. \tag{36.1.26}$$

Therefore we find for the $j = 1$ terms in (1.24) the results

$$\begin{aligned}
\{\mathcal{R}(\partial f/\partial x)\}\{\mathcal{R}(\partial(\mathcal{R}g)/\partial p_x)\} &= \{\partial(\mathcal{R}f)/\partial x)\}(-1)\{\mathcal{R}^2(\partial g/\partial p_x)\} \\
&= -(\partial f^r/\partial x)(\partial g/\partial p_x),
\end{aligned} \tag{36.1.27}$$

$$\begin{aligned}
-\{\mathcal{R}(\partial f/\partial p_x)\}\{\mathcal{R}(\partial(\mathcal{R}g)/\partial x)\} &= +\{\partial(\mathcal{R}f)/\partial p_x\}\{\mathcal{R}^2(\partial g/\partial x)\} \\
&= (\partial f^r/\partial p_x)(\partial g/\partial x).
\end{aligned} \tag{36.1.28}$$

Analogous results hold for the $j = 2$ terms, which involve the y, p_y pair. And for the $j = 3$ terms, which involve the τ, p_τ pair, we find the results

$$\begin{aligned}
\{\mathcal{R}(\partial f/\partial \tau)\}\{\mathcal{R}(\partial(\mathcal{R}g)/\partial p_\tau)\} &= -\{\partial(\mathcal{R}f)/\partial \tau\}\{\mathcal{R}^2(\partial g/\partial p_\tau)\} \\
&= -(\partial f^r/\partial \tau)(\partial g/\partial p_\tau),
\end{aligned} \tag{36.1.29}$$

$$\begin{aligned}
-\{\mathcal{R}(\partial f/\partial p_\tau)\}\{\mathcal{R}(\partial(\mathcal{R}g)/\partial \tau)\} &= -\{\partial(\mathcal{R}f/\partial p_\tau)\}(-1)\{\mathcal{R}^2(\partial g/\partial \tau)\} \\
&= (\partial f^r/\partial p_\tau)(\partial g/\partial \tau).
\end{aligned} \tag{36.1.30}$$

Now put all these results into (1.24) to obtain the relation

$$\begin{aligned}\mathcal{R} : f : \mathcal{R}g &= \sum_j \{\mathcal{R}(\partial f/\partial q_j)\}\{\mathcal{R}(\partial(\mathcal{R}g)/\partial p_j)\} \\ &- \{\mathcal{R}(\partial f/\partial p_j)\}\{\mathcal{R}(\partial(\mathcal{R}g)/\partial q_j)\} \\ &= -\sum_j (\partial f^r/\partial q_j)(\partial g/\partial p_j) - (\partial f^r/\partial p_j)(\partial g/\partial q_j) \\ &= -[f^r, g] = - : f^r : g. \end{aligned} \tag{36.1.31}$$

Evidently (1.23) is the operator version of (1.31).

Let us next determine the effect of reversal on Lie transformations. From (1.21) and (1.23) we find the additional property

$$\begin{aligned}\mathcal{R} : f :^n \mathcal{R} &= \mathcal{R} : f :: f :: f : \cdots : f : \mathcal{R} \\ &= \mathcal{R} : f : \mathcal{R}\mathcal{R} : f : \mathcal{R}\mathcal{R} : f : \mathcal{R} \cdots \mathcal{R} : f : \mathcal{R} \\ &= (\mathcal{R} : f : \mathcal{R})^n = (-1)^n : \mathcal{R}f :^n = (-1)^n : f^r :^n . \end{aligned} \tag{36.1.32}$$

Suppose $\mathcal{M}$ is a map that, for some f, can be written in the single exponent form

$$\mathcal{M} = \exp(: f :) = \sum_{n=0}^{\infty} : f :^n /n!. \tag{36.1.33}$$

Then, from (1.32) and (1.33), we find the result

$$\begin{aligned}\mathcal{R}\mathcal{M}\mathcal{R} &= \sum_{n=0}^{\infty} \mathcal{R} : f :^n \mathcal{R}/n! = \sum_{n=0}^{\infty} (-1)^n : \mathcal{R}f :^n /n! \\ &= \exp(- : \mathcal{R}f :) = \exp(- : f^r :). \end{aligned} \tag{36.1.34}$$

The stage is set to define the effect of reversal on maps. Suppose $\mathcal{M}$ is any map that sends initial points z^i to final points z^f,

$$z^f = \mathcal{M}z^i. \tag{36.1.35}$$

Reverse both z^i and z^f to yield $\mathcal{R}z^i$ and $\mathcal{R}z^f$. We *define* the reversed map $\mathcal{M}^r$ to be that map which sends $\mathcal{R}z^f$ to $\mathcal{R}z^i$,

$$\mathcal{M}^r\mathcal{R}z^f = \mathcal{R}z^i. \tag{36.1.36}$$

See Figure 1.1. Combining (1.35) and (1.36) gives the result

$$\mathcal{M}^r\mathcal{R}\mathcal{M}z^i = \mathcal{R}z^i. \tag{36.1.37}$$

Equivalently, we have the operator relation

$$\mathcal{M}^r\mathcal{R}\mathcal{M} = \mathcal{R}. \tag{36.1.38}$$

This relation can be solved for $\mathcal{M}^r$ to give the intermediate result

$$\mathcal{M}^r = \mathcal{R}(\mathcal{R}\mathcal{M})^{-1} = \mathcal{R}\mathcal{M}^{-1}\mathcal{R}^{-1}, \tag{36.1.39}$$

and use of (1.21) in (1.39) gives the final equivalent definition for $\mathcal{M}^r$:

$$\mathcal{M}^r = \mathcal{R}\mathcal{M}^{-1}\mathcal{R}. \tag{36.1.40}$$

Note that, in analogy to (1.21), reversing a map twice leaves it unchanged:

$$\begin{aligned}(\mathcal{M}^r)^r &= (\mathcal{R}\mathcal{M}^{-1}\mathcal{R})^r = \mathcal{R}(\mathcal{R}\mathcal{M}^{-1}\mathcal{R})^{-1}\mathcal{R} \\ &= \mathcal{R}\mathcal{R}^{-1}\mathcal{M}\mathcal{R}^{-1}\mathcal{R} = \mathcal{M}.\end{aligned} \tag{36.1.41}$$

From (1.21), (1.38), and (1.40) we deduce the chain of relations

$$\mathcal{M}^r\mathcal{R}\mathcal{M}\mathcal{R} = \mathcal{I}, \tag{36.1.42}$$

$$\mathcal{M}^r\mathcal{R}(\mathcal{M}^{-1})^{-1}\mathcal{R} = \mathcal{I}, \tag{36.1.43}$$

$$\mathcal{M}^r(\mathcal{M}^{-1})^r = \mathcal{I}, \tag{36.1.44}$$

$$(\mathcal{M}^{-1})^r = (\mathcal{M}^r)^{-1}. \tag{36.1.45}$$

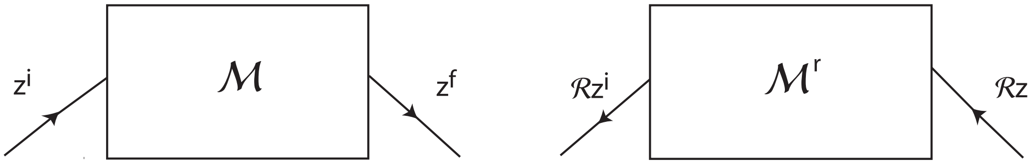

Figure 36.1.1: Actions of a map $\mathcal{M}$ and its reversed counterpart $\mathcal{M}^r$.

We also observe that if $\mathcal{M}$ can be written in the single exponent form (1.33), then use of (1.34) and (1.40) shows that there is the relation

$$\mathcal{M}^r = \mathcal{R}\exp(- : f :)\mathcal{R} = \exp(: f^r :). \tag{36.1.46}$$

If $\mathcal{M}$ is a symplectic map, so is $\mathcal{M}^r$. To prove this, let M^r be the Jacobian matrix of $\mathcal{M}^r$. From (1.40) and the chain rule we find the result

$$M^r = RM^{-1}R. \tag{36.1.47}$$

Let us check whether M^r is a symplectic matrix. We find from (3.1.2), (1.47), and (1.11) the result

$$\begin{aligned}(M^r)^TJM^r &= R(M^{-1})^TRJRM^{-1}R \\ &= -R(M^{-1})^TJM^{-1}R = -RJR = J.\end{aligned} \tag{36.1.48}$$

We see that M^r is a symplectic matrix, and hence $\mathcal{M}^r$ is a symplectic map. The observant reader will have noticed that the same conclusion could have been reached immediately from the discussion surrounding equations (1.13) through (1.18).

Suppose we combine (1.47) with the symplectic condition. From the symplectic condition (3.1.2) we deduce that

$$M^{-1} = -JM^TJ, \tag{36.1.49}$$

and hence (1.47) can also be written in the form

$$M^r = JRM^TJR = JRM^T(JR)^{-1}. \tag{36.1.50}$$

Here we have also used (1.11) and (1.9).

From (1.50) it follows that M and M^r have the *same spectrum*. Indeed, let P and P^r be the *characteristic polynomials* of M and M^r,

$$P(\lambda) = \det(M - \lambda I), \tag{36.1.51}$$

$$P^r(\lambda) = \det(M^r - \lambda I). \tag{36.1.52}$$

Then, by use of (1.50), we have the result

$$\begin{aligned} P^r(\lambda) &= \det(M^r - \lambda I) = \det[JRM^T(JR)^{-1} - \lambda I] \\ &= \det[(JR)(M^T - \lambda I)(JR)^{-1}] \\ &= \det(JR)\det[(JR)^{-1}]\det(M^T - \lambda I) \\ &= \det(M - \lambda I) = P(\lambda). \end{aligned} \tag{36.1.53}$$

The last task for this section is to determine the effect of reversal on a relation involving the action of a map on a function. Suppose the function h is the result of the symplectic map $\mathcal{M}$ acting on the function g,

$$h = \mathcal{M}g. \tag{36.1.54}$$

Letting $\mathcal{R}$ act on both sides of (1.54) and using (1.21) and (1.42) give the results

$$\mathcal{R}h = \mathcal{R}\mathcal{M}g = \mathcal{R}\mathcal{M}\mathcal{R}\mathcal{R}g = (\mathcal{M}^r)^{-1}\mathcal{R}g, \tag{36.1.55}$$

or

$$h^r = (\mathcal{M}^r)^{-1}g^r. \tag{36.1.56}$$

36.2 Applications

Suppose $\mathcal{M}$ is a product of several maps $\mathcal{M}_1$ to $\mathcal{M}_n$,

$$\mathcal{M} = \mathcal{M}_1\mathcal{M}_2\mathcal{M}_3\cdots\mathcal{M}_n. \tag{36.2.1}$$

Then, from (1.21) and (1.22), there is the result

$$\begin{aligned} \mathcal{M}^r &= \mathcal{R}(\mathcal{M}_1\mathcal{M}_2\mathcal{M}_3\cdots\mathcal{M}_n)^{-1}\mathcal{R} \\ &= \mathcal{R}(\mathcal{M}_n^{-1}\cdots\mathcal{M}_3^{-1}\mathcal{M}_2^{-1}\mathcal{M}_1^{-1})\mathcal{R} \\ &= \mathcal{R}\mathcal{M}_n^{-1}\mathcal{R}\cdots\mathcal{R}\mathcal{M}_3^{-1}\mathcal{R}\mathcal{R}\mathcal{M}_2^{-1}\mathcal{R}\mathcal{R}\mathcal{M}_1^{-1}\mathcal{R} \\ &= \mathcal{M}_n^r\cdots\mathcal{M}_3^r\mathcal{M}_2^r\mathcal{M}_1^r. \end{aligned} \tag{36.2.2}$$

Thus, the reverse of a product of maps is the product of the reverses of the individual maps taken in *opposite* order.

Define a map $\mathcal{M}$ to be *reversal symmetric* if it equals its reverse,

$$\mathcal{M}^r = \mathcal{M}. \tag{36.2.3}$$

For a reversal symmetric map (1.38) can be rewritten in the forms

$$\mathcal{R}\mathcal{M}\mathcal{R} = \mathcal{M}^{-1} \text{ or } \mathcal{M}\mathcal{R}\mathcal{M} = \mathcal{R}; \tag{36.2.4}$$

$$\mathcal{R}\mathcal{M}\mathcal{R}\mathcal{M} = \mathcal{I}, \tag{36.2.5}$$

$$\mathcal{M}\mathcal{R}\mathcal{M}\mathcal{R} = \mathcal{I}, \text{ or} \tag{36.2.6}$$

$$(\mathcal{R}\mathcal{M})^2 = (\mathcal{M}\mathcal{R})^2 = \mathcal{I}. \tag{36.2.7}$$

Here we have used (1.21). A map whose square is the identity is called an *involution.* We have seen that $\mathcal{R}\mathcal{M}$ and $\mathcal{M}\mathcal{R}$ are involutions if $\mathcal{M}$ is reversal symmetric. According to (1.21), $\mathcal{R}$ is also an involution. Finally, since $\mathcal{M}^k$ will be reversal symmetric if $\mathcal{M}$ is reversal symmetric, the maps $\mathcal{R}\mathcal{M}^k$ and $\mathcal{M}^k\mathcal{R}$ for any k are also involutions,

$$(\mathcal{R}\mathcal{M}^k)(\mathcal{R}\mathcal{M}^k) = (\mathcal{R}\mathcal{M}^k\mathcal{R})(\mathcal{M}^k) = \mathcal{M}^{-k}\mathcal{M}^k = \mathcal{I}, \tag{36.2.8}$$

$$(\mathcal{M}^k\mathcal{R})(\mathcal{M}^k\mathcal{R}) = \mathcal{M}^k(\mathcal{R}\mathcal{M}^k\mathcal{R}) = \mathcal{M}^k\mathcal{M}^{-k} = \mathcal{I}. \tag{36.2.9}$$

Moreover, there are the obvious identities

$$\mathcal{M} = \mathcal{R}\mathcal{R}\mathcal{M} = (\mathcal{R})(\mathcal{R}\mathcal{M}), \tag{36.2.10}$$

$$\mathcal{M} = \mathcal{M}\mathcal{R}\mathcal{R} = (\mathcal{M}\mathcal{R})(\mathcal{R}), \tag{36.2.11}$$

$$\mathcal{M}^k = \mathcal{R}\mathcal{R}\mathcal{M}^k = (\mathcal{R})(\mathcal{R}\mathcal{M}^k), \tag{36.2.12}$$

$$\mathcal{M}^k = \mathcal{M}^k\mathcal{R}\mathcal{R} = (\mathcal{M}^k\mathcal{R})(\mathcal{R}). \tag{36.2.13}$$

They show that if $\mathcal{M}$ is reversal symmetric, then $\mathcal{M}$ and $\mathcal{M}^k$ for any k can be written as the product of two involutions. The discovery and classification of the fixed points (closed orbits) of a map are greatly simplified if the map can be written as the product of two involutions. See Section 7.

Suppose $\mathcal{M}$ can be written in the single exponent form (1.33), and is reversal symmetric. Then we see from (1.46) that the generator f must satisfy the relation

$$f^r = f. \tag{36.2.14}$$

Suppose $\mathcal{M}$ can be written as a product of several maps $\mathcal{M}_1$ to $\mathcal{M}_n$ and their reverses,

$$\mathcal{M} = \mathcal{M}_1\mathcal{M}_2 \cdots \mathcal{M}_n\mathcal{M}_n^r \cdots \mathcal{M}_2^r\mathcal{M}_1^r. \tag{36.2.15}$$

Then, simple calculation shows that $\mathcal{M}$ is reversal symmetric. Indeed, from (2.2) and (1.40) we find the result

$$\begin{aligned} \mathcal{M}^r &= (\mathcal{M}_1^r)^r(\mathcal{M}_2^r)^r \cdots (\mathcal{M}_n^r)^r\mathcal{M}_n^r \cdots \mathcal{M}_2^r\mathcal{M}_1^r \\ &= \mathcal{M}_1\mathcal{M}_2 \cdots \mathcal{M}_n\mathcal{M}_n^r \cdots \mathcal{M}_2^r\mathcal{M}_1^r = \mathcal{M}. \end{aligned} \tag{36.2.16}$$

We next claim, based on end-to-end symmetry, that the transfer maps $\mathcal{M}$ for many common beamline elements are reversal symmetric. These elements include drifts, bends (including combined-function bends) with equal entry and exit angles, quadrupoles, sextupoles, octupoles, etc. This statement holds even if fringe-field and multipole effects are included provided the element in question has end-to-end symmetry. We will also show that the transfer map for a short on-phase RF cavity (a cavity that maintains bunching, but provides no net acceleration) is reversal symmetric. Finally, we note that the transfer map for a solenoid with end-to-end symmetry is *not* reversal symmetric. Instead, the reversed map for such a solenoid is the map for that solenoid with opposite magnetic field. That is, if $\mathcal{M}[\boldsymbol{B}(\boldsymbol{r})]$ is the map for such a solenoid with magnetic field $\boldsymbol{B}(\boldsymbol{r})$, there is the relation

$$\mathcal{M}^r[\boldsymbol{B}(\boldsymbol{r})] = \mathcal{M}[-\boldsymbol{B}(\boldsymbol{r})]. \tag{36.2.17}$$

Here we have used a square-bracket notation to indicate that the map $\mathcal{M}$ is a *functional* of the magnetic field $\boldsymbol{B}(\boldsymbol{r})$.

Imagine integrating (10.1.8) to find the map $\mathcal{M}$ for some beamline element. Divide the integration interval into $2N$ equal segments each of "duration" h. Label the intervals $1, 2, \cdots N$ followed by $\tilde{N}, \cdots \tilde{2}, \tilde{1}$. Then $\mathcal{M}$ can be written in the product form

$$\mathcal{M} = \mathcal{M}_1\mathcal{M}_2 \cdots \mathcal{M}_N\mathcal{M}_{\tilde{N}} \cdots \mathcal{M}_{\tilde{2}}\mathcal{M}_{\tilde{1}} \tag{36.2.18}$$

where $\mathcal{M}_j$ is the map for the j^{th} segment. The segments N and $\tilde{N}$ are on either side of the center of the element, and the segments 1 and $\tilde{1}$ are at the leading and trailing ends, etc. For each map $\mathcal{M}_j$ we have an approximation of the form

$$\mathcal{M}_j = \exp(-h : H_j :) + O(h^2) \tag{36.2.19}$$

where H_j is the Hamiltonian evaluated at the center of the j^{th} segment. Let us compute $(\mathcal{M}_j)^r$. From (1.34), (1.46), and (2.19) we find the result

$$(\mathcal{M}_j)^r = \exp[-h : (H_j)^r :] + O(h^2). \tag{36.2.20}$$

We now make the symmetry assumption

$$(H_{\tilde{j}})^r = H_j \text{ for } j = 1, 2, \cdots N. \tag{36.2.21}$$

It then follows that

$$(\mathcal{M}_{\tilde{j}})^r = \mathcal{M}_j + O(h^2) \tag{36.2.22}$$

and, by (1.41),

$$\mathcal{M}_{\tilde{j}} = (\mathcal{M}_j)^r + O(h^2). \tag{36.2.23}$$

Correspondingly, we may rewrite (2.18) in the form

$$\mathcal{M} = \mathcal{M}_1\mathcal{M}_2 \cdots \mathcal{M}_N(\mathcal{M}_N)^r \cdots (\mathcal{M}_2)^r(\mathcal{M}_1)^r + O(Nh^2). \tag{36.2.24}$$

Here, as a worst case estimate, we assume that all the $O(h^2)$ terms in (2.18) add constructively to produce a possible term of order Nh^2 in (2.24). Comparison of (2.15), (2.16), and (2.24) gives the result

$$\mathcal{M}^r = \mathcal{M} + O(Nh^2). \tag{36.2.25}$$

Now let the number N of segments approach infinity and the duration h of each approach zero. Then in this limit, $Nh^2 \to 0$, and we see that $\mathcal{M}^r$ must equal $\mathcal{M}$ exactly, and hence $\mathcal{M}$ is reversal symmetric.

There is a related result that is also of use. Let us write (2.18) in the form

$$\mathcal{M} = \mathcal{M}_\ell \mathcal{M}_t \tag{36.2.26}$$

where $\mathcal{M}_\ell$, the *leading* half of $\mathcal{M}$, is given by the product

$$\mathcal{M}_\ell = \mathcal{M}_1 \mathcal{M}_2 \cdots \mathcal{M}_N, \tag{36.2.27}$$

and $\mathcal{M}_t$, the *trailing* half of $\mathcal{M}$, is given by the product

$$\mathcal{M}_t = \mathcal{M}_{\tilde{N}} \cdots \mathcal{M}_{\tilde{2}} \mathcal{M}_{\tilde{1}}. \tag{36.2.28}$$

From (2.27) there is the relation

$$(\mathcal{M}_\ell)^r = (\mathcal{M}_N)^r \cdots (\mathcal{M}_2)^r (\mathcal{M}_1)^r, \tag{36.2.29}$$

and by combining this relation with (2.23) we obtain the estimate

$$(\mathcal{M}_\ell)^r = \mathcal{M}_{\tilde{N}} \cdots \mathcal{M}_{\tilde{2}} \mathcal{M}_{\tilde{1}} + O(Nh^2) = \mathcal{M}_t + O(Nh^2). \tag{36.2.30}$$

Again let the number N of segments approach infinity and the duration h of each approach zero so that $Nh^2 \to 0$. By so doing we conclude that the estimate (2.30) must in fact be the equality

$$(\mathcal{M}_\ell)^r = \mathcal{M}_t. \tag{36.2.31}$$

A few words need to be said about the symmetry assumption (2.21). Consider first *static* elements for which H does not depend on τ. In this case it is only necessary to examine how H depends on p_x and p_y. For a drift H_j is an even function (depends only on p_x^2 and p_y^2) and, of course, independent of the segment j. Therefore (2.21) holds. The same is true for the *body* of any multipole (including dipoles and combined-function dipoles), and therefore (2.21) again holds.

At the ends of a multipole H can have odd terms in p_x and p_y. For example, for a quadrupole, the Hamiltonian is of the form

$$H = -[(p_t/c)^2 - m^2c^2 - (p_x - qA_x)^2 - (p_y - qA_y)^2]^{1/2} - qA_z. \tag{36.2.32}$$

Here we have abandoned the notation (1.1). Instead, z is now a Cartesian coordinate in the longitudinal direction, and we take it to be the *independent* variable. Also, p_t is the negative of the total energy. The vector potential $\boldsymbol{A}$ for a quadruple has an expansion (shown through fourth order) of the form

$$A_x = \frac{g'(z)}{4}(x^3 - xy^2) + \cdots \,, \tag{36.2.33}$$

$$A_y = -\frac{g'(z)}{4}(y^3 - x^2y) + \cdots \,, \tag{36.2.34}$$

$$A_z = -\frac{g(z)}{2}(x^2 - y^2) + \frac{g''(z)}{12}(x^4 - y^4) + \cdots \,. \tag{36.2.35}$$

Here $g(z)$ is the on-axis field gradient, and the quantities $g'(z)$ and $g''(z)$ are derivatives of g with respect to z. We note that once $g(z)$ is specified (and quadrupole symmetry is imposed), then all other terms are determined by the Maxwell equations. Inspection of (2.32) shows that H is unchanged by the substitution $(p_x, p_y) \to (-p_x, -p_y)$ provided there is also the substitution $(A_x, A_y) \to (-A_x, -A_y)$. Suppose, for convenience, we choose the z coordinate so that $z = 0$ is at the center of the quadrupole. Then, for what we would intuitively call a symmetric quadrupole in the sense of having end-to-end symmetry, $g(z)$ should be an *even* function of z,

$$g(-z) = g(z). \tag{36.2.36}$$

From (2.36) we deduce that $g''(z)$, $g^{iv}(z)$, etc. are then also *even* functions of z; and $g'(z)$, $g'''(z)$, etc. are *odd* functions of z. It follows from (2.33) through (2.35) that, for a quadrupole with end-to-end symmetry, A_x and A_y are odd functions of z,

$$A_x(x, y, -z) = -A_x(x, y, z), \tag{36.2.37}$$

$$A_y(x, y, -z) = -A_y(x, y, z), \tag{36.2.38}$$

and A_z is an even function,

$$A_z(x, y, -z) = A_z(x, y, z). \tag{36.2.39}$$

[Note that the conditions (2.37) through (2.39) imply for the magnetic field the symmetry relations $B_{x,y}(x, y, -z) = B_{x,y}(x, y, z)$ and $B_z(x, y, -z) = -B_z(x, y, z)$]. From (2.32) and (2.37) through (2.39) we conclude that

$$H^r(-z) = H(z), \tag{36.2.40}$$

and therefore (2.21) is again satisfied. Thus, our intuitive sense of symmetry for a quadrupole coincides with the precise definition (2.21) for the Hamiltonian, which in turn implies the reversal symmetry condition (2.3) for the associated transfer map.

The same can be shown to be true for any multipole, including skew multipoles, with end-to-end symmetry. Finally, the same can be shown to be true for any dipole, with or without additional multipoles intended or otherwise, provided the magnet (including all multipole and fringe fields) has end-to-end symmetry. [Note that the Hamiltonian (2.32) can also be used for curved elements providing the bending angle is less than π. And for larger bend angles an analogous treatment can be formulated using cylindrical coordinates.] That is, in all these cases the relations (2.37) through (2.39) hold, and they imply the relation (2.40). By contrast, the transfer map for a dipole with unequal entry and exit angles, or for a combined function dipole with excessive quadrupole field at one end, will not be reversal symmetric.

Consider next the case of a short RF cavity phased to act as a buncher. Such an idealized cavity can be described by a map $\mathcal{M}$ of the form (1.32) with f given by the relation

$$f = (V/\omega) \cos \omega\tau. \tag{36.2.41}$$

Here V and ω are the voltage and frequency of the cavity. We see that f is *even* in τ, and therefore $f^r = f$. It follows that $\mathcal{M}$ is reversal symmetric. The case of a finite length RF cavity with realistic electromagnetic fields awaits investigation. Finally, it is evident that the transfer map for a short RF cavity phased to operate as an accelerating element rather than a bunching element [$\cos\omega\tau$ replaced by $\cos(\omega\tau+\phi)$] is not reversal symmetric.

We have seen that the transfer maps for many common beam-line elements are reversal symmetric. Suppose that $\mathcal{M}_1$, $\mathcal{M}_2$, and $\mathcal{M}_3$ are reversal symmetric maps. Then, by (2.1) and (2.2), the maps $\mathcal{M}$ given by products of the form

$$\mathcal{M} = \mathcal{M}_1\mathcal{M}_2\mathcal{M}_1, \tag{36.2.42}$$

$$\mathcal{M} = \mathcal{M}_1\mathcal{M}_2\mathcal{M}_3\mathcal{M}_2\mathcal{M}_1 \tag{36.2.43}$$

will be reversal symmetric. For example, $\mathcal{M}_1$ could be the map for a drift and $\mathcal{M}_2$ could be the map for a quadrupole. It follows that the map for a quadrupole sandwiched between two equal length drifts, given by (2.42), is reversal symmetric. Or $\mathcal{M}_1$ and $\mathcal{M}_3$ could be maps for quadrupoles and $\mathcal{M}_2$ could be the map for a drift. Then (2.43) would be the map for a quadrupole triplet, and we conclude that such maps are reversal symmetric. In the case of solenoids with end-to-end symmetry we could consider maps of the form

$$\mathcal{M} = \mathcal{M}_1\mathcal{M}_2\mathcal{M}_3 \tag{36.2.44}$$

where $\mathcal{M}_1$ is a solenoid map, $\mathcal{M}_2$ is a drift or quadrupole, and $\mathcal{M}_3$ is a map for an identical solenoid except for a reversed field. These maps (2.44) would also be reversal symmetric.

It frequently happens that a given map $\mathcal{M}$ is not reversal symmetric, but is *conjugate* to a map $\mathcal{N}$ that is reversal symmetric. That is, given $\mathcal{M}$, there exists a conjugating map $\mathcal{A}$ such that $\mathcal{M}$ can be written in the form

$$\mathcal{M} = \mathcal{A}^{-1}\mathcal{N}\mathcal{A} \tag{36.2.45}$$

where $\mathcal{N}$ is reversal symmetric. Consider, for example, the case of a FODO cell. Its map $\mathcal{M}$ is given by the product

$$\mathcal{M} = \mathcal{F}\mathcal{O}\mathcal{D}\mathcal{O} \tag{36.2.46}$$

where $\mathcal{F}$ and $\mathcal{D}$ are the maps for (horizontally) *focusing* and *defocussing* quadrupoles and $\mathcal{O}$ is the map for a *drift* (or a reversal symmetric dipole). Evidently $\mathcal{M}$ is not reversal symmetric although, according to our previous discussion, its factors are. However, we know that $\mathcal{F}$ (including all multipole and fringe-field effects) can be written as the product

$$\mathcal{F} = \mathcal{F}_\ell\mathcal{F}_t \tag{36.2.47}$$

where $\mathcal{F}_\ell$ and $\mathcal{F}_t$ are the maps for the leading and trailing halves of the focusing quadrupole. Moreover, there is the relation

$$\mathcal{F}_\ell^r = \mathcal{F}_t. \tag{36.2.48}$$

As a result of (2.47) $\mathcal{M}$ can be written in the form

$$\mathcal{M} = \mathcal{F}_\ell\mathcal{F}_t\mathcal{O}\mathcal{D}\mathcal{O} = \mathcal{F}_\ell\mathcal{F}_t\mathcal{O}\mathcal{D}\mathcal{O}\mathcal{F}_\ell\mathcal{F}_\ell^{-1} = \mathcal{A}^{-1}\mathcal{N}\mathcal{A} \tag{36.2.49}$$

with

$$\mathcal{A}^{-1} = \mathcal{F}_\ell \tag{36.2.50}$$

and

$$\mathcal{N} = \mathcal{F}_t \mathcal{O}\mathcal{D}\mathcal{O}\mathcal{F}_\ell. \tag{36.2.51}$$

Let us compute the reverse of $\mathcal{N}$. We find, using (2.1) and (2.48), the result

$$\mathcal{N}^r = \mathcal{F}_\ell^r \mathcal{O}^r \mathcal{D}^r \mathcal{O}^r \mathcal{F}_t^r = \mathcal{F}_t \mathcal{O}\mathcal{D}\mathcal{O}\mathcal{F}_\ell = \mathcal{N}. \tag{36.2.52}$$

Therefore, $\mathcal{N}$ is reversal symmetric. This example illustrates that the one-turn map for a ring is often reversal symmetric providing the surface of section (location at which the one-turn map is computed) is properly chosen.

As a second illustration, suppose that (through some order) $\mathcal{M}$ can be brought to normal form. (For example, assume that the eigenvalues of the linear part of $\mathcal{M}$ lie on the unit circle and that the corresponding tunes are not resonant through some order.) Then we may take $\mathcal{A}$ to be the normalizing map, and $\mathcal{N}$ to be the normal form of $\mathcal{M}$. The map $\mathcal{N}$ can be written in terms of a single exponent,

$$\mathcal{N} = \exp(:h:). \tag{36.2.53}$$

In the case of a static ring (no RF) h takes the form

$$\begin{aligned} h &= -(\phi_x/2)(p_x^2 + x^2) - (\phi_y/2)(p_y^2 + y^2) + b^1 p_\tau^2 + b^2 p_\tau^3 + b^3 p_\tau^4 \\ &\quad + a_{xx}(p_x^2 + x^2)^2 + a_{xy}(p_x^2 + x^2)(p_y^2 + y^2) + a_{yy}(p_y^2 + y^2)^2 \\ &\quad + c_x^1 (p_x^2 + x^2) p_\tau + c_x^2 (p_x^2 + x^2) p_\tau^2 \\ &\quad + c_y^1 (p_y^2 + y^2) p_\tau + c_y^2 (p_y^2 + y^2) p_\tau^2 + \cdots . \end{aligned} \tag{36.2.54}$$

We see that h is a power series in the quantities K_x, K_y, and p_τ where

$$K_x = (p_x^2 + x^2), \tag{36.2.55}$$

$$K_y = (p_y^2 + y^2). \tag{36.2.56}$$

The quantities $[\phi/(2\pi)]$ are (fractional) tunes, the quantities b are related to phase slip (momentum compaction), the quantities a are related to anharmonicities, and the quantities c are related to chromaticities. In the dynamic case h takes the form

$$\begin{aligned} h &= -(\phi_x/2)K_x - (\phi_y/2)K_y - (\phi_\tau/2)K_\tau \\ &\quad + a_{xx}K_x^2 + a_{yy}K_y^2 + a_{\tau\tau}K_\tau^2 + a_{xy}K_x K_y \\ &\quad + a_{x\tau}K_x K_\tau + a_{y\tau}K_y K_\tau + \cdots . \end{aligned} \tag{36.2.57}$$

Now h is a power series in K_x, K_y, and K_τ with K_x, K_y defined as above and

$$K_\tau = (p_\tau^2 + \tau^2). \tag{36.2.58}$$

We see that in both cases $h^r = h$, and therefore $\mathcal{N}$ is reversal symmetric. Of course, the normal form procedure usually leads to divergent series and therefore these normal form results are only approximate in the formal sense of holding to any order, but usually not exactly.

We have defined a map $\mathcal{M}$ to be reversal symmetric if it satisfies the condition (2.3). We now define a map to be reversal *antisymmetric* if it satisfies the condition

$$\mathcal{M}^r = \mathcal{M}^{-1}. \tag{36.2.59}$$

Suppose $\mathcal{M}$ can be written in the single exponent form (1.33), and is reversal antisymmetric. Then we see from (1.46) that the generator f must satisfy the relation

$$f^r = -f. \tag{36.2.60}$$

Note that reversal antisymmetric maps form a subgroup. In particular, if two maps $\mathcal{M}_1$ and $\mathcal{M}_2$ are reversal antisymmetric, so is their product $\mathcal{M}_1\mathcal{M}_2$:

$$(\mathcal{M}_1\mathcal{M}_2)^r = \mathcal{M}_2^r\mathcal{M}_1^r = (\mathcal{M}_2^{-1})(\mathcal{M}_1^{-1}) = (\mathcal{M}_1\mathcal{M}_2)^{-1}. \tag{36.2.61}$$

Correspondingly, functions that satisfy (2.60) form a Lie algebra under Poisson bracketing. Indeed, if f and g are *any* two functions, there is the general relation

$$\mathcal{R}[f,g] = \mathcal{R} : f : g = \mathcal{R} : f : \mathcal{R}\mathcal{R}g = - : f^r : g^r = -[f^r, g^r]. \tag{36.2.62}$$

And, if f and g satisfy (2.60), there is the result

$$\mathcal{R}[f,g] = -[f,g]. \tag{36.2.63}$$

Thus, if f and g change sign under reversal, so does their Poisson bracket.

We close this section by showing that under certain circumstances a symplectic map $\mathcal{M}$ can be written uniquely as the product of a reversal symmetric symplectic map and a reversal antisymmetric symplectic map. Given any symplectic map $\mathcal{M}$, define an associated symplectic map $\mathcal{B}$ by the relation

$$\mathcal{B} = \mathcal{M}\mathcal{M}^r. \tag{36.2.64}$$

Then, by (2.1) and (2.2), $\mathcal{B}$ is reversal symmetric. Assume that it is possible to find a *square root* $\mathcal{S}$ for $\mathcal{B}$, and that this square root is also reversal symmetric. That is, assume there is an $\mathcal{S}$ satisfying

$$\mathcal{S}^r = \mathcal{S} \tag{36.2.65}$$

such that

$$\mathcal{B} = \mathcal{S}^2. \tag{36.2.66}$$

For example, suppose that $\mathcal{B}$ can be written in the single exponent form

$$\mathcal{B} = \exp(: f :) \tag{36.2.67}$$

and that f has the property (2.14). Then we may define $\mathcal{S}$ by the relation

$$\mathcal{S} = \exp(: f : /2). \tag{36.2.68}$$

Next define a symplectic map $\mathcal{A}$ by the relation

$$\mathcal{A} = \mathcal{S}^{-1}\mathcal{M}. \tag{36.2.69}$$

Then $\mathcal{A}$ will be reversal antisymmetric. Indeed, we have the results

$$\mathcal{A}^r = \mathcal{M}^r \mathcal{S}^{-1}, \tag{36.2.70}$$

$$\mathcal{A}\mathcal{A}^r = \mathcal{S}^{-1}\mathcal{M}\mathcal{M}^r\mathcal{S}^{-1} = \mathcal{S}^{-1}\mathcal{B}\mathcal{S}^{-1} = \mathcal{S}^{-1}\mathcal{S}^2\mathcal{S}^{-1} = \mathcal{I}, \tag{36.2.71}$$

and therefore $\mathcal{A}$ is reversal antisymmetric. Finally, (2.69) can be rewritten in the form

$$\mathcal{M} = \mathcal{S}\mathcal{A}. \tag{36.2.72}$$

We see that, under the assumptions made, $\mathcal{M}$ can be written as the product of a reversal symmetric map $\mathcal{S}$ and a reversal antisymmetric map $\mathcal{A}$, and we have found expressions for each.

Exercises

36.2.1. Review the first part of Exercise 6.2.9. Let $\mathcal{S}_3$ be the set of all reversal antisymmetric symplectic maps. Show that $\mathcal{S}_3$ forms a group, and that there is the inclusion relation

$$\mathcal{S}_0 \supset \mathcal{S}_1 \supset \mathcal{S}_2 \supset \mathcal{S}_3. \tag{36.2.73}$$

36.3 General Consequences for Straight and Circular Machines

Suppose $\mathcal{M}$ has a factorization of the form

$$\mathcal{M} = \mathcal{L}\ \exp: f_3 : \exp : f_4 : \cdots . \tag{36.3.1}$$

Here $\mathcal{L}$ is the linear part of $\mathcal{M}$. Then, we find for $\mathcal{M}^r$ the factorization

$$\begin{aligned} \mathcal{M}^r &= \cdots [\exp(: f_4 :)]^r [\exp(: f_3 :)]^r \mathcal{L}^r \\ &= \cdots \exp(: f_4^r :) \exp(: f_3^r :)\mathcal{L}^r. \end{aligned} \tag{36.3.2}$$

Here we have used (2.2) and (1.46). Also, if the action of $\mathcal{L}^r$ is described by the matrix L^r, then the operator relation

$$\mathcal{L}^r = \mathcal{R}\mathcal{L}^{-1}\mathcal{R} \tag{36.3.3}$$

yields the matrix relation

$$L^r = RL^{-1}R \tag{36.3.4}$$

consistent with (1.47). Also, as done before for (1.49), we deduce from the symplectic condition (3.1.2) that (3.3) can also be written in the form

$$L^r = JRL^TJR. \tag{36.3.5}$$

Let us (in the 6×6 case) write L using the standard matrix notation,

$$L = \begin{pmatrix} L_{11} & L_{12} & L_{13} & L_{14} & L_{15} & L_{16} \\ L_{21} & L_{22} & L_{23} & L_{24} & L_{25} & L_{26} \\ L_{31} & L_{32} & L_{33} & L_{34} & L_{35} & L_{36} \\ L_{41} & L_{42} & L_{43} & L_{44} & L_{45} & L_{46} \\ L_{51} & L_{52} & L_{53} & L_{54} & L_{55} & L_{56} \\ L_{61} & L_{62} & L_{63} & L_{64} & L_{65} & L_{66} \end{pmatrix}. \tag{36.3.6}$$

Then, upon evaluating (3.5), we find that L^r is the matrix

$$L^r = \begin{pmatrix} L_{22} & L_{12} & L_{42} & L_{32} & -L_{62} & -L_{52} \\ L_{21} & L_{11} & L_{41} & L_{31} & -L_{61} & -L_{51} \\ L_{24} & L_{14} & L_{44} & L_{34} & -L_{64} & -L_{54} \\ L_{23} & L_{13} & L_{43} & L_{33} & -L_{63} & -L_{53} \\ -L_{26} & -L_{16} & -L_{46} & -L_{36} & L_{66} & L_{56} \\ -L_{25} & -L_{15} & -L_{45} & -L_{35} & L_{65} & L_{55} \end{pmatrix}. \tag{36.3.7}$$

Now suppose that $\mathcal{M}$ is reversal symmetric so that (2.3) holds. Taken together (2.3) and (3.2) give the result

$$\cdots \exp(:f_4^r:)\exp(:f_3^r:)\mathcal{L}^r = \mathcal{L}\exp(:f_3:)\exp(:f_4:)\cdots . \tag{36.3.8}$$

The right side of (3.8) can be rewritten in the form

$$\begin{aligned} \mathcal{L}\exp(:f_3:)\exp(:f_4:)\cdots &= \mathcal{L}\exp(:f_3:)\exp(:f_4:)\cdots\mathcal{L}^{-1}\mathcal{L} \\ &= \cdots\exp(:g_4:)\exp(:g_3:)\mathcal{L}, \end{aligned} \tag{36.3.9}$$

where the quantities $g_3, g_4, \cdots$ are yet to be determined. Upon comparing (3.8) and (3.9) we see that reversal symmetry requires the relations

$$\mathcal{L}^r = \mathcal{L}, \tag{36.3.10}$$

$$f_m^r = g_m. \tag{36.3.11}$$

The linear part $\mathcal{L}$ of $\mathcal{M}$ must be reversal symmetric, and the Lie generators of the nonlinear part must satisfy (3.11).

To work out the implications of (3.11) for the nonlinear part in more detail, we must find the g_m in terms of the f_m. From (3.9) we conclude that there is the relation

$$\exp(:\mathcal{L}f_3:)\exp(:\mathcal{L}f_4:)\cdots = \cdots\exp(:g_4:)\exp(:g_3:). \tag{36.3.12}$$

Now use the Baker-Campbell-Hausdorff series (8.2.28) and (8.2.29) to combine the exponents on each side of (3.12) and equate terms of like degree. Doing so yields the relations

$$g_3 = \mathcal{L}f_3, \tag{36.3.13}$$

$$g_4 = \mathcal{L}f_4, \tag{36.3.14}$$

$$g_5 = \mathcal{L}f_5 + [\mathcal{L}f_3, \mathcal{L}f_4], \tag{36.3.15}$$

$$g_6 = \mathcal{L}f_6 + [\mathcal{L}f_3, \mathcal{L}f_5] + (1/2)[\mathcal{L}f_3, [\mathcal{L}f_3, \mathcal{L}f_4]], \text{ etc.} \tag{36.3.16}$$

Finally, employ (3.11) in the relations (3.13) through (3.16) to find the results

$$f_3^r = \mathcal{L}f_3, \tag{36.3.17}$$

$$f_4^r = \mathcal{L}f_4, \tag{36.3.18}$$

$$f_5^r = \mathcal{L}f_5 + [\mathcal{L}f_3, \mathcal{L}f_4], \tag{36.3.19}$$

$$f_6^r = \mathcal{L}f_6 + [\mathcal{L}f_3, \mathcal{L}f_5] + (1/2)[\mathcal{L}f_3, [\mathcal{L}f_3, \mathcal{L}f_4]], \text{ etc.} \tag{36.3.20}$$

Let us explore the consequences of reversal symmetry for $\mathcal{L}$. The relation (3.15) implies the associated matrix relation

$$L^r = L. \tag{36.3.21}$$

In view of (3.6) and (3.7), and in the 6×6 case, simple enumeration shows that reversal symmetry places on the entries in L the 15 restrictions listed below:

$$L_{11} = L_{22}, \tag{36.3.22}$$

$$L_{13} = L_{42}, \tag{36.3.23}$$

$$L_{14} = L_{32}, \tag{36.3.24}$$

$$L_{15} = -L_{62}, \tag{36.3.25}$$

$$L_{16} = -L_{52}, \tag{36.3.26}$$

$$L_{23} = L_{41}, \tag{36.3.27}$$

$$L_{24} = L_{31}, \tag{36.3.28}$$

$$L_{25} = -L_{61}, \tag{36.3.29}$$

$$L_{26} = -L_{51}, \tag{36.3.30}$$

$$L_{33} = L_{44}, \tag{36.3.31}$$

$$L_{35} = -L_{64}, \tag{36.3.32}$$

$$L_{36} = -L_{54}, \tag{36.3.33}$$

$$L_{45} = -L_{63}, \tag{36.3.34}$$

$$L_{46} = -L_{53}, \tag{36.3.35}$$

$$L_{55} = L_{66}. \tag{36.3.36}$$

Of course, there are also restrictions on L that follow from the symplectic condition. Suppose that $\mathcal{M}$ is a static (time independent) map. From the work of Section 19.4 we know that in the static case L must have the form

$$L = \begin{pmatrix} L_{11} & L_{12} & L_{13} & L_{14} & 0 & (\check{L}\delta)_1 \\ L_{21} & L_{22} & L_{23} & L_{24} & 0 & (\check{L}\delta)_2 \\ L_{31} & L_{32} & L_{33} & L_{34} & 0 & (\check{L}\delta)_3 \\ L_{41} & L_{42} & L_{43} & L_{44} & 0 & (\check{L}\delta)_4 \\ -\delta_2 & \delta_1 & -\delta_4 & \delta_3 & 1 & L_{56} \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{36.3.37}$$

Recall that we have previously defined a matrix $\hat{L}$ by the rule

$$\hat{L} = \begin{pmatrix} L_{11} & L_{12} & L_{13} & L_{14} & 0 & 0 \\ L_{21} & L_{22} & L_{23} & L_{24} & 0 & 0 \\ L_{31} & L_{32} & L_{33} & L_{34} & 0 & 0 \\ L_{41} & L_{42} & L_{43} & L_{44} & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}, \tag{36.3.38}$$

and that we have used the notation

$$\hat{L} = \begin{pmatrix} \check{L} & 0 \\ 0 & I \end{pmatrix} \tag{36.3.39}$$

where $\check{L}$ is the 4×4 matrix

$$\check{L} = \begin{pmatrix} L_{11} & L_{12} & L_{13} & L_{14} \\ L_{21} & L_{22} & L_{23} & L_{24} \\ L_{31} & L_{32} & L_{33} & L_{34} \\ L_{41} & L_{42} & L_{43} & L_{44} \end{pmatrix}. \tag{36.3.40}$$

See (19.*.*). Moreover, we know that the linear map $\hat{\mathcal{L}}$ associated with the matrix $\hat{L}$ is a symplectic map, and hence $\hat{L}$ and $\check{L}$ are symplectic matrices.

Suppose, now, that the static linear map described by (3.37) is also reversal symmetric so that the conditions (3.22) through (3.36) also hold. Then, from the form (3.37) for L, it is evident that the five conditions (3.25), (3.29), (3.32), (3.34), and (3.36) on the matrix elements L_{15} through L_{55} are automatically satisfied. By contrast, the four conditions (3.26), (3.30), (3.33), and (3.35) on the matrix elements L_{16} through L_{46} yield the relations

$$(\check{L}\delta)_1 = -\delta_1, \tag{36.3.41}$$

$$(\check{L}\delta)_2 = \delta_2, \tag{36.3.42}$$

$$(\check{L}\delta)_3 = -\delta_3, \tag{36.3.43}$$

$$(\check{L}\delta)_4 = \delta_4. \tag{36.3.44}$$

In the spirit of (3.40), let us use J and R as given by (3.2.10) and (1.5) to define associated 4×4 matrices $\check{J}$ and $\check{R}$,

$$\check{J} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix}, \tag{36.3.45}$$

$$\check{R} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}. \tag{36.3.46}$$

With the aid of $\check{R}$ the relations (3.41) through (3.44) can be written in the more compact forms

$$\check{L}\delta = -\check{R}\delta \tag{36.3.47}$$

or

$$\check{R}\check{L}\delta = -\delta. \tag{36.3.48}$$

Moreover, the remaining six reversal symmetry relations (3.22), (3.23), (3.24), (3.27), (3.28), and (3.31) for the entries of $\check{L}$ can be written in the compact form

$$\check{L} = \check{J}\check{R}\check{L}^T\check{J}\check{R}. \tag{36.3.49}$$

Finally, the entries of $\check{L}$ must also satisfy the symplectic condition

$$\check{L}^T\check{J}\check{L} = \check{J}. \tag{36.3.50}$$

The imposition of reversal symmetry on $\mathcal{L}$ also implies an associated relation that must be satisfied by the f_1 in (19.*.*). This relation can be obtained by matrix and vector manipulation using (19.*.*) and (3.48). It is also instructive to obtain the condition on f_1 by Lie manipulation starting with (19.*.*). Rewrite (19.*.*) in the explicit form

$$\mathcal{L} = \exp(:\xi p_\tau^2:)\exp(:p_\tau f_1:)\hat{\mathcal{L}}, \tag{36.3.51}$$

and apply reversal to find the equivalent relation

$$\begin{aligned}\mathcal{L}^r &= \hat{\mathcal{L}}^r\exp(:p_\tau f_1^r:)\exp(:\xi p_\tau^2:)\\ &= \exp(:\xi p_\tau^2:)\hat{\mathcal{L}}^r\exp(:p_\tau f_1^r:)(\hat{\mathcal{L}}^r)^{-1}\hat{\mathcal{L}}^r\\ &= \exp(:\xi p_\tau^2:)\exp(:p_\tau\hat{\mathcal{L}}^r f_1^r:)\hat{\mathcal{L}}^r.\end{aligned} \tag{36.3.52}$$

Here we have also used (8.2.27). Now require that $\mathcal{L}$ satisfy the reversal symmetry condition (3.10). Comparison of (3.51) and (3.52) then gives the relation

$$\hat{\mathcal{L}}^r = \hat{\mathcal{L}}, \tag{36.3.53}$$

which is equivalent to (3.49), and the relation

$$\hat{\mathcal{L}}^r f_1^r = f_1. \tag{36.3.54}$$

In view of (3.53), the relation (3.54) can also be written in the form

$$f_1^r = \hat{\mathcal{L}}^{-1}f_1, \tag{36.3.55}$$

which is equivalent to (3.47) or (3.48).

36.4 Consequences for some Special Cases

Let us explore the implication of reversal symmetry for some special cases. Again assume that $\mathcal{M}$ is static, and suppose further that $\check{L}$ does not couple the x, p_x, and y, p_y degrees of freedom. In this case L as given by (3.37) takes the form

$$L = \begin{pmatrix} a & b & 0 & 0 & 0 & \check{\delta}_1 \\ c & d & 0 & 0 & 0 & \check{\delta}_2 \\ 0 & 0 & e & f & 0 & \check{\delta}_3 \\ 0 & 0 & g & h & 0 & \check{\delta}_4 \\ -\delta_2 & \delta_1 & -\delta_4 & \delta_3 & 1 & L_{56} \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix} \tag{36.4.1}$$

where

$$\check{\delta}_a = (\check{L}\delta)_a. \tag{36.4.2}$$

And, by combining (3.6), (3.7), and (3.48), L^r takes the form

$$L^r = \begin{pmatrix} d & b & 0 & 0 & 0 & -\delta_1 \\ c & a & 0 & 0 & 0 & \delta_2 \\ 0 & 0 & h & f & 0 & -\delta_3 \\ 0 & 0 & g & e & 0 & \delta_4 \\ -\check{\delta}_2 & -\check{\delta}_1 & -\check{\delta}_4 & -\check{\delta}_3 & 1 & L_{56} \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{36.4.3}$$

Imposing the reversal symmetry condition (3.21) yields the relations

$$\check{\delta}_1 = -\delta_1, \tag{36.4.4}$$

$$\check{\delta}_2 = \delta_2, \tag{36.4.5}$$

$$\check{\delta}_3 = -\delta_3, \tag{36.4.6}$$

$$\check{\delta}_4 = \delta_4, \tag{36.4.7}$$

which echo (3.41) through (3.44), and the additional relations

$$a = d, \tag{36.4.8}$$

$$e = h. \tag{36.4.9}$$

Moreover, the symplectic condition (3.50) provides the relations

$$ad - bc = 1, \tag{36.4.10}$$

$$eh - fg = 1. \tag{36.4.11}$$

Suppose we further assume that, say in the x, p_x plane, the system is *imaging* (and therefore $b = 0$) or *telescopic* (and therefore $c = 0$). Then it follows from (4.8) and (4.10) that

$$a = d = \pm 1. \tag{36.4.12}$$

Similar conclusions hold for the y, p_y plane. We have learned that if a system is reversal symmetric and imaging or telescopic, then (up to a sign) the system must have unit magnification or unit "parallelization".

Suppose instead that the eigenvalues of $\check{L}$ lie on the unit circle (but differ from ± 1) and that the x, p_x and y, p_y degrees of freedom are uncoupled. Then $\hat{\mathcal{L}}$ can be written in the form

$$\hat{\mathcal{L}} = \exp(: f_2 :) \tag{36.4.13}$$

where

$$\begin{aligned} f_2 = \; & - \;\; (\phi_x/2)(\beta_x p_x^2 + 2\alpha_x x p_x + \gamma_x x^2) \\ & - \;\; (\phi_y/2)(\beta_y p_y^2 + 2\alpha_y y p_y + \gamma_y y^2). \end{aligned} \tag{36.4.14}$$

Here $[\phi_x/(2\pi)]$ and $[\phi_y/2\pi]$ are the horizontal and vertical (fractional) tunes, and $\alpha_x, \beta_x, \gamma_x$ and $\alpha_y, \beta_y, \gamma_y$ are the horizontal and vertical Courant-Snyder (Twiss) functions. Then reversal symmetry requires the relation (2.14) from which it follows that

$$\alpha_x = \alpha_y = 0. \tag{36.4.15}$$

Thus, the Courant-Snyder ellipses for both the x and y degrees of freedom are *upright* if $\mathcal{M}$ is reversal symmetric.

36.5 Consequences for Closed Orbit in a Circular Machine

There is a further factorization of a static linear sympletic map $\mathcal{L}$ as given by (19.*.*) that is of use. Let $\mathcal{A}_d$ be the map given by the relation

$$\mathcal{A}_d = \exp(: p_\tau g_1 :) \tag{36.5.1}$$

where g_1 is yet to be determined (but does not depend on τ and p_τ). Here we use the subscript d to indicate that $\mathcal{A}_d$ is analogous to $\mathcal{D}$ as given by (19.*.*). Consider the map $\mathcal{N}_d$ given by

$$\mathcal{N}_d = \mathcal{A}_d \mathcal{L} \mathcal{A}_d^{-1}. \tag{36.5.2}$$

From (19.*.*) we have the result

$$\mathcal{N}_d = \mathcal{A}_d \mathcal{C} \mathcal{D} \hat{\mathcal{L}} \mathcal{A}_d^{-1} = \mathcal{C} \mathcal{A}_d \mathcal{D} \hat{\mathcal{L}} \mathcal{A}_d^{-1} = \mathcal{C} \mathcal{A}_d \mathcal{D} \hat{\mathcal{L}} \mathcal{A}_d^{-1} \hat{\mathcal{L}}^{-1} \hat{\mathcal{L}}. \tag{36.5.3}$$

At this point we ask if there is a choice of $\mathcal{A}_d$ such that

$$\mathcal{A}_d \mathcal{D} \hat{\mathcal{L}} \mathcal{A}_d^{-1} \hat{\mathcal{L}}^{-1} = \mathcal{C}(\xi') \tag{36.5.4}$$

where $\mathcal{C}(\xi')$ is a map of the form (19.*.*). With the aid of (5.13.14), (8.2.27) and the Baker-Campbell-Hausdorff series (3.7.34) we find the result

$$\begin{aligned} & \mathcal{A}_d \mathcal{D} \hat{\mathcal{L}} \mathcal{A}_d^{-1} \hat{\mathcal{L}}^{-1} = \\ & \exp(: p_\tau g_1 :) \exp(: p_\tau f_1 :) \hat{\mathcal{L}} \exp(- : p_\tau g_1 :) \hat{\mathcal{L}}^{-1} = \\ & \exp(: p_\tau g_1 :) \exp(: p_\tau f_1 :) \exp(- : p_\tau \hat{\mathcal{L}} g_1) \\ & = \exp\{: p_\tau (g_1 + f_1 - \hat{\mathcal{L}} g_1) :\} \times \\ & \exp\{: (p_\tau^2/2)(-[f_1, \hat{\mathcal{L}} g_1] + [g_1, f_1] - [g_1, \hat{\mathcal{L}} g_1]) :\}. \end{aligned} \tag{36.5.5}$$

We see that (5.4) can be achieved providing a g_1 can be found such that

$$(\hat{\mathcal{L}} - \mathcal{I})g_1 = f_1. \tag{36.5.6}$$

Inspection of (3.39) and (3.40) shows that (5.6) can be solved (uniquely) to obtain g_1 in terms of f_1 providing $\check{L}$ as given by (3.40) does not have $+1$ as an eigenvalue. That is, neither transverse tune is integer. For the record, we also note that when g_1 is specified by (5.6), the map $\mathcal{C}(\xi')$ is given by the relation

$$\xi' = [g_1, f_1]/2. \tag{36.5.7}$$

By combining (5.3) and (5.4), we find the relation

$$\mathcal{N}_d = \mathcal{C}(\eta)\hat{\mathcal{L}} \tag{36.5.8}$$

with $\mathcal{C}(\eta)$ given by the product

$$\mathcal{C}(\eta) = \mathcal{C}(\xi)\mathcal{C}(\xi') = \mathcal{C}(\xi + \xi'). \tag{36.5.9}$$

Finally, solving (5.2) for $\mathcal{L}$ and use of (5.8) yields the factorization

$$\mathcal{L} = \mathcal{C}(\eta)\mathcal{A}_d^{-1}\hat{\mathcal{L}}\mathcal{A}_d. \tag{36.5.10}$$

The quantities η and g_1 appearing in $\mathcal{C}(\eta)$ and $\mathcal{A}_d$ have a physical interpretation. In analogy with (19.*.*), write g_1 in the form

$$g_1 = \Delta_2 x - \Delta_1 p_x + \Delta_4 y - \Delta_3 p_y. \tag{36.5.11}$$

The operator relation (5.10) is equivalent to the matrix relation

$$L = A_d\hat{L}A_d^{-1}C(\eta) = A_d C(\eta)\hat{L}A_d^{-1} \tag{36.5.12}$$

where $C(\eta)$ and A_d are the matrices associated with $\mathcal{C}(\eta)$ and $\mathcal{A}_d$. In analogy with (19.*.*) and (19.*.*) they are given by the equations

$$C(\eta) = C(\xi + \xi'), \tag{36.5.13}$$

$$A_d = D(\Delta), \tag{36.5.14}$$

$$A_d^{-1} = D(-\Delta). \tag{36.5.15}$$

[Note that in writing (5.12) we have employed the fact that $C(\eta)$ commutes with A_d^{-1}, $\hat{L}$, and A_d.] Now let $z^0(p_\tau)$ be the vector with all zero entries save for p_τ in the last entry,

$$z^0(p_\tau) = (0, 0, 0, 0, 0, p_\tau). \tag{36.5.16}$$

It evidently has the properties

$$\hat{L}z^0(p_\tau) = z^0(p_\tau), \tag{36.5.17}$$

$$C(\eta)z^0(p_\tau) = \bar{z}^0(p_\tau) \tag{36.5.18}$$

where $\bar{z}^0(p_\tau)$ has the entries

$$\bar{z}^0(p_\tau) = (0, 0, 0, 0, \eta p_\tau, p_\tau). \tag{36.5.19}$$

Next let $z^c(p_\tau)$ be the vector defined by the relation

$$z^c(p_\tau) = A_d z^c(p_\tau). \tag{36.5.20}$$

Carrying out the indicated multiplication shows that it has the entries

$$z^c(p_\tau) = (\Delta_1 p_\tau, \Delta_2 p_\tau, \Delta_3 p_\tau, \Delta_4 p_\tau, 0, p_\tau). \tag{36.5.21}$$

Also, by construction, it has the property

$$z^0(p_\tau) = A_d^{-1} z^c(p_\tau). \tag{36.5.22}$$

Finally, let us apply L to $z^c(p_\tau)$. From (5.12), (5.17) through (5.20), and (5.22) we find the result

$$\begin{aligned} L z^c(p_\tau) &= A_d C'' \hat{L} A_d^{-1} z^c(p_\tau) = A_d C'' \hat{L} z^0(p_\tau) \\ &= A_d C'' z^0(p_\tau) = A_d z^0(p_\tau) = \bar{z}^c(p_\tau) \end{aligned} \tag{36.5.23}$$

where $\bar{z}^c(p_\tau)$ is the vector

$$\bar{z}^c(p_\tau) = A_d \bar{z}^0(p_\tau). \tag{36.5.24}$$

From (19.*.*), (5.14), (5.19), and (5.24) we find that $\bar{z}^c(p_\tau)$ has the entries

$$\bar{z}^c(p_\tau) = (\Delta_1 p_\tau, \Delta_2 p_\tau, \Delta_3 p_\tau, \Delta_4 p_\tau, \eta p_\tau, p_\tau). \tag{36.5.25}$$

Comparison of (5.21) and (5.25) shows that $z^c(p_\tau)$ and $\bar{z}^c(p_\tau)$ *agree* in all entries except for the fifth. We conclude that the quantities $\Delta_a p_\tau$, for $a = 1$ to 4, are the transverse phase-space coordinates for the *closed* orbit (in the linear approximation to $\mathcal{M}$ described by $\mathcal{L}$). Thus, the quantities Δ_1 and Δ_3 are dispersions, and Δ_2 and Δ_4 are their momentum counterparts. And, as is evident from the fifth components of $z^c(p_\tau)$ and $\bar{z}^c(p_\tau)$, the quantity ηp_τ is the differential time-of-flight on the closed orbit. Correspondingly, η is the *phase slip* factor.

What can be said about g_1 and $\mathcal{A}_d$ if $\mathcal{L}$ is reversal symmetric? Rewrite (5.6) in the form

$$f_1 = \hat{\mathcal{L}} g_1 - g_1. \tag{36.5.26}$$

Applying reversal produces the equivalent relation [see (1.56)]

$$f_1^r = (\hat{\mathcal{L}}^r)^{-1} g_1^r - g_1^r, \tag{36.5.27}$$

and multiplying both sides of this relation by $\hat{\mathcal{L}}^r$ yields the result

$$\hat{\mathcal{L}}^r f_1^r = g_1^r - \hat{\mathcal{L}}^r g_1^r. \tag{36.5.28}$$

Now suppose that $\mathcal{L}$ is reversal symmetric so that (3.53) and (3.54) hold. Then (5.28) becomes

$$f_1 = g_1^r - \hat{\mathcal{L}} g_1^r, \tag{36.5.29}$$

and this result when combined with (5.26) yields the relation

$$(\hat{\mathcal{L}} - \mathcal{I})g_1 = -(\hat{\mathcal{L}} - \mathcal{I})g_1^r. \tag{36.5.30}$$

We have already assumed that $(\hat{\mathcal{L}} - \mathcal{I})$ is invertible, and therefore (5.30) implies the relation

$$g_1^r = -g_1. \tag{36.5.31}$$

This is the condition for $\mathcal{A}_d$ to be reversal antisymmetric. We have learned that if $\mathcal{L}$ is reversal symmetric, it can be written in the form (5.10) with $\mathcal{A}_d$ being reversal antisymmetric,

$$\mathcal{A}_d^r = \mathcal{A}_d^{-1}. \tag{36.5.32}$$

Moreover, comparison of (5.11) and (5.31) shows that there is the relation

$$\Delta_2 = \Delta_4 = 0 \tag{36.5.33}$$

if $\mathcal{L}$ is reversal symmetric. In view of (5.21), this relation can also be written in the form

$$Rz^c(p_\tau) = z^c(p_\tau). \tag{36.5.34}$$

If $\mathcal{L}$ is reversal symmetric the off-energy closed orbit has no transverse momentum components (at the ring location for which $\mathcal{L}$ is computed).

How do the quantities Δ_a and η vary from place to place around a ring? We will see shortly that η is constant. First let us consider the Δ_a. Suppose that in the linear approximation the one-turn map $\mathcal{L}$ for a ring can be written as the product of $2n$ maps in the form

$$\mathcal{L} = \mathcal{L}_1\mathcal{L}_2 \cdots \mathcal{L}_n\mathcal{L}_{\tilde{n}} \cdots \mathcal{L}_{\tilde{2}}\mathcal{L}_{\tilde{1}} \tag{36.5.35}$$

with

$$\mathcal{L}_{\tilde{j}} = \mathcal{L}_j^r. \tag{36.5.36}$$

Figure 5.1 illustrates such a ring. In view of (5.36), we may say that the ring has location 0 as a symmetry point. From (2.15) and (2.16) we see that $\mathcal{L}$ is reversal symmetric, i.e. (3.10) holds. Our task is to compute the closed-orbit quantities Δ_a at various other locations (Poincaré surfaces of section) j and $\tilde{j}$ around the ring.

Introduce the maps $\mathcal{S}^j$ and $\mathcal{S}^{\tilde{j}}$ defined by the rules

$$\mathcal{S}^j = \mathcal{L}_1\mathcal{L}_2 \cdots \mathcal{L}_j, \tag{36.5.37}$$

$$\mathcal{S}^{\tilde{j}} = \mathcal{L}_{\tilde{j}} \cdots \mathcal{L}_{\tilde{2}}\mathcal{L}_{\tilde{1}}, \tag{36.5.38}$$

and let S^j and $S^{\tilde{j}}$ be their corresponding matrices. Let z^{cj} be the closed-orbit vector at location j. In analogy to (5.21) we write it in the form

$$z^{cj}(p_\tau) = (\Delta_1^j p_\tau, \Delta_2^j p_\tau, \Delta_3^j p_\tau, \Delta_4^j p_\tau, *, p_\tau) \tag{36.5.39}$$

where the entry labeled $*$ need not concern us. Also, from (5.21) and (5.34), the closed-orbit vector at location 0, denote it by $z^{c0}(p_\tau)$, is given by the relation

$$z^{c0}(p_\tau) = z^c(p_\tau) = (\Delta_1^0 p_\tau, 0, \Delta_3^0 p_\tau, 0, 0, p_\tau) \tag{36.5.40}$$

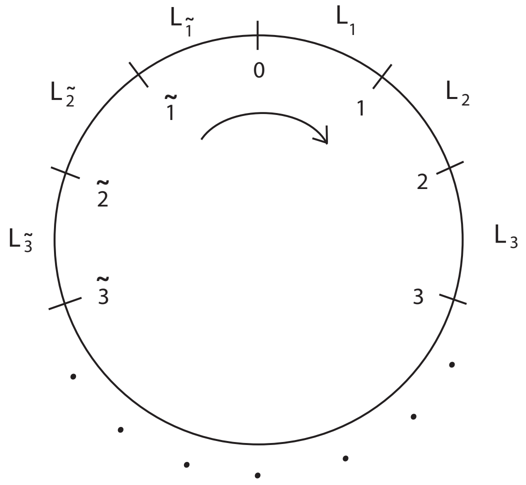

Figure 36.5.1: Schematic drawing of a ring showing the locations (Poincaré surfaces of section) $0; 1, \tilde{1}; 2, \tilde{2}; 3, \tilde{3}$; etc.

with $\Delta_1^0 = \Delta_1$ and $\Delta_3^0 = \Delta_3$. Then, inspection of Figure 5.1 shows that the closed-orbit vector at location j must be the result of propagating the closed-orbit initial conditions from location 0 to location j. That is, there is the vector and matrix relation

$$z^{cj}(p_\tau) = S^j z^{c0}. \tag{36.5.41}$$

Similarly, let $z^{c\tilde{j}}$ be the closed-orbit vector at location $\tilde{j}$, and write it in the form

$$z^{c\tilde{j}}(p_\tau) = (\Delta_1^{\tilde{j}} p_\tau, \Delta_2^{\tilde{j}} p_\tau, \Delta_3^{\tilde{j}} p_\tau, \Delta_4^{\tilde{j}} p_\tau, *, p_\tau). \tag{36.5.42}$$

Then, by following the closed orbit *backwards* from location 0 to location $\tilde{j}$, we see that there is the relation

$$z^{c\tilde{j}} = (S^{\tilde{j}})^{-1} z^{c0}. \tag{36.5.43}$$

We are now prepared to compare z^{cj} and $z^{c\tilde{j}}$. From (5.36) through (5.38) it is easily checked that there is the operator relation

$$(\mathcal{S}^j)^r = \mathcal{S}^{\tilde{j}} \tag{36.5.44}$$

and hence also the corresponding matrix relation

$$(S^j)^r = S^{\tilde{j}}. \tag{36.5.45}$$

It follows that (5.43) can be written in the form

$$\begin{aligned} z^{c\tilde{j}} &= ((S^j)^r)^{-1} z^{c0} = (R(S^j)^{-1}R)^{-1} z^{c0} \\ &= RS^jRz^{c0} = RS^jz^{c0} = Rz^{cj}. \end{aligned} \tag{36.5.46}$$

Here we have also used (1.8), (3.4), and (5.34). From (5.46) we conclude that there are the relations

$$\Delta_1^{\tilde{j}} = \Delta_1^j, \tag{36.5.47}$$

$$\Delta_2^{\tilde{j}} = -\Delta_2^j, \tag{36.5.48}$$

$$\Delta_3^{\tilde{j}} = \Delta_3^j, \tag{36.5.49}$$

$$\Delta_4^{\tilde{j}} = -\Delta_4^j. \tag{36.5.50}$$

We have learned that Δ_1 and Δ_3 are "even" functions of position about the symmetry location 0, and Δ_2 and Δ_4 are "odd" functions.

36.6 Consequences for Courant-Snyder Functions in a Circular Machine

We next turn to the task of determining the behavior of the Courant-Snyder lattice functions (as well as the phase slip η) for a ring with a reversal symmetric one-turn map, and for a ring that also has a symmetry point. Some preparatory work is required. The relation (5.10) can be rewritten in the form

$$\mathcal{L} = \mathcal{A}_d^{-1}[\mathcal{C}(\eta)\hat{\mathcal{L}}]\mathcal{A}_d. \tag{36.6.1}$$

In this form we see that a general $\mathcal{L}$ has been expressed as the similarity transform of the simpler map $\mathcal{C}(\eta)\hat{\mathcal{L}}$. Let us now further simplify $\hat{\mathcal{L}}$ itself. With reference to (3.39) and (3.40), suppose that the eigenvalues of $\check{L}$ lie on the unit circle and are distinct. Then, according to normal form theory, there is a symplectic matrix $\check{A}_b$ such that

$$\check{A}_b^{-1}\check{L}\check{A}_b = \check{N}_b \tag{36.6.2}$$

where $\check{N}_b$ takes the simple (*normal*) form

$$\check{N}_b(\phi_1,\phi_2) = \begin{pmatrix} \cos\phi_1 & \sin\phi_1 & 0 & 0 \\ -\sin\phi_1 & \cos\phi_1 & 0 & 0 \\ 0 & 0 & \cos\phi_2 & \sin\phi_2 \\ 0 & 0 & -\sin\phi_2 & \cos\phi_2 \end{pmatrix}. \tag{36.6.3}$$

Here the quantities ϕ are the (eigen) phase advances of $\check{L}$ and the $[\phi/(2\pi)]$ are the (eigen) tunes. The subscript b indicates the connection that $\check{A}_b$ and $\check{N}_b$ have with *betatron* oscillations.

In the spirit of (3.39), let $\hat{A}_b$ and $\hat{N}_b$ denote the matrices

$$\hat{A}_b = \begin{pmatrix} \check{A}_b & 0 \\ 0 & I \end{pmatrix}, \tag{36.6.4}$$

$$\hat{N}_b = \begin{pmatrix} \check{N}_b & 0 \\ 0 & I \end{pmatrix}, \tag{36.6.5}$$

and let $\mathcal{A}_b$ and $\mathcal{N}_b$ denote the corresponding symplectic maps. Then the matrix relation (6.2) is equivalent to the map relation

$$\mathcal{A}_b\hat{\mathcal{L}}\mathcal{A}_b^{-1} = \mathcal{N}_b. \tag{36.6.6}$$

We note that $\mathcal{N}_b$ can be written in the Lie form

$$\mathcal{N}_b = \exp(:h_2:) \tag{36.6.7}$$

with

$$h_2 = -(\phi_1/2)(p_x^2 + x^2) - (\phi_2/2)(p_y^2 + y^2). \tag{36.6.8}$$

The relation (6.6) can also be written in the form

$$\hat{\mathcal{L}} = \mathcal{A}_b^{-1}\mathcal{N}_b\mathcal{A}_b, \tag{36.6.9}$$

and then inserted into (6.1) to give the relation

$$\mathcal{L} = \mathcal{A}_d^{-1}\mathcal{C}(\eta)\mathcal{A}_b^{-1}\mathcal{N}_b\mathcal{A}_b\mathcal{A}_d. \tag{36.6.10}$$

From (19.*.*) and (6.4) it is evident that $\mathcal{C}(\eta)$ and $\mathcal{A}_b^{-1}$ commute. Therefore (6.10) can be cast in the still simpler form

$$\mathcal{L} = \mathcal{A}^{-1}\mathcal{N}\mathcal{A} \tag{36.6.11}$$

where

$$\mathcal{A} = \mathcal{A}_b\mathcal{A}_d, \tag{36.6.12}$$

$$\mathcal{N} = \mathcal{C}(\eta)\mathcal{N}_b. \tag{36.6.13}$$

Inspection of (19.*.*), (5.13), (6.7), and (6.8) shows that $\mathcal{N}$ can be written in the form

$$\mathcal{N} = \exp(:h_2:) \tag{36.6.14}$$

with

$$h_2 = -(\phi_1/2)(p_x^2 + x^2) - (\phi_2/2)(p_y^2 + y^2) - (\eta/2)p_\tau^2. \tag{36.6.15}$$

Let us again explore the effect of reversal. Applying reversal to (6.6) produces the equivalent result

$$(\mathcal{A}_b^{-1})^r\hat{\mathcal{L}}^r\mathcal{A}_b^r = \mathcal{N}_b^r, \tag{36.6.16}$$

which can be rewritten in the form

$$(\mathcal{A}_b^r)^{-1}\hat{\mathcal{L}}^r\mathcal{A}_b^r = \mathcal{N}_b. \tag{36.6.17}$$

Here we have used (2.2) and the fact that $\hat{\mathcal{N}_b}$ is manifestly reversal symmetric. Let us solve (6.16) and (6.17) for $\hat{\mathcal{L}}$ and $\hat{\mathcal{L}}^r$ to yield the relations

$$\hat{\mathcal{L}} = \mathcal{A}_b^{-1}\mathcal{N}_b\mathcal{A}_b, \tag{36.6.18}$$

$$\hat{\mathcal{L}}^r = \mathcal{A}_b^r\mathcal{N}_b(\mathcal{A}_b^r)^{-1}. \tag{36.6.19}$$

Now suppose that $\mathcal{L}$ is reversal symmetric, in which case $\hat{\mathcal{L}}$ is also reversal symmetric. See (3.53). Then comparison of (6.18) and (6.19) gives the relation

$$\mathcal{A}_b^{-1}\mathcal{N}_b\mathcal{A}_b = \mathcal{A}_b^r\mathcal{N}_b(\mathcal{A}_b^r)^{-1}, \tag{36.6.20}$$

which can be rewritten in the forms

$$(\mathcal{A}_b^r)^{-1}\mathcal{A}_b^{-1}\mathcal{N}_b\mathcal{A}_b\mathcal{A}_b^r = \mathcal{N}_b, \tag{36.6.21}$$

$$(\mathcal{A}_b\mathcal{A}_b^r)^{-1}\mathcal{N}_b(\mathcal{A}_b\mathcal{A}_b^r) = \mathcal{N}_b, \tag{36.6.22}$$

$$\mathcal{N}_b(\phi_1,\phi_2)(\mathcal{A}_b\mathcal{A}_b^r) = (\mathcal{A}_b\mathcal{A}_b^r)\mathcal{N}_b(\phi_1,\phi_2). \tag{36.6.23}$$

In the last form we have made explicit the dependence of $\mathcal{N}_b$ on ϕ_1 and ϕ_2.

The relation (6.23) states that the product $(\mathcal{A}_b\mathcal{A}_b^r)$ *commutes* with $\mathcal{N}_b$. Inspection of (6.7) and (6.8) shows that (6.23) can hold only if the product $(\mathcal{A}_b\mathcal{A}_b^r)$ is of the form

$$\mathcal{A}_b\mathcal{A}_b^r = \mathcal{N}_b(\phi_1',\phi_2') \tag{36.6.24}$$

for some values of ϕ_1' and ϕ_2'. We now show that, without loss of the desired relations (6.6) through (6.8), we can require the condition

$$\mathcal{A}_b\mathcal{A}_b^r = \mathcal{I} \text{ or } \mathcal{A}_b^r = \mathcal{A}_b^{-1}. \tag{36.6.25}$$

That is, if $\mathcal{L}$ is reversal symmetric, there is a reversal antisymmetric $\mathcal{A}_b$ that accomplishes the desired goals (6.6) through (6.8). Indeed, given an $\mathcal{A}_b$ that satisfies (6.24), define an associated map $\bar{\mathcal{A}}_b$ by the rule

$$\bar{\mathcal{A}}_b = \mathcal{N}_b(-\phi_1'/2,-\phi_2'/2)\mathcal{A}_b. \tag{36.6.26}$$

From (6.6) we see that it satisfies the desired normalizing relation,

$$\begin{aligned}\bar{\mathcal{A}}_b\hat{\mathcal{L}}\bar{\mathcal{A}}_b^{-1} &= \mathcal{N}_b(-\phi_1'/2,-\phi_2'/2)\mathcal{A}_b\hat{\mathcal{L}}\mathcal{A}_b^{-1}[\mathcal{N}_b(-\phi_1'/2,-\phi_2'/2)]^{-1}\\ &= \mathcal{N}_b(-\phi_1'/2,-\phi_2'/2)\mathcal{N}_b(\phi_1,\phi_2)[\mathcal{N}_b(-\phi_1'/2,-\phi_2'/2)]^{-1}\\ &= \mathcal{N}_b(\phi_1,\phi_2).\end{aligned} \tag{36.6.27}$$

Also, it has the desired product relation,

$$\begin{aligned}\bar{\mathcal{A}}_b\bar{\mathcal{A}}_b^r &= \mathcal{N}_b(-\phi_1'/2,-\phi_2'/2)\mathcal{A}_b\mathcal{A}_b^r\mathcal{N}_b(-\phi_1'/2,-\phi_2'/2)\\ &= \mathcal{N}_b(-\phi_1'/2,-\phi_2'/2)\mathcal{N}_b(\phi_1',\phi_2')\mathcal{N}_b(-\phi_1'/2,-\phi_2'/2)\\ &= \mathcal{I}.\end{aligned} \tag{36.6.28}$$

The generalized Courant-Snyder quadratic invariants I_x and I_y (which include the possibility of coupling between the x, p_x and y, p_y degrees of freedom) are defined by the rules

$$I_x = \mathcal{A}_b^{-1}(p_x^2 + x^2), \tag{36.6.29}$$

$$I_y = \mathcal{A}_b^{-1}(p_y^2 + y^2). \tag{36.6.30}$$

In the no-coupling case they take the form

$$I_x = \beta_x p_x^2 + 2\alpha_x x p_x + \gamma_x x^2, \text{ etc.} \tag{36.6.31}$$

The relations (6.29) and (6.30) have the reversed counterparts

$$I_x^r = \mathcal{A}_b^r(p_x^2 + x^2), \text{ etc.} \tag{36.6.32}$$

Here we have used (1.56). Now assume that $\mathcal{L}$ is reversal symmetric so that $\mathcal{A}_b$ can be taken to satisfy (6.25). In this case we find the relations

$$I_x^r = \mathcal{A}_b^r(p_x^2 + x^2) = \mathcal{A}_b^{-1}(p_x^2 + x^2) = I_x, \text{ etc.} \tag{36.6.33}$$

Thus, if $\mathcal{L}$ is reversal symmetric, the generalized Courant-Snyder invariants (at the location for which $\mathcal{L}$ is computed) are free of terms that are *odd* in the momenta.

We now explore how I_x, I_y, and η vary about a ring that has a symmetry point. Refer again to Figure 5.1. Let $\mathcal{L}^0$ be the one-turn map starting at location 0,

$$\mathcal{L}^0 = \mathcal{L}_1\mathcal{L}_2\cdots\mathcal{L}_n\mathcal{L}_{\tilde{n}}\cdots\mathcal{L}_{\tilde{2}}\mathcal{L}_{\tilde{1}} = \mathcal{L}. \tag{36.6.34}$$

Similarly, let $\mathcal{L}^1$ and $\mathcal{L}^{\tilde{1}}$ be the maps starting at the locations 1 and $\tilde{1}$. For these maps we find the results

$$\begin{aligned} \mathcal{L}^1 &= \mathcal{L}_2\mathcal{L}_3\cdots\mathcal{L}_n\mathcal{L}_{\tilde{n}}\cdots\mathcal{L}_{\tilde{2}}\mathcal{L}_{\tilde{1}}\mathcal{L}_1 \\ &= \mathcal{L}_1^{-1}\mathcal{L}_1\mathcal{L}_2\mathcal{L}_3\cdots\mathcal{L}_n\mathcal{L}_{\tilde{n}}\cdots\mathcal{L}_{\tilde{2}}\mathcal{L}_{\tilde{1}}\mathcal{L}_1 \\ &= \mathcal{L}_1^{-1}\mathcal{L}\mathcal{L}_1, \end{aligned} \tag{36.6.35}$$

$$\begin{aligned} \mathcal{L}^{\tilde{1}} &= \mathcal{L}_{\tilde{1}}\mathcal{L}_1\mathcal{L}_2\cdots\mathcal{L}_n\mathcal{L}_{\tilde{n}}\cdots\mathcal{L}_{\tilde{3}}\mathcal{L}_{\tilde{2}} \\ &= \mathcal{L}_{\tilde{1}}\mathcal{L}_1\mathcal{L}_2\cdots\mathcal{L}_n\mathcal{L}_{\tilde{n}}\cdots\mathcal{L}_{\tilde{1}}\mathcal{L}_{\tilde{2}}\mathcal{L}_{\tilde{1}}\mathcal{L}_{\tilde{1}}^{-1} \\ &= \mathcal{L}_{\tilde{1}}\mathcal{L}\mathcal{L}_{\tilde{1}}^{-1}. \end{aligned} \tag{36.6.36}$$

In the same way we find for $\mathcal{L}^2$ and $\mathcal{L}^{\tilde{2}}$ the results

$$\mathcal{L}^2 = \mathcal{L}_2^{-1}\mathcal{L}_1^{-1}\mathcal{L}\mathcal{L}_1\mathcal{L}_2 = (\mathcal{L}_1\mathcal{L}_2)^{-1}\mathcal{L}(\mathcal{L}_1\mathcal{L}_2), \tag{36.6.37}$$

$$\mathcal{L}^{\tilde{2}} = \mathcal{L}_{\tilde{2}}\mathcal{L}_{\tilde{1}}\mathcal{L}\mathcal{L}_{\tilde{1}}^{-1}\mathcal{L}_{\tilde{2}}^{-1} = (\mathcal{L}_{\tilde{2}}\mathcal{L}_{\tilde{1}})\mathcal{L}(\mathcal{L}_{\tilde{2}}\mathcal{L}_{\tilde{1}})^{-1}. \tag{36.6.38}$$

Finally, in terms of the maps $\mathcal{S}^j$ and $\mathcal{S}^{\tilde{j}}$ defined by (5.37) and (5.38), the relations (6.34) through (6.38) etc. take the general form

$$\mathcal{L}^j = (\mathcal{S}^j)^{-1}\mathcal{L}\mathcal{S}^j, \tag{36.6.39}$$

$$\mathcal{L}^{\tilde{j}} = (\mathcal{S}^{\tilde{j}})\mathcal{L}(\mathcal{S}^{\tilde{j}})^{-1}. \tag{36.6.40}$$

Insert the representation (6.11) into (6.39) and (6.40) to obtain the relations

$$\mathcal{L}^j = (\mathcal{S}^j)^{-1}\mathcal{A}^{-1}\mathcal{N}\mathcal{A}(\mathcal{S}^j), \tag{36.6.41}$$

$$\mathcal{L}^{\tilde{j}} = (\mathcal{S}^{\tilde{j}})\mathcal{A}^{-1}\mathcal{N}\mathcal{A}(\mathcal{S}^{\tilde{j}})^{-1}. \tag{36.6.42}$$

These relations can be rewritten in the form

$$\mathcal{L}^j = (\mathcal{A}^j)^{-1}\mathcal{N}^j\mathcal{A}^j, \tag{36.6.43}$$

$$\mathcal{L}^{\tilde{j}} = (\mathcal{A}^{\tilde{j}})^{-1}\mathcal{N}^{\tilde{j}}\mathcal{A}^{\tilde{j}}, \tag{36.6.44}$$

where

$$\mathcal{A}^{j} = \mathcal{A}\mathcal{S}^{j}, \tag{36.6.45}$$

$$\mathcal{N}^{j} = \mathcal{N}, \tag{36.6.46}$$

$$\mathcal{A}^{\tilde{j}} = \mathcal{A}(\mathcal{S}^{\tilde{j}})^{-1}, \tag{36.6.47}$$

$$\mathcal{N}^{\tilde{j}} = \mathcal{N}. \tag{36.6.48}$$

Comparison of (6.46) and (6.48) immediately gives the result

$$\mathcal{N}^{\tilde{j}} = \mathcal{N}^{j}, \tag{36.6.49}$$

from which we conclude that ϕ_1, ϕ_2 and η are *global* properties of a ring. [See (6.15).] Their values are independent of the choice of the surface of section. Note that in arriving at this conclusion no assumptions were required about reversal symmetry.

Next, in analogy to (6.12), make the factorizations

$$\mathcal{A}^{j} = \mathcal{A}_b^{j}\mathcal{A}_d^{j}, \tag{36.6.50}$$

$$\mathcal{A}^{\tilde{j}} = \mathcal{A}_b^{\tilde{j}}\mathcal{A}_d^{\tilde{j}}. \tag{36.6.51}$$

Here the maps $\mathcal{A}_d^{j}$ and $\mathcal{A}_d^{\tilde{j}}$ are defined by the analogs of (5.1) and (5.11):

$$\mathcal{A}_d^{j} = \exp(:p_\tau g_1^{j}:) \tag{36.6.52}$$

with

$$g_1^{j} = \Delta_2^{j}x - \Delta_1^{j}p_x + \Delta_4^{j}y - \Delta_3^{j}p_y; \tag{36.6.53}$$

$$\mathcal{A}_d^{\tilde{j}} = \exp(:p_\tau g_1^{\tilde{j}}:) \tag{36.6.54}$$

with

$$g^{\tilde{j}} = \Delta_2^{\tilde{j}}x - \Delta_1^{\tilde{j}}p_x + \Delta_4^{\tilde{j}}y - \Delta_3^{\tilde{j}}p_y. \tag{36.6.55}$$

So far we have not necessarily assumed that $\mathcal{L}$ is reversal symmetric and that the ring has 0 as a symmetry point. Do so now. Then (5.47) through (5.50) can be used to rewrite (6.53) in the form

$$g_1^{j} = -\Delta_2^{\tilde{j}}x - \Delta_1^{\tilde{j}}p_x - \Delta_4^{\tilde{j}}y - \Delta_3^{\tilde{j}}p_y. \tag{36.6.56}$$

Now we see that there is the relation

$$(g_1^{j})^r = -g_1^{\tilde{j}}, \tag{36.6.57}$$

from which it follows that

$$(\mathcal{A}_d^{j})^r = (\mathcal{A}_d^{\tilde{j}})^{-1}. \tag{36.6.58}$$

We also know that, since $\mathcal{L}$ is reversal symmetric, the maps $\mathcal{A}_d$ and $\mathcal{A}_b$ are reversal antisymmetric. See (5.32) and (6.25). It follows from the group property for reversal antisymmetric maps that $\mathcal{A}$ as given by (6.12) is also reversal antisymmetric,

$$\mathcal{A}^r = \mathcal{A}^{-1}. \tag{36.6.59}$$

We are now prepared to study the relation between $\mathcal{A}_b^j$ and $\mathcal{A}_b^{\tilde{j}}$. Solving (6.50) and (6.51) for $\mathcal{A}_b^j$ and $\mathcal{A}_b^{\tilde{j}}$ and using (6.45) and (6.47) give the results

$$\mathcal{A}_b^j = \mathcal{A}^j(\mathcal{A}_d^j)^{-1} = \mathcal{A}\mathcal{S}^j(\mathcal{A}_d^j)^{-1}, \tag{36.6.60}$$

$$\mathcal{A}_b^{\tilde{j}} = \mathcal{A}^{\tilde{j}}(\mathcal{A}_d^{\tilde{j}})^{-1} = \mathcal{A}(\mathcal{S}^{\tilde{j}})^{-1}(\mathcal{A}_d^{\tilde{j}})^{-1}. \tag{36.6.61}$$

Let us compute the map $((\mathcal{A}_b^j)^r)^{-1}$. From (6.60) we find the results

$$(\mathcal{A}_b^j)^r = ((\mathcal{A}_d^j)^{-1})^r(\mathcal{S}^j)^r\mathcal{A}^r, \tag{36.6.62}$$

$$\begin{aligned} ((\mathcal{A}_b^j)^r)^{-1} &= (\mathcal{A}^r)^{-1}((\mathcal{S}^j)^r)^{-1}(\mathcal{A}_d^j)^r \\ &= \mathcal{A}(\mathcal{S}^{\tilde{j}})^{-1}(\mathcal{A}_d^{\tilde{j}})^{-1} \\ &= \mathcal{A}_b^{\tilde{j}}. \end{aligned} \tag{36.6.63}$$

Here we have used (5.44), (6.58), and (6.59). Note that (6.63) can also be written in the form

$$(\mathcal{A}_b^j)^r = (\mathcal{A}_b^{\tilde{j}})^{-1}, \tag{36.6.64}$$

which is analogous to the relation (6.58) for $(\mathcal{A}_d^j)^r$.

We are ready for the coup de maître. The horizontal Courant-Snyder (eigen) invariants at the locations j and $\tilde{j}$ are given by the expressions

$$I_x^j = (\mathcal{A}_b^j)^{-1}(p_x^2 + x^2), \tag{36.6.65}$$

$$I_x^{\tilde{j}} = (\mathcal{A}_b^{\tilde{j}})^{-1}(p_x^2 + x^2); \tag{36.6.66}$$

and there are analogous expressions for their vertical counterparts. Now apply the reversal operation to (6.65). Doing so gives the result

$$(I_x^j)^r = (\mathcal{A}_b^j)^r(p_x^2 + x^2) = (\mathcal{A}_b^{\tilde{j}})^{-1}(p_x^2 + x^2) = I_x^{\tilde{j}}. \tag{36.6.67}$$

Similarly, there is the relation

$$(I_y^j)^r = I_y^{\tilde{j}}. \tag{36.6.68}$$

Consider the coefficients of the monomials in I_x^j or I_y^j that are *even* under $\mathcal{R}$. The relations (6.67) and (6.68) show that these coefficients are also *even* functions of position about the symmetry location 0. For example, in the no-coupling case (6.31), there are the relations

$$\beta_x^{\tilde{j}} = \beta_x^j, \tag{36.6.69}$$

$$\gamma_x^{\tilde{j}} = \gamma_x^j. \tag{36.6.70}$$

Next consider the coefficients of the monomials in I_x^j or I_y^j that are *odd* under $\mathcal{R}$. The relations (6.67) and (6.68) show that these coefficients are also *odd* functions of position about the symmetry location 0. For example, in the non-coupling case (6.31) there is the relation

$$\alpha_x^{\tilde{j}} = -\alpha_x^j. \tag{36.6.71}$$

36.7 Some Nonlinear Consequences

So far we have mostly explored the consequences of reversal symmetry for $\mathcal{L}$, the linear part of $\mathcal{M}$. We now explore some of the consequences of reversal symmetry for the full map $\mathcal{M}$. One line of inquiry would be to generalize the results of the previous Sections 5 and 6 to include nonlinear terms. Equations (5.25) and (5.39) give the linear terms of a power series (in p_τ) expansion of $z^{cj}(p_\tau)$. The higher order terms in this expansion could be found and their dependence on the location j could be explored. Similarly a full normalization of $\mathcal{M}$ [analogous to that given in (6.11) for its linear part $\mathcal{L}$] could be found. The *betatron* part of the associated normalizing map could then be used in (6.65), etc., to find the generalized Courant-Snyder invariants that take into account all nonlinear effects through any desired order. These invariants contain, in addition to quadratic monomials, monomials of degree 3 and higher. When considered as functions of location j, the coefficients of these monomials yield *nonlinear* lattice functions. Just how these coefficients depend on j could also be explored.

We will leave these generalizations to the reader. Instead, we will devote this section to the exploration of how reversal symmetry affects the dynamic aperture of a ring including the location of fixed points, and how it limits the kind of nonlinearities that can occur in $\mathcal{M}$.

Consider the map $\mathcal{M}$ on two-dimensional phase space given by the product

$$\mathcal{M}(\theta) = \exp[-(\phi/4) :p^2 + q^2:] \exp(:q^3:) \exp[-(\phi/4) :p^2 + q^2 :]. \tag{36.7.1}$$

As described in Section 1.2.3, this map consists of a $\phi/2$ phase advance, followed by a sextupole kick, followed again by a $\phi/2$ phase advance. It may be viewed as describing horizontal betatron motion in an idealized storage ring with a single thin *sextupole* insertion S, and an *observation* point O (Poincaré surface of section) located diametrically across the ring from the sextupole insertion. Recall Figure 1.2.8. We verified in Section 18.8.4 that this map is a variant of the usual Hénon map, and differs from it only by a linear change of variables. Now we note that $\mathcal{M}$ as given by (7.1) is reversal symmetric.

Figure 7.1, which is a replication of Figure 1.2.9, shows the dynamic aperture for our variant of the Hénon map for the case $\phi/(2\pi) = .22$. Points in the black area of the q, p (mapping) plane remain there under repeated application of the map. [Actually, the points shown remain there for at least 10,000 iterations ($\mathcal{M}^n$ with $n \leq 10,000$).] By contrast, any point launched in the white area eventually iterates away to infinity. Inspection of the figure suggests symmetry about the q axis. That is, all features of the figure are invariant under reversal.

By construction, the map sends the origin into itself (the origin is a fixed point of $\mathcal{M}$), and the origin is unchanged under reversal. Not shown, because it is unstable and also outside the viewing window, there is also a fixed point of $\mathcal{M}$ at $p = 0$ and $q = .7158$, and this point is also unchanged under reversal. Next observe that there are 5 islands. They surround 5 fixed points of the map $\mathcal{M}^5$. [Note that the tune $\phi/(2\pi) = .22$ is close to 1/5.] These fixed points appear to be located symmetrically about the q axis. Also, each island is surrounded by 6 smaller islands. These smaller islands surround fixed points of $\mathcal{M}^{30}$, and these fixed points appear to be located symmetrically about the q axis. Finally, the whole

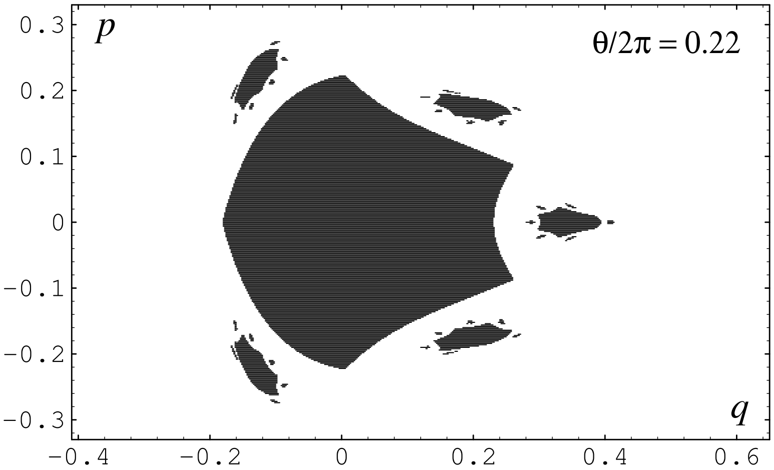

Figure 36.7.1: The dynamic aperture of the Hénon map for the case $\phi/(2\pi) = 0.22$.

dynamic aperture for our variant of the Hénon map appears to be symmetrical about the q axis. That is, the dynamic aperture appears to be invariant under reversal.

To explore these conjectures, let us first think about fixed points of $\mathcal{M}$ and its powers. Suppose $\mathcal{M}$ is a general map in any number of phase-space dimensions, and suppose z^f is a *fixed* point,

$$\mathcal{M}z^f = z^f. \tag{36.7.2}$$

Suppose also that $\mathcal{M}$ is reversal symmetric so that (2.5) holds. Applying $\mathcal{RMR}$ to both sides of (7.2) yields the result

$$\mathcal{RMRM}z^f = \mathcal{RMR}z^f. \tag{36.7.3}$$

Use of (2.5) in (7.3) gives the relation

$$z^f = \mathcal{RMR}z^f, \tag{36.7.4}$$

which, in view of (1.21), can be rewritten as

$$\mathcal{M}(\mathcal{R}z^f) = (\mathcal{R}z^f). \tag{36.7.5}$$

We see that if z^f is a fixed point of $\mathcal{M}$, so is the point $\mathcal{R}z^f$. An analogous result holds for powers of $\mathcal{M}$ because $\mathcal{M}^n$ will be reversal symmetric when $\mathcal{M}$ is reversal symmetric: If z^f is a fixed point of $\mathcal{M}^n$, so is the point $\mathcal{R}z^f$.

We define a fixed point z^f to be *symmetric* if it satisfies the relation

$$\mathcal{R}z^f = z^f. \tag{36.7.6}$$

For example, for the Hénon map of Figure 7.1, the origin, and the point $(q,p) = (.7158, 0)$ not shown, are symmetric fixed points of $\mathcal{M}$; and $(q,p) = (.3458, 0)$ is a symmetric fixed point of $\mathcal{M}^5$. From appearances there are two symmetric fixed points of $\mathcal{M}^{30}$: those on the q axis and surrounding the fixed point of $\mathcal{M}^5$ also on the q axis. The discovery (or ruling out the existence) of symmetric fixed points is easier than the discovery of general fixed points. Let Fix $(\mathcal{R})$ be the set of points z satisfying

$$\mathcal{R}z = z. \tag{36.7.7}$$

From the definition (1.2) and (1.3) of $\mathcal{R}$ it is evident that (for a 6-dimensional phase space) the set Fix $(\mathcal{R})$ is 3 dimensional. [In general, if the dimension of phase space is $2m$, the dimension of Fix $(\mathcal{R})$ is m.] Consequently, the dimension of the space to be searched to find a symmetric fixed point is only half as large as the dimension of the full phase space that must be searched to find a general fixed point.

We next remark that we have found that $\mathcal{R}$ and $\mathcal{R}\mathcal{M}^k$ and $\mathcal{M}^k\mathcal{R}$ (for any k) are all involutions. See (2.8) and (2.9). Moreover, they are all antisymplectic. We have also seen that Fix $(\mathcal{R})$ is m dimensional. Based on a theorem of *Bochner* and *Montgomery*, it can be shown that the sets Fix $(\mathcal{R}\mathcal{M}^k)$ and Fix $(\mathcal{M}^k\mathcal{R})$ are also m dimensional if phase space is $2m$ dimensional. That is, the set of points obeying

$$\mathcal{R}\mathcal{M}^k z = z \tag{36.7.8}$$

is m dimensional for any value of k, and so is the set of points obeying

$$\mathcal{M}^k\mathcal{R}z = z. \tag{36.7.9}$$

See References 19, 22, and 23 in the Bibliography at the end this chapter.

Suppose that z^f is the fixed point of some power $\mathcal{M}$, say $\mathcal{M}^n$, but not of some lower power. Suppose that z^f is also symmetric. Then more can be said. For example, suppose $n = 2$. Then we have the relations

$$\mathcal{M}^2 z^f = z^f, \tag{36.7.10}$$

$$\mathcal{M}^2\mathcal{M}z^f = \mathcal{M}\mathcal{M}^2 z^f = \mathcal{M}z^f. \tag{36.7.11}$$

Thus z^f and $\mathcal{M}z^f$ are *two distinct* fixed points of $\mathcal{M}^2$. By assumption z^f is symmetric. What about $\mathcal{M}z^f$? We have the relations

$$\mathcal{R}\mathcal{M}z^f = \mathcal{R}\mathcal{M}\mathcal{R}\mathcal{R}z^f = \mathcal{M}^{-1}z^f = \mathcal{M}^{-1}\mathcal{M}^2 z^f = \mathcal{M}z^f. \tag{36.7.12}$$

Here we have used (1.21), (1.40), (7.6), and (7.10). We see that $\mathcal{M}z^f$ is also a symmetric fixed point. It is easy to show that this result can be generalized to the case of any even n: If z^f is a symmetric fixed point of $\mathcal{M}^n$, then $\mathcal{M}^{n/2}z^f$ is also a symmetric fixed point of $\mathcal{M}^n$. Thus, symmetric fixed points of $\mathcal{M}^n$ occur in pairs when n is even. As an example, we have now proved that the two fixed points of $\mathcal{M}^{30}$ that appear to lie on the q axis in Figure 5.1 are indeed symmetric.

The case of odd n is a bit more complicated. Suppose for example that $n = 3$. Then, if z^f is a fixed point of $\mathcal{M}^3$, so are the two other points $\mathcal{M}z^f$ and $\mathcal{M}^2 z^f$. By assumption z^f is symmetric. For $\mathcal{M}z^f$ and $\mathcal{M}^2 z^f$ we find the following results:

$$\mathcal{R}\mathcal{M}z^f = \mathcal{R}\mathcal{M}\mathcal{R}\mathcal{R}z^f = \mathcal{M}^{-1}z^f \tag{36.7.13}$$

from which it follows that

$$(\mathcal{M}^2\mathcal{R})(\mathcal{M}z^f) = (\mathcal{M}z^f); \tag{36.7.14}$$

$$\mathcal{R}\mathcal{M}^2 z^f = \mathcal{R}\mathcal{M}^2\mathcal{R}\mathcal{R}z^f = \mathcal{M}^{-2}z^f \tag{36.7.15}$$

from which it follows that

$$(\mathcal{M}\mathcal{R})(\mathcal{M}^2 z^f) = \mathcal{M}^{-1}z^f = \mathcal{M}^{-1}\mathcal{M}^3 z^f = (\mathcal{M}^2 z^f). \tag{36.7.16}$$

We know that $\mathcal{R}$ and $\mathcal{M}\mathcal{R}$ and $\mathcal{M}^2\mathcal{R}$ are involutions. Thus, the relations (7.6), (7.14), and (7.16) are all analogous: Some particular fixed point is invariant under some particular involution.

Finally, suppose the set of points that satisfies (7.9) for some $k = k_1$ *intersects* the set of points that satisfies (7.9) for some other $k = k_2$. That is, suppose there is a common point w such that

$$\mathcal{M}^{k_1}\mathcal{R}w = w, \tag{36.7.17}$$

$$\mathcal{M}^{k_2}\mathcal{R}w = w. \tag{36.7.18}$$

Then we have the relation

$$\mathcal{M}^{k_2}w = \mathcal{M}^{k_2}\mathcal{M}^{k_1}\mathcal{R}w = \mathcal{M}^{k_1}\mathcal{M}^{k_2}\mathcal{R}w = \mathcal{M}^{k_1}w, \tag{36.7.19}$$

and therefore

$$\mathcal{M}^{k_1-k_2}w = w. \tag{36.7.20}$$

We have found a fixed point, namely w, of the map $\mathcal{M}^{k_1-k_2}$! Note that this fixed point need not be symmetric. For some problems it is possible to construct the m-dimensional manifolds Fix $(\mathcal{M}^k\mathcal{R})$ that satisfy (7.9) for various values of k, and then determine their intersections to find fixed points of $\mathcal{M}^n$. See References 12 and 19 in the Bibliography at the end of this chapter.

So far we have studied fixed points. Next consider general points. What can be said about symmetry for them? We can think about this question for a general map $\mathcal{M}$ in any number of phase-space dimensions as follows: Suppose $\mathcal{M}$ sends the origin into itself. Let N be some large integer, and let Σ be some set in phase space such that all the points $\mathcal{M}^n z$ with $z \in \Sigma$ and $n \in [1, 2N]$ have some desirable property such as being near the origin. Let Γ be the set $\mathcal{M}^N\Sigma$. It is the set of all points obtained by letting $\mathcal{M}^N$ act on all points in Σ. Evidently Γ is a set such that all the points $\mathcal{M}^n z$ with $z \in \Gamma$ and $n \in [-N, N]$ have the same desirable property. Now suppose that $\mathcal{M}$ is reversal symmetric. Then Γ is also reversal symmetric,

$$\Gamma^r = \Gamma. \tag{36.7.21}$$

That is, if the phase-space point z is in Γ, so is the point z^r.

To see the truth of this assertion, suppose $z \in \Gamma$. Consider the set of points $\mathcal{M}^n z^r$ for $n \in [1, N]$. From (1.21) and (1.39) we have the result

$$\begin{aligned}
\mathcal{M}^n z^r &= \mathcal{M}^n\mathcal{R}z = \mathcal{R}\mathcal{R}\mathcal{M}^n\mathcal{R}z \\
&= \mathcal{R}(\mathcal{R}\mathcal{M}\mathcal{R})^n z = \mathcal{R}(\mathcal{M}^r)^{-n}z \\
&= \mathcal{R}\mathcal{M}^{-n}z.
\end{aligned} \tag{36.7.22}$$

Here, in the last step, we have used the assumption that $\mathcal{M}$ is reversal symmetric. Now we know that the sequence of points $\mathcal{M}^{-n}z$ is well behaved since $z \in \Gamma$. Therefore the sequence of points $\mathcal{R}\mathcal{M}^{-n}z$ is well behaved. (Note that, for any point $\bar{z}$, the points $\bar{z}$ and $\bar{z}^r$ are equidistant from the origin.) It follows from (7.22) that the sequence of points $\mathcal{M}^n z^r$ is well behaved.

Next consider the set of points $\mathcal{M}^{-n}z^r$. In this case we have the result

$$\begin{aligned} \mathcal{M}^{-n}z^r &= \mathcal{M}^{-n}\mathcal{R}z = \mathcal{R}\mathcal{R}\mathcal{M}^{-n}\mathcal{R}z \\ &= \mathcal{R}(\mathcal{R}\mathcal{M}^{-1}\mathcal{R})^n z = \mathcal{R}(\mathcal{M}^r)^n z \\ &= \mathcal{R}\mathcal{M}^n z. \end{aligned} \tag{36.7.23}$$

By hypothesis the sequence of points $\mathcal{M}^n z$ is well behaved, and therefore by (7.23) the sequence $\mathcal{M}^{-n}z^r$ is well behaved.

We have learned that the points $\mathcal{M}^n z^r$ are well behaved for $n \in [-N, N]$. It follows that $z^r \in \Gamma$, and hence (7.21) is correct.

We end this section with an exploration of what restrictions reversal invariance places on the nonlinear part of $\mathcal{M}$. Technically, we have already found these restrictions. They are given by the relations (3.17) through (3.20). What we want to do here is to explore these restrictions in more detail using some of the results of previous sections. For brevity we will treat only the case of static maps, which is actually somewhat more complicated than the dynamic case.

Rather than working with $\mathcal{M}$, it is convenient to work with the related map $\mathcal{M}'$ defined by the relation

$$\mathcal{M}' = \mathcal{A}\mathcal{M}\mathcal{A}^{-1} \tag{36.7.24}$$

with $\mathcal{A}$ given by (6.12). From the representation (3.1) and (6.11) it follows that $\mathcal{M}'$ has the representation

$$\begin{aligned} \mathcal{M}' &= \mathcal{A}\mathcal{L}\exp(:f_3:)\exp(:f_4:)\cdots\mathcal{A}^{-1} \\ &= [\mathcal{A}\mathcal{L}\mathcal{A}^{-1}][\mathcal{A}\exp(:f_3:)\exp(:f_4:)\cdots\mathcal{A}^{-1}] \\ &= \mathcal{N}\exp(:g_3:)\exp(:g_4:)\cdots \end{aligned} \tag{36.7.25}$$

where the g_m are given by the relation

$$g_m = \mathcal{A}f_m. \tag{36.7.26}$$

Next use the Baker-Campbell-Hausdorff series to combine the exponents of the nonlinear terms on the right side of (7.25),

$$\exp(:g_3:)\exp(:g_4:)\exp(:g_5:)\cdots = \exp(:h:) \tag{36.7.27}$$

where

$$h = h_3 + h_4 + h_5 + h_6 + \cdots . \tag{36.7.28}$$

with

$$h_3 = g_3, \tag{36.7.29}$$

$$h_4 = g_4, \tag{36.7.30}$$

$$h_5 = g_5 + (1/2)[g_3, g_4], \tag{36.7.31}$$

$$h_6 = g_6 + (1/2)[g_3, g_5] + (1/12)[g_3, [g_3, g_4]], \text{ etc.} \tag{36.7.32}$$

The net result is that $\mathcal{M}'$ can be written in the form form

$$\mathcal{M}' = \mathcal{N} \exp(: h :). \tag{36.7.33}$$

If $\mathcal{M}$ is reversal symmetric, $\mathcal{M}'$ will also be reversal symmetric,

$$(\mathcal{M}')^r = (\mathcal{A}^{-1})^r \mathcal{M}^r \mathcal{A}^r = \mathcal{A}\mathcal{M}\mathcal{A}^{-1} = \mathcal{M}'. \tag{36.7.34}$$

Here we have used (6.59), which holds if $\mathcal{M}$ is reversal symmetric. Now employ the representation (7.33) in (7.34) to obtain the condition

$$\exp(: h^r :)\mathcal{N} = \mathcal{N} \exp(: h :) \tag{36.7.35}$$

or

$$\exp(: h^r :) = \mathcal{N} \exp(: h :)\mathcal{N}^{-1} \tag{36.7.36}$$

from which it follows that

$$h^r = \mathcal{N} h. \tag{36.7.37}$$

Here we have used (8.2.27) and the fact that $\mathcal{N}$ is reversal symmetric as is evident from (6.14) and (6.15).

To explore the implications of (7.37) it is convenient to expand h in a *static resonance* basis. Introduce polynomials $R_{abcde}(z)$ and $I_{abcde}(z)$ defined by the relations

$$R_{abcde}(z) = \text{ Re } [(x + ip_x)^a (x - ip_x)^b (y + ip_y)^c (y - ip_y)^d p_\tau^e], \tag{36.7.38}$$

$$I_{abcde}(z) = \text{ Im } [(x + ip_x)^a (x - ip_x)^b (y + ip_y)^c (y - ip_y)^d p_\tau^e], \tag{36.7.39}$$

Here the quantities (exponents) a through e are integers. The first few such polynomials of interest are given by the relations

$$R_{11001} = (x^2 + p_x^2)p_\tau, \tag{36.7.40}$$

$$R_{00111} = (y^2 + p_y^2)p_\tau, \tag{36.7.41}$$

$$I_{11001} = I_{00111} = 0, \tag{36.7.42}$$

$$R_{30000} = x^3 - 3xp_x^2, \tag{36.7.43}$$

$$I_{30000} = 3x^2 p_x - p_x^3, \tag{36.7.44}$$

$$R_{20100} = x^2 y - p_x^2 y - 2xp_x p_y, \tag{36.7.45}$$

$$I_{20100} = x^2 p_y - p_x^2 p_y + 2xp_y y. \tag{36.7.46}$$

It is evident from (7.38) and (7.39) that the R_{abcde} and I_{abcde} form a basis for all static polynomials; and it is also evident that they have the simple reversal properties

$$R_{abcde}^r = R_{abcde}, \tag{36.7.47}$$

$$I_{abcde}^r = -I_{abcde}. \tag{36.7.48}$$

They also have simple properties under the action of $\mathcal{N}$, which will allow us to exploit (7.37). From (6.15) we have the results

$$\mathcal{N}(x \pm ip_x) = [\exp(\pm i\phi_1)](x \pm ip_x), \tag{36.7.49}$$

$$\mathcal{N}(y \pm ip_y) = [\exp(\pm i\phi_2)](y \pm ip_y), \tag{36.7.50}$$

$$\mathcal{N}p_\tau = p_\tau. \tag{36.7.51}$$

Introduce the *resonance* phase advances ψ_{abcd} defined by the rules

$$\psi_{abcd} = (a-b)\phi_1 + (c-d)\phi_2. \tag{36.7.52}$$

It follows from (8.3.52) and (7.49) through (7.52) that there are the relations

$$\mathcal{N}R_{abcde} = (\cos\psi_{abcd})R_{abcde} - (\sin\psi_{abcd})I_{abcde}, \tag{36.7.53}$$

$$\mathcal{N}I_{abcde} = (\sin\psi_{abcd})R_{abcde} + (\cos\psi_{abcd})I_{abcde}. \tag{36.7.54}$$

We are now ready to work out the implications of (7.37). Expand h in terms of the static resonance basis by writing

$$h = \sum_{abcde} A_{abcde}R_{abcde} + B_{abcde}I_{abcde}. \tag{36.7.55}$$

Then, by (7.47) and (7.48), we have the relation

$$h^r = \sum_{abcde} A_{abcde}R_{abcde} - B_{abcde}I_{abcde}; \tag{36.7.56}$$

and by (7.53) and (7.54) we have the relation

$$\begin{aligned}\mathcal{N}h &= \sum_{abcde}[A_{abcde}\cos\psi_{abcd} + B_{abcde}\sin\psi_{abcd}]R_{abcde} \\ &+ [-A_{abcde}\sin\psi_{abcd} + B_{abcde}\cos\psi_{abcd}]I_{abcde}.\end{aligned} \tag{36.7.57}$$

Upon comparing (7.56) and (7.57) we see that (7.37) implies the restrictions

$$A_{abcde}(-1+\cos\psi_{abcd}) + B_{abcde}\sin\psi_{abcd} = 0, \tag{36.7.58}$$

$$-A_{abcde}\sin\psi_{abcd} + B_{abcde}(1+\cos\psi_{abcd}) = 0. \tag{36.7.59}$$

These restrictions are equivalent, and yield the final result

$$B_{abcde} = [\tan(\psi_{abcd}/2)]A_{abcde}. \tag{36.7.60}$$

What we have learned is that if $\mathcal{M}$ is reversal symmetric, then the net Lie generator of its nonlinear part has only about half the number of linearly independent nonlinear basis generators that it otherwise might have. For example, suppose we were to employ, in a reversal symmetric system, various nonlinear correctors (sextupoles, octupoles, etc.) to drive various A_{abcde} to zero in the representation (7.55). Then, according to (7.60), the corresponding B_{abcde} would also automatically be driven to zero. Applications of this principal include the construction of high-order achromats.

Chapter 38

Analyticity and Convergence

We have learned from Poincaré's Theorem 1.3.3 that trajectories will be analytic functions of the initial conditions in some domain if the right sides of the equations of motion (1.3.4) are analytic. Appendix F shows that for particle motion in electric and magnetic fields this desired analyticity is realized under very general circumstances. Correspondingly, the Taylor map (7.5.5) will converge in some domain about the origin.

The purpose of this chapter is to describe in some detail what is meant by analyticity and to apply the results of Analytic Function Theory to various problems of interest. Section 38.1 reviews briefly what is needed for the case of one complex variable, and much of its material should already be familiar to the reader. Sections 38.2 and 38.3 treat the case of several complex variables, and may be less familiar. The remaining sections discuss various applications.

38.1 Analyticity in One Complex Variable

In the theory of analytic functions of one complex variable, there are two common ways to *define* analyticity due to Riemann and Weierstrass, respectively. Riemann's approach assumes that the function in question, call it $f(z)$, is defined in some domain (open set) $\mathcal{D}$ of the complex z plane. It then says that f is analytic at the point z if it is *complex* (or *totally*) differentiable there. Complex or totally differentiable means that the limit

$$f'(z) = \lim_{\zeta \to 0} [f(z+\zeta) - f(z)]/\zeta \tag{38.1.1}$$

exists and is the same for all possible ways (e.g. directions) in which the complex variable ζ can approach zero. This definition leads directly to the Cauchy-Riemann equations. Further, f is said to be analytic in $\mathcal{D}$ if f is analytic at each point in $\mathcal{D}$.

In comparison to Weierstrass' definition of analyticity, which will be presented shortly, Riemann's definition is remarkably succinct. It also has some other advantages. For example, it immediately follows from the chain rule for differentiation that the composition of two analytic functions produces a function that is again analytic. That is, if f and g are analytic functions, then $h(z)$ defined by the rule

$$h(z) = g(f(z)) \tag{38.1.2}$$

is also an analytic function. (Of course, for z values of interest, the range of f must also be in the domain of g.) We have the mantra "an analytic function of an analytic function is analytic".

By contrast, Weierstrass defines analyticity in terms of representations by convergent Taylor series. His definition is more involved and, in order to discuss Taylor series, we first must remind ourselves of some properties of infinite sequences and infinite series. We will do this by recalling definitions and stating theorems without proof. Further information may be found in the references listed at the end of this chapter.

Definition 1.1: Consider an infinite sequence c_m of real or complex numbers. We say that this sequence *converges* to a number c,

$$\lim_{m\to\infty} c_m = c,$$

if, given any $\epsilon > 0$, there exists a positive integer N such that

$$|c_m - c| < \epsilon \text{ if } m > N.$$

Definition 1.2: Suppose the sequence c_m has the property that, given any $\epsilon > 0$, there exists an N such that

$$|c_\ell - c_m| < \epsilon \text{ if } \ell, m > N.$$

Such a sequence is called *Cauchy* or *fundamental.*

Theorem 1.1: A sequence is convergent if and only if it is Cauchy.

Definition 1.3: Consider an infinite series $\sum\limits_{n=0}^{\infty} b_n$. We say that this series converges to the (finite) value s if the sequence of partial sums s_m, with

$$s_m = \sum_{n=0}^{m} b_n, \tag{38.1.3}$$

converges to the value s.

Definition 1.4: If an infinite series does not converge, we say that it is *divergent.* By this definition, divergence includes the possibility that the sequence of partial sums increases (in absolute value) without bound, or has more than one limit point. For example, the sequence of partial sums for the series 1, 1/2, 1/3, 1/4 $\cdots$ grows without bound, and the sequence of partial sums for the series 1, -1, 1, -1, $\cdots$ has the limit points 1 and 0.

Theorem 1.2: If the infinite series $\sum b_n$ converges, then its terms b_n must tend to zero,

$$\lim_{n\to\infty} b_n = 0.$$

Theorem 1.3: Suppose the terms b_n are all real and alternate in sign. Suppose also that

$$\lim_{n\to\infty} b_n = 0.$$

Then the series $\sum b_n$ converges.

Definition 1.5: We say that the infinite series $\sum b_n$ converges *absolutely* if the series $\sum |b_n|$ converges.
Theorem 1.4: If the infinite series $\sum b_n$ converges absolutely, then it also converges in the sense of Definition 1.3.
Definition 1.6: Suppose $g(m)$ is a function that provides an invertible mapping of the (non-negative) integers onto themselves (a bijection). Then we say that the series

$$\sum_{m=0}^{\infty} b_{g(m)} \tag{38.1.4}$$

is a *rearrangement* of the series $\sum b_n$.
Theorem 1.5: If the infinite series $\sum b_n$ converges absolutely, then all *rearrangements* of the series $\sum b_n$ converge (in the sense of Definition 1.3 and also absolutely), and they all converge to the same value s.
Definition 1.7: Supposes that the infinite series $\sum b_n$ converges, but not absolutely. That is, the series $\sum |b_n|$ diverges. Then we say that the series $\sum b_n$ converges *conditionally.*
Theorem 1.6 (Riemann): Suppose that the b_n are all real and the series $\sum b_n$ converges conditionally. Then, there are rearrangments of the series that diverge. Moreover, given any (real) number s', there are rearrangements of the series that converge to s'.
Theorem 1.7 (Levy): Suppose the (possibly complex) series $\sum b_n$ is conditionally convergent. Then there is at least one line in the complex plane such that, upon selecting any point w' on that line, there is a rearrangement of the series $\sum b_n$ that converges to w'.
Theorem 1.8 (Steinitz): All the possible sums of a conditionally convergent complex series obtained by rearrangement lie on a straight line or else cover the whole complex plane.

Definitions 1.5 through 1.7 and Theorems 1.4 through 1.8 illustrate the importance of absolute convergence and the need to handle conditionally convergent series with care.

We are now prepared to discuss Taylor series. Without loss of generality, we will for the most part restrict our attention to Taylor series about the origin. Suppose the terms b_n in an infinite series are of the form $a_n z^n$ where z is a complex variable and (a_n) is a sequence of complex numbers. In this case we have the result
Theorem 1.9 (Abel): Suppose that for some (possibly complex) nonzero value $z = z'$ the series $\sum a_n z^n$ converges. Then the series converges absolutely for $|z| < |z'|$.
Moreover, suppose a *radius of convergence* R is defined in terms of the coefficients a_n by the rule

$$1/R = \limsup_{n\to\infty} |a_n|^{1/n}. \tag{38.1.5}$$

Then we have the more specific result
Theorem 1.10 (Cauchy-Hadamard): The series $\sum a_n z^n$ converges absolutely for every z with $|z| < R$, and the convergence is uniform in every closed disk $|z| \leq \rho < R$. (*Uniform* means that given any closed disk and any ϵ as in Definition 1.1, there is an associated N that suffices for all points z in the disk.) If $|z| > R$, the terms in the series are unbounded, and (by Theorem 1.2) the series is divergent. Suppose the series is differentiated term by term any number of times. Then the resulting series is also absolutely convergent for $|z| < R$, and uniformly convergent in every closed disk $|z| \leq \rho < R$.

At this point we observe that if the radius of convergence R of a Taylor series is nonzero, then (by Theorem 1.10) we obtain an infinitely differentiable function f in some neighborhood of the origin by writing

$$f(z) = \sum_{n=0}^{\infty} a_n z^n. \tag{38.1.6}$$

Moreover, we have the relations

$$a_n = (1/n!) f^{(n)}(0). \tag{38.1.7}$$

We are ready for Weierstrass' definition of analyticity. According to his definition, a function f is analytic in the domain $\mathcal{D}$ if, for any point $z^0 \in \mathcal{D}$, the function $f(z)$ has a convergent Taylor expansion about z^0,

$$f(z) = \sum_{n=0}^{\infty} a_n(z^0)(z - z^0)^n. \tag{38.1.8}$$

[Here we have used the notation $a_n(z^0)$ to indicate that the expansion coefficients in general depend on the expansion point z^0.] The definition of Weierstrass has the advantage that initially f need not be defined for complex values of z. For example, when working around the origin, we may at first require only that f have an expansion of the form (1.6) with z real and near zero. Then the series (1.6) automatically *extends* the definition of f to complex values of z. Moreover, it can be verified that the expansion point z^0, which was initially the origin in (1.6), can subsequently be moved to any point in the open disk $|z| < R$ and (26.1.8) will hold. Thus, with Weierstrass' definition, a function that is represented by a Taylor series about the origin is automatically analytic within its disk of convergence. Conversely, if a function is analytic in the disc $|z| < R$, then it will have a Taylor expansion about the origin that converges within that disc.

Contour integration is a fundamental tool in the Theory of Functions of a Single Complex Variable. Applications include the integral formula specified by
Theorem 1.11 (Cauchy): An analytic function f has the representation

$$f(z) = (1/2\pi i) \oint dz' f(z')/(z' - z). \tag{38.1.9}$$

Also, its Taylor coefficients can be found by contour integration. Suppose f is analytic about the origin in a disc of radius R. Let $R' = R - \epsilon$ where ϵ is any small positive number. Then the Taylor coefficients of f about the origin are given by the integrals

$$a_n = (1/2\pi i) \oint_{|z|=R'} dz f(z)/z^{n+1}. \tag{38.1.10}$$

Use of this representation provides the bound

$$|a_n| \leq K(R')^{-n} \tag{38.1.11}$$

where the constant K is given by the relation

$$K = \text{ max } |f(z)| \text{ over the points } |z| = R'. \tag{38.1.12}$$

Suppose f is some given analytic function, and we wish to find the radius of convergence for its Taylor expansion about some point, say the origin. One procedure would be to find its Taylor coefficients and then form the limit (1.5). However, there is an easier way. Simply find the location of the singularity of f that is closest to the origin. Consistent with Theorems 1.10 and 1.11, its distance from the origin will be R.

Finally, we remark that Cauchy's integral formula can be obtained from Riemann's definition of analyticity; and this formula, in turn, can be used to prove the existence of convergent Taylor expansions. Thus we have the key result that Riemann's and Weierstrass' definitions of analyticity are mathematically equivalent.

Historically, the adjective *holomorphic* was used to describe the case where a function was analytic as defined by Riemann, and the adjective *analytic* was used for analyticity as defined by Weierstrass. Now, because these two definitions are mathematically equivalent, these two adjective are commonly used interchangeably.

38.2 Analyticity in Several Complex Variables

The Theory of Functions of Several Complex Variables proceeds in a way that is somewhat analogous to the case of one complex variable, but it is much richer and much less explored. Again there are two ways to define analyticity. According to Riemann, a function $f(z) = f(z_1, z_2, \cdots z_m)$ of m complex variables is analytic if it is analytic (complex differentiable) in each variable *separately*.

As before, Riemann's definition immediately shows that the composition of two analytic functions produces an analytic function. For example, let $f(z_1, z_2, \cdots z_m)$ be an analytic function of m complex variables, and let $g(w)$ be an analytic function of the single complex variable w. Then, by the chain rule, $h(z_1, z_2, \cdots z_m)$ defined by

$$h(z_1, z_2, \cdots z_m) = g(f(z_1, z_2, \cdots z_m)) \tag{38.2.1}$$

is also an analytic function of the m complex variables $z_1, z_2, \cdots z_m$ providing the range of f is in the domain of g for the z values of interest.

According to Weierstrass, a function of m complex variables is analytic in the neighborhood of a point $z^0 = (z_1^0, z_2^0, \cdots z_m^0)$ if it has a convergent multiple Taylor expansion of the form

$$f(z) = f(z_1, z_2, \cdots z_m) = \sum [a_{n_1, n_2, \cdots n_m}(z^0)][(z_1 - z_1^0)^{n_1}(z_2 - z_2^0)^{n_2} \cdots (z_m - z_m^0)^{n_m}]. \tag{38.2.2}$$

The definition of Weierstrass again has the advantage that initially f need not be defined for complex values of the z_ℓ. For example, when working around the origin, we may at first require only that f have an expansion of the form (2.2) with $z^0 = 0$ and the z_ℓ real and near zero. Then, as will become evident in our subsequent discussion, the series expansion automatically extends the definition of f to complex values of the z_ℓ. Moreover, we also get analyticity in an open set.

The handling of *multiple* Taylor series requires some care. For notational simplicity, we mostly limit our discussion to the case of two complex variables and to expansions about the origin. The extension to more variables and general expansion points will generally be obvious.

In the case of double Taylor series about the origin, we have expressions of the form

$$f(z) = f(z_1, z_2) = \sum_{jk} a_{jk} z_1^j z_2^k. \tag{38.2.3}$$

Since this is a double Taylor series, there are many ways of listing its terms sequentially, and the meaning of the infinite sum of these terms is not well defined as it stands. By an *ordering* or *arrangement* of these terms, we mean some procedure for putting the pairs of integers j, k into one-to-one correspondence (a bijection) with the integers $n = 0, 1, 2, \cdots$. Since the set of pairs of integers and the set of integers both have the same cardinality, such a correspondence is always possible. We will denote this correspondence by writing

$$j = j(n), \tag{38.2.4}$$

$$k = k(n).$$

In particular, for any correspondence and given any pair j', k', there is always a unique finite number m such that

$$j' = j(m),$$

$$k' = k(m). \tag{38.2.5}$$

With these ideas in mind we see that, to be precise and without serious loss of generality, we may consider in place of the double series (2.3) a *simple* series of the form

$$f(z) = f(z_1, z_2) = \sum_{n=0}^{\infty} a_{j(n),k(n)} z_1^{j(n)} z_2^{k(n)} = \sum_{n=0}^{\infty} b_n(z) \tag{38.2.6}$$

with

$$b_n(z) = a_{j(n),k(n)} z_1^{j(n)} z_2^{k(n)}. \tag{38.2.7}$$

The treatment of such series is amenable to the methods of Definition 1.3. Figure 2.1 illustrates two of many possible orderings for the case of a double series. In ordering a, successive terms are taken sequentially from the two sides of ever larger squares. In ordering b, successive terms are taken sequentially from the long sides of ever larger triangles.

We can now discuss the convergence properties of multiple Taylor series. First, we define the *convergence set* $\mathcal{T}$ of a Taylor series to be the set of all points for which the series (2.6) converges for some ordering. We have already seen that, according to Theorem 1.10, the convergence set for a Taylor series in one complex variable is a disc. What can be said about the "shape" of the convergence set $\mathcal{T}$ for a Taylor series in several complex variables? We begin with a several complex variable analog of Theorem 1.9.

Theorem 2.1: Suppose that for some pair of (possibly complex) nonzero values z_1', z_2' and some ordering the series (2.6) converges. Define real positive numbers R_1', R_2' by the relations

$$R_1' = |z_1'|, \ R_2' = |z_2'|. \tag{38.2.8}$$

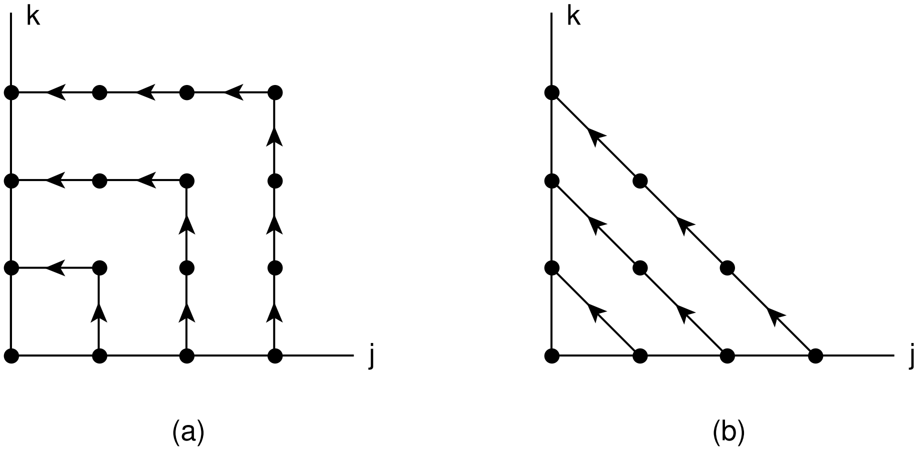

Figure 38.2.1: Two of many possible orderings for the terms in a double series.

Let $\mathcal{P}$ denote the domain (called a *polydisc* or *polycylinder* or *polycircle* about the origin with radii R'_ℓ)

$$|z_1| < R'_1,\ |z_2| < R'_2. \tag{38.2.9}$$

Then, the series (2.6) converges absolutely for all $z_1, z_2 \in \mathcal{P}$, and (by Theorem 1.5) for any ordering. Moreover, by a result of *Fubini*, the iterated series

$$f(z) = f(z_1, z_2) = \sum_{j=0}^{\infty} z_1^j \sum_{k=0}^{\infty} a_{jk} z_2^k = \sum_{k=0}^{\infty} z_2^k \sum_{j=0}^{\infty} a_{jk} z_1^j \tag{38.2.10}$$

also converge (including absolutely) for $z_1, z_2 \in \mathcal{P}$. Finally, all the various series and orderings converge to the same value.

The theorem just quoted, like Theorem 1.9, can be extended. To do so requires the introduction of some notation and further definitions. With regard to notation, let $\boldsymbol{\tau} = (\tau_1, \tau_2 \cdots \tau_m)$ be a collection of m complex numbers. Then by the symbol $\boldsymbol{\tau}z$ we mean the collection of variables $(\tau_1 z_1, \tau_2 z_2, \cdots \tau_m z_m)$. We are ready to give

Definition 2.1: Suppose $\mathcal{R}$ is a set having the property that if z is in $\mathcal{R}$, then so is $\boldsymbol{\tau}z$ providing the τ_ℓ satisfy $|\tau_\ell| \leq 1$. Such a set is called a *complete Reinhardt* set with center at the origin.

A complete Reinhardt set can be descripted pictorially by a *Reinhardt diagram*. Figure 2.2 shows a Reinhardt diagram for the case of two complex variables. Note that the diagram displays the real numbers $|z_1|$ and $|z_2|$. The complete Reinhardt set corresponds to the shaded area. It may also include portions of the axes, called *thorns*, that correspond to the dark lines that extend from the shaded area. A thorn is a polydisc all of whose radii are zero save one.

We next need to define a *logarithmically convex* complete Reinhardt set. Suppose we replot Figure 2.2 in terms of the variables $w_\ell = \log |z_\ell|$. Figure 2.3 shows the resulting *logarithmic image* of the shaded area in Figure 2.2. This image is *convex* if any two points in it can be joined by a straight line that is also in the image. With these concepts in mind we may state

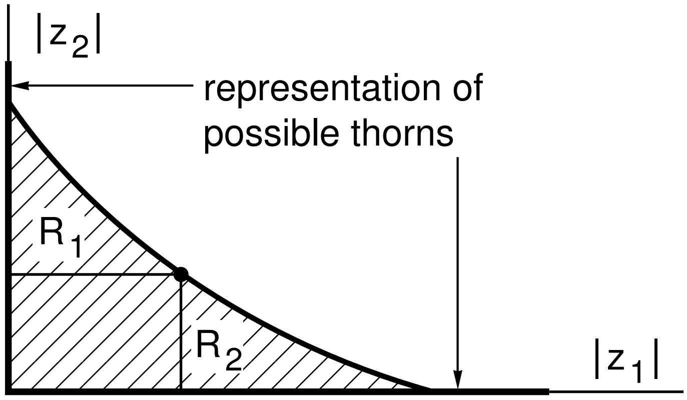

Figure 38.2.2: Possible Reinhardt diagram for the case of two complex variables. The complete Reinhardt set consists of those points $z = (z_1, z_2)$ for which the pairs $|z_1|$, $|z_2|$ lie in the shaded area, or the darkened portions of the axes representing possible thorns. The quantities R_1, R_2 on the boundary of the shaded area are conjugate radii.

Definition 2.2: A complete Reinhardt set is logarithmically convex if the logarithmic image of the "shaded" portion of its corresponding Reinhardt diagram (ignoring possible thorns) is convex.

We are now prepared to describe the characteristic features of the convergence set $\mathcal{T}$ of a Taylor series in several complex variables. The result will be given for a Taylor series about the origin,

$$f(z) = f(z_1, z_2, \cdots z_m) = \sum a_{n_1,n_2,\cdots n_m} z_1^{n_1} z_2^{n_2} \cdots z_m^{n_m}, \tag{38.2.11}$$

but can be easily extended to any expansion point z^0 by simple translation.

Theorem 2.2: The (absolute) convergence set of a multiple Taylor series of the form (2.11) is the *interior* of some logarithmically convex complete Reinhardt set about the origin. (This interior is called a logarithmically convex complete Reinhardt *domain*.) The series also converges absolutely in possible thorns of the set save perhaps at their "tips". Suppose the series is differentiated term by term any number of times with respect to any number of its variables. Then the resulting series is also absolutely convergent. Moreover, let R_ℓ be the value of $|z_\ell|$ at a point on the boundary of the set excluding points for which some $|z_\ell| = 0$. (Note that this requirement excludes thorns.) See Figure 2.2. Then the R_ℓ, called *conjugate radii*, satisfy the condition [a generalization of (1.5)]

$$\limsup_{|n|\to\infty} [|a_{n_1,n_2,\cdots n_m}| R_1^{n_1} R_2^{n_2} \cdots R_m^{n_m}]^{1/|n|} = 1. \tag{38.2.12}$$

Here we have introduced the notation

$$|n| = n_1 + n_2 + \cdots + n_m. \tag{38.2.13}$$

For points on the boundary of the logarithmically convex complete Reinhardt set the series may or may not converge, either absolutely or conditionally. Finally, for any point z outside the set, the terms in the series are unbounded, and hence the series is divergent for any ordering.

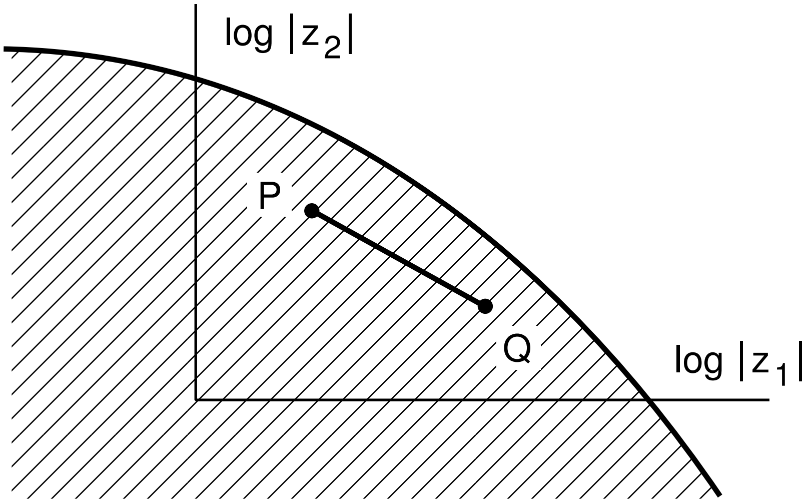

Figure 38.2.3: The logarithmic image of the shaded area in Figure 2.2. This image is convex if any two points P, Q in the image can be joined by a straight line that is also in the image.

According to this theorem, a convergent multiple Taylor series about the origin defines an infinitely differentiable function (with respect to all variables) in a logarthmically convex complete Reinhardt domain about the origin. Moreover, we have the relations

$$a_{n_1,n_2,\cdots n_m} = (1/n_1!)(1/n_2!)\cdots(1/n_m!)\partial_1^{n_1}\partial_2^{n_2}\cdots\partial_m^{n_m} f(z)|_{z=0}\,. \tag{38.2.14}$$

Finally, it can be shown that the expansion point z^0, which was initially the origin in (2.11), can subsequently be moved to any interior point in the logarithmically convex complete Reinhardt domain and (2.2) will hold for z sufficiently near z^0. Thus, a function of several complex variables that is represented by a multiple Taylor series about the origin is automatically analytic within its logarithmically convex complete Reinhardt domain of convergence. Conversely, if a function is analytic in a logarithmically convex complete Reinhardt domain about the origin, then it will have a Taylor expansion about the origin that converges within this logarithmically convex complete Reinhardt domain.

Contour integration also plays an important role in the Theory of Several Complex Variables. For example, there is a generalized Cauchy's Theorem which shows that functions of several complex variables have integral representations of the form

$$\begin{aligned} &f(z) = f(z_1, z_2, \cdots z_m) = \\ &(1/2\pi i)^m \oint\oint\cdots\oint dz_1' dz_2' \cdots dz_m' \times \\ &f(z')/(z_1' - z_1)(z_2' - z_2)\cdots(z_m' - z_m). \end{aligned} \tag{38.2.15}$$

Also, the Taylor coefficients (2.14) can be found by contour integration. Let ϵ be any small positive number. Define quantities R_ℓ' by the relation

$$R_\ell' = R_\ell - \epsilon \tag{38.2.16}$$

where the R_ℓ are some set of conjugate radii. Then the Taylor coefficients of f about the origin are given by the integrals

$$a_{n_1,n_2,\cdots n_m} = (1/2\pi i)^m \oint\limits_{|z_1|=R_1'} \oint\limits_{|z_2|=R_2'} \cdots \oint\limits_{|z_m|=R_m'} dz_1 dz_2 \cdots dz_m f(z)/(z_1^{n_1+1} z_2^{n_1+1} \cdots z_m^{n_m+1}). \tag{38.2.17}$$

From this representation we deduce the Cauchy bound

$$|a_{n_1,n_2,\cdots n_m}| \leq K(R_1')^{-n_1}(R_2')^{-n_2} \cdots (R_m')^{-n_m} \tag{38.2.18}$$

where the constant K is given by the relation

$$K = \max|f(z)| \text{ over the points } |z_1| = R_1', |z_2| = R_2', \cdots |z_m| = R_m'. \tag{38.2.19}$$

Finally, starting from Riemann's definition of analyticity, Hartogs showed that analyticity in each variable separately implies continuity as well with respect to the set of all variables. The generalized Cauchy's Theorem (2.15) then follows; and from it follows the existence of convergent multiple Taylor expansions. Thus, Hartogs obtained the celebrated result that Riemann's and Weierstrass' definitions of analyticity are also equivalent in the much more difficult case of several complex variables.

We have seen at the end of Section 31.1 that, in the case of a function of one complex variable, it is possible to determine the radius of convergence of its Taylor series simply from a knowledge of the locations of the singularities of the function. The same is true for a function of several complex variables: the logarithmically convex complete Reinhardt domain of convergence of its multiple Taylor series expansion can be found from a knowledge of the locations of its singularities. However, the calculation is considerably more involved.

Consider, for simplicity, the case of a function $f(z_1, z_2)$ of two complex variables and its Taylor expansion about the origin. First we examine the two functions $f_1(z_1) = f(z_1, 0)$ and $f_2(z_2) = f(0, z_2)$. They are analytic functions of a single complex variable, and the radii of convergence of their Taylor expansions can be found using the method described at the end of Section 31.1. These two radii determine the tips of the two possible thorns represented in Figure 2.2.

Next we determine the conjugate radii R_1 and R_2. To do so we carry out the following steps:

1. Write z_1 in the form
$$z_1 = \hat{z}_1(\phi_1) = R_1 \exp(i\phi_1). \tag{38.2.20}$$

2. Hold R_1 fixed and positive, and initially small.

3. Examine the function
$$g_2(z_2, \phi_1) = f(\hat{z}_1, z_2). \tag{38.2.21}$$

4. Find the locations of the singularities of g_2 (viewed as a function of z_2) in the complex z_2 plane for each value of $\phi_1 \in [0, 2\pi)$.

5. Follow these singularities as ϕ_1 varies from 0 to 2π.

6. Define R_2 by the relation
$$R_2 = \min_{\phi_1} |z_2^c(\phi_1)| \tag{38.2.22}$$
where $|z_2^c(\phi_1)|$ is the distance from the origin of the singularity of g_2 that is *closest* to the origin for each value of ϕ_1.

7. Repeat steps 1 through 6 above, while slowly increasing the value of R_1, until R_2 becomes zero.

The result of this process is the set of R_1, R_2 values that describe the boundary of the logarithmically convex complete Reinhardt domain. See Figure 2.4. Alternatively, we may carry out a similar process, but interchange the roles of z_1 and z_2. See Figure 2.5. It can be shown that both processes yield identical sets of R_1, R_2 values.

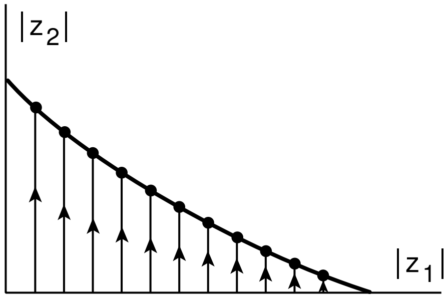

Figure 38.2.4: Determining the conjugate radii by fixing R_1 and searching for the closest singularity in z_2 as ϕ_1 varies to yield R_2.

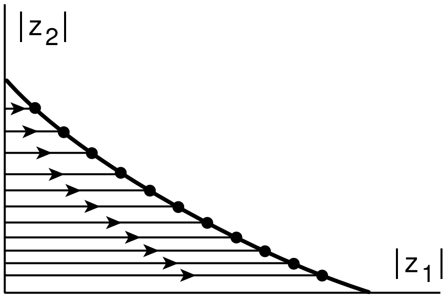

Figure 38.2.5: Determining the conjugate radii by fixing R_2 and searching for the closest singularity in z_1 as ϕ_2 varies to yield R_1.

Example 2.1: Consider the function of three variables defined by the equation
$$\psi(\boldsymbol{r}) = [x_1^2 + (x_2 - 1)^2 + x_3^2]^{-1/2}. \tag{38.2.23}$$

Up to a normalization, ψ is the electrostatic potential due to a point charge located at unit distance from the origin along the x_2 axis. See Figure 2.6.

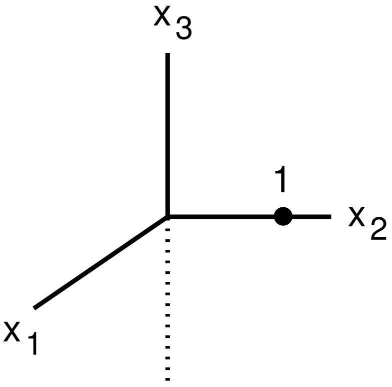

Figure 38.2.6: A point charge located at unit distance from the origin along the x_2 axis.

Suppose we expand $\psi(\boldsymbol{r})$ in a triple Taylor series about the origin,

$$\psi(\boldsymbol{r}) = \sum_{jk\ell} a_{jk\ell} x_1^j x_2^k x_3^\ell. \tag{38.2.24}$$

To examine the convergence of this series, we consider the function

$$f(z) = [z_1^2 + (z_2 - 1)^2 + z_3^2]^{-1/2}. \tag{38.2.25}$$

It is singular when the argument of the square root vanishes,

$$z_1^2 + (z_2 - 1)^2 + z_3^2 = 0. \tag{38.2.26}$$

The Reinhardt diagram in this case is 3-dimensional. An extension of the method just described shows that its boundary is given by the relation

$$R_1 = \min_{\phi_2,\phi_3} |\{-[R_2 \exp(i\phi_2) - 1]^2 - [R_3 \exp(i\phi_3)]^2\}^{1/2}| \text{ with } R_2, R_3 \in [0,1], \tag{38.2.27}$$

or equivalently,

$$R_1^2 = \min_{\phi_2,\phi_3} |[R_2 \exp(i\phi_2) - 1]^2 + [R_3 \exp(i\phi_3)]^2| \text{ with } R_2, R_3 \in [0,1]. \tag{38.2.28}$$

This result follows, esssentially, from solving (2.26) for z_1. Now it is easily verified from geometric considerations in the complex plane that the minimum sought in (2.28) occurs when $\phi_2 = 0$ and $\phi_3 = \pi/2$. See Exercise 2.4. Consequently, we have the result

$$R_1^2 = (R_2 - 1)^2 - R_3^2 \text{ or } R_1^2 + R_3^2 = (R_2 - 1)^2. \tag{38.2.29}$$

This is just the equation for a cone. See Figure 2.7.
Example 2.2: Suppose instead we hold x_3 fixed (and real) and simply expand $\psi(\boldsymbol{r})$ in a double Taylor series in x_1 and x_2 about the origin,

$$\psi(x_1, x_2; x_3) = \sum_{jk} a_{jk}(x_3) x_1^j x_2^k. \tag{38.2.30}$$

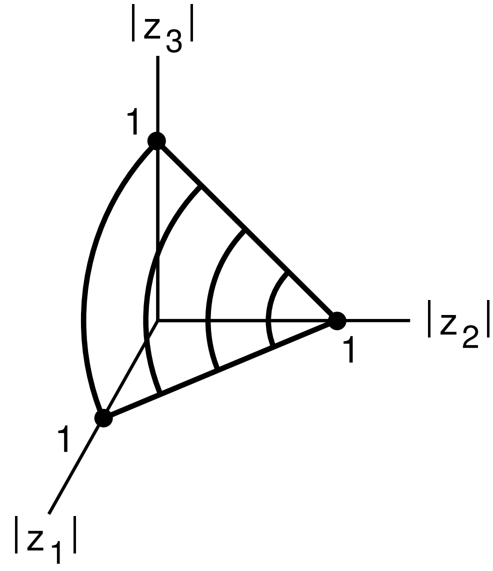

Figure 38.2.7: The Reinhardt diagram for the series (2.24), which represents the function $f(z)$ given by (2.25), is a cone.

To study the convergence of this series we must consider the function

$$f(z;x_3) = [z_1^2 + (z_2-1)^2 + x_3^2]^{-1/2}, \tag{38.2.31}$$

which is singular when

$$z_1^2 + (z_2-1)^2 + x_3^2 = 0. \tag{38.2.32}$$

For this simpler 2-dimensional example direct application of (2.20) through (2.22) gives the result

$$R_2 = \min_{\phi_1} |1 \pm [-R_1^2 \exp(2i\phi_1) - x_3^2]^{1/2}|. \tag{38.2.33}$$

In general the evaluation of (2.33) requires numerical computation. However for the special case $x_3 = 0$, there is the simple result

$$R_1 + R_2 = 1 \text{ when } x_3 = 0. \tag{38.2.34}$$

Figure 2.8 shows, for three values of x_3, the Reinhardt diagrams in the $|z_1|$, $|z_2|$ plane of the series (2.30) that represents $f(z;x_3)$. It is easily verified that the boundaries of these diagrams in the $|z_1| = 0$ and $|z_2| = 0$ planes are hyperbolas,

$$R_2^2 = 1 + x_3^2 \text{ when } |z_1| = 0, \tag{38.2.35}$$

$$R_1^2 = 1 + x_3^2 \text{ when } |z_2| = 0. \tag{38.2.36}$$

Some observations are in order. Note that the double series (2.30) is an iterated version of the triple series (2.24),

$$\psi = \sum_{jk\ell} a_{jk\ell} x_1^j x_2^k x_3^\ell = \sum_{jk} x_1^j x_2^k \sum_{\ell} a_{jk\ell} x_3^\ell = \sum_{jk} a_{jk}(x_3) x_1^j x_2^k, \tag{38.2.37}$$

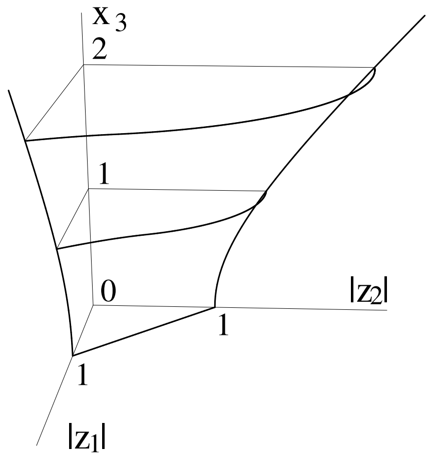

Figure 38.2.8: Reinhardt diagrams, for three values of x_3, of the series (2.30) that represents $f(z; x_3)$. Diagrams for negative values of x_3 are not shown since the diagrams for $\pm x_3$ are identical.

with

$$a_{jk}(x_3) = \sum_{\ell} a_{jk\ell} x_3^{\ell}. \tag{38.2.38}$$

Next we observe from Figure 2.8 that, unlike the previous example of Figure 2.7, the size of the convergence set *increases* with increasing $|x_3|$. We see that summation over some of the variables in a multiple series can yield a series with an extended convergence domain.

We close this section by describing briefly a remarkable feature of analytic functions of *one* complex variable, and a further remarkable feature of functions of *many* complex variables that distinguishes them from functions of a single complex variable. These features have to do with *analytic continuation*.

We begin with functions of a single complex variable, which we call w. Suppose $g(w)$ is such a function that is defined and analytic in some arbitrarily shaped simply-connected domain $\mathcal{D}$. Then we may attempt to extend g beyond $\mathcal{D}$ by analytic continuation. In its simplest description, analytic continuation consists of two steps:

1. Choose some path that leads out of $\mathcal{D}$.

2. Make successive related Taylor expansions of g in overlapping discs along the path. In this process, the Taylor coefficients for the expansion in an adjacent subsequent disc are found from those for the previous disc by multiply differentiating the Taylor expansion for the previous disc and evaluating the result at the new expansion point. That is, two successive Taylor series must give identical values for g in the region where their expansion discs overlap.

See Figure 2.9. However, this process may fail. (The convergence radii of successive Taylor expansions may shrink to zero.) It can be shown that there are functions that are anaytic in $\mathcal{D}$, but cannot be extended in an analytic way beyond the boundary of $\mathcal{D}$. Such functions are said to have a *natural boundary*, which, in this case, is the boundary of $\mathcal{D}$. [Basically, a function (of a single complex variable) with a natural boundary has a dense set of singularities on the boundary that prevent its analytic extension beyond the boundary.] Thus, given any arbitrarily shaped boundary in the complex plane, it is possible to find a function that has this boundary as a natural boundary.

A function that is specified and analytic on a small domain is called a *germ*. What we have learned is the remarkable fact that a germ specifies the full function. If a function of a single variable is defined and analytic is some domain ever so small (it could even be a small line segment), then the function is uniquely extendable over the whole domain to which it can be continued until it is defined everywhere (perhaps in a multiple sheeted way) or a natural boundary is encountered. Moreover, any boundary in the complex plane is a potential natural boundary for some analytic function.

The case of analytic functions of many complex variables is very different. Again, one can begin with a function defined in a small domain, a germ, and then attempt to extend the domain by analytic continuation. But, remarkably, now there are restrictions to what could possibly be natural boundaries.

Specifically, suppose again that $\mathcal{D}$ is some arbitrary domain, but now in C^m, the space of m complex variables. Suppose also that $f(z_1, z_2, \cdots z_m)$ is some function that is analytic in $\mathcal{D}$, and we seek to analytically continue f beyond $\mathcal{D}$. (To carry out analytic continuation in C^m, one may use overlapping polydiscs.) What can be said about this challenge?

Consider, for example, a function $f(z_1, z_2)$ of two complex variables that is analytic within the complete Reinhardt domain whose Reinhardt diagram is displayed in Figure 2.10. Figure 2.11, which shows the logarithmic image of Figure 2.10, illustrates that this domain is not logarithmically convex. However, it becomes logarithmically convex if the region corrresponding to the area below the dashed curved line segment (which is the inverse image of the dashed straight line segment in Figure 2.11) is added to the region corresponding to the shaded area. Indeed, this is the minimum territory that must be added to make the full domain logarithmically convex. A domain augmented in this way is called the *logarithmically convex hull* of the original domain.

It can be shown that *any* function $f(z_1, z_2)$ that is analytic in the complete Reinhardt domain described by the Reinhardt diagram of Figure 2.10 must have an analytic continuation into the minimal logarithmically convex extension obtained by adding to the Reinhardt diagram the area below the dashed curved line. Of course, there may be some functions that can be analytically continued even further. However, there will be other functions that cannot.

Suppose a domain has the property that there exists a function that is analytic in the domain, but this function cannot be analytically continued beyond the domain. Such a domain is called a *domain of holomorphy*. The determination of domains of holomorphy is a major topic in the Theory of Analytic Functions of Several Complex Variables. An important result, for our purposes, is that any logarithmically convex complete Reinhardt domain is a domain of holomorphy.

Often one begins with some particular domain, and would like to know the smallest domain of holomorphy that contains this domain. Such a domain is said to be an *envelope of holomorphy* for the original domain. This question is important, because *any* function that is analytic in the original domain must automatically be analytic in its envelope of holomorphy.

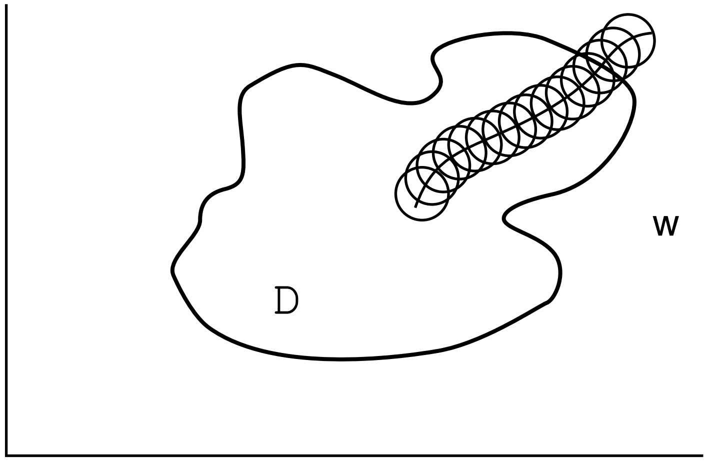

Figure 38.2.9: Analytic continuation along a path out of a domain $\mathcal{D}$ in the complex w plane by making successive related Taylor expansions in overlapping disks along the path.

Roughly speaking, for functions of many complex variables, the known existence of some analyticity often implies the existence of more analyticity.

We conclude that the complete Reinhardt domain described by the Reinhardt diagram of Figure 2.10 is not a domain of holomorphy. By contrast, the minimal logarithmically convex extension of this domain, which is a logarithmically convex complete Reinhardt domain, is a domain of holomorphy. Moreover, it is the envelope of holomorphy for the original domain.

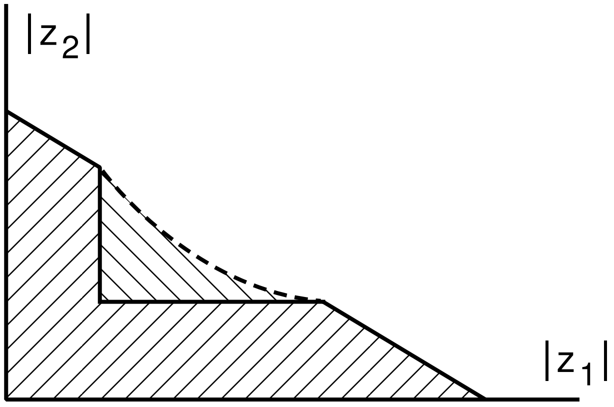

Figure 38.2.10: Reinhardt diagram for a complete Reinhardt domain that is not logarithmically convex. The dashed *curved* line segment is the inverse image of the dashed *straight* line segment in Figure 2.11. The domain becomes logarithmically convex if the region corresponding to the area below the dashed line is annexed to that corresponding to the shaded area.

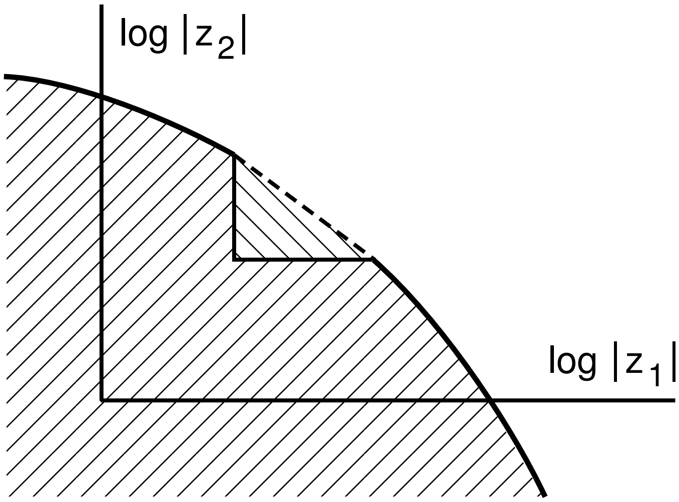

Figure 38.2.11: The logarithmic image of the shaded region of Figure 2.10. Augmenting the image by adding the area below the dashed *straight* line segment makes the image convex.

Exercises

38.2.1. Consider the function

$$f(z) = 1/[1 - (z_1 + z_2)]. \tag{38.2.39}$$

Expand f in a double Taylor series about the origin, and determine the convergence set of this series. Verify that the set is logarithmically convex.

38.2.2. Repeat Exercise 2.1 above for the function

$$f(z) = 1/(1 - z_1 z_2). \tag{38.2.40}$$

38.2.3. Repeat Exercise 2.1 above for the function

$$f(z) = 1/[1 - (z_1 + z_2 + z_1 z_2)]. \tag{38.2.41}$$

38.2.4. Find the ϕ_2, ϕ_3 values that minimize (2.28) by drawing suitable pictures (in the complex plane) of the sets

$$[R_2 \exp(i\phi_2) - 1]^2, \tag{38.2.42}$$

$$[R_3 \exp(i\phi_3)]^2, \tag{38.2.43}$$

$$[R_2 \exp(i\phi_2) - 1]^2 + [R_3 \exp(i\phi_3)]^2. \tag{38.2.44}$$

Verify (2.29).

38.2.5. Verify (2.33) through (2.36). Write a computer program to evaluate R_2 as given by (2.33).

38.2.6. Find the first few coefficients $a_{jk}(x_3)$ as given by (2.30) and (2.38). Replace x_3 by the complex variable z_3, and determine the domain of analyticity for the $a_{jk}(z_3)$.

38.2.7. Consider the map, described by (1.4.21) and (1.4.22), that arises from the monomial Hamiltonian (1.4.20). Suppose this map is expanded in a double Taylor series about the origin. Determine the convergence set for this series, and verify that it is logarithmically convex. Discuss the analytic properties of the Hénon map given by (1.2.23).

38.2.8. Exercise about *real environment.*

38.3 Convergence of Homogeneous Polynomial Series

We have seen in Section 31.2 that, to work with multiple Taylor series in a precise way, it is necessary to order their terms. In this section we will explore the effect of ordering and then *grouping* various terms together during the process of summation. In particular, we will study the effect of grouping terms of like degree together to form homogeneous polynomials, and then summing the resulting series of homogeneous polynomials. For us such series are of particular interest because, as we have seen in earlier chapters, they arise naturally in the Lie algebraic treatment of maps.

As an illustration of the concept of grouping terms, consider the simple series (2.6). Let n_0, n_1, n_2, $n_3 \cdots$ be a set of increasing integers with $n_0 = 0$. Suppose we write the series (2.6) in the form

$$f(z) = \sum_{n=0}^{\infty} b_n(z) = \sum_{n=0}^{n_1-1} b_n(z) + \sum_{n=n_1}^{n_2-1} b_n(z) + \sum_{n=n_2}^{n_3-1} b_n(z) + \cdots = \sum_{\ell=0}^{\infty} \sum_{n=n_\ell}^{n_{\ell+1}-1} b_n(z) = \sum_{\ell=0}^{\infty} c_\ell(z)$$

with

$$c_\ell(z) = \sum_{n=n_\ell}^{n_{\ell+1}-1} b_n(z). \tag{38.3.1}$$

We have carried out group sums of the kind $(b_{n_\ell} + b_{n_\ell+1} + b_{n_\ell+2} + \cdots + b_{n_{\ell+1}-1})$ to produce the quantities c_ℓ, and then formed an infinite sum over the c_ℓ.

What can be said about the convergence of the sum $\sum c_\ell$? According to Definition 1.3, to answer this question we must examine the sequence of partial sums. However inspection reveals that, by construction, the sequence of partial sums of $\sum c_\ell$ is a *subsequence* of the sequence of partial sums of $\sum b_n$. Now we know that every subsequence of a convergent sequence is also convergent; indeed, it must converge to the same limit that the full sequence converges to. Moreover, a subsequence may be convergent even if the full sequence is not. We conclude that the grouping of terms can never spoil the convergence of a series, and it may even help in the sense that it may yield a finite result for what would otherwise have been a divergent series. In the case that it helps, and in the context of multiple Taylor series, we would like to show that the result obtained by arranging and grouping is equivalent to that obtained by analytic continuation out of the original domain of convergence of the series.

Let us apply grouping to the ordering of Figure 2.1b. Suppose the successive groups consist of the terms corresponding to the long sides of the successive triangles. Evidently, the terms corresponding to the long side of any given triangle all have degree $(j + k)$, and their sum is a homogeneous polynomial of degree $(j+k)$. Thus, with this ordering and grouping, the sum (2.6) can be rewritten in the form

$$f(z) = \sum_{n=0}^{\infty} a_{j(n),k(n)} z_1^{j(n)} z_2^{k(n)} = \sum_{\ell=0}^{\infty} P_\ell(z) \tag{38.3.2}$$

where $P_\ell(z)$ is the homogeneous polynomial of total degree ℓ

$$P_\ell(z) = \sum_{j+k=\ell} a_{j,k} z_1^j z_2^k. \tag{38.3.3}$$

We have ordered and grouped a double Taylor series into what we will call a *homogeneous polynomial* series. Evidently, an analogous ordering and grouping can be carried out for any multiple Taylor series. Moreover, we know from the results of Sections 31.1 and 31.2, and the arguments just made, that the homogeneous polynomial series must converge in the same set as the original Taylor series, and must converge to the same result. Indeed, we have from (3.3) the inequality

$$|P_\ell(z)| \leq \sum_{j+k=\ell} |a_{j,k} z_1^j z_2^k|. \tag{38.3.4}$$

Consequently, the homogeneous polynomial series $\sum P_\ell$ converges absolutely whenever the Taylor series converges absolutely. Finally, the homogeneous polynomial series may even converge *outside* the convergence set of the underlying Taylor series.

How can we find the convergence set of the homogenous polynomial series? Remarkably, we will see that this task is *easier* than finding the convergence set of the underlying Taylor series.

Suppose λ is some complex number. By the symbol λz we mean the collection of variables $(\lambda z_1, \lambda z_2, \cdots \lambda z_m)$. Also, $|z|$ will denote the magnitude of z defined by the rule

$$|z|^2 = \sum_{\ell=1}^{m} |z_\ell|^2 = \sum_{\ell=1}^{m} (x_\ell^2 + y_\ell^2) \tag{38.3.5}$$

with

$$z_\ell = x_\ell + i y_\ell. \tag{38.3.6}$$

[However, for exponents we continue to use (2.13).] Consider the function $g(\lambda, z)$ defined by the relation

$$g(\lambda, z) = f(\lambda z) \tag{38.3.7}$$

where $f(z)$ is analytic about the origin and therefore has a convergent expansion of the form (2.11). Combining (2.11) and (3.7) gives the expansion

$$\begin{aligned} g(\lambda, z) = f(\lambda z) &= \sum a_{n_1,n_2,\cdots n_m} (\lambda z_1)^{n_1} (\lambda z_2)^{n_2} \cdots (\lambda z_m)^{n_m} \\ &= \sum \lambda^{|n|} a_{n_1,n_2,\cdots n_m} z_1^{n_1} z_2^{n_2} \cdots z_m^{n_m}. \end{aligned} \tag{38.3.8}$$

For any fixed z, this series will converge for sufficiently small λ. To see this, make some simple estimates. Let $R_1, R_2, \cdots R_m$ be some set of (nonzero) conjugate radii as described in Theorem 2.2, and let R be the smallest of them,

$$R = \min R_\ell. \tag{38.3.9}$$

Next define R' by

$$R' = R - \epsilon \tag{38.3.10}$$

where ϵ is a small positive number. Then from (2.18) we get the bound

$$|a_{n_1,n_2,\cdots n_m}| \le K(R')^{-|n|}. \tag{38.3.11}$$

Also, from (3.5) we have the bounds

$$|z_\ell| \le |z|, \tag{38.3.12}$$

$$|z_1^{n_1} z_2^{n_2} \cdots z_m^{n_m}| \le |z|^{|n|}. \tag{38.3.13}$$

It follows that the series (3.8) has the comparison series

$$\text{comparison series } = \sum K(|\lambda||z|/R')^{|n|} = K\sum_{\ell=0}^{\infty}(|\lambda||z|/R')^\ell \sum_{|n|=\ell} 1. \tag{38.3.14}$$

A moment's reflection shows that the second sum in (3.14) is $N(\ell, m)$, the number of monomials of degree ℓ in m variables,

$$\sum_{|n|=\ell} 1 = N(\ell, m) = (\ell + m - 1)!/[\ell!(m-1)!]. \tag{38.3.15}$$

See (7.3.36). Moreover, for fixed m the quantity $N(\ell, m)$ is a *polynomial* in ℓ of degree $(m-1)$, and for large ℓ has the behavior

$$N(\ell, m) \sim \ell^{m-1}/(m-1)!. \tag{38.3.16}$$

It follows that the comparison series (3.14), and therefore also the series (3.8), converge provided λ is small enough to satisfy the inequality

$$|\lambda| < R'/|z|. \tag{38.3.17}$$

We have seen that the series (3.8) for $g(\lambda, z)$ converges absolutely for sufficiently small λ and z. It follows from the discussion of Section 31.2 that g is an analytic function, in the vicinity of the origin, of all the $(m+1)$ complex variables $z_1, z_2, \cdots z_m$ *and* λ. Moreover, the terms in the series for g can be arranged and grouped to take the form

$$g(\lambda, z) = \sum_{\ell=0}^{\infty} \lambda^\ell \sum_{|n|=\ell} a_{n_1,n_2,\cdots n_m} z_1^{n_1} z_2^{n_2} \cdots z_m^{n_m} = \sum_{\ell=0}^{\infty} \lambda^\ell P_\ell(z) \tag{38.3.18}$$

where $P_\ell(z)$ is the homogeneous polynomial

$$P_\ell(z) = \sum_{|n|=\ell} a_{n_1,n_2,\cdots n_m} z_1^{n_1} z_2^{n_2} \cdots z_m^{n_m}. \tag{38.3.19}$$

Correspondingly, for f itself we have the homogeneous polynomial expansion

$$f(z) = g(1, z) = \sum_{\ell=0}^{\infty} P_\ell(z). \tag{38.3.20}$$

For fixed z, regard (3.18) as a Taylor series in λ with Taylor coefficients $P_\ell(z)$. By essentially the same arguments we have just endured, these coefficients have the bound

$$|P_\ell(z)| \le KN(\ell, m)(|z|/R')^\ell. \tag{38.3.21}$$

Consequently, as expected, this series will converge and produce an analytic function of λ at least within the disc (3.17). It follows from Theorem 1.11 that the $P_\ell(z)$ are given by the integrals

$$P_\ell(z) = (1/2\pi i) \oint d\lambda g(\lambda, z)/\lambda^{\ell+1} = (1/2\pi i) \oint d\lambda f(\lambda z)/\lambda^{\ell+1} \tag{38.3.22}$$

for any contour about the origin in the λ plane for which (3.17) holds. Continue to hold z fixed. Let $\lambda_c(z)$ be the singularity of $g(\lambda, z) = f(\lambda z)$ in the λ plane that is *closest* to the origin. Since $f(\lambda z)$ is always analytic in the disc (3.17), we know that $\lambda_c(z)$ is always nonzero. Define a radius R'' by the rule

$$R'' = \rho|\lambda_c(z)| \tag{38.3.23}$$

where ρ is any number slightly less than but arbitrarily near 1,

$$\rho \simeq 1 \text{ but } \rho < 1. \tag{38.3.24}$$

Then the λ contour in (3.22) can be expanded to give the relation

$$P_\ell(z) = (1/2\pi i) \oint_{|\lambda|=R''} d\lambda f(\lambda z)/\lambda^{\ell+1} \tag{38.3.25}$$

and the bound

$$|P_\ell(z)| \le M/(R'')^\ell \tag{38.3.26}$$

where

$$M = \max |f(\lambda z)| \text{ for } |\lambda| = R''. \tag{38.3.27}$$

We conclude that the homogeneous polynomial expansion (3.20) converges absolutely and uniformly provided $\lambda_c(z)$ satisfies the relation

$$|\lambda_c(z)| \ge \rho' > 1. \tag{38.3.28}$$

Conversely, the series (3.18) must diverge for any λ that satisfies

$$|\lambda| > |\lambda_c(z)|. \tag{38.3.29}$$

For if it converged, then (by Theorem 1.9 and the discussion surrounding it) $g(\lambda, z)$ would be analytic in a disc having a radius larger than $|\lambda_c|$, and could not be singular at $\lambda = \lambda_c$. Finally we note that the calculations involved in the relations (3.22) through (3.27), and the divergence criterion associated with (3.29), hold for general z.

We now have the ingredients for determining the domain of convergence of a homogeneous polynomial expansion. The recipe is this:

1. Let $\mathcal{S}^{2m-1}$ be the unit sphere in C^m defined by the condition

$$|z| = 1. \tag{38.3.30}$$

2. For any point $\hat{z} \in \mathcal{S}^{2m-1}$ let $\lambda_c(\hat{z})$ be the singularity of $f(\lambda\hat{z})$ in the λ plane that is closest to the origin.

3. Define the positive number $\sigma(\hat{z})$ by the rule

$$\sigma(\hat{z}) = |\lambda_c(\hat{z})|. \tag{38.3.31}$$

4. Let $\zeta(\hat{z})$ be the *ray* that goes from the origin to the point $\sigma(\hat{z})\hat{z}$,

$$\zeta(\hat{z}) = \text{ set of all points } r\sigma\hat{z} \text{ with } r \in [0, 1]. \tag{38.3.32}$$

5. Let $\mathcal{H}$ be the union of all rays $\zeta(\hat{z})$ for all points $\hat{z} \in \mathcal{S}^{2m-1}$,

$$\mathcal{H} = \bigcup_{\hat{z} \in \mathcal{S}^{2m-1}} \zeta(\hat{z}). \tag{38.3.33}$$

Then the convergence set of the homogeneous polynomial expansion (3.20) is $\mathcal{H}$. Specifically, the homogeneous polynomial expansion converges absolutely for all z in the interior of $\mathcal{H}$. Moreover, if z is any point in the exterior of $\mathcal{H}$, the terms $P_\ell(z)$ are unbounded for increasing ℓ, and hence the homogeneous polynomial expansion diverges at all exterior points.

We note that this recipe is considerably simpler, particularly in the case of many complex variables, than the analogous recipe given in Section 31.2 for finding conjugate radii of Taylor series. Moreover, it has the advantage that it can be applied, if desired, using only *real* points $\hat{x}$ in $\mathcal{S}^{2m-1}$. This feature is of interest because, in the context of maps, we often need to know only about the convergence of series when all variables are real. Finally, we observe that by construction the *interior* of the convergence set $\mathcal{H}$ has the property that if z is in $\mathcal{H}$, then so is τz where τ is any complex number satisfying $|\tau| \leq 1$. See Exercise 3.4. A domain having this property is called a *complete circular* domain. Thus, the natural domain of convergence for a homogeneous polynomial series is a complete circular domain.

The statements just made about convergence and divergence are easily proved. First, given any $z \neq 0$, there is a unique ray that goes from the origin to z, and this ray (extended if necessary) intersects $\mathcal{S}^{2m-1}$ in the point $\hat{z}$ given by

$$\hat{z} = z/|z|. \tag{38.3.34}$$

Now suppose that z is in the *interior* of $\mathcal{H}$. Then z can be written in the form

$$z = r\sigma(\hat{z})\hat{z} \text{ with } 0 < r \leq \rho'' < \rho < 1. \tag{38.3.35}$$

Here ρ is the same number that appears in (3.23). For $P_\ell(z)$ we find, by using (3.23), (3.26), (3.31), and (3.35), the result

$$\begin{aligned} |P_\ell(z)| &= |P_\ell(r\sigma\hat{z})| = |(r\sigma)^\ell P_\ell(\hat{z})| \\ &\leq |(\rho''\sigma)^\ell P_\ell(\hat{z})| = (\rho''/\rho)^\ell |(\rho\sigma)^\ell P_\ell(\hat{z})| \\ &= (\rho''/\rho)^\ell |(\rho|\lambda_c(\hat{z})|)^\ell P_\ell(\hat{z})| \\ &= (\rho''/\rho)^\ell |(R'')^\ell P_\ell(\hat{z})| \leq (\rho''/\rho)^\ell M. \end{aligned} \tag{38.3.36}$$

However, from (3.35) we have the inequality

$$(\rho''/\rho) < 1. \tag{38.3.37}$$

It follows that (3.20) has a geometric series as a comparison series, and hence it converges absolutely when z is an interior point in $\mathcal{H}$.

To complete the proof, suppose that z is in the *exterior* of $\mathcal{H}$. Then z can be written in the form

$$z = r\sigma(\hat{z})\hat{z} \text{ with } r > 1. \tag{38.3.38}$$

For $P_\ell(z)$ we find the result

$$P_\ell(z) = P_\ell(r\sigma\hat{z}) = (r\sigma)^\ell P_\ell(\hat{z}) \tag{38.3.39}$$

and (3.20) becomes

$$\sum_{\ell=0}^{\infty} P_\ell(z) = \sum_{\ell=0}^{\infty} (r\sigma)^\ell P_\ell(\hat{z}), \tag{38.3.40}$$

which is a series of the form (3.18) with

$$\lambda = r\sigma. \tag{38.3.41}$$

Since $r > 1$, we see from (3.31) and (3.41) that

$$|\lambda| = |r\sigma| = r|\lambda_c| > |\lambda_c|, \tag{38.3.42}$$

and conclude from (3.29) that the series (3.40) is divergent. Because (3.40) is a divergent Taylor series, the terms $P_\ell(z)$ that comprise it must be unbounded. See (3.39) and Theorem 1.9.

It remains to be shown that if the homogeneous polynomial series converges outside the convergence set of the underlying Taylor series, then it provides an analytic continuation of the function specified by the Taylor series. The reader has the pleasure of working out a proof in Exercise 3.5.

Example 3.1: Consider again the function $\psi(\boldsymbol{r})$ given by (2.23). Suppose the series (2.24) is grouped into homogeneous polynomials,

$$\psi(x_1, x_2, x_3) = \sum_{jk\ell} a_{jk\ell} x_1^j x_2^k x_3^\ell = \sum_{m=0}^{\infty} \sum_{j+k+\ell=m} a_{jk\ell} x_1^j x_2^k x_3^\ell = \sum_{m=0}^{\infty} P_m(x_1, x_2, x_3) \tag{38.3.43}$$

where

$$P_m(x_1,x_2,x_3)=\sum_{j+k+\ell=m} a_{jk\ell}x_1^j x_2^k x_3^\ell. \tag{38.3.44}$$

Let us determine the domain of convergence of this homogeneous polynomial series in the (real) x_1,x_2,x_3 3-dimensional space. We parameterize points $\hat{x}_1,\hat{x}_2,\hat{x}_3\in\mathcal{S}^3$ by writing

$$\hat{x}_2=\sin\theta, \tag{38.3.45}$$

$$\hat{x}_1=\cos\theta\cos\phi, \tag{38.3.46}$$

$$\hat{x}_3=\cos\theta\sin\phi. \tag{38.3.47}$$

From (2.26) we see that singularities in λ satisfy the equation

$$(\lambda\cos\theta\cos\phi)^2+(\lambda\sin\theta-1)^2+(\lambda\cos\theta\sin\phi)^2=0.$$

This equation has the solutions

$$\lambda=\sin\theta\pm i\cos\theta \tag{38.3.48}$$

from which we find that

$$|\lambda_c|=1. \tag{38.3.49}$$

It follows that the homogeneous polynomial series (3.43) for $\psi(x_1,x_2,x_3)$ converges in the *unit ball* about the origin,

$$0\le x_1^2+x_2^2+x_3^2\le 1. \tag{38.3.50}$$

Note that this set includes points that lie outside the convergence set described by the Reinhardt diagram of Figure 2.7.

Example 3.2: Suppose the series (2.30) is grouped into homogeneous polynomials,

$$\psi(x_1,x_2;x_3)=\sum_{jk} a_{jk}(x_3)x_1^j x_2^k=\sum_{\ell=0}^{\infty}\sum_{j+k=\ell} a_{jk}(x_3)x_1^j x_2^k=\sum_{\ell=0}^{\infty}P_\ell(x_1,x_2;x_3) \tag{38.3.51}$$

where

$$P_\ell(x_1,x_2;x_3)=\sum_{j+k=\ell} a_{jk}(x_3)x_1^j x_2^k. \tag{38.3.52}$$

For fixed (real) x_3, let us determine the convergence set of this homogeneous polynomial series in the (real) x_1, x_2 plane. We parameterize points $\hat{x}_1,\hat{x}_2\in\mathcal{S}^2$ by writing the relations

$$\hat{x}_1=\cos\phi, \tag{38.3.53}$$

$$\hat{x}_2=\sin\phi. \tag{38.3.54}$$

Then, from(2.32), we see that singularities in λ satisfy the equation

$$(\lambda\cos\phi)^2+(\lambda\sin\phi-1)^2+x_3^2=0. \tag{38.3.55}$$

This equation has the solutions

$$\lambda=\sin\phi\pm i[\cos^2\phi+x_3^2]^{1/2} \tag{38.3.56}$$

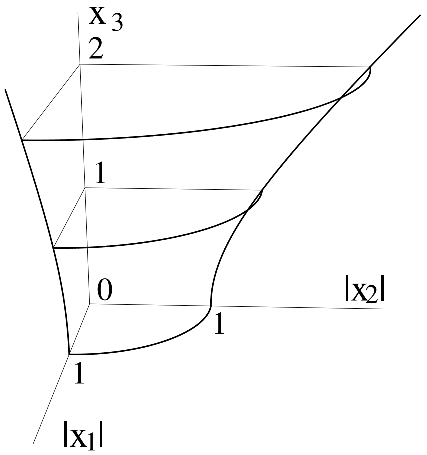

Figure 38.3.1: Real x_1, x_2 convergence sets for the homogeneous polynomial series (3.51) for various values of x_3. Together they form a hyperbola of revolution. Sets are not shown for negative values of x_3 since the sets for $\pm x_3$ are identical.

from which we find that

$$|\lambda_c| = (1 + x_3^2)^{1/2}. \tag{38.3.57}$$

It follows that the homogeneous polynomial series (3.51) for $\psi(x_1, x_2; x_3)$ converges in a *disc* about the origin in the x_1,x_2 plane with radius $(1+x_3^2)^{1/2}$. Figure 3.1 shows several of these discs for various values of x_3. Together they form the hyperbola of revolution

$$x_1^2 + x_2^2 = 1 + x_3^2. \tag{38.3.58}$$

Note that these sets include points that lie outside the convergence sets described by the Reinhardt diagrams of Figure 2.8.

Exercises

38.3.1. Find the convergence set in the real x_1, x_2 plane for the homogeneous polynomial expansion about the origin of the function f given by (2.39).

38.3.2. Repeat Exercise 3.1 for the f given by (2.40).

38.3.3. Repeat Exercise 3.1 for the f given by (2.41).

38.3.4. Verify Equations (3.45) through (3.50).

38.3.5. Verify Equations (3.53) through (3.58).

38.3.6. Verify that the interior of the convergence set $\mathcal{H}$ constructed following the steps (3.30) through (3.33) is a complete circular domain.

38.3.7. Show that if the homogeneous polynomial series converges outside the convergence set of the underlying Taylor series, then it provides an analytic continuation of the function specified by the Taylor series.

38.3.8. Consider the map, described by (1.4.21) and (1.4.22), that arises from the monomial Hamiltonian (1.4.20). See Exercise 2.7. Suppose this map is expanded in a homogeneous polynomial series about the origin. Find the convergence set in the real q, p plane for this expansion.

38.3.9. Using the methods of this section, determine the domain of analyticity and the convergence set for the monopole doublet $\psi(x, y, z)$ given by (13.11.3).

38.4 Application to Potentials and Fields

38.5 Application to Taylor Maps: The Anharmonic Oscillator

38.6 Application to Taylor Maps: The Pendulum

38.7 Convergence of the BCH Series

38.8 Convergence of Lie Transformations and the Factored Product Representation

Chapter 39

Truncated Power Series Algebra

39.1 Introduction

With regard to the simplest transcendental function, the exponential function, it has been said that

> *God created e^x but never heard of a polynomial.*

In this chapter we will be studying polynomials in multiple variables. For mortals, polynomials are a major portal to the transcendent.

Anyone familiar with the rudiments of Computer Science recognizes that the proper choice of algorithm can make an enormous difference in both computational speed and storage requirements. Thus, of several different algorithms which execute the same computational task, some may perform much better than others. Recall, for example, the problem of sorting n items: the number of operations required for the simple *bubble sort* method scales as n^2, while that for the more sophisticated *quick sort* or *heap sort* scales as only $n \log_2 n$. As a second example, the operation count for the ordinary discrete Fourier transform scales as n^2 (where n is the number of data points) while that for the celebrated fast (discrete) Fourier transform again scales as $n \log_2 n$.

The purpose of this chapter is to describe how truncated power series (finite sums of monomials in several variables) can be manipulated by computer. We will explore various methods for labeling and storing monomials together with their relation to efficient algorithms for executing various polynomial operations. These operations, which we refer to as Truncated Power Series Algebra (TPSA), include addition, multiplication, differentiation, Poisson bracketing, the commutation of vector fields, and the composition of functions. The emphasis here will be on computational speed, storage requirements, and program flexibility. Section 32.2 describes how monomials may be labeled and stored. Subsequent sections describe how truncated power series composed of these monomials can be added, multiplied, and otherwise manipulated.

Since TPSA has important applications to the study of dynamical systems, our discussion will often be couched in those terms — sometimes with a particular emphasis on applications to accelerator physics. However, we stress that much of the material presented here applies generically to any use of TPSA.

Before discussing possible schemes for storing and manipulating polynomials, we introduce some useful terminology and definitions: A typical monomial in d variables may be written in the form

$$z_1^{j_1} z_2^{j_2} \cdots z_d^{j_d}, \tag{39.1.1}$$

where the exponents j_k are a set of non-negative integers. We shall sometimes write the d-tuple of exponents $(j_1, \cdots, j_d)$ simply as a vector j, and similarly abbreviate the corresponding monomial by writing

$$z_1^{j_1} \cdots z_d^{j_d} = z^j. \tag{39.1.2}$$

Indeed, for the sake of brevity we shall sometimes refer to the exponent vector j as "the monomial j". For the degree of this monomial, we introduce the notation

$$|j| = j_1 + j_2 + \cdots + j_d. \tag{39.1.3}$$

Recall from Section 7.3 that $N(m, d)$, the number of monomials of degree m in d variables, is given by the binomial coefficient

$$N(m, d) = \left(\begin{array}{c} m + d - 1 \\ m \end{array} \right) = \frac{(m + d - 1)!}{m!(d - 1)!}. \tag{39.1.4}$$

Various values of $N(m, d)$ are listed in Table 7.3.1. Also $S(m, d)$, the number of monomials of degrees 1 through m in d variables, is given by the relation

$$S(m, d) = \left(\begin{array}{c} m + d \\ m \end{array} \right) - 1 = \frac{(m + d)!}{m!d!} - 1. \tag{39.1.5}$$

See Section 7.9. Various values of $S(m, d)$ are listed in Table 7.9.1. Finally, for some calculations it is also useful to employ the quantity $S_0(m, d)$, the number of monomials of degrees 0 through m in d variables. It is given by the relation

$$S_0(m, d) = S(m, d) + 1 = \left(\begin{array}{c} m + d \\ m \end{array} \right) = \left(\begin{array}{c} m + d \\ d \end{array} \right) = \frac{(m + d)!}{m!d!}. \tag{39.1.6}$$

39.2 Monomial Indexing

Any program that manipulates polynomials must have a scheme for labeling and storing the coefficients of the basis monomials. In this section we will describe some ways in which this can be done.

39.2.1 An Obvious but Memory Intensive Method

One very obvious such scheme uses a multi-dimensional array indexed by the monomial exponents. For purposes of illustration, consider the six-variable case. Then, using a phase-space notation, we have monomials of the form

$$z^j = X^{j_1} P_x^{j_2} Y^{j_3} P_y^{j_4} \tau^{j_5} P_\tau^{j_6}. \tag{39.2.1}$$

Suppose, for example, we are interested in the case of homogeneous polynomials of degrees 0 through 12. Then each j_k lies in the interval $[0,12]$, we have a $13 \times 13 \times \cdots$ (six factors) array, and such an array requires $13^6 \simeq 4.8 \times 10^6$ storage locations. By contrast, the entry for $S(12,6)$ in Tablel 7.9.1 shows that in principle only 18,564 ($= 18,563 + 1$) locations should be required. In general, if we use an $(m+1) \times (m+1) \cdots$ (d factors) array to store the coefficients of monomials of degree 0 through m in d variables, we shall need $(m+1)^d$ storage locations. This number is much larger than $S_0(m,d)$. As a consequence, it is desirable — even essential — to consider other possible schemes for labeling and storing monomials.

39.2.2 Polynomial Grading

Implicit in our discussion so far is the assumption that the objects of interest really are polynomials of degrees 0 through m. More explicitly, we assume that we are interested in *grading* polynomials according to their *total* degree. See Section 8.9. For phase-space variables this assumption seems natural, because we expect that the possible excursions from a design trajectory (in suitable scaled coordinates) could be of comparable size in any direction. It may be less natural (and perhaps a different treatment is called for) if we wish simultaneously to make expansions in various parameter variables. Indeed, in this latter case it might be better to have a scheme where the orders of the phase-space variables and the parameter variables could be set independently. One would then have polynomials in the phase-space variables whose coefficients are either numbers or polynomials in the parameter variables.

A remark about nomenclature: Consider the set of all (zero or positive) integers $j_1 \cdots j_d$ that obey the condition

$$|j| \leq m \tag{39.2.2}$$

for a fixed value of m. They form a collection of $S_0(m,d)$ points in d-dimensional space. Some authors refer to this set of points as a *pyramid.* The reader is invited to sketch these points in the cases $d = 2$ and $d = 3$ to see why the name is apt. A set of values assigned to points on a pyramid is referred to as a pyramidal data structure. Finally, some authors refer to sets of points of the kind described in Subsection 32.2.1 as (possible high dimensional) *boxes* or *cubes.* See Appendix S.

39.2.3 Monomial Ordering

Because a well-defined ordering facilitates the systematic implementation of polynomial algebra on a computer, we will continue this section by describing the concept of monomial orderings.

A *monomial ordering* is a relation $>$ on the set of all monomials (exponents) $\alpha = (\alpha_1, \alpha_2 \cdots)$ that satisfies the following three conditions:

1. The relation $>$ is a *total ordering*, meaning that for any two monomials α and β, exactly one of the following statements holds true:

$$\alpha > \beta \ , \quad \alpha = \beta \ , \quad \beta > \alpha. \tag{39.2.3}$$

This condition allows us to arrange the terms of a polynomial in an unambiguous way.

2. If $\alpha > \beta$, then $(\alpha+\gamma) > (\beta+\gamma)$. To see the value of this condition, note that multiplying both z^α and z^β by z^γ yields the results $z^{\alpha+\gamma}$ and $z^{\beta+\gamma}$. Now consider a polynomial whose terms are ordered using the relation $>$. If the above condition holds, then multiplying this polynomial (term-by-term) by z^γ will not alter the arrangement of the terms.

3. The relation $>$ is a *well-ordering*, meaning that every strictly decreasing sequence $\alpha > \beta > \gamma > \cdots$ must eventually terminate. This condition facilitiates proofs that various polynomial algorithms terminate after a finite number of steps.

Suppose we take the $S_0(m,d)$ monomials of degrees 0 through m in d variables, and list them sequentially in some fashion. Next we try to declare that this list constitutes a monomial ordering. For example, as we go down the list, we might declare that each successive monomial is less than all its predecessors. This declaration is consistent with the requirements 1 and 3. However, it generally violates requirement 2. Consequently, we will distinguish between *orderings* and *arrangements*. By an arrangement we will mean any sequential listing, whereas an ordering will mean a monomial ordering as defined above.

The following examples illustrate some of the commonly used monomial orderings. Here we will somes write $z^\alpha > z^\beta$ if $\alpha > \beta$.

Example 1. Lexicographic Order (lex). Let $\alpha = (\alpha_1, \cdots, \alpha_d)$, $\beta = (\beta_1, \cdots, \beta_d)$. We say $\alpha >_{\rm lex} \beta$ if in the vector difference $\alpha - \beta$ the *left-most* nonzero entry is *positive*. (Note that this construction is identical to that used to order weights in Section 5.8.)

For lexicographic ordering we have the relations

$$(1,0,\cdots,0) >_{\rm lex} (0,1,\cdots,0) >_{\rm lex} \cdots >_{\rm lex} (0,0,\cdots,1), \tag{39.2.4}$$

or, to use a more familiar notation,

$$z_1 >_{\rm lex} z_2 >_{\rm lex} \cdots >_{\rm lex} z_d. \tag{39.2.5}$$

Therefore the variables z_i themselves are arranged in descending order as their subscript label increases. Moreover, it is easily checked that

$$(z_i)^m >_{\rm lex} (z_j)^n \text{ whenever } i < j, \tag{39.2.6}$$

independent of the powers m, n (but assuming $m > 0$).

Unfortunately, this latter property can be inconvenient for problems where the total degree of monomials is important. (A common such problem in accelerator physics is the construction of a factorized Lie map.) However, there is a simple remedy to this situation: first order monomials by total degree, then apply lex ordering only to monomials of the same total degree. A formal definition of this scheme is given in the next example.

Example 2. Graded Lexicographic Order (glex, sometimes called grlex). We say $\alpha >_{\rm glex} \beta$ if either $|\alpha| > |\beta|$, or $|\alpha| = |\beta|$ and $\alpha >_{\rm lex} \beta$.

For monomials of degree one,

$$z_1 >_{\rm glex} z_2 >_{\rm glex} \cdots >_{\rm glex} z_d, \tag{39.2.7}$$

just as for lex order. For quadratic monomials,

$$z_1^2 >_{\text{glex}} z_1z_2 >_{\text{glex}} z_1z_3 >_{\text{glex}} \cdots >_{\text{glex}} z_2^2 >_{\text{glex}} z_2z_3 >_{\text{glex}} \cdots >_{\text{glex}} z_d^2. \tag{39.2.8}$$

Example 3. Graded Reverse Lexicographic Order (grevlex). In this ordering we say $\alpha >_{\text{grevlex}} \beta$ if either $|\alpha| > |\beta|$, or $|\alpha| = |\beta|$ and the *right-most* nonzero entry in the vector difference $\alpha - \beta$ is *negative.*

The grevlex order may seem less intuitive than glex, but it does have certain advantages. As with glex, the variables themselves are ordered:

$$z_1 >_{\text{grevlex}} z_2 >_{\text{grevlex}} \cdots >_{\text{grevlex}} z_d. \tag{39.2.9}$$

For quadratic monomials, by contrast,

$$z_1^2 >_{\text{grevlex}} z_1z_2 >_{\text{grevlex}} z_2^2 >_{\text{grevlex}} z_1z_3 >_{\text{grevlex}} \cdots >_{\text{grevlex}} z_d^2. \tag{39.2.10}$$

Thus as one scans monomials of a fixed degree in descending grevlex order, one encounters later variables only after earlier ones have been "exhausted".

39.2.4 Labeling Based on Ordering

We will now describe how monomial ordering can be used to assign a label or index to each monomial.[1] Basically, the idea is to list the monomials in some sequence, and then label the monomials by where they occur in the list.

Consider, as a case of special interest, monomials in 6 variables as in (2.1). We have found it useful to list them in the arrangement shown in Table 2.1 below. Note that the monomials are graded: First the monomial of degree 0 appears, next those of degree 1, then those of degree 2, etc. Now let us, for the moment, regard each exponent $j = (j_1 \cdots j_6)$ as some six-digit number having the digits (reading from left to right) j_1 through j_6. Then observe that within each group of monomials of fixed degree these six-digit numbers appear in descending order as one reads down a column. For example, the monomials of degree 1 have the ordering $100000 > 010000 > 001000 > 000100 > 000010 > 000001$. Similarly, the monomials of degree 2 have the ordering $200000 > 110000 > 101000 > 100100 > \cdots$, etc. That is, for a given degree, the monomials appear in descending lex order. We will refer to this arrangement of monomials as *modified glex sequencing.*

Finally, each monomial has been given an *index*, starting with 0 for the monomial of degree 0, that increases by 1 for each successive monomial.[2] Thus, as the index increases, we first encounter the monomial of degree 0, then those of degree 1, then those of degree 2, etc. Furthermore, as the index *increases* within each set of monomials of a given degree, we encounter monomials in *descending* lex order. Note, as is easily verified by comparison of Tables 7.9.1 and 2.1, that there is the relation

$$\text{index } (00000m) = S(m, 6). \tag{39.2.11}$$

[1] Equivalently, we will assign a label to each point in a pyramid.

[2] This is the indexing scheme used in the program *MaryLie.* MaryLie is a program for charged-particle beam transport based on Lie algebraic methods. It is named in honor of Queen Henrietta Maria, patron of the English colony that was to become the state of Maryland, and Sophus Lie.

We remark that one might consider a true glex ordering in which the monomials of a given degree would occur in *ascending* lexicographic order as the index increased. According to (2.6) and (2.7), however, such an indexing scheme would list temporal variables first, and this order is not convenient for applications to accelerator physics.

There is, though, another arrangement that is satisfactory, and perhaps even superior: One could list the monomials by degree as before, and within each degree arrange them in descending reverse lexicographical (revlex) order. This could be called *modified grevlex sequencing*. Table 2.2 illustrates, for the case of 6 variables, an indexing scheme based on this procedure. Note that monomials with temporal variables now occur at the end of each monomial set of a given degree.

Table 39.2.1: Modified glex sequencing, a possible glex related indexing scheme for monomials in 6 variables.

39.2.5 Formulas for Lowest and Highest Indices

For future reference, we note that any indexing scheme based on a graded ordering has the property that all the indices associated with monomials of a fixed degree are contiguous and lie within a fixed range. For example, reference to Tables 2.1 or 2.2 shows that (in the case of 6 variables) monomials of degree 2 begin at index 7 and end at index 27, and those of degree 3 begin at index 28 and end at index 83. Let *itop(ideg)* be the highest (top) index for monomials of degree *ideg*, and let *ibot(ideg)* be the lowest (bottom) index. Then we have the relations

$$itop(ideg) = S(ideg, d), \tag{39.2.12}$$

$$ibot(ideg) = itop(ideg - 1) + 1 = S[(ideg - 1), d] + 1. \tag{39.2.13}$$

Here d is the number of variables. Table 2.3 lists values of *ibot* and *itop* for the case of 6 variables ($d = 6$).

Table 39.2.3: Lowest and highest indices for monomials of degree *ideg* in 6 variables.

ideg	*ibot*	*itop*

12	12736	18563

39.2.6 The Giorgilli Formula

By construction, use of Table 2.1 (or Table 2.2) assigns a unique index i to each monomial exponent j. Moreover, i takes on every possible (non-negative) integer value. Therefore, there is a invertible function $i(j)$ that provides a 1-to-1 mapping between the integers and the exponent vectors j. To proceed further, it would be very useful to have an explicit formula for $i(j)$. Such a formula, which we will call the *Giorgilli* formula, exists. We will illustrate it for the case of 6 variables with monomials indexed as in Table 2.1. In this case the exponent vectors have the form $j = (j_1, \cdots, j_6)$. We begin by defining the integers

$$n(\ell; j_1, \cdots, j_6) = \ell - 1 + \sum_{k=0}^{\ell-1} j_{6-k} \tag{39.2.14}$$

for $\ell \in \{1, 2, \cdots 6\}$. Then to the general monomial z^j we assign the index

$$i(j) = i(j_1, \cdots j_6) = \sum_{\ell=1}^{6} \text{ Binomial } [n(\ell; j_1, \cdots j_6), \ell]. \tag{39.2.15}$$

Here the quantities

$$\text{Binomial } [n, \ell] = \left(\begin{array}{c} n \\ \ell \end{array} \right) = \left\{ \begin{array}{ccc} \frac{n!}{\ell!(n-\ell)!} & , & 0 \leq \ell \leq n \\ 0 & , & \text{otherwise} \end{array} \right\} \tag{39.2.16}$$

denote the usual binomial coefficients.

39.2.7 Finding the Required Binomial Coefficients

At this point something needs to be said about what binomial coefficients are actually required and how they can be computed. Note that the formula (2.15) can be written in the form

$$i(j_1, \cdots, j_6) = \text{ Binomial } [n(1; j_1, \cdots, j_6), 1] + \sum_{\ell=2}^{6} \text{ Binomial } [n(\ell; j_1, \cdots j_6), \ell]. \quad (39.2.17)$$

From (2.14) we obtain

$$n(1; j_1, \cdots j_6) = j_6, \quad (39.2.18)$$

and we know that

$$\text{Binomial } [j_6, 1] = j_6. \quad (39.2.19)$$

Thus we may write (2.15) as

$$i(j_1, \cdots, j_6) = j_6 + \sum_{\ell=2}^{6} \text{ Binomial } [n(\ell; j_1, \cdots j_6), \ell]. \quad (39.2.20)$$

Now let *maxdeg* be the maximum degree of the polynomials being stored. Then we have the inequality

$$\sum_{k=0}^{\ell-1} j_{6-k} \leq maxdeg. \quad (39.2.21)$$

Consequently, according to (2.14), $n(\ell; j_1, \cdots, j_6)$ must lie in the range

$$n \in [\ell - 1, \ell - 1 + maxdeg]. \quad (39.2.22)$$

We therefore need only those binomial coefficients Binomial $[n, \ell]$ with $\ell \in [2, 6]$ and, for each ℓ, values of n lying in the range (2.22).

As an example, Exhibit 2.1 shows a program that computes and stores the required binomial coefficients for the case $maxdeg = 6$. It uses the recursion relation (7.3.56), and needs to be executed only once.

Exhibit 32.2.1: A program to compute and store binomial coefficients.

```
      subroutine binom5
c
c     computes a table of the binomial coefficients
c
      implicit double precision (a-h,o-z)
      integer bin5(24,20)
      common /bin5/ bin5
      save/bin5/
      do 1 i=1,20
      bin5(i,1)=i
      do 1 k=2,20
      if (i-k) 2,3,4
    2 bin5(i,k)=0
      go to 1
    3 bin5(i,k)=1
      go to 1
    4 ip=i-1
      kp=k-1
      bin5(i,k)=bin5(ip,kp)+bin5(ip,k)
    1 continue
      return
      end
```

39.2.8 Computation of the Index i Given the Exponent Array j

We will prove eventually that the formula (2.15) does indeed produce the indexing scheme of Table 2.1. Before doing so we will exhibit a computer program that computes $i(j)$. As an example, Exhibit 2.2 shows a computer program that computes $i(j)$ using (2.20) and stored binomial coefficients, and assuming $maxdeg = 6$. For efficiency, the required binomial coefficients have been hard-wired in, and arranged in a convenient order, with the use of a *data* statement. Alternatively, they could have been computed and rearranged in advance, using a variant of the program shown in Exhibit 2.1, and then stored in a common block for use in the program of Exhibit 2.2.

Note that the program requires various binomial lookups and 10 integer adds to compute an index for the case of 6 variables. In the general case of d variables, computing an index requires $2(d-1)$ such adds. The program is therefore reasonably fast.

Exhibit 32.2.2: A program to compute the index $i(j)$ using (2.20) and stored binomial coefficients.

```
      subroutine ndex(j,ind)
c
c  This subroutine calculates the MaryLie index ind, given j1 through j6
c  which are stored in the array j, based on the Giorgilli formula.
c  The use of rearrangement in this algorithm is due to Liam Healy.
c  AJD 6/20/95
c
      integer j(6)
c  cord = cumulative order: sum of exponents from ib-th to 6th.
      integer cord
c  obin = binomial coefficients rearranged to speed up calculation
c         obin(m,i)=Binomial[(m+6-i),(7-i)]
      integer obin(0:6,5)
      save obin
      data obin
     & /0,1,7,28,84,210,462,
     &  0,1,6,21,56,126,252,
     &  0,1,5,15,35, 70,126,
     &  0,1,4,10,20, 35, 56,
     &  0,1,3, 6,10, 15, 21/
c
c  calculate the index
      ind=j(6)
      cord=ind
      do 100 ib=5,1,-1
        cord=cord+j(ib)
  100   ind=ind+obin(cord,ib)
c
      return
      end
```

39.2.9 Preparing a Look-Up Table for the Exponent Array j Given the Index i

Given any exponent array j, we have seen how to compute a corresponding index $i(j)$. There is also the inverse problem: Given an index i, find the exponent array

$$j(i) = \{j_1(i), j_2(i), \cdots j_d(i)\} \tag{39.2.23}$$

that corresponds to this index. From a computational perspective, the most efficient procedure is to prepare a look-up table (a rectangular array) that contains this information.

One way to construct an appropriate look-up table involves finding an algorithm for generating—in the general case of d variables—a modified glex sequence of exponents. With such an algorithm we can produce a look-up table of exponents simply by storing successive d-tuples of exponents as they are generated. In particular, we can initialize the index by setting $i = 0$ for the first exponent vector, $(0, 0, \cdots, 0)$, and then increment i by 1 with each successive exponent vector in the sequence. We now outline a method for generating a modified glex sequence.

As described earlier, one may view the exponents j_1 through j_d that define a particular monomial as the components of a vector $j = (j_1, \cdots j_d)$. Let us refer to any given sequence of such vectors simply as a *list*. Now look at Table 2.1 or recall the definition of glex ordering to see that the list of monomials of a given degree m always begins with the vector

$$j = (m, 0, \cdots 0) \tag{39.2.24}$$

and ends with the vector

$$j = (0, \cdots 0, m). \tag{39.2.25}$$

In addition, the very next element in the list after (2.25) is the vector

$$j = (m + 1, 0, \cdots 0), \tag{39.2.26}$$

which begins the list of monomials of degree $m + 1$. We conclude that it is easy to specify the monomials that begin and end the degree m portion of a modified glex sequence, and to make the transition from the last monomial of degree m to the first one of degree $m + 1$.

We now seek a rule that converts any given j vector, for some monomial of degree m, into the j vector for the next monomial in the list. If the j vector has the form (2.25), then obviously the next j vector has the form (2.26). Otherwise, it is evident that some of the entries in j must be increased and some decreased in such a way as to keep the total degree constant. Moreover, to achieve a modified glex sequence, the entries on the "left end" of j (those j_k with smaller k) should be decreased as little as possible, and the entries on the "right end" of j (those j_k with larger k) should be increased as much as possible. A careful examination of the entries in Table 2.1 shows that one may convert from any j vector not of the form (2.25) to the next j vector via the following sequence of steps:

- Store the value of j_d as $icarry$, and then set $j_d = 0$.
- Test the j_k from right to left to find the right-most non-zero j_k. Let ℓnzj be the subscript for this j_k. (Here ℓnzj is a mnemonic for "last non-zero j".) Thus j_ℓ, with $\ell = \ell nzj$, is the last non-zero component of j.
- Decrease j_ℓ by 1, set $j_{\ell+1} = (1 + icarry)$, and leave intact all other entries of j.

The result of these steps is the next j in the list.

For example, consider the j in Table 2.1 having index 33, $j = (200001)$. In this case we have $icarry = 1$, and setting $j_6 = 0$ yields the vector (200000). We then find that the right-most non-zero entry is j_1; hence $\ell nzj = 1$ and (with $\ell = \ell nzj = 1$) $j_\ell = j_1 = 2$. Decreasing j_1 by 1 and replacing $j_{\ell+1} = j_2$ by $(1 + icarry)$, we find the new vector (120000). Examination of Table 2.1 shows that this vector has index 34, as desired. Readers are invited to check other cases in Table 2.1 to satisfy themselves that this procedure works in general.

Exhibit 2.3 shows a routine that carries out the algorithm just described in the case of 6 variables and assuming $maxdeg = 4$. This routine has the further feature [resulting from the initialization of ℓ (ℓnzj) and the use of suitable 'if' statements] that it also automatically makes the transition from the last monomial of degree m to the first one of degree $m + 1$; and it does so by use of the same algorithm just described for generating successive j vectors elsewhere in the list. That is, the same algorithm also produces the transition from (2.25) to (2.26). Readers are also invited to check that this procedure works as claimed.

Exhibit 32.2.3: A program to produce a look-up table for the exponents $j(i)$.

```
      subroutine jtable
c
c  This program creates the look-up table jtbl based on a method of Liam Healy:
c        ind = monomial index and imax = maximum value of ind.
c        ipsv = phase space variable and id = number of phase space variables.
c        For example when id=6, ipsv= 1...id corresponds to X...P_t.
c        jtbl(ipsv,ind) is the exponent of phase space variable
c        'ipsv' (1 to id)  for monomial index 'ind' (1 to imax).
c        For example, when id=6, monomial number 109 is X*P_X*P_X*P_t.
c        Consequently, jtbl(1 to 6,109)=1,2,0,0,0,1.
c
      parameter (imax = 209, id=6)
      dimension jtbl(id,imax)
c  j = array of exponents
      dimension j(id)
c  initialize exponents
      data j/id*0/
c  icarry = temporarily stored value of j(id).
c  lnzj = last non-zero j
c
c  Sequentially create exponent table jtbl
c
      do 150 ind=1,imax
c  set quantities
        icarry=j(id)
        j(id)=0
        lnzj=0
c  search for last nonzero j
        do 100 ipsv=1,id-1
          if (j(ipsv).gt.0) lnzj=ipsv
  100   continue
c  find next set of exponents
        if (lnzj.gt.0) j(lnzj)=j(lnzj)-1
        j(lnzj+1)=1+icarry
c  store exponents in jtbl
        do 120 ipsv=1,id
          jtbl(ipsv,ind)=j(ipsv)
  120   continue
  150 continue
c
c write out table
      do 70 i=1,imax
      write(6,500) i,

     & jtbl(4,i),jtbl(5,i),jtbl(6,i)
  500 format (1h ,i4,2x,3(i2,1x,i2,2x))
   70 continue
c
      end
```

39.2.10 Verification of the Giorgilli Formula

The last task for this section, as promised, is to show that the formula (2.15) does indeed produce modified glex indexing. For this purpose, the reader is invited to examine Table 2.4 which displays a modified glex sequence for the simple case of 3 variables through terms of degree 4.

Consider the $N(m,d)$ monomials of degree m in d variables. We may view each of these monomials $(z_1^{j_1}z_2^{j_2}\cdots z_d^{j_d})$ as a product of two constituent monomials:

$$z_1^{j_1}z_2^{j_2}\cdots z_d^{j_d} = z_1^{j_1} \times z_2^{j_2}\cdots z_d^{j_d}. \tag{39.2.27}$$

Thus, for example, monomials of degree two in three variables comprise three distinct groups (see Table 2.4):

1. z_1^2 times a monomial of degree zero in the two variables z_2 and z_3;

2. z_1^1 times monomials of degree one in the two other variables;

3. z_1^0 times monomials of degree two in the two other variables.

In general, of course, one may write all the monomials of order m in d variables as products between the monomial $z_1^{j_1}$—with $j_1 \in \{0,1,\ldots,m\}$—and the monomials of order $m-j_1$ in the remaining $d-1$ variables. The reader may observe that listing the monomials in a modified glex sequence—as in Table 2.4—makes clear the structure just described.

Consider now only those monomials of fixed degree m, and examine their exponents as listed in the modified glex sequence. The reader should note that because the exponents (of fixed degree) are listed in *descending* lexicographic order, eliminating the left-most column—the exponents j_1—will leave behind $d-1$ columns which contain exactly the modified glex sequence for the monomials in $d-1$ variables of degree m and smaller. Thus, for example, the transformation displayed in Figure 2.1 shows explicitly how this happens for degree-three monomials in three variables: removing the left column leaves behind the listing, in a modified glex sequence, of all monomials in two variables of degree zero through three.

As a consequence of the observation just described, the index of a given monomial can be determined by using a simple counting procedure, which we illustrate with the following example:

- Look at Table 2.4 and select an exponent, say $j=(1,0,2)$, whose index is to be determined. This exponent j represents a monomial of *degree* 3 ($|j| = j_1+j_2+j_3 = 1+0+2 = 3$) in 3 variables.

Table 39.2.4: Modified glex sequence for j in 3 variables.

Index	j_1	j_2	j_3
1	1	0	0
2	0	1	0
3	0	0	1
4	2	0	0
5	1	1	0
6	1	0	1
7	0	2	0
8	0	1	1
9	0	0	2
10	3	0	0
11	2	1	0
12	2	0	1
13	1	2	0
14	1	1	1
15	1	0	2
16	0	3	0
17	0	2	1
18	0	1	2
19	0	0	3
20	4	0	0
21	3	1	0
22	3	0	1
23	2	2	0
24	2	1	1
25	2	0	2
26	1	3	0
27	1	2	1
28	1	1	2
29	1	0	3
30	0	4	0
31	0	3	1
32	0	2	2
33	0	1	3
34	0	0	4

Figure 39.2.1: Sample extraction of a two-column array from a three-column array.

$$\begin{array}{ccc} 3 & 0 & 0 \\ 2 & 1 & 0 \\ 2 & 0 & 1 \\ 1 & 2 & 0 \\ 1 & 1 & 1 \\ 1 & 0 & 2 \\ 0 & 3 & 0 \\ 0 & 2 & 1 \\ 0 & 1 & 2 \\ 0 & 0 & 3 \end{array} \quad \mapsto \quad \begin{array}{cc} 0 & 0 \\ 1 & 0 \\ 0 & 1 \\ 2 & 0 \\ 1 & 1 \\ 0 & 2 \\ 3 & 0 \\ 2 & 1 \\ 1 & 2 \\ 0 & 3 \end{array}$$

- Dropping the first entry from j yields a reduced exponent $j' = (0, 2)$, which represents a monomial of *degree* 2 ($|j'| = j_2 + j_3 = 0 + 2 = 2$) in 2 variables.

- Dropping the first two entries from j yields $j'' = (2)$, which represents a monomial of *degree* 2 ($|j''| = j_3 = 2$) in 1 variable.

- Record the *degrees* of j, j', and j'', as described in the previous steps. In the present case we obtain the numbers $|j| = 3$, $|j'| = 2$, and $|j''| = 2$, respectively. Based on these degrees, construct a "path" through Table 2.4, as illustrated in Figure 2.2: Begin the path at the top and proceed down the j_1 column until you reach exponents of degree $|j| = 3$. Then shift over one column and proceed down the j_2's until you reach exponents of degree $|j'| = 2$. Finally, shift over to the last column and proceed down the j_3's until you reach exponents of degree $|j''| = 2$.

- Now determine the index by the evident procedure of simply adding together the "lengths" of the vertical portions of the path just constructed, and then adding 1. The lengths are given by the relations

$$\begin{aligned} \text{length along } j_1 \text{ column} &= S(2, 3), && (39.2.28) \\ \text{length along } j_2 \text{ column} &= S_0(1, 2), && (39.2.29) \\ \text{length along } j_3 \text{ column} &= S_0(1, 1), && (39.2.30) \end{aligned}$$

and hence the index of the monomial $j = (1, 0, 2)$ is given by

$$i(j) = i(1, 0, 2) = S(2, 3) + S_0(1, 2) + S_0(1, 1) + 1. \qquad (39.2.31)$$

Using (1.6), we may write (2.31) in the more pleasing form

$$i(1, 0, 2) = S_0(2, 3) + S_0(1, 2) + S_0(1, 1) = 10 + 3 + 2 = 15, \qquad (39.2.32)$$

in agreement with the index given in Table 2.4 (or Figure 2.2).

Figure 39.2.2: Path to the exponent $j = (1, 0, 2)$ down the modified glex sequence in 3 variables.

Index	j_1	j_2	j_3	
1	1	0	0	
2	0	1	0	
3	0	0	1	
4	2	0	0	
5	1	1	0	$S(2,3) = 9 = S_0(2,3) - 1$
6	1	0	1	
7	0	2	0	
8	0	1	1	
9	0	0	2	
10	3	0	0	
11	2	1	0	$S_0(1,2) = 3$
12	2	0	1	
13	1	2	0	$S_0(1,1) = 2$
14	1	1	1	
15	1	0	2	1
16	0	3	0	
17	0	2	1	
18	0	1	2	
19	0	0	3	
20	4	0	0	
21	3	1	0	
22	3	0	1	
23	2	2	0	
24	2	1	1	
25	2	0	2	
26	1	3	0	
27	1	2	1	
28	1	1	2	
29	1	0	3	
30	0	4	0	
31	0	3	1	
32	0	2	2	
33	0	1	3	
34	0	0	4	

By generalizing the procedure of the example just described, we can now state a procedure for determining the index $i(j)$ for any monomial whose exponent list is given by $j = (j_1, j_2, \ldots, j_d)$.

1. For each $\nu \in \{1, \ldots, d\}$ define m_ν as the degree of the monomial obtained by dropping from the exponent list j the first $(\nu - 1)$ entries:
$$m_\nu = \sum_{k=\nu}^{d} j_k. \tag{39.2.33}$$
2. Then define i_ν as the total number of monomials in $d - (\nu - 1)$ variables which have degree *less* than m_ν:
$$i_\nu = S_0(m_\nu - 1, d - \nu + 1). \tag{39.2.34}$$
3. The index $i(j)$ is then given by the formula
$$i(j_1, \ldots, j_d) = \sum_{\nu=1}^{d} i_\nu. \tag{39.2.35}$$

Finally, we must demonstrate that the prescription just given for determining the index is indeed equivalent to the formula (2.15). To see this, note first that
$$m_\nu = \sum_{k=\nu}^{d} j_k = \sum_{k=0}^{d-\nu} j_{d-k}. \tag{39.2.36}$$
Then recall the definition (2.14) and simply compute:
$$\begin{aligned} i(j_1, \ldots, j_d) &= \sum_{\nu=1}^{d} i_\nu = \sum_{\nu=1}^{d} S_0(m_\nu - 1, d - \nu + 1) = \sum_{\nu=1}^{d} \begin{pmatrix} m_\nu + d - \nu \\ d - \nu + 1 \end{pmatrix} \\ &= \sum_{\nu=1}^{d} \begin{pmatrix} (\sum_{k=0}^{d-\nu} j_{d-k}) + d - \nu \\ d - \nu + 1 \end{pmatrix} = \sum_{\ell=1}^{d} \begin{pmatrix} (\sum_{k=0}^{\ell-1} j_{d-k}) + \ell - 1 \\ \ell \end{pmatrix} \\ &= \sum_{\ell=1}^{d} \begin{pmatrix} n(\ell; j) \\ \ell \end{pmatrix}. \end{aligned} \tag{39.2.37}$$
This result confirms that the formula (2.15) does indeed return the desired index.

Exercises

39.2.1. Verify that one can easily convert between the glex and grevlex orderings by a “double reversal” procedure: among each set of monomials of a given degree first reverse the order of the variables, then reverse the order of the monomials. For example, consider the monomials of degree 2 in 3 variables. Under glex ordering we have
$$z_1^2 > z_1 z_2 > z_1 z_3 > z_2^2 > z_2 z_3 > z_3^2. \tag{39.2.38}$$

Now reverse the order of the variables by making the replacement $z_1,\ z_2,\ z_3 \to z_3,\ z_2,\ z_1$, and replace $>$ by $<$. Then (2.38) becomes

$$z_3^2 < z_2z_3 < z_1z_3 < z_2^2 < z_1z_2 < z_1^2, \tag{39.2.39}$$

or, equivalently,

$$z_1^2 > z_1z_2 > z_2^2 > z_1z_3 > z_2z_3 > z_3^2. \tag{39.2.40}$$

Upon comparing (2.40) and (2.10), we see that (2.40) is in grevlex order.

39.3 Scalar Multiplication and Polynomial Addition

The use of any indexing scheme optimizes the operations of scalar multiplication and polynomial addition. Let $M_i(z)$ denote the generic monomial

$$M_i(z) = z^{j(i)}, \tag{39.3.1}$$

where it is assumed that the exponent j vectors (arrays) are indexed by an index i. Suppose f is any truncated power series. Then, since the M_i form a basis, there is a unique decomposition of the form

$$f = \sum_i f^i M_i \tag{39.3.2}$$

where the f^i are known coefficients. Indeed, the function f is stored by storing each coefficient f^i at the i^{th} location in some array.

Now suppose h is some other function that is related to f by scalar multiplication:

$$h = af \tag{39.3.3}$$

where a is some scalar. Then h has the decomposition

$$h = \sum_i h^i M_i \tag{39.3.4}$$

with the coefficients h^i given by the relation

$$h^i = af^i. \tag{39.3.5}$$

Thus, when any indexing scheme is employed, multiplication of a function by a scalar is equivalent to scalar multiplication of a vector.

Next suppose that f and g are any two polynomials, and we wish to compute the sum

$$h = f + g. \tag{39.3.6}$$

Then we have unique decompositions

$$f = \sum_i f^i M_i, \tag{39.3.7}$$

$$g = \sum_i g^i M_i, \tag{39.3.8}$$

$$h = \sum_i h^i M_i, \tag{39.3.9}$$

where the f^i and g^i are known coefficients, and the h^i are to be determined by (3.6). It follows, again from the fact that the M_i form a basis, that we have the relation

$$h^i = f^i + g^i. \tag{39.3.10}$$

Thus, when any indexing scheme is employed, polynomial addition is equivalent to the simple process of vector addition.

39.4 Polynomial Multiplication

Multiplication of polynomials is more complicated than addition. As before, define basis monomials $M_i(z)$ by (3.1). Also, suppose the polynomials f and g have the decompositions

$$f = \sum_i f^i M_i, \tag{39.4.1}$$

$$g = \sum_k g^k M_k, \tag{39.4.2}$$

and we wish to compute the product

$$h = fg. \tag{39.4.3}$$

The polynomial h will have the decomposition

$$h = \sum_\ell h^\ell M_\ell, \tag{39.4.4}$$

and the problem is two determine the h^ℓ from the relation

$$\begin{aligned} h &= \sum_\ell h^\ell M_\ell = fg = \sum_i f^i M_i \sum_k g^k M_k \\ &= \sum_{i,k} f^i g^k M_i M_k. \end{aligned} \tag{39.4.5}$$

We see that the basic problem consists of computing the products $M_i M_k$.

There are at least 3 ways to solve this problem in the context of indexing:

1. Given the indices i and k, find (say by table look-up) the corresponding exponents $j(i)$ and $j(k)$. Add these exponents as vectors to get the resultant "sum" exponent vector j^s,

   $$j^s = j(i) + j(k). \tag{39.4.6}$$

   Here we have reckoned with the obvious relation

   $$z^{j(i)} z^{j(k)} = z^{j(i)+j(k)} = z^{j^s}. \tag{39.4.7}$$

Next find the index ℓ corresponding to j^s. If the monomials have been indexed using modified glex sequencing, one can evaluate the Giorgilli formula (2.15) for this purpose to find

$$\ell = i(j^s). \tag{39.4.8}$$

Finally, increment h^ℓ by the quantity $f^i g^k$. (Here we have assumed that all the h^ℓ were initially set to zero.)

2. Given the indices i and k, find directly from a specially prepared look-up table the corresponding value of ℓ. Then increment h^ℓ by the quantity $f^i g^k$.

3. Given the index ℓ, use specially prepared *look-back* tables to find all indices i and k such that

$$M_i M_k = M_\ell. \tag{39.4.9}$$

Then increment h^ℓ by all the products $f^i g^k$.

All these methods will be discussed and compared in subsequent sections. At this point we simply remark that the computation of the products $M_i M_k$ is facilitated by the use of a *graded* indexing scheme. Since we are limiting our computations and their results to polynomials of degree less than or equal to m, we know that many of the products $M_i M_k$ need not be computed because their results are monomials of degree larger than m. The identification of such unneeded products is easy in any graded indexing scheme, because the degree of a product is the sum of the degrees of the factors.

39.5 Look-Up Tables

Let f and g be two polynomials. They can be decomposed into sums of homogeneous polynomials, and hence can be written in the form

$$f = f_0 + f_1 + f_2 + f_3 + f_4 + f_5 + f_6 + \cdots , \tag{39.5.1}$$

$$g = g_0 + g_1 + g_2 + g_3 + g_4 + g_5 + g_6 + \cdots . \tag{39.5.2}$$

Here f_m and g_m denote homogeneous polynomials of degree m. Correspondingly, the product fg of any two polynomials can also be organized into terms of common degree. Doing so gives the result

$$\begin{aligned} fg &= (f_0g_0)_0 + (f_0g_1 + g_0f_1)_1 + (f_0g_2 + g_0f_2 + f_1g_1)_2 \\ &+ (f_0g_3 + g_0f_3 + f_1g_2 + g_1f_2)_3 + (f_0g_4 + g_0f_4 + f_1g_3 + g_1f_3 + f_2g_2)_4 \\ &+ (f_0g_5 + g_0f_5 + f_1g_4 + g_1f_4 + f_2g_3 + g_2f_3)_5 \\ &+ (f_0g_6 + g_0f_6 + f_1g_5 + g_1f_5 + f_2g_4 + g_2f_4 + f_3g_3)_6 + \cdots . \end{aligned} \tag{39.5.3}$$

Here the terms appearing in fg have been collected according to their degrees using parentheses, and the parentheses have been given a subscript indicating the degree of the terms enclosed.

There is no particular problem in carrying out multiplications of the form f_0g_m and g_0f_m (since this operation is equivalent to scalar multiplication if the entries in g_m and f_m are viewed as the components of a vector). Multiplications of the form $f_m g_n$ and $g_m f_n$ with $m, n > 0$ are more complicated to execute.

Suppose we rearrange the computationally intensive terms (those not of the form $f_0 g_m$ and $g_0 f_m$) in (5.3) as shown below:

$$\begin{aligned}
&\text{computationally intensive terms } = \\
&(f_1g_1) + (f_1g_2 + f_1g_3 + f_1g_4 + f_1g_5 + \cdots) + (g_1f_2 + g_1f_3 + g_1f_4 + g_1f_5 + \cdots) \\
&+(f_2g_2) + (f_2g_3 + f_2g_4 + \cdots) + (g_2f_3 + g_2f_4 + \cdots) \\
&+(f_3g_3) + \cdots . \qquad (39.5.4)
\end{aligned}$$

If these multiplications were to be performed with the aid of a look-up table, what would this table look like, and how big would it be?

As a simple but instructive example, consider the case of polynomials through degree 4 in 2 variables ($m = 4$ and $d = 2$). Table 5.1 below shows, using phase-space notation, the monomials for this case listed in a modified glex sequence. We wish to multiply polynomials composed of these monomials, but only retain terms through degree 4.

Table 39.5.1: Modified glex sequence when $m = 4$ and $d = 2$.

i	j_1	j_2	$\vert j\vert$	monomial
1	1	0	1	X
2	0	1		P_x
3	2	0	2	X^2
4	1	1		XP_x
5	0	2		P_x^2
6	3	0	3	X^3
7	2	1		X^2P_x
8	1	2		XP_x^2
9	0	3		P_x^3
10	4	0	4	X^4
11	3	1		X^3P_x
12	2	2		$X^2P_x^2$
13	1	3		XP_x^3
14	0	4		P_x^4

Now consider the result of multiplying a monomial in f with index if and a monomial in g with index ig. The result will be some monomial in h with index ih. (Here, to simplify notation, we denote the relevant indices by if, ig, and ih rather than the i, k, ℓ of the previous Section.) Table 5.2 shows a multiplication table for this process. It gives, for each value of if and ig, the value of ih corresponding to the product monomial. Entries with an asterisk "*" correspond to monomials having degree greater than 4. See Table 5.1. These entries fall outside our interest. Consider, for example, the relation

$$X^2 \times XP_x = X^3P_x. \qquad (39.5.5)$$

Inspection of Table 5.1 shows that the monomials X^2 and XP_x have the indices $if = 3$ and $ig = 4$, respectively; and their product X^3P_x has the index $ih = 11$. Correspondingly, the entry in Table 5.2 for $if = 3$ and $ig = 4$ has the value $ih = 11$.

Table 39.5.2: Multiplication table (when $m = 4$ and $d = 2$) giving values of ih.

$if\backslash ig$	1	2	3	4	5	6	7	8	9	10	11	12	13	14

Note that Table 5.2 has the form of a *symmetric* matrix with 5 diagonal entries and 18 entries above the diagonal. This symmetry results from the commutativity of (ordinary) multiplication. Let $\{m, d\}$ denote the number of locations (look-up table size) required to store a multiplication table when this symmetry is taken into account. Then we have the result $\{4, 2\} = (5 + 18) = 23$. Table 5.3 lists values of $\{m, d\}$ for various values of m and d.

As will be seen in later sections, it may sometimes be advantageous to sacrifice the savings in storage associated with symmetry in order to gain speed. We should therefore also calculate the storage required when symmetry is ignored. Let $\{m, d\}^{ns}$ denote the number of locations required to store the *full* multiplication table when symmetry is not taken into account. (Here the superscript ns denotes *no symmetry.*) Then we have the result $\{4, 2\}^{ns} = (5 + 18 + 18) = 41$. Table 5.4 lists values of $\{m, d\}^{ns}$ for various values of m and d.

We close this section with a description of how the dimensions $\{m, d\}$ and $\{m, d\}^{ns}$ can be computed in a general case. Suppose, for example, we wish to know the dimensionality of the look-up table associated with the terms displayed in (5.4). (This is equivalent to retaining terms through degree $m = 6$.) Let us also consider the case of 6 variables, $d = 6$. Thus, we need to find $\{6, 6\}$ and $\{6, 6\}^{ns}$.

We begin with the case where symmetry is taken into account. Since the portion of the look-up table associated with (f_1g_1) is 6×6 and symmetric, we have the result

$$\{f_1g_1\} = [(6 \times 6) - 6)]/2 + 6 = (6 \times 7)/2 = 21. \tag{39.5.6}$$

Here we use the notation { } to denote the dimensionality of the associated portion of the look-up table. Similarly, we find the results

Table 39.5.3: Multiplication look-up table size for polynomials of degree 1 through m in various numbers of variables.

m	$\{m,16\}^{ns}$	$\{m,17\}^{ns}$	$\{m,18\}^{ns}$	$\{m,19\}^{ns}$	$\{m,20\}^{ns}$	$\{m,21\}^{ns}$
2	256	289	324	361	400	441
3	4608	5491	6480	7581	8800	10143
4	49216	61846	76761	94221	114500	137886
5	395200	523090	682101	877591	1115500	1402380
6	2611456	3636487	4976595	6704853	8906360	11679493

Here we use the notation $\{f_m\}$ and $\{g_m + \cdots + g_n\}$ to denote the dimensionality of the spaces of polynomials of degree m and degrees m through n, respectively. Similarly, we find the results

$$\begin{aligned}\{f_2g_3 + f_2g_4\} &= \{f_2\} \times \{g_3 + g_4\} \\ &= 21 \times (56 + 126) = 3822. \end{aligned} \tag{39.5.10}$$

Finally we note that, by symmetry, the evaluation of $(f_1g_2 + f_1g_3 + f_1g_4 + f_1g_5)$ and $(g_1f_2 + g_1f_3 + g_1f_4 + g_1f_5)$ can be done with the same look-up information, and similarly for $(f_2g_3 + f_2g_4)$ and $(g_2f_3 + g_2f_4)$, etc. Thus, we have covered all possibilities for polynomials of degree 1 through 6. We find that the total dimension of the look-up table for such polynomials (in 6 variables) is given by the sum

$$\{6, 6\} = 21 + 231 + 1596 + 2730 + 3822 = 8400. \tag{39.5.11}$$

Consider next the case where symmetry is ignored. Then (for $d = 6$) we have the results

$$\{f_1g_1\}^{ns} = 6 \times 6 = 36, \tag{39.5.12}$$

$$\{f_2g_2\}^{ns} = 21 \times 21 = 441, \tag{39.5.13}$$

$$\{f_3g_3\}^{ns} = 56 \times 56 = 3136. \tag{39.5.14}$$

The quantities (5.9) and (5.10) remain unchanged, but equal numbers of storage locations must now be allocated for their reversed counterparts. Consequently, we find that the total number of storage locations required through degree 6 (in 6 variables) when symmetry is not exploited is given by the relation

$$\{6, 6\}^{ns} = 36 + 441 + 3136 + 2 \times 2730 + 2 \times 3822 = 16,717. \tag{39.5.15}$$

We see that this number is slightly less than twice (5.11).

It is remarkable how much the decision to retain only terms through degree m (e.g. ignore the * terms in Table 5.2) affects the size of the multiplication look-up table. Consider the case of polynomials of degree 1 through 12 in 6 variables. According to Table 7.9.1 there are

$$S(12, 6) = 18,563 \tag{39.5.16}$$

basis monomials in this case. Thus one might naively expect that

$$18,563 \times 18,563 \simeq 3.4 \times 10^8 \tag{39.5.17}$$

storage locations would be required for a multiplication look-up table. This number is prohibitively large. However, examination of Table 5.4 gives the much smaller result

$$\{12, 6\}^{ns} = 2,667,029. \tag{39.5.18}$$

According to (2.10) and (5.16) the largest index in the case $m = 12$ and $d = 6$ is 18,563. We note that 2^{15} = 32,768. Thus, the indices could all be stored in 2 byte entries, and the storage required by (5.18) would be approximately 5.3 megabytes.

Exercises

39.5.1.

39.6 Scripts

Suppose we wish to carry out some calculation that potentially involves a great deal of index manipulation, and suppose we have some simple-minded method for doing so. What we can then do is carry out this simple-minded method, while at the same time making and keeping a *record* of the *results* of the *index manipulation*. We will call this record a *script*. Then, any time we wish to repeat the calculation, we can bypass the need for index manipulation by use of the script.

As an example of this approach, consider the problem of multiplying two polynomials f and g to find the product

$$h = fg. \tag{39.6.1}$$

For simplicity, we consider only the computationally intensive terms (5.4). Exhibit 6.1 shows a simple-minded procedure for doing so.

Exhibit 32.6.1: Simple-minded program for polynomial multiplication.

```
c  Loop over degree ifdeg and indices if and ig.
      do 10 ifdeg=1,maxdeg-1
      do 20 if=ibot(ifdeg),itop(ifdeg)
      do 30 ig=1,itop(maxdeg-ifdeg)
c  Look up exponent vectors corresponding to if and ig and add them.
      do l=1,6
      jf(l)=jtbl(l,if)
      jg(l)=jtbl(l,ig)
      jsum(l)=jf(l)+jg(l)
      end do
c  Find the index of vector sum.
      call ndex(jsum,ih)
c  Carry out multiplication, and store result in h(ih).
      h(ih)=h(ih)+f(if)*g(ig)
   30 continue
   20 continue
   10 continue
c
      return
      end
```

What is shown is a fragment of a FORTRAN program with various parameter and dimension statements omitted. The procedure employs a triple loop that goes through all relevant degrees in f and all relevant index pairs if and ig. Suppose *maxdeg* is the maximum degree of the monomials we wish to retain. Then, in the factor f, we only need work with monomials whose degree *ifdeg* lies in the range $1 \le ifdeg \le maxdeg - 1$. Note that exponents (and hence degrees) add under the operation of multiplication; and recall that we are only considering computationally intensive terms so that in both the factors f, g only terms of degree 1 and higher appear. Correspondingly, when working with terms of degree *ifdeg* in the factor f, the only terms in g that are required are those whose degree *igdeg* lies in the range $1 \leq igdeg \leq maxdeg - ifdeg$. All these considerations are implemented conveniently, as shown, with the use of the arrays *ibot* and *itop*. See Section 32.2.5.

For each *if*, *ig* pair the following operations are performed:

1. Look up the corresponding exponents jf and jg from a previously prepared and stored table *jtbℓ*.

2. Add these exponents to find the resulting exponent.

3. Compute the index *ih* corresponding to this exponent.

4. Carry out the multiplication of the monomial coefficients from f and g, and increment the monomial coefficient of h corresponding to the index *ih* found in step 3 by the resulting product.

Evidently this procedure requires numerous look-ups (step 1), numerous additions (step 2), and numerous calls to an index computation routine (in this case the subroutine *ndex*, see Exhibit 2.2).

Exhibit 6.2 shows the same routine except that step 4 above is replaced by storage of the relevant index triplets if, ig, and ih. They are stored sequentially in terms of a “counting” index *ic*. The result of running this routine is the arrays (look-up tables) *iftbℓ*, *igtbℓ*, and *ihtbℓ*. The size of each of these arrays is $\{m, d\}^{ns}$ with $m = maxdeg$ and (in this example) $d = 6$. The array *icmin*, whose purpose will be described later, is also filled.

```
Exhibit 32.6.2: Program for preparation of script for polynomial multiplication.
This program prepares the tables iftbl, igtbl, ihtbl, and records their size,
icmax.  It also fills the array icmin.

c  Initialize counter.
      ic=0
c  Loop over degree ifdeg and indices if and ig.
      do 10 ifdeg=1,maxdeg-1
      do 20 if=ibot(ifdeg),itop(ifdeg)
      do 30 ig=1,itop(maxdeg-ifdeg)
c  Look up exponent vectors corresponding to if and ig and add them.
      do l=1,6
      jf(l)=jtbl(l,if)
      jg(l)=jtbl(l,ig)
      jsum(l)=jf(l)+jg(l)
      end do
c  Find the index of vector sum.
      call ndex(jsum,ih)
c  Update counter and fill tables.
      ic=ic+1
      iftbl(ic)=if
      igtbl(ic)=ig
      ihtbl(ic)=ih
c  Fill icmin.
      if(ig .eq. 1) icmin(if)=ic
  30  continue
  20  continue
  10  continue
c  Set icmax
      icmax=ic
c
      return
      end
```

The arrays *iftbℓ*, *igtbℓ*, and *ihtbℓ* can now be used as a script to carry out multiplication. Exhibit 6.3 shows how. We see, by comparing Exhibits 6.1 and 6.3, that the triple loop has been replaced by a single loop, and all index and exponent manipulations and calculations are replaced by table look up. Indeed, the routine consists entirely of the actual calculation to be performed (step 4 above) and table look up. Evidently this program should run far faster than that of Exhibit 6.1. The price paid for this speed is the storage required for the tables *iftbℓ*, *igtbℓ*, and *ihtbℓ*.

```
Exhibit 32.6.3: Program for polynomial multiplication using a script.

      do 10 ic=1,icmax
      if=iftbl(ic)
      ig=igtbl(ic)
      ih=ihtbl(ic)
  10  h(ih)=h(ih)+f(if)*g(ig)
      end

An even more compact program for polynomial multiplication using a script.

      do 10 ic=1,icmax
  10  h(ihtbl(ic))=h(ihtbl(ic))+f(iftbl(ic))*g(igtbl(ic))
      end
```

Now that we understand the basic idea of how a script works, we should seek to optimize the procedure. In particular, the tables *iftbℓ* and *igtbℓ* are not actually necessary. This is good because their size, $\{m, d\}^{ns}$, can be quite large.

Here the arrays *ibot* and *itop* can again be utilized. Consider the program fragment shown in Exhibit 6.4. Evidently, by construction, this code will produce the *same* set of *if* and *ig* values, and in the *same order*, as those stored in the routine of Exhibit 6.2 and used in the routine of Exhibit 6.3. Thus, the need for the tables *iftbℓ* and *igtbℓ* has been eliminated.

```
Exhibit 32.6.4: Program for producing if and ig pairs using less storage and
fewer look ups.

      do 10 ifdeg=1,maxdeg-1
      do 20 if=ibot(ifdeg),itop(ifdeg)
      do 30 ig=1,itop(maxdeg-ifdeg)
      .
      .
      .
   30 continue
   20 continue
   10 continue
      end
```

We are now ready to reap the fruit of our deliberations. We know that the routine of Exhibit 6.4 produces the same if and ig values, and in the same order, as those stored in the routine of Exhibit 6.2 and used in the multiplication routine of Exhibit 6.3. Also, we see from Exhibit 6.2 that the pointer ic is incremented by 1 each time an if, ig pair is produced. As a result of these facts, we may write a multiplication routine equivalent to that of Exhibit 6.3 using the loop structure of Exhibit 6.4. This multiplication routine is shown in Exhibit 6.5 below. We see that this routine uses the table $ihtb\ell$, as does the routine of Exhibit 6.3, but does not use the tables $iftb\ell$ and $igtb\ell$. As noted earlier, this is a considerable savings in storage since these tables may be large.

Exhibit 32.6.5: Program for polynomial multiplication using only one index look-up table.

```
      ic=1
      do 10 ifdeg=1,maxdeg-1
      do 20 if=ibot(ifdeg),itop(ifdeg)
      do 30 ig=1,itop(maxdeg-ifdeg)
      h(ihtbl(ic))=h(ihtbl(ic))+f(if)*g(ig)
      ic=ic+1
   30 continue
   20 continue
   10 continue
      end
```

There is one last possible improvement to be considered. Suppose one of the factors in (3.1), say f, is sparse. This is often the case in problems of practical interest. In this case, the program shown in Exhibit 6.5 can be improved to exploit sparseness in f. To see how this may be done, consider the contents of the arrays $iftb\ell$, $igtb\ell$, and $ihtb\ell$. Table 6.1, for example, shows the contents of these arrays in the case $m = maxdeg = 4$ and $d = 2$. Inspection of Table 6.1 shows that for each value of if there is a minimum value of ic for which $iftb\ell(ic) = if$. Evidently, for a given value of if, the minimum value of ic occurs when $ig = 1$. Suppose these values are put in an array which we will call $icmin(if)$. For example, Table 6.2 shows such an array in the case $m = 4$ and $d = 2$. Finally, inspection of the code in Exhibit 6.2 shows how the array $icmin$ can be constructed in general, and in particular for the case $d = 6$.

Table 39.6.1: Contents of the arrays $iftb\ell$, $igtb\ell$, and $ihtb\ell$ in the case $m = 4$ and $d = 2$.

Now consider the program shown in Exhibit 6.6 below. It tests the factor $f(if)$ before going into the do loop over ig. This whole loop is skipped if $f(if)$ is zero. If this loop were ever skipped in the program of Exhibit 6.5, the value of ic would be upset because it is incremented within this loop. However, if ic is properly set each time the program goes into this loop, which is what use of the array *icmin* does, then ic always has the proper value even if this loop has possibly been skipped for some earlier values of if.

Exhibit 32.6.6: Program for polynomial multiplication using only one index look-up table and designed to exploit possible sparseness in the factor f.

```
      do 10 ifdeg=1,maxdeg-1
      do 20 if=ibot(ifdeg),itop(ifdeg)
      if(f(if) .ne. 0.d0) then
      ic=icmin(if)
      do 30 ig=1,itop(maxdeg-ifdeg)
      h(ihtbl(ic))=h(ihtbl(ic))+f(if)*g(ig)
      ic=ic+1
   30 continue
      endif
   20 continue
   10 continue
      end
```

Let us briefly compare the theoretical speeds of the programs shown in Exhibits 6.5 and 6.6. We see that the program in Exhibit 6.6 makes $ifmax = itop(maxdeg - 1) =$

$S(maxdeg-1,d)$ “if” tests. See (2.20). When an if test is passed, there is the additional burden of an $icmin(if)$ look up. However, when an if test fails, there is a savings of $igmax = itop(maxdeg - ifdeg)$ additions and multiplies as well as the overhead and other operations associated with the ig loop. Since $igmax$ can often be large, and multiplications are slow, we conclude (providing the if test burden is not too large) that the program of Exhibit 6.6 should be significantly faster than that of Exhibit 6.5 if f is sparse, and only slightly slower if f is dense.

In many applications both f and g are known to be homogeneous. Homogeneity may be viewed as a kind of sparseness, and this sparseness can also be exploited to produce a still faster multiplication routine. Exhibit 6.7 shows such a routine. Note that it is now necessary to offset the counter ic by the amount *icoff* to take into account the fact that the ig loop now begins at $ig = ibot(igdeg)$ rather than $ig = 1$.

Exhibit 32.6.7: Program for polynomial multiplication using only one index look-up table and designed to exploit the fact that f and g are homogeneous of degrees ifdeg and igdeg, respectively. It is also designed to exploit possible additional sparseness in the factor f.

```
      icoff=itop(igdeg-1)
      do 10 if=ibot(ifdeg),itop(ifdeg)
      if(f(if) . ne. 0.d0) then
      ic=icmin(if)+icoff
      do 20 ig=ibot(igdeg),itop(igdeg)
      h(ihtbl(ic))=h(ihtbl(ic))+f(if)*g(ig)
      ic=ic+1
   20 continue
      endif
   10 continue
      end
```

Suppose it is known in advance which entries in f are nonzero. Then it is possible to eliminate the if statements in programs like those in Exhibits 6.6 and 6.7 with a possible improvement in computational speed—particularly in the case of vector or pipe-lined computer architecture for which the if test burden is relatively large. If (exactly) k entries in f are known to be *nonzero*, then we can set up an array $nzf(i)$ such that the values $nzf(i)$ with $i \in [1,k]$ are the indices for the nonzero entries in f. With this array in hand we can, for example, reformulate the routine of Exhibit 6.7 as shown in Exhibit 6.8. Here we assume, as in Exhibit 6.7, that f is homogeneous of degree $ifdeg$. We remark that by the introduction of still further arrays it is possible to exploit known sparseness in both f and g.

Exhibit 32.6.8: Program for polynomial multiplication using only one look-up table, known sparseness in f, and homogeneity in f and g.

```
      icoff=itop(igdeg-1)
      do 10 i=1,k
      if=nzf(i)
      ic=icmin(if)+icoff
      do 20 ig=ibot(igdeg),itop(igdeg)
      h(ihtbl(ic))=h(ihtbl(ic))+f(if)*g(ig)
```

```
   ic=ic+1
20 continue
10 continue
   end
```

Note that the look-up table *ihtbℓ* in Exhibits 6.5 through 6.8 has size $\{m,d\}^{ns}$. We close this section by commenting that it is also possible to write multiplication routines that employ a look-up table having the minimum size $\{m,d\}$. That is, it is possible to write a routine that exploits the commutative symmetry of multiplication. However, we have not found a way of doing so that simultaneously exploits sparseness.

Exercises

39.6.1.

39.7 Look-Back Tables

Consider the array $ihtb\ell(ic)$ of ih values described in Section 6. See, for example, the right column of Table 6.1. For each value of ic ranging from 1 through $icmax = \{m,d\}^{ns}$, there is a corresponding value of ih, and this value lies in the range $(d+1)$ through $S(m,d)$. (Note that there are no zero or first order monomials under consideration since we are only worried about computationally intensive terms.) Since $\{m,d\}^{ns} > S(m,d)$, there are generally many ic values that yield a given value of ih. Indeed, in (6.1) there are many factors $f(if)$ and $g(ig)$ that contribute to a given $h(ih)$.

Next look at the program in Exhibit 6.3. We see that ic runs *successively* through the values 1,2,$\cdots icmax$. However, we also see that the same result would be achieved if ic ran through the values 1,2,$\cdots icmax$ in *any* order. That is, the outcome of following the script is *independent* of the order in which its instructions are executed. Suppose the array $ihtb\ell(ic)$ is rearranged so that the entries are listed in order of increasing ih. At the same time we rearrange the arrays $iftb\ell$ and $igtb\ell$. Finally, we set up a new ic index that again runs successively through the values 1,2,$\cdots icmax$. For example, Table 7.1 below shows the result of this rearrangement applied to Table 6.1.

Examine Table 7.1. We see that for each value of ih in the column $ihtb\ell$ there are corresponding values of if and ig in the columns $iftb\ell$ and $igtb\ell$, respectively. These if, ig pairs are the indices for the monomials that are *factors* of the monomial labelled by ih. Thus, the arrays $iftb\ell$ and $igtb\ell$ (after the rearrangement just described) provide what we have called look-back tables. That is, given some ih, we can look back using these tables to find the if, ig pairs that produced this ih. We note that each table has $\{m,d\}^{ns}$ entries.

These look-back tables can be used to construct a program for multiplication. To do this, we make some observations. We see that for each value of ih in the column $ihtb\ell$ there is a minimum (bottom) value of the variable new ic, call it $icbot$, and a maximum (top) value, call it $ictop$. Use these observations to construct two arrays: $icbot(ih)$ and $ictop(ih)$. For example, Table 7.2 shows the contents of these arrays in the case $m=4$ and $d=2$.

Also, we see that ih has the minimum value $ihmin$ given by the relation

$$ihmin = d + 1, \tag{39.7.1}$$

and a maximum value $ihmax$ given by

$$ihmax = S(m, d) \tag{39.7.2}$$

with, in this case, $m = maxdeg = 4$ and $d = 2$.

Table 39.7.1: The result of rearranging Table 6.1 in order of increasing ih.

Now look at Exhibit 7.1. It shows a program for polynomial multiplication using the arrays $iftb\ell$ and $igtb\ell$ as look-back tables. (Note that, although we have used the same notation, here the tables $iftb\ell$ and $igtb\ell$ are *rearranged* versions of their original counterparts.) We see that, with the use of the arrays *icbot* and *ictop*, the program ranges over all the proper values of *ic*, and therefore from our previous discussion must give the same result as the program of Exhibit 6.3.

Exhibit 32.7.1: Program for polynomial multiplication using look-back tables.

```
      do 10 ih=ihmin,ihmax
      do 20 ic=icbot(ih),ictop(ih)
      h(ih)=h(ih)+f(iftbl(ic))*g(igtbl(ic))
   20 continue
   10 continue
      end
```

How do the programs shown in Exhibits 6.5 and 7.1 compare? Here are some reasons to believe that (for multiplication) the use of look-up tables is preferable to the use of look-back tables:

1. Examine Table 6.1. Evidently successive values of $iftb\ell(ic)$ and $igtb\ell(ic)$ are *contiguous* as one goes down the list (increments ic). Therefore successive values of $f[iftb\ell(ic)]$ and $g[igtb\ell(ic)]$ are adjacent in memory. Since modern computers are often designed to fetch many adjacent items from memory at once and place them in fast-access cache memory or in on-chip registers in anticipation that they may be needed shortly, one expects there may be relatively few separate calls to slow access memory to find the coefficients in f and g when look-up tables are used. Note, by contrast, that successive values of $ihtb\ell(ic)$ are not contiguous. Therefore there is the penalty that the results of multiplication have to be scattered into slow access memory. They are, however, not too widely dispersed since if f and g are of given degrees (as in Exhibit 6.7), then all the entries in h will at least be of the same fixed degree, and therefore (in a graded indexing scheme) stored fairly close together. Moreover, if monomial ordering is used, then for each fixed if and all successive ig, the relevant ih values also occur in increasing order. We conclude that, with the use of look-up tables, access to the coefficients in both f and g may be fast, and access to the coefficients in h may be somewhat slow. Now examine Table 7.1. Here the successive values of $ihtb\ell(ic)$ are contiguous. However, those of $iftb\ell(ic)$ and $igtb\ell(ic)$ are not. Indeed, the entries in f and g that need to be accessed are not even of fixed degree. We conclude that, with the use of look-back tables, access to the coefficients in *both* f and g may be quite slow, and *only* access to the coefficients in h may be fast. Therefore, the use of look-up tables is likely to yield faster code.

2. It appears that the look-back method requires the storage of two tables of dimension $\{m, d\}^{ns}$, while the look-up method involves the storage of only one. As we have seen, these tables may be large. However, this objection may not be as serious as it sounds. Examination of Table 7.1 shows that, for each fixed value of $ihtb\ell$, there is a close relation between the contents of $iftb\ell$ and $igtb\ell$. Indeed, one list is the reverse of the other. Therefore, at the expense of some slightly more complicated logic and a few additional look ups, it may be possible to work with a single table of dimension $\{m, d\}^{ns}$.

3. The look-back method also requires storage of the arrays *icbot* and *ictop* which are each roughly of size $S(m, d)$. The look-up method requires the additional arrays *ibot* and *itop* which are only of size $(maxdeg + 1)$ with $maxdeg = m$.

4. Finally, the look-up method can be modified to exploit possible sparseness and homogeneity as shown in Exhibits 6.6 through 6.8. This does not seem to be possible for the look-back method.

Strictly speaking, some of the consideration listed above apply only to the case of computation with one processor. Suppose one has several processors available in some form of large-scale parallel architecture. Then one might assign the computation of various $h(ih)$ values to various processors, all to be computed in parallel. In this case, each computation would use look-back tables, and the use of look-back tables might be preferable to the use of look-up tables.

Let us pause to reflect. Look back over our discussion so far in this section, and the content of the previous two sections. After some thought, we see that what we have learned is that the idea of a script is a unifying concept, and that the use of a look-up table and the use of look-back tables are simply alternate ways of going through the script. Indeed, if we look at Table 6.1 and regard the indices if and ig as entries in a two-component number (if, ig) with most significant digit if and least significant digit ig, then we see that these numbers are arranged in increasing size as we go down the list. Alternatively, if we look at Table 7.1, we see that the list has been "graded" according to the value of ih; and the items having a given ih are again arranged in increasing size based on the two-component numbers (if, ig).

We close this section by observing that look-back tables can sometimes be employed to optimal advantage for other calculations. Their use in the calculation of Poisson brackets is described in Section 8. Here we describe their use in the evaluation of polynomials. Suppose $f(z)$ is a polynomial written in the form

$$f(z) = \sum_i f_i M_i(z), \tag{39.7.3}$$

where the f_i are a given set of coefficients, and we wish to know the value of f at the point $z = w$. Here, as before in Section 32.3, we have used the notation

$$M_i(z) = z^{j(i)}. \tag{39.7.4}$$

The coefficients f_i may be viewed as the entries in a *vector* of dimension $S_0(m, d)$. Define another such vector with entries γ_i given by the relation

$$\gamma_i = M_i(w). \tag{39.7.5}$$

Then the value $f(w)$ can be written in the form

$$f(w) = \sum_i f_i \gamma_i. \tag{39.7.6}$$

We see that (7.6) can be viewed as a *vector dot product* and, providing we know the entries γ_i, this dot product can be computed very efficiently by computers having vector or pipe-lined architecture.

But how can be find the γ_i in an efficient manner? If we use indexing based on a modified *glex* sequence, we have the results

$$\gamma_0 = 1, \tag{39.7.7}$$

$$\gamma_i = w_i \text{ for } i = 1, 2, \cdots d. \tag{39.7.8}$$

Moreover, we claim there are two look-back tables $i1(i)$ and $i2(i)$ such that the remaining γ_i can found from a recursion relation of the form

$$\gamma_i = [\gamma_{i1(i)}][\gamma_{i2(i)}]\ ,\ i = d + 1, \cdots S(m, d). \tag{39.7.9}$$

Thus, it is possible to evaluate the γ_i by carrying out only $[S(m, d) - d]$ multiplications.

To see how to construct the tables $i1(i)$ and $i2(i)$, we observe that each $M_i(z)$ of degree $n = |j(i)|$, and assuming $n \geq 2$, can be factored as the product of a *first* degree monomial with index $i1(i)$ and another monomial of degree $n - 1$ having index $i2(i)$:

$$M_i(z) = [M_{i1(i)}(z)][M_{i2(i)}(z)]. \tag{39.7.10}$$

Exhibit 7.2 shows a routine written to find two tables $i1(i)$ and $i2(i)$ having this property. Inspection of the routine shows that it works as follows: Find and examine the exponent $j(i)$. Proceeding from the left, let $j_k(i)$ be the first nonzero entry in $j(i)$. By construction k must lie in the range $1 \leq k \leq d$, and we have the result

$$z^{j(i)} = z_1^{j_1} z_2^{j_2} \cdots z_d^{j_d} = z_k z^{j'(i)} \tag{39.7.11}$$

where the exponent array $j'(i)$ has the entries

$$j'_\ell(i) = j_\ell(i) - 1 \text{ when } \ell = k, \tag{39.7.12}$$

$$j'_\ell(i) = j_\ell(i) \text{ when } \ell \neq k. \tag{39.7.13}$$

Now define the table entries $i1(i)$ and $i2(i)$ by the rules

$$i1(i) = \text{ index for } z_k = k, \tag{39.7.14}$$

$$i2(i) = \text{ index for the exponent } j'(i). \tag{39.7.15}$$

Table 7.3 displays the result of running this routine for the case $m = 3$ and $d = 6$. The entries in this table should be compared with those in Table 2.1.

Exhibit 7.3 shows a routine for computing the γ_i based on the relations (7.7) through (7.9). Look at Table 7.3. We see that the results of the algorithm of Exhibit 7.2 have the pleasing feature that, for the most part, the values of $i2(i)$ are contiguous for successive values of i. Inspection of the routine of Exhibit 7.3 shows that it requires the values $\gamma_{i1(i)}$ and $\gamma_{i2(i)}$ for successive values of i. Since the addresses are usually contiguous, it is very likely that the values of the required $\gamma_{i1(i)}$ and $\gamma_{i2(i)}$ will either be in fast-access cache or in registers when needed, and consequently this routine should be very fast.

Exhibit 32.7.2: Program for factoring monomials. It produces arrays i1(i) and i2(i) such that monomial(i)=monomial(i1(i))*monomial(i2(i)) and the monomials monomial(i1(i)) in the first factor are all of degree one.

```

39.7.1.

39.8 Poisson Bracketing

When computing Poisson brackets of homogeneous polynomials, there are three natural cases to consider. First, there are brackets of the form $[f_1, g_1]$. They are trivial to compute in view of (1.7.10). Next in order of complexity are brackets of the form $[f_m, z_a]$ with $m \geq 2$. They will be referrred to as *single-variable* Poisson brackets, and are an essential ingredient in the computation of $\mathcal{M}z_a$ as in (7.1.1). With the aid of (7.6.10), they can be evaluated by the formula

$$: f_m : z_a = [f_m, z_a] = -\partial f_m / \partial z_a^*. \tag{39.8.1}$$

Finally, there are brackets of the form $[f_m, g_n]$ with $m, n \geq 2$. They will be called *general* Poisson brackets.

The purpose of this section is to describe efficient algorithms for the computation of single-variable and general Poisson brackets.

We begin with the case of single-variable Poisson brackets. That is, we wish to compute

$$g =: f : z_a. \tag{39.8.2}$$

For the discussion of Poisson brackets it is convenient to order the q's and p's in conjugate pairs and to define z^j (for the case of a 6-dimensional phase-space) in analogy with (2.1),

$$z^j = q_1^{j_1} p_1^{j_2} q_2^{j_3} p_2^{j_4} q_3^{j_5} p_3^{j_6}. \tag{39.8.3}$$

Then, for example and in agreement with (8.1), we find the result

$$: z^j : q_1 = [z^j, q_1] = -\partial z^j/\partial p_1 = -j_2 q_1^{j_1} p_1^{j_2 - 1} q_2^{j_3} p_2^{j_4} q_3^{j_5} p_3^{j_6}. \tag{39.8.4}$$

Evidently every monomial single-variable Poisson bracket $[z^j, z_a]$ results in at most one term, and many produce none. This circumstance can be exploited using look-back tables. Suppose the monomial z^k with

$$z^k = q_1^{k_1} p_1^{k_2} q_2^{k_3} p_2^{k_4} q_3^{k_5} p_3^{k_6} \tag{39.8.5}$$

produces the monomial z^j as a result of the multiplication

$$z^k z_b = z^j. \tag{39.8.6}$$

Then we have the result

$$\partial z^j/\partial z_b = j_b z^k \tag{39.8.7}$$

with j_b guaranteed to be nonzero. Let $i = i(k)$ be the index of the monomial with exponent k. Then, corresponding to the relation (8.6), we can define a single-variable multiplication table $msv(i, b)$ by the rule

$$msv(i, b) = \text{ index of monomial with exponent } j. \tag{39.8.8}$$

Exhibit 8.1 below shows a program that prepares a script for single-variable Poisson bracketing. It makes the single-variable multiplication table $msv(i, b)$ as well as the tables $coef(i, b)$ and $scoef(i, b)$, which contain various coefficients such as the $(-j_2)$ that appears in (8.4). From their construction it is evident that all these tables have the modest dimension $itop(maxdeg - 1) \times 6$. [Actually the table $coef(i, b)$ is not needed for single-variable Poisson bracketing, but is useful for multplication-based general Poisson bracketing. See Exhibit 8.5.]

c
      return
      end
```

Exhibit 8.2 shows the actual single-variable Poisson bracketing routine that uses the script prepared by the program of Exhibit 8.1. It works directly with the index ig for each monomial in the result g, and uses the table msv to look back to find the index $if = msv(ig, k)$ of the monomial in f that produced this result. Because each monomial in f contributes to at most one term in g, no attempt has been made to exploit possible sparseness in f. To test in advance of their use the various $f(if)$ to see if they vanished would result in significant computational overhead with little associated reward. Finally, we note that, due to the use of monomial ordering, successive if values appear in an increasing sequence. The required $f(if)$ values are therefore likely to be in cache or in on-chip registers.

Exhibit 32.8.2: Program for single variable Poisson bracket.

```
      subroutine svpb(f,ideg,k,g)
c
c This subroutine finds the single variable Poisson
```

```
c bracket g=:f:z_k.  Here f is homogeneous of degree ideg.
c
      do ig=ibot(ideg-1),itop(ideg-1)
      g(ig)=scoef(ig,k)*f(msv(ig,k))
      end do
c
      return
      end
```

We next turn to the general Poisson bracket case. We wish to compute $h = [f, g]$ when both f and g are of degree two and higher. For a 6-dimensional phase space, the Poisson bracket of any two monomials is given by the standard rule

$$[z^j, z^k] = \sum_{i=1}^{3} (\partial z^j/\partial q_i)(\partial z^k/\partial p_i) - (\partial z^j/\partial p_i)(\partial z^k/\partial q_i). \tag{39.8.9}$$

At first count it might appear that a typical monomial Poisson bracket could contain 6 distinct terms. In fact, there are at most 3 distinct terms. To verify this assertion, consider the $i = 1$ terms on the right side of (8.9). They give the result

$$\begin{aligned}
&(\partial z^j/\partial q_1)(\partial z^k/\partial p_1) - (\partial z^j/\partial p_1)(\partial z^k/\partial q_1)\\
&= (j_1 z_1^{j_1-1} z_2^{j_2} z_3^{j_3} z_4^{j_4} \cdots)(k_2 z_1^{k_1} z_2^{k_2-1} z_3^{k_3} z_4^{k_4} \cdots)\\
&\quad -(j_2 z_1^{j_1} z_2^{j_2-1} z_3^{j_3} z_4^{j_4} \cdots)(k_1 z_1^{k_1-1} z_2^{k_2} z_3^{k_3} z_4^{k_4} \cdots)\\
&= (j_1 k_2 - j_2 k_1)(z_1^{j_1+k_1-1} z_2^{j_2+k_2-1} z_3^{j_3+k_3} z_4^{j_4+k_4} \cdots).
\end{aligned} \tag{39.8.10}$$

Evidently in the Poisson bracket result there is at most one monomial term for each value of i in the sum (8.9), and there is none whenever (for odd ℓ) the coefficient $(j_\ell k_{\ell+1} - j_{\ell+1} k_\ell)$ vanishes.

Exhibit 8.3 below shows a program that prepares a script for general Poisson bracketing.

```

The sizes of the arrays produced by this script can be quite large. The array *nt* is indexed by the integer variable *ic2*, and has dimension *maxic2*. The arrays *pbcoef* and *ih* are indexed by the integer variable *ic1*, and have dimension *maxic1*. The values of *maxic1* and *maxic2* are listed in Table 8.1 for various values of *maxdeg*, the maximum degree of the polynomials one is considering.

The computation of *maxic2* is elementary. The variable *ic2* labels all possible *if*, *ig* pairs that can potentially occur in a Poisson bracket calculation, and *maxic2* is the total number of such pairs. For example, if $maxdeg = 3$, we have to consider Poisson bracket terms of the form $[f_2, f_2]$, $[f_2, f_3]$, and $[f_3, f_2]$. Inspection of Table 7.3.1 shows that (for a 6-dimensional phase space) there are 21 f_2 basis monomials and 56 f_3 basis monomials. Thus, in this case we expect the result

$$\mathit{maxic2} = 21 \times 21 + 21 \times 56 + 56 \times 21 = 441 + 1176 + 1176 = 2793,$$

in agreement with the corresponding entry in Table 8.1. We note that the quantites $\mathit{maxic2}(maxdeg)$ for Lie (Poisson bracket) multiplication are much larger than their counterparts $\{maxdeg, 6\}^{ns}$ for ordinary multiplication. Compare Tables 5.4 and 8.1. This increased size results from the (-2) term in (7.6.16), which does not occur for ordinary multiplication. As a simple example, many of the absent terms denoted by an asterisk "*" in Table 5.2 for ordinary multiplication would not be absent for Poisson bracket multiplication.

The computation of *maxic1* is more complicated, and is most easily done simply by counting as in Exhibit 8.3. As described earlier, each possible *if*, *ig* monomial pair is labeled by a value of *ic2*. The quantity *nt(ic2)* is the number of monomial terms that result from Poisson bracketing the monomial pair with label *ic2*. We have already seen that this number (including the possibility of a vanishing bracket) ranges from 0 to 3. The quantity *maxic1* is the sum over *nt*,

$$\mathit{maxic1} = \sum_{\mathit{ic2}=1}^{\mathit{maxic2}} \mathit{nt(ic2)}. \tag{39.8.11}$$

Thus, for a fixed value of *maxdeg*, the quantity *maxic1* is the number of nonzero monomials that can occur in a Poisson bracket calculation including repetitions.

Inspection of Table 8.1 shows that *maxic1*, for *maxdeg* ≤ 6, is smaller than or comparable to *maxic2*. Evidently, although the Poisson bracket of each monomial pair could potentially produce as many as 3 monomial terms, most Poisson brackets produce fewer or are in fact zero. By contrast, *maxic1* exceeds *maxic2* for *maxdeg* > 6.

Table 39.8.1: Array sizes *maxic1* and *maxic2* (in the case of 6 phase-space variables) for various values of *maxdeg*.

maxdeg	*maxic1*	*maxic2*	*maxdeg*	*maxic1*	*maxic2*
2	210	441	8	648342	570619
3	1662	2793	9	1514382	1231279
4	7986	11221	10	3320694	2518565
5	29622	35917	11	6902358	4923317
6	92802	99421	12	13701822	9254645
7	257190	247933			

Exhibit 8.4 shows the actual general Poisson bracket routine that uses the script prepared by the program of Exhibit 8.3. It is designed to exploit possible sparseness in f and known homogeneity in both f and g. The array *pbcoef(ic1)* contains precomputed (and nonzero) coefficients of the form $(j_\ell k_{\ell+1} - j_{\ell+1} k_\ell)$, and the look-up table *ih(ict1)* specifies where contributions to the various terms in h are to be placed. For each if,*ig* pair, the *ih* values for successive *ict1* values are arranged in increasing order in the hope of rapid memory access. Thanks to the contents of the array *nt(ic2)*, only potentially nonzero terms are computed. The arrays *irst1* and *irst2* set the counters *ic1* and *ic2* to take into account skipped terms due to sparseness and homogeneity.

Exhibit 32.8.4: Script-driven program for general Poisson bracket.

```
      subroutine pb(f,ifdeg,g,igdeg,h)
c
c This subroutine computes the Poisson bracket
c h=[f,g].  The input polynomials f and g are
c homogeneous of degrees ifdeg and igdeg, respectively.
c
c clear h
c
      do i=1,imax
      h(i)=0.d0
      end do
c
c find offsets
c
      ic1=irst1(itop(ifdeg-1),igdeg)
      ic2=irst2(itop(ifdeg-1),igdeg)
c
c loop over if and ig
c
      do 10 if=ibot(ifdeg),itop(ifdeg)
      if(f(if) .eq. 0.d0) then
      ic1=irst1(if,igdeg)
      ic2=irst2(if,igdeg)
      go to 10
      end if
      do 20 ig=ibot(igdeg),itop(igdeg)
      if(g(ig) .eq. 0.d0) then
      ic1=ic1+nt(ic2)
      ic2=ic2+1
      go to 20
      end if
      if(nt(ic2) .ne. 0) then
      prod=f(if)*g(ig)
      do 30 it=1,nt(ic2)
      h(ih(ic1)) = h(ih(ic1)) + pbcoef(ic1)*prod
      ic1=ic1+1
   30 continue
      end if
      ic2=ic2+1
   20 continue
   10 continue
c
      return
      end
```

As remarked earlier, Table 8.1 shows that the script arrays required to drive the routine of Exhibit 8.4 can be quite large for vaues of *maxdeg* beyond 9. This may not be an issue as memory becomes ever more plentiful. However, it is worth remarking that there is an alternate approach that requires much less memory but, of course, is computationally slower. What one can do, as in the case of single-variable Poisson brackets, is use look-back tables to find the various terms in $\partial f/\partial z_a$ and $\partial g/\partial z_b$, and then use look-up tables, as in Exhibit 6.8, to carry out the multiplications $(\partial f/\partial z_a)(\partial g/\partial z_b)$. Exhibit 8.5 below shows a general Poisson bracket routine that uses this procedure.

Exhibit 32.8.5: General Poisson bracket program based on multiplication.

```
      subroutine pb(f,ifdeg,g,igdeg,h)
c
      data icon /2,1,4,3,6,5/
c
      icoff=ibot(igdeg-1)
      do 10 iz=1,6
      izc=icon(iz)
c
      do 20 ifl=ibot(ifdeg-1),itop(ifdeg-1)
      if=msv(ifl,iz)
      if(f(if) .ne. 0.d0) then
      ic=icmin(ifl)+icoff
      do 30 igl=ibot(igdeg-1),itop(igdeg-1)
      ig=msv(igl,izc)
      if(g(ig).ne. 0.d0) then
      fac=scoef(ifl,iz)*coef(igl,izc)
      h(ihtbl(ic))=h(ihtbl(ic))+fac*f(if)*g(ig)
      end if
      ic=ic+1
  30  continue
      end if
  20  continue
  10  continue
c
      return
      end
```

39.9 Linear Map Action

Let f be any function of the $2n$ phase-space variables z, and let M be any $2n \times 2n$ matrix. Then we define a *transformed* function g by the rule

$$g(z) = f(Mz). \tag{39.9.1}$$

One may view (9.1) as the action of the linear (usually but not necessarily symplectic) map respresented by the matrix M on the function f. See (8.4.23) and (10.4.36) where actions of this type arise in the concatenation and computation of maps. The purpose of this section is to describe an efficient algorithm for carrying out the operation (9.1).

To achieve efficiency, it is useful to employ a precomputed list of variables $jvblist(iv, ind)$. Here ind is a monomial index, and for an nth-order monomial there will be n non-zero variable numbers. For example, for the indexing scheme of Table 2.1, the monomial with index 7 is $X^2 = XX$. Correspondingly, the variable list (array) *jvblist* will have the entries

$$jvblist(iv = 1 \text{ to } 2, 7) = 1, 1. \tag{39.9.2}$$

As a second example, the monomial with index 19 is YP_y. Correspondingly *jvblist* will have the entries

$$jvblist(iv = 1 \text{ to } 2, 19) = 3, 4. \tag{39.9.3}$$

For a third example, the monomial with index 77 is $P_y\tau^2 = P_y\tau\tau$. Correspondingly *jvblist* will have the entries

$$jvblist(iv = 1 \text{ to } 3, 77) = 4, 5, 5. \tag{39.9.4}$$

Exhibit 9.1 below shows a program that produces *jvblist*. It is a modification of the program in Exhibit 2.3 so that both *jtbl* and *jvblist* are created simultaneously.

Exhibit 32.9.1: A program to produce both jtbl and jvblist based on a method of Liam Healy.

```

c
      return
      end
```

39.10 General Vector Fields

Let $\boldsymbol{f} = (f_1, f_2, \cdots f_d)$ be a collection of d functions of z, and suppose each function f_a is a truncated power series in z. Let $\mathcal{L}_{\boldsymbol{f}}$ be the vector field associated with $\boldsymbol{f}$. See Section 5.3. Using the tools already developed, it is easy to envision how to construct programs that would represent, multiply by scalars, and from linear combinations of such vector fields. We simply store and manipulate the underlying collections of functions in the obvious way.

Beyond these operations, we would also like to apply $\mathcal{L}_{\boldsymbol{f}}$ to a function g where it assumed that g is also a truncated power series. That is, we wish to find the truncated power series for h defined by the equation

$$h = \mathcal{L}_{\boldsymbol{f}}\, g = \sum_a f_a(\partial g/\partial z_a). \tag{39.10.1}$$

Moreover, suppose $\boldsymbol{f}$ and $\boldsymbol{g}$ are two collections of truncated power series. Let $\mathcal{L}_{\boldsymbol{f}}$ and $\mathcal{L}_{\boldsymbol{g}}$ be their associated vector fields. It is easily verified that the commutator of two vector fields is again a vector field. That is, there is a collection of functions $\boldsymbol{h}$ such that

$$\#\mathcal{L}_{\boldsymbol{f}}\#\mathcal{L}_{\boldsymbol{g}} = \{\mathcal{L}_{\boldsymbol{f}}, \mathcal{L}_{\boldsymbol{g}}\} = \mathcal{L}_{\boldsymbol{f}}\mathcal{L}_{\boldsymbol{g}} - \mathcal{L}_{\boldsymbol{g}}\mathcal{L}_{\boldsymbol{f}} = \mathcal{L}_{\boldsymbol{h}}. \tag{39.10.2}$$

Given the collections of truncated power series for $\boldsymbol{f}$ and $\boldsymbol{g}$, we would like to find the collection of truncated power series for $\boldsymbol{h}$.

The purpose of this section is to describe programs for computing h in (10.1) and $\boldsymbol{h}$ in (10.2).

It is evident from (10.1) that the computation of h involves partial differentiation and function multiplication. The same is true for the computation of $\boldsymbol{h}$. From the representation

$$\mathcal{L}_{\boldsymbol{h}} = \sum_b h_b(\partial/\partial z_b) \tag{39.10.3}$$

and (10.2) we find the result

$$h_a = \mathcal{L}_{\boldsymbol{h}} z_a = \mathcal{L}_{\boldsymbol{f}} \mathcal{L}_{\boldsymbol{g}} z_a - \mathcal{L}_{\boldsymbol{g}} \mathcal{L}_{\boldsymbol{f}} z_a = \mathcal{L}_{\boldsymbol{f}} g_a - \mathcal{L}_{\boldsymbol{g}} f_a. \tag{39.10.4}$$

Therefore, the computation of commutators involves the action (10.1) of vector fields on functions which, in turn, again involves partial differentiation and function multiplication.

In principle, it is possible to write scripted programs that would perform all the operations in (10.1) and (10.3) in an optimal way. However, for simplicity, we will only describe a scripted program for partial differentiation. This program can then be used in conjunction with those for multplication and addition to carry out all the required operations.

The operation of partial differentiation is similar to, and in fact simpler than, single-variable Poisson bracketing. See (8.1). Therefore, it is conviently done with the aid of a script and look-back tables. Exhibit 10.1 shows a program that generates a script for partial differentiation. It makes the single-variable multiplication table $msv(ic, k)$ and the table $coef(ic, k)$ that contains the coefficients j_b that occur in (8.7). Finally, Exhibit 10.2 shows the partial differentiation routine that uses the script prepared by the program of Exhibit 10.1.

Størmer-Cowell and Nyström Integration Methods

The differential equations of classical mechanics often involve only second derivatives with *no* first derivatives present. In this case it is possible to work directly with the second order equations instead of converting them into a first order set of twice the dimensionality. The result can be a saving in computer time and an increase in accuracy. We shall describe methods due to *Størmer* and *Cowell* and *Nyström*. See Chapter 2 for notation.

A.1 Preliminary Derivation of Størmer-Cowell Method

Consider a set of second-order equations of the form

$$\ddot{\boldsymbol{y}}(t) = \boldsymbol{f}(\boldsymbol{y}, t). \tag{A.1.1}$$

[We remark that if a Hamiltonian is of the form $H = p \cdot p/2 + V(q,t)$, it leads to differential equations of the form (1.1).] Then, using arguments similar to those of Chapter 2, we have the integration formulas

$$\nabla^2 \boldsymbol{y}^{n+1} = \nabla^2 D^{-2} \boldsymbol{f}^{n+1}, \tag{A.1.2}$$

$$\nabla^2 \boldsymbol{y}^{n+1} = \nabla^2 (1-\nabla)^{-1} D^{-2} \boldsymbol{f}^{n}. \tag{A.1.3}$$

By expanding (1.2) and (1.3) and using (2.4.13), we may rewrite our results as

$$\boldsymbol{y}^{n+1} = 2\boldsymbol{y}^n - \boldsymbol{y}^{n-1} + h^2[\nabla/\log(1-\nabla)]^2 \boldsymbol{f}^{n+1}, \tag{A.1.4}$$

$$\boldsymbol{y}^{n+1} = 2\boldsymbol{y}^n - \boldsymbol{y}^{n-1} + h^2(1-\nabla)^{-1}[\nabla/\log(1-\nabla)]^2 \boldsymbol{f}^{n}. \tag{A.1.5}$$

As in Chapter 2, we interpret the right sides (1.4) and (1.5) in terms of power series. After truncation we obtain the predictor and corrector formulas

$$\boldsymbol{y}^{n+1} = 2\boldsymbol{y}^n - \boldsymbol{y}^{n-1} + h^2 \sum_{k=0}^{N} \alpha_k \nabla^k \boldsymbol{f}^{n+1}, \qquad (\mathit{corrector}) \tag{A.1.6}$$

$$\boldsymbol{y}^{n+1} = 2\boldsymbol{y}^n - \boldsymbol{y}^{n-1} + h^2 \sum_{k=0}^{N} \beta_k \nabla^k \boldsymbol{f}^n, \qquad (\textit{predictor}) \qquad \text{(A.1.7)}$$

or the expanded versions

$$\boldsymbol{y}^{n+1} = 2\boldsymbol{y}^n - \boldsymbol{y}^{n-1} + h^2 \sum_{k=0}^{N} \overset{\sim N}{\alpha_k} \; \boldsymbol{f}^{n+1-k}, \qquad (\textit{corrector}) \qquad \text{(A.1.8)}$$

$$\boldsymbol{y}^{n+1} = 2\boldsymbol{y}^n - \boldsymbol{y}^{n-1} + h^2 \sum_{k=0}^{N} \overset{\sim N}{\beta_k} \; \boldsymbol{f}^{n-k}. \qquad (\textit{predictor}) \qquad \text{(A.1.9)}$$

The corrector and predictor truncation errors associated with (1.6) and (1.7) may be estimated using arguments similar to the Adams case. The result is

$$\boldsymbol{y}^{n+1}_{\text{true}} - \boldsymbol{y}^{n+1}_{\text{corr}} \approx h^{N+3}\alpha_{N+1}(d^{N+3}\boldsymbol{y}/dt^{N+3})|_{t=t^n}, \qquad \text{(A.1.10)}$$

$$\boldsymbol{y}^{n+1}_{\text{true}} - \boldsymbol{y}^{n+1}_{\text{pred}} \approx h^{N+3}\beta_{N+1}(d^{N+3}\boldsymbol{y}/dt^{N+3})|_{t=t^n}. \qquad \text{(A.1.11)}$$

Note that the predictor and corrector are one order higher accurate than their Adams counterparts. See (2.4.37) and (2.4.38). This increase in accuracy arises from the fact that the original differential equations being integrated are second order with no first derivatives present.

The coefficients α_k, β_k are listed in Table 1 below, and the associated coefficients $\overset{\sim N}{\alpha_k}, \overset{\sim N}{\beta_k}$ are listed in Tables 2 and 3.

Table 1

5				1	1578	5568	884504	1961426
6					-221	-1551	-368272	-1086220
7						190	90032	397724
8							-9829	-86752
9								8547

The denominator of each of the coefficients of the first line is to be repeated for all the coefficients of the corresponding column.

Table 3
The Størmer-Cowell Predictor Coefficients $\overset{\sim}{\beta}{}^{N}_{k}$.

k N	2	3	4	5	6	7	8	9
0	$\frac{13}{12}$	$\frac{14}{12}$	$\frac{299}{240}$	$\frac{317}{240}$	$\frac{168398}{120960}$	$\frac{176648}{120960}$	$\frac{5537111}{3628800}$	$\frac{5766235}{3628800}$
1	−2	−5	−176	−266	−185844	−243594	−9209188	−11271304
2	1	4	194	374	317946	491196	21390668	29639132
3		−1	−96	−276	−311704	−600454	−31323196	−50569612
4			19	109	184386	473136	30831050	59700674
5				−18	−60852	−234102	−20331636	−49202260
6					8630	66380	8646188	27892604
7						−8250	−2148868	−10397332
8							237671	2299787
9								−229124

The denominator of each of the coefficients of the first line is to be repeated for all the coefficients of the corresponding column. Note that the entries for $N = 6$ and $N = 7$ are not reduced to lowest terms. Both numerator and denominator should be divided by two.

Exercises

A.1.1. Make a study of the $\overset{\sim}{\alpha}$'s and $\overset{\sim}{\beta}$'s similar to that made in Exercise 2.4.4 for the $\tilde{a}$'s and $\tilde{b}$'s.

A.2 Summed Formulation

In principle the integration formulas (1.8) and (1.9) can be used as they stand. However in practice it has been found that a so called *summed* formulation has better performance with respect to round-off errors. It also reduces the truncation error by an additional factor of h without requiring additional starting values. Because the derivation of the summed formulation is a bit involved, we shall first state the procedure, and then provide the derivation.

A.2.1 Procedure

Suppose we know the values $\boldsymbol{y}^0 \cdots \boldsymbol{y}^N$ and $\boldsymbol{f}^0 \cdots \boldsymbol{f}^N$ from some starting routine such as Runge-Kutta. [Note that to use standard Runge-Kutta, one must first convert the set (1.1) into a first-order set. There are variants of Runge-Kutta due to *Nyström* that work directly with (1.1). See Section 5 at the end of this appendix.] We use the starting values to make some preparatory calculations. Define vectors $\boldsymbol{G}^n$ for $n = -1, 0, \cdots, N$ by the rule

$$\boldsymbol{G}^{-1} = 0, \tag{A.2.1}$$

$$\boldsymbol{G}^n = h \sum_{m=0}^{n} \boldsymbol{f}^m \ \text{ for } n \in [0, N].$$

Next define a vector $\boldsymbol{\sigma}$ using

$$\boldsymbol{\sigma} = h^{-1}(\boldsymbol{y}^N - \boldsymbol{y}^{N-1}) - \sum_{k=0}^{N+1} \overset{\sim}{\alpha}{}_k^{N+1}\, \boldsymbol{G}^{N-k}. \tag{A.2.2}$$

Finally, define vectors $\boldsymbol{g}^n$ for $n = -1, 0, \cdots, N$ by writing

$$\boldsymbol{g}^n = \boldsymbol{G}^n + \boldsymbol{\sigma}. \tag{A.2.3}$$

This completes the preparatory calculations.

The integration routine itself is given by the rules

$$\boldsymbol{y}^{n+1} = \boldsymbol{y}^n + h \sum_{k=0}^{N+1} \overset{\sim}{\alpha}{}_k^{N+1}\, \boldsymbol{g}^{n+1-k}, \qquad (\textit{corrector}) \tag{A.2.4}$$

$$\boldsymbol{y}^{n+1} = \boldsymbol{y}^n + h \sum_{k=0}^{N+1} \overset{\sim}{\beta}{}_k^{N+1}\, \boldsymbol{g}^{n-k}, \qquad (\textit{predictor}) \tag{A.2.5}$$

$$\boldsymbol{g}^{n+1} = \boldsymbol{g}^n + h\boldsymbol{f}^{n+1}. \tag{A.2.6}$$

Their truncation errors have the estimates

$$\boldsymbol{y}^{n+1}_{\text{true}} - \boldsymbol{y}^{n+1}_{\text{corr}} \approx h^{N+4}\alpha_{N+2}(d^{N+4}\boldsymbol{y}/dt^{N+4})|_{t=t^n}, \tag{A.2.7}$$

$$\boldsymbol{y}^{n+1}_{\text{true}} - \boldsymbol{y}^{n+1}_{\text{pred}} \approx h^{N+3}\beta_{N+1}(d^{N+3}\boldsymbol{y}/dt^{N+3})|_{t=t^n}. \tag{A.2.8}$$

Note that the corrector error is a factor of h smaller than that of the predictor. Whether or not this improvement in accuracy is realized in practice depends upon how many times the corrector is iterated. It can be shown that the simplest sequence *PEC* is insufficient. For this reason, and to check the convergence of successive iterations, it is better to use the sequences *PECEC* or *PECECE*.

A.2.2 Derivation

We now present the derivation for this procedure. We begin by rewriting (1.6) and (1.7) with an upper summation limit of $N + 1$:

$$\nabla^2 \boldsymbol{y}^{n+1} = h^2 \sum_{k=0}^{N+1} \alpha_k \nabla^k \boldsymbol{f}^{n+1}, \qquad (\textit{corrector}) \tag{A.2.9}$$

$$\nabla^2 \boldsymbol{y}^{n+1} = h^2 \sum_{k=0}^{N+1} \beta_k \nabla^k \boldsymbol{f}^{n}. \qquad (\textit{predictor}) \tag{A.2.10}$$

We observe that the vectors $\boldsymbol{g}^n$ obey the rules

$$\boldsymbol{g}^{-1} = \boldsymbol{\sigma}, \tag{A.2.11}$$

$$\boldsymbol{g}^n = h \sum_{m=0}^{n} \boldsymbol{f}^m + \boldsymbol{\sigma} \text{ for } n \geq 0.$$

It is easily checked that

$$\nabla \boldsymbol{g}^n = h\boldsymbol{f}^n \text{ for } n \geq \ 0. \tag{A.2.12}$$

Insert (2.12) into (2.9). The result is

$$\nabla^2 \boldsymbol{y}^{n+1} = h\nabla \sum_{k=0}^{N+1} \alpha_k \nabla^k \boldsymbol{g}^{n+1}. \tag{A.2.13}$$

Suppose we could peel off a ∇ from each side of (2.13). The result would be

$$\nabla \boldsymbol{y}^{n+1} = h \sum_{k=0}^{N+1} \alpha_k \nabla^k \boldsymbol{g}^{n+1}. \tag{A.2.14}$$

Normally this operation is not justified since, by (2.4.5), the two sides of (2.14) could differ by a *constant* vector. However, in our case we assert that the value of $\boldsymbol{\sigma}$ was cleverly defined in (2.2) to insure that (2.14) would be correct. To check this claim, set $n+1 = N$ in (2.14). The result, using (2.3), is

$$\nabla \boldsymbol{y}^N = h\alpha_o \boldsymbol{\sigma} + h \sum_{k=0}^{N+1} \alpha_k \nabla^k \boldsymbol{G}^N. \tag{A.2.15}$$

From Table 1 we find $\alpha_o = 1$, and, after expansion, we see that (2.15) is equivalent to (2.2). Thus (2.14) is correct. Upon expansion it gives the corrector (2.4).

Let us now work on the predictor (2.10). Use of (2.12) gives

$$\nabla^2 \boldsymbol{y}^{n+1} = h\nabla \sum_{k=0}^{N+1} \beta_k \nabla^k \boldsymbol{g}^n. \tag{A.2.16}$$

Again we peel off a ∇ from each side, but this time we must insert a constant vector $\boldsymbol{c}$. The result is

$$\nabla \boldsymbol{y}^{n+1} = h \sum_{k=0}^{N+1} \beta_k \nabla^k \boldsymbol{g}^n + \boldsymbol{c}. \tag{A.2.17}$$

What should $\boldsymbol{c}$ be? We shall see that to within sufficient accuracy it can be set to zero. Assuming this to be the case, the expansion of (2.17) gives the predictor (2.5).

We now estimate the size of $\boldsymbol{c}$. From the analog of (2.4.20) for $\boldsymbol{g}$ we find

$$\boldsymbol{g}^n = (1 - \nabla)\boldsymbol{g}^{n+1} \tag{A.2.18}$$

so that (2.17) can also be written as

$$\nabla \boldsymbol{y}^{n+1} = h(1-\nabla)\sum_{k=0}^{N+1} \beta_k \nabla^k \boldsymbol{g}^{n+1} + \boldsymbol{c}. \tag{A.2.19}$$

Subtract (2.14) from (2.19). The result is

$$\boldsymbol{c} = h[\sum_{k=0}^{N+1} \alpha_k \nabla^k - (1-\nabla)\sum_{k=0}^{N+1} \beta_k \nabla^k]\boldsymbol{g}^{n+1}. \tag{A.2.20}$$

From their definition in (1.4) and (1.5), the coefficients α_k and β_k satisfy the identity

$$(1-z)\sum_0^\infty \beta_k z^k = \sum_0^\infty \alpha_k z^k. \tag{A.2.21}$$

It follows that

$$\sum_{k=0}^{N+1} \alpha_k \nabla^k - (1-\nabla)\sum_{k=0}^{N+1} \beta_k \nabla^k = \beta_{N+1}\nabla^{N+2}. \tag{A.2.22}$$

Using (2.12) and (2.22), the expression for $\boldsymbol{c}$ can be simplified to give

$$\boldsymbol{c} = h^2 \beta_{N+1} \nabla^{N+1} \boldsymbol{f}^{n+1}. \tag{A.2.23}$$

Finally, remembering that $\boldsymbol{f} = \ddot{\boldsymbol{y}}$ and using (2.4.12) we find

$$\boldsymbol{c} \approx h^{N+3}\beta_{N+1}(d^{N+3}\boldsymbol{y}/dt^{N+3})|_{t=t^n}. \tag{A.2.24}$$

Since (2.17) is equivalent to (2.10), we know it has the intrinsic error given in (1.11) with N replaced by $N+1$. This error is of order h smaller than $\boldsymbol{c}$. Thus the error made in dropping $\boldsymbol{c}$ is the dominant predictor error, and (2.8) is correct.

Exercises

A.2.1. Verify (2.21).

A.3 Computation of First Derivative

It often happens that values of $\dot{\boldsymbol{y}}$ are required at various points of a trajectory. For example, from time to time we may need the velocity to compute the energy. If the trajectory is being integrated with the Adams method, the velocity is available at each step. However, with Størmer-Cowell only the coordinates $\boldsymbol{y}^n$ are computed.

This apparent defect can be overcome with numerical differentiation. We observe that by using (2.4.13) the equation

$$\dot{\boldsymbol{y}}^{n+1} = D\boldsymbol{y}^{n+1} \tag{A.3.1}$$

can be written in the form

$$\dot{\boldsymbol{y}}^{n+1} = -h^{-1}\ \log(1-\nabla)\boldsymbol{y}^{n+1}. \tag{A.3.2}$$

To use (3.2) as it stands requires the storage of previous $\boldsymbol{y}$'s. However, we may rewrite it in the form

$$\dot{\boldsymbol{y}}^{n+1} = -h^{-1}[\log(1-\nabla)/\nabla]\nabla\boldsymbol{y}^{n+1}, \tag{A.3.3}$$

or using (2.14),

$$\dot{\boldsymbol{y}}^{n+1} = -[\log(1-\nabla)/\nabla]\sum_{0}^{N+1}\alpha_k\nabla^k\boldsymbol{g}^{n+1}. \tag{A.3.4}$$

From the definition of the coeffients a_k and α_k [see (2.4.23), (1.4), and (1.6)] we learn that

$$-\ [\log(1-z)/z]\sum_{0}^{\infty}\alpha_k z^k = \sum_{0}^{\infty}a_k z^k. \tag{A.3.5}$$

Consequently, we also may write to within sufficient accuracy

$$\dot{\boldsymbol{y}}^{n+1} = \sum_{k=0}^{N+2}a_k\nabla^k\boldsymbol{g}^{n+1}, \tag{A.3.6}$$

or expanding out,

$$\dot{\boldsymbol{y}}^{n+1} = \sum_{k=0}^{N+2}\tilde{a}_k^{N+2}\ \boldsymbol{g}^{n+1-k}. \tag{A.3.7}$$

We conclude that $\dot{\boldsymbol{y}}$ can be computed in terms of the stored $\boldsymbol{g}$'s any time it is required. [If the reader is wondering about the upper summation limit of $N+2$ in (3.6) and (3.7), it is not a misprint. He or she should see Exercise 4.2 at the end of Section A.4.]

Exercises

A.3.1. Verify (3.5).

A.4 Example Program and Numerical Results

We show below, with some associated subroutines, a summed Størmer-Cowell program.

A.4.1 Program

The program is written to solve (2.2.5) with the initial conditions (2.2.6). We have set $N=3$ and $h=1/10$, and the solution is initiated with the Runge-Kutta routine rk3 using a step size of $h/20$.

Exercises

A.4.1. Compare the error estimate (2.7) with the actual error made in the example above.

A.4.2. Check the derivation of (3.7) and find a formula similar to (2.7) for the expected error in $\dot{\boldsymbol{y}}$. Compare with the error in the example above. Suppose the sum in (3.6) were terminated at $N+1$. Show that the error in its expanded form, the analog of (3.7), would then be larger.

A.5 Nyström Runge-Kutta Methods

We close this appendix with a brief description of Nyström Runge-Kutta (NRK) methods. They are analogous to ordinary Runge-Kutta methods, but are designed to work directly with second-order equations of the form (1.1). We will present methods that are analogous to the Runge-Kutta methods RK3 given by (2.3.2), (2.3.3) and RK4 given by (2.3.4), (2.3.5). Unlike Størmer-Cowell methods, we will need integration formulas for both $\boldsymbol{y}$ and $\dot{\boldsymbol{y}}$.

The method that is analogous to RK3 is given by

$$\boldsymbol{y}^{n+1} = \boldsymbol{y}^n + h\dot{\boldsymbol{y}}^n + (h^2/6)(\boldsymbol{a} + 2\boldsymbol{b}), \tag{A.5.1}$$

$$\dot{\boldsymbol{y}}^{n+1} = \dot{\boldsymbol{y}}^n + (h/6)(\boldsymbol{a} + 4\boldsymbol{b} + \boldsymbol{c}), \tag{A.5.2}$$

where at each step

$$\boldsymbol{a} = \boldsymbol{f}(\boldsymbol{y}^n, t^n), \tag{A.5.3}$$

$$\boldsymbol{b} = \boldsymbol{f}[\boldsymbol{y}^n + (h/2)\dot{\boldsymbol{y}}^n + (h^2/8)\boldsymbol{a}, t^n + h/2], \tag{A.5.4}$$

$$\boldsymbol{c} = \boldsymbol{f}[\boldsymbol{y}^n + h\dot{\boldsymbol{y}}^n + (h^2/2)\boldsymbol{b}, t^n + h]. \tag{A.5.5}$$

This is a three-stage fourth-order method. That is, it is locally correct through order h^4, and makes local errors of order h^5. Note that this method is one order higher in accuracy than its counterpart RK3. Accordingly, we will call it NRK4. This increase in accuracy again arises from the fact that the original differential equations being integrated are second order with no first derivatives present.

The method that is analogous to RK4 is given by

$$\boldsymbol{y}^{n+1} = \boldsymbol{y}^n + h\dot{\boldsymbol{y}}^n + (h^2/192)(23\boldsymbol{a} + 75\boldsymbol{b} - 27\boldsymbol{c} + 25\boldsymbol{d}), \tag{A.5.6}$$

$$\dot{\boldsymbol{y}}^{n+1} = \dot{\boldsymbol{y}}^n + (h/192)(23\boldsymbol{a} + 125\boldsymbol{b} - 81\boldsymbol{c} + 125\boldsymbol{d}), \tag{A.5.7}$$

where at each step

$$\boldsymbol{a} = \boldsymbol{f}(\boldsymbol{y}^n, t^n), \tag{A.5.8}$$

$$\boldsymbol{b} = \boldsymbol{f}[\boldsymbol{y}^n + (2/5)h\dot{\boldsymbol{y}}^n + (2/25)h^2\boldsymbol{a}, t^n + (2/5)h], \tag{A.5.9}$$

$$\boldsymbol{c} = \boldsymbol{f}[\boldsymbol{y}^n + (2/3)h\dot{\boldsymbol{y}}^n + (2/9)h^2\boldsymbol{a}, t^n + (2/3)h], \tag{A.5.10}$$

$$\boldsymbol{d} = \boldsymbol{f}[\boldsymbol{y}^n + (4/5)h\dot{\boldsymbol{y}}^n + (4/25)h^2(\boldsymbol{a} + \boldsymbol{b}), t^n + (4/5)h]. \tag{A.5.11}$$

This is a four-stage fifth-order method, and is again one order higher in accuracy than its counterpart RK4. Accordingly, we will call it NRK5.

Nyström Runge-Kutta methods can also be described in terms of Butcher tableaux. Let $\bar{b}$, b, and c be s-dimensional vectors with real entries, and let $\bar{a}$ be an $s \times s$ matrix with real entries. Consider stepping formulas of the form

$$\boldsymbol{y}^{n+1} = \boldsymbol{y}^n + h\dot{\boldsymbol{y}}^n + h^2 \sum_{i=1}^{s} \bar{b}_i \boldsymbol{k}_i, \tag{A.5.12}$$

$$\dot{\boldsymbol{y}}^{n+1} = \dot{\boldsymbol{y}}^n + h \sum_{i=1}^{s} b_i \boldsymbol{k}_i, \tag{A.5.13}$$

where at each step

$$\boldsymbol{k}_i = \boldsymbol{f}(\boldsymbol{y}^n + hc_i\dot{\boldsymbol{y}}^n + h^2 \sum_{j=1}^{s} \bar{a}_{ij}\boldsymbol{k}_j,\ t^n + c_i h). \tag{A.5.14}$$

Evidently the procedures (5.1) through (5.5) and (5.6) through (5.11) are of this form.

In terms of the the notation just introduced, the general problem now is to impose various conditions on the vectors $\bar{b}$, b, and c and the matrix $\bar{a}$ so that the integration method will be of some particular order m, and perhaps have some other desirable properties. For this purpose, it is convenient to arrange the vectors $\bar{b}$, b, and c and the matrix $\bar{a}$ into a tableau (again called a Butcher tableau) of the form

$$\begin{array}{c|ccc} c_1 & \bar{a}_{11} & \cdots & \bar{a}_{1s} \\ \vdots & \vdots & & \vdots \\ c_s & \bar{a}_{s1} & \cdots & \bar{a}_{ss} \\ \hline & & & \\ & \bar{b}_1 & \cdots & \bar{b}_s \\ \hline & b_1 & \cdots & b_s \end{array}\ . \tag{A.5.15}$$

The Butcher tableau for NRK4, the method (5.1) through (5.5), is

$$\begin{array}{c|ccc} 0 & 0 & 0 & 0 \\ 1/2 & 1/8 & 0 & 0 \\ 1 & 0 & 1/2 & 0 \\ \hline & 1/6 & 2/6 & 0 \\ \hline & 1/6 & 4/6 & 1/6 \end{array} . \tag{A.5.16}$$

The Butcher tableau for NRK5, the method (5.6) through (5.11), is

$$\begin{array}{c|cccc} 0 & 0 & 0 & 0 & 0 \\ 2/5 & 2/25 & 0 & 0 & 0 \\ 2/3 & 2/9 & 0 & 0 & 0 \\ 4/5 & 4/25 & 4/25 & 0 & 0 \\ \hline & 23/192 & 75/192 & -27/192 & 25/192 \\ \hline & 23/192 & 125/192 & -81/192 & 125/192 \end{array} . \tag{A.5.17}$$

At this point we observe that, as in the case of ordinary Runge Kutta, it is sometimes useful to rewrite the relations (5.12) through (5.14) in a somewhat different form. At each step introduce intermediate times t_i and coordinates $\boldsymbol{y}_i$ by the rules

$$t_i = t^n + c_i h, \tag{A.5.18}$$

$$\boldsymbol{y}_i = \boldsymbol{y}^n + hc_i\dot{\boldsymbol{y}}^n + h^2\sum_{j=1}^{s}\bar{a}_{ij}\boldsymbol{k}_j. \tag{A.5.19}$$

With this convention (5.14) can be rewritten in the form

$$\boldsymbol{k}_i = \boldsymbol{f}(\boldsymbol{y}_i, t_i). \tag{A.5.20}$$

Finally we copy (5.12) and (5.13) and place them last,

$$\boldsymbol{y}^{n+1} = \boldsymbol{y}^n + h\dot{\boldsymbol{y}}^n + h^2\sum_{i=1}^{s}\bar{b}_i\boldsymbol{k}_i, \tag{A.5.21}$$

$$\dot{\boldsymbol{y}}^{n+1} = \dot{\boldsymbol{y}}^n + h\sum_{i=1}^{s}b_i\boldsymbol{k}_i, \tag{A.5.22}$$

Evidently the relations (5.18) through (5.22) are equivalent to the relations (5.12) through (5.14), but in this expanded form it is clear that the $\boldsymbol{k}_i$ are the values of $\boldsymbol{f}$ at the intermediate points t_i, $\boldsymbol{y}_i$.

Finally, we remark that there are Nyström counterparts to embedded Runge-Kutta pairs so that it is possible to develop Nyström procedures with adaptive step-size control. Also, as described in Section 12.2, there are symplectic Nyström-Runge-Kutta procedures. See the books of Hairer *et al.* and Sanz-Serna and Calvo listed in the bibliography at the end of this appendix.

Exercises

A.5.1. Apply one step of the fourth-order Nyström method (5.1) through (5.5) to the differential equation

$$\ddot{y} = t^2 \tag{A.5.23}$$

with the initial conditions

$$y(0) = 0 \text{ and } \dot{y}(0) = 0. \tag{A.5.24}$$

That is, use (5.1) and (5.2) to compute $y(h)$ and $\dot{y}(h)$. Verify that your result has the advertised accuracy. Repeat the calculation for the case $\ddot{y} = t^3$, and show that, as expected, the result is not exact.

Appendix B

Computer Programs for Numerical Integration

In this appendix we list computer programs that are more efficient versions of those described in Chapter 2. The programs are all subroutines, and need to be supplemented by a main calling program and input and output statements of the reader's own design. For the most part, the programs are self-explanatory. All the integration programs call the subroutine *eval* (or *feval*), which computes the vector $\boldsymbol{f}$ appearing in the differential equation $\dot{\boldsymbol{y}} = \boldsymbol{f}(\boldsymbol{y}, t)$. To change from one set of differential equations to another, it is only necessary to change *eval.* The integration routines themselves are general purpose. One only need specify *ne*, the number of equations to be simultaneously integrated. As listed, the routines are set up to integrate the equation used in the Examples in Chapter 2, *i.e.* $\ddot{x} + x = 2t$.

The routines given in this appendix are suitable for *semi-serious* use. Readers who wish to pursue numerical integration in a serious way may wish to use a canned integration package. Much work has gone into writing some such routines. However, the reader should be sure to understand how the package he or she has selected actually works. Some produce unpleasant surprises. See the references at the end of Chapter 2.

B.1 A 3^{rd} Order Runge-Kutta Routine

B.1.1 Butcher Tableau for $RK3$

The Butcher tableau for $RK3$ is given in (2.3.9).

B.1.2 The Routine $RK3$

```
      subroutine rk3 (h,ns,nf,t,y)
c This is a Runge Kutta routine that makes local errors of order
c h**4.  h is the step size, ns is the number of steps, t is the
c time, and y is the dependent variable array.  Finally, nf is a
c flag to control whatever.
c In the next line, put in after ne the number of equations to be
c integrated.
      parameter (ne=2)
      dimension y(ne),yt(ne),f(ne),a(ne),b(ne),c(ne)
c yt is a temporary storage array and f is ydot.
c a, b, and c are used in integration.
      tint=t
c tint is the initial time.
      do 100 i=1,ns
      call eval (t,y,f)
c eval is a subroutine that evaluates ydot.
      do 10 j=1,ne
   10 a(j)=h*f(j)
      do 20 j=1,ne
   20 yt(j)=y(j)+.5*a(j)
      tt=t+.5*h
c tt is a temporary time
      call eval (tt,yt,f)
      do 30 j=1,ne
   30 b(j)=h*f(j)
      do 40 j=1,ne
   40 yt(j)=y(j)+2.*b(j)-a(j)
      tt=t+h
      call eval (tt,yt,f)
      do 50 j=1,ne
   50 c(j)=h*f(j)
      do 60 j=1,ne
   60 y(j)=y(j)+(a(j)+4.*b(j)+c(j))/6.
      t=tint+float(i)*h
  100 continue
      return
      end
```

Note: The *flag* `nf` is not actually used. It is incorporated to make the program easier to modify.

B.2 A 4^{th} Order Runge-Kutta Routine

B.2.1 Butcher Tableau for $RK4$

The Butcher tableau for $RK4$ is given in (2.3.10).

B.2.2 The Routine $RK4$

```
      subroutine rk4 (h,ns,nf,t,y)
c This is a Runge Kutta routine that makes local errors of order
c h**5.  h is the step size, ns is the number of steps, t is the
c time, and y is the dependent variable array.  Finally, nf is a
c flag to control whatever.
c In the next line, put in after ne the number of equations to be
c integrated.
      parameter (ne=2)
      dimension y(ne),yt(ne),f(ne),a(ne),b(ne),c(ne),d(ne)
c yt is a temporary storage array and f is ydot.
c a, b, c, and d are used in integration.
      tint=t
c tint is the initial time.
      do 100 i=1,ns
      call eval (t,y,f)
c eval is a subroutine that evaluates ydot.
      do 10 j=1,ne
   10 a(j)=h*f(j)
      do 20 j=1,ne
   20 yt(j)=y(j)+.5*a(j)
      tt=t+.5*h
c tt is a temporary time
      call eval (tt,yt,f)
      do 30 j=1,ne
   30 b(j)=h*f(j)
      do 40 j=1,ne
   40 yt(j)=y(j)+.5*b(j)
      call eval (tt,yt,f)
      do 50 j=1,ne
   50 c(j)=h*f(j)
      do 60 j=1,ne
   60 yt(j)=y(j)+c(j)
      tt=t+h
      call eval (tt,yt,f)
      do 70 j=1,ne
   70 d(j)=h*f(j)
      do 80 j=1,ne
   80 y(j)=y(j)+(a(j)+2.*b(j)+2.*c(j)+d(j))/6.
      t=tint+float(i)*h
  100 continue
      return
      end
```

Note: The *flag* `nf` is not actually used. It is incorporated to make the program easier to modify.

B.3 A Subroutine to Compute f

```
      subroutine eval (t,y,f)
c This is a subroutine that evaluates ydot.
      dimension y(*),f(*)
c In the following lines put in the expressions for the f(i).
      f(1)=y(2)
      f(2)=2.*t-y(1)
      return
      end
```

B.4 A Partial Double-Precision Version of $RK3$

```
      subroutine rk3pdp (h,ns,nf,t,y)
c This is a Runge Kutta routine that works in partial double precision
c and makes local errors of order h**4.  h is the step size, ns is the
c number of steps, t is the time, and y is the dependent variable array.
c Finally, nf is a flag to control whatever.
c In the next line, put in after ne the number of equations to be
c integrated.
      parameter (ne=2)
      dimension y(ne),yt(ne),f(ne),a(ne),b(ne),c(ne),yd(ne)
      double precision yd
c yt is a temporary storage array and f is ydot.
c yd is a double precision storage array.
c a, b, and c are used in integration.
      tint=t
c tint is the initial time.
      do 2 j=1,ne
    2 yd(j)=dble(y(j))
c The input array y is transferred into the double precision array yd.
c Beginning of rk3 loop.
      do 100 i=1,ns
      call eval (t,y,f)
c eval is a subroutine that evaluates ydot.
      do 10 j=1,ne
   10 a(j)=h*f(j)
      do 20 k=1,ne
   20 yt(j)=y(j)+.5*a(j)
      tt=t+.5*h
c tt is a temporary time
      call eval (tt,yt,f)
      do 30 j=1,ne
   30 b(j)=h*f(j)
      do 40 j=1,ne
   40 yt(j)=y(j)+2.*b(j)-a(j)
      tt=t+h
      call eval (tt,yt,f)
      do 50 j=1,ne
   50 c(j)=h*f(j)
      do 60 j=1,ne
   60 yd(j)=yd(j)+dble((a(j)+4.*b(j)+c(j))/6.)
c The array yd is incremented in double precision.
      t=tint+float(i)*h
      do 70 j=1,ne
   70 y(j)=sngl(yd(j))
c Preparation of y for transfer out or the next run through the loop.
  100 continue
      return
      end
```

The *error curve* for this routine is exactly the same as that given in Figure (2.3.1) when the step size h is .05 or larger. However, for smaller h the error curve is much better. The error continues to decrease as h^3 until h reaches a value a little less than 10^{-7} and then remains approximately constant as h is decreased further. This is because the only serious round-off error occurs in the statement $y(j) = sngl(yd(j))$, and this error is independent of the number of steps. We see that partial double precision is worthwhile if good accuracy is required.

B.5 A 6^{th} Order 8 Stage Runge-Kutta Routine

This section describes a sixth-order eight-stage Runge-Kutta routine. Note that, according to Table 2.3.1, it should be possible to achieve sixth-order accuracy using seven stages. Therefore the routine in this section, while workable, is not optimal with regard to employing only the minimum number of required stages. On the other hand, again according to Table 2.3.1, there is no eight-stage method that has an order higher than six.

B.5.1 Butcher Tableau for $RK6$

The Butcher tableau for RK6 is

$$\begin{array}{c|cccccccc}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1/2 & 1/2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1/2 & 0 & 1/2 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
\hline
 & 1/6 & 2/6 & 2/6 & 1/6 & * & * & * & *
\end{array} . \tag{B.5.1}$$

B.5.2 The Routine $RK6$

```
      subroutine rk6(h,ns,t,y)
c  Written by Rob Ryne, Spring 1986, based on a routine of
c  J. Milutinovic.
c  For a reference, see page 76 of F. Ceschino and J. Kuntzmann,
c  Numerical Solution of Initial Value Problems, Prentice Hall 1966.
c  This integration routine makes local truncation errors at each
c  step of order h**7.
c  That is, it is locally correct through terms of order h**6.
c  Each step requires 8 function evaluations: The method has
c  8 stages.
c
      implicit double precision (a-h,o-z)
c
      parameter (ne=2)
      dimension y(ne),yt(ne),f(ne),a(ne),b(ne),c(ne),d(ne),
     # e(ne),g(ne),o(ne),p(ne)
c
      tint=t
      do 200 i=1,ns
      call feval(t,y,f)
      do 10 j=1,ne
   10 a(j)=h*f(j)
      do 20 j=1,ne
   20 yt(j)=y(j)+a(j)/9.d+0
      tt=t+h/9.d+0
      call feval(tt,yt,f)
      do 30 j=1,ne
   30 b(j)=h*f(j)
      do 40 j=1,ne
   40 yt(j)=y(j) + (a(j) + 3.d+0*b(j))/24.d+0
      tt=t+h/6.d+0
      call feval(tt,yt,f)
      do 50 j=1,ne
   50 c(j)=h*f(j)
      do 60 j=1,ne
   60 yt(j)=y(j)+(a(j)-3.d+0*b(j)+4.d+0*c(j))/6.d+0
      tt=t+h/3.d+0
      call feval(tt,yt,f)
      do 70 j=1,ne
   70 d(j)=h*f(j)
      do 80 j=1,ne
   80 yt(j)=y(j) + (-5.d+0*a(j) + 27.d+0*b(j) -
     # 24.d+0*c(j) + 6.d+0*d(j))/8.d+0
      tt=t+.5d+0*h
      call feval(tt,yt,f)
      do 90 j=1,ne
   90 e(j)=h*f(j)
      do 100 j=1,ne
  100 yt(j)=y(j) + (221.d+0*a(j) - 981.d+0*b(j) +
     # 867.d+0*c(j)- 102.d+0*d(j) + e(j))/9.d+0
      tt = t+2.d+0*h/3.d+0
      call feval(tt,yt,f)
      do 110 j=1,ne
  110 g(j)=h*f(j)
      do 120 j=1,ne
  120 yt(j) = y(j)+(-183.d+0*a(j)+678.d+0*b(j)-472.d+0*c(j)-
     #  66.d+0*d(j)+80.d+0*e(j) + 3.d+0*g(j))/48.d+0
      tt = t + 5.d+0*h/6.d+0
      call feval(tt,yt,f)
      do 130 j=1,ne
  130 o(j)=h*f(j)
      do 140 j=1,ne
  140 yt(j) = y(j)+(716.d+0*a(j)-2079.d+0*b(j)+1002.d+0*c(j)+
     # 834.d+0*d(j)-454.d+0*e(j)-9.d+0*g(j)+72.d+0*o(j))/82.d+0
      tt = t + h
      call feval(tt,yt,f)
      do 150 j=1,ne
  150 p(j)=h*f(j)
      do 160 j=1,ne
  160 y(j) = y(j)+(41.d+0*a(j)+216.d+0*c(j)+27.d+0*d(j)+
     #  272.d+0*e(j)+27.d+0*g(j)+216.d+0*o(j)+41.d+0*p(j))/840.d+0
      t=tint+i*h
  200 continue
      return
      end
```

Note: This program calls the subroutine `feval`, which is another name for `eval`.

B.6 Embedded Runge-Kutta Pairs

In this section we will describe the construction of Runge-Kutta pairs and provide two examples. Our discussion here is meant to provide background, but not actual code. As in the case of other adaptive codes, much time has been spent by professional mathematicians and numerical analysts writing optimal code for embedded Runge-Kutta procedures. Readers are advised not to try writing such code on their own without first exploring existing programs and without being prepared to expend considerable time and effort.

B.6.1 Preliminaries

Section 2.5.1 sketched the possibility of pairs of Runge-Kutta methods whose orders differ (usually by one) and that, in making one integration step, share many or all intermediate evaluation points. By subtracting the higher-order result from the lower-order result, one can estimate the error in the lower-order result, and adjust the step size accordingly. In this section we will describe two examples of Runge-Kutta pairs. Each example has the feature that both methods of each pair employ the same $\boldsymbol{k}$ vectors. Thus both methods can be carried out simultaneously with little added expense.

Equations (2.3.6) through (2.3.8) described the general Runge-Kutta method and its characterization by an associated Butcher table. If there are two methods that utilize the same $\boldsymbol{k}$ vectors, we may make definitions of the form

$$\boldsymbol{y}^{n+1} = \boldsymbol{y}^n + h\sum_{i=1}^{s} b_i\boldsymbol{k}_i, \quad \text{stepping formula} \tag{B.6.1}$$

$$\hat{\boldsymbol{y}}^{n+1} = \boldsymbol{y}^n + h\sum_{i=1}^{s} \hat{b}_i\boldsymbol{k}_i, \quad \text{error estimator} \tag{B.6.2}$$

where at each step

$$\boldsymbol{k}_i = \boldsymbol{f}(\boldsymbol{y}^n + h\sum_{j=1}^{s} a_{ij}\boldsymbol{k}_j,\ t^n + c_i h). \tag{B.6.3}$$

This pair of methods may be described by an extended Butcher tableau of the form

$$\begin{array}{c|ccc}
c_1 & a_{11} & \cdots & a_{1s} \\
\vdots & \vdots & & \vdots \\
c_s & a_{s1} & \cdots & a_{ss} \\
\hline
 & b_1 & \cdots & b_s \\
\hline
 & \hat{b}_1 & \cdots & \hat{b}_s
\end{array} \tag{B.6.4}$$

As the annotation is intended to indicate, the relation (6.1) is to be used as a stepping formula to propagate the solution, and the relation (6.2) is to be used in conjunction with (6.1) to estimate and control the local error in making a given step.

B.6.2 Fehlberg 4(5) Pair

Fehlberg was the first to propose and develop embedded pairs. One such pair, called Fehlberg 4(5), is that described by the (extended) Butcher tableau below:

Butcher Tableau for Fehlberg 4(5)

$$\begin{array}{c|cccccc}
0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{4} & \frac{1}{4} & 0 & 0 & 0 & 0 & 0 \\
\frac{3}{8} & \frac{3}{32} & \frac{9}{32} & 0 & 0 & 0 & 0 \\
\frac{12}{13} & \frac{1932}{2197} & -\frac{7200}{2197} & \frac{7296}{2197} & 0 & 0 & 0 \\
1 & \frac{439}{216} & -8 & \frac{3680}{513} & -\frac{845}{4104} & 0 & 0 \\
\frac{1}{2} & -\frac{8}{27} & 2 & -\frac{3544}{2565} & \frac{1859}{4104} & -\frac{11}{40} & 0 \\
\hline
 & \frac{25}{216} & 0 & \frac{1408}{2565} & \frac{2197}{4104} & -\frac{1}{5} & 0 \\
\hline
 & \frac{16}{135} & 0 & \frac{6656}{12825} & \frac{28561}{56430} & -\frac{9}{50} & \frac{2}{55}
\end{array} \tag{B.6.5}$$

The procedure has $s = 6$ stages. The stepping formula is locally exact through terms of order h^4. The error estimator is locally exact through terms of order h^5. This procedure is therefore referred to as a 4(5) procedure. Because the stepping formula used to propagate the solution is of order 4, the whole procedure itself is locally exact through terms of order $m = 4$. Note that, according to Table 2.3.1, the highest order a 6-stage method can have is $m = 5$. Although the order 4 is relatively low in view of the number of stages involved, there is some freedom in selecting the entries in the matrix a and the vectors b and $\hat{b}$; and Fehlberg selected them to minimize the size of the order h^5 error terms in the stepping formula.

Error Estimation

Since $\boldsymbol{y}^{n+1}$ is locally exact through order 4 and $\hat{\boldsymbol{y}}^{n+1}$ is locally exact through order 5, we may define a local error vector $\boldsymbol{\Delta}^n$ by the rule

$$\boldsymbol{\Delta}^n = \boldsymbol{y}^{n+1} - \hat{\boldsymbol{y}}^{n+1} = h \sum_{i=1}^{6} d_i \boldsymbol{k}_i \tag{B.6.6}$$

where

$$d_i = b_i - \hat{b}_i. \tag{B.6.7}$$

Note that in this approach only $\boldsymbol{y}^{n+1}$ is computed using (6.1), $\hat{\boldsymbol{y}}^{n+1}$ is not computed, and $\boldsymbol{\Delta}^n$ is computed using the far right side of (6.6). So doing minimizes work and round-off error.

Control of Step Size

We now wish to use $||\boldsymbol{\Delta}^n||$ to control the subsequent step size h_{n+1} or to specify how to repeat, if necessary, the current step with a smaller step size.[1] Exactly how to do so is an art based on considerable experience with various possibilities, and is best left to professional numerical analysts. Typical programs require the user to specify some desired *tolerance* Tol and perhaps some initial step size h_0, and the program automatically adjusts the step size as the integration proceeds based on this information.[2] As is the case with adaptive predictor-corrector and extrapolation methods, the prospective user is advised to first try and understand programs professionally written before attempting to write any of his/her own.

Interpolation-Dense Output

When employing a fixed step size method it is easy to integrate from some initial time t^0 to the final time $t^0 + T$ simply by requiring the relation

$$Nh = T \tag{B.6.8}$$

between the step size h and the interval duration T. Recall Section 2.1. However, when the time step is variable, the time $t^0 + T$ is generally not among the times t^n at which the $\boldsymbol{y}^n$ are computed, and so the quantity $\boldsymbol{y}(t^0 + T)$ is not among the $\boldsymbol{y}^n$.

In the case of a Runge-Kutta method, since it is a single-step method, this problem of finding an accurate $\boldsymbol{y}(t^0 + T)$ is fairly easy to solve. First, over the course of integration, monitor the times t^n and find the first such time, call it t^{n^*}, for which

$$t^{n^*} \geq t^0 + T. \tag{B.6.9}$$

Next, define a step size h^* by the rule

$$h^* = t^0 + T - t^{n^*}. \tag{B.6.10}$$

Note that $h^* \leq 0$. Finally, execute one step of the Rung-Kutta method in use with the time step h^* and the initial condition $\boldsymbol{y}^{n^*}$. So doing determines $\boldsymbol{y}(t^0 + T)$ to the accuracy of the integration method. In effect, this method integrates backward from the time t^{n^*} to the time $t^0 + T$.

There are some situations, for example when graphical output is needed, in which one desires an accurate and efficient method for finding $\boldsymbol{y}(t^n + \theta h_n)$ for any $\theta \in [0, 1]$. There are procedures that prepare, at each integration step, polynomials in θ for this purpose, and these procedures utilize the $\boldsymbol{k}$ vectors computed in the course of a Runge-Kutta step. See, for example, the book of Hairer, Nørsett, and Wanner cited at the end of this appendix.

[1] For computational efficiency, in this application it is convenient to define the vector norm $|| * ||$ to be the component moduli sum norm (3.7.20).

[2] There are also procedures for determining h_0 automatically so that only Tol need be specified.

B.6.3 Dormand-Prince 5(4) Pair

Inspired by the work of Fehlberg, Dormand and Prince and others developed procedures for which the stepping formula is higher order than the error estimator, and the stepping formula is optimized to minimize its still higher-order error terms.[3] One procedure of Dormand and Prince is specified by the following Butcher tableau:

Butcher Tableau for Dormand-Prince 5(4)

$$\begin{array}{c|ccccccc}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{5} & \frac{1}{5} & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{3}{10} & \frac{3}{40} & \frac{9}{40} & 0 & 0 & 0 & 0 & 0 \\

\end{array} \tag{B.6.11}$$

The procedure has 7 stages. But the method for the stepping formula is FSAL, and therefore only requires the work of a 6-stage method after the first integration step. See the material at the end of Subsection 2.3.4. The stepping formula is locally exact through terms of order h^5. The error estimator is locally exact through terms of order h^4. This method is therefore referred to as a 5(4) method.[4] Because the stepping formula is of order 5, and is used to propagate the solution, the whole procedure itself is locally exact through terms of order $m = 5$. Note that, according to Table 2.3.1, the highest order a 6-stage method can have is $m = 5$. Thus the order is optimum in view of the effective number of stages involved. Moreover, there is still some freedom in selecting the entries in the matrix a and the vectors b and $\hat{b}$. As mentioned at the beginning of this subsection, Dormand and Prince selected them to minimize the size of the order h^6 error terms in the stepping formula.[5]

[3] Procedures that use the higher-order formula for stepping are called *local extrapolation* procedures. Note that here the word *extrapolation* has a different meaning than in Section 2.6.

[4] Some authors use the notation (4)5. However, whatever the notation, it is always the order of the stepping formula that is not in parentheses, and the order of the error estimator that is in parentheses.

[5] Why choose, for the stepping formula, a seven-stage FSAL method rather than a six-stage non-FSAL method? Both choices could yield a fifth-order stepping formula and a fourth-order error estimator. Dor-

Error Estimation

Since $\boldsymbol{y}^{n+1}$ is locally exact through order 5 and $\hat{\boldsymbol{y}}^{n+1}$ is locally exact through order 4, we may now define a local error vector $\boldsymbol{\Delta}^n$ by the rule

$$\boldsymbol{\Delta}^n = \hat{\boldsymbol{y}}^{n+1} - \boldsymbol{y}^{n+1} = -h \sum_{i=1}^{7} d_i \boldsymbol{k}_i. \tag{B.6.12}$$

Note that in carrying out the sum (6.12) the $i = 2$ term may be omitted since, according to (6.11), both b_2 and $\hat{b}_2$ vanish, and therefore $d_2 = 0$.

Control of Step Size

We again wish to use $||\boldsymbol{\Delta}^n||$ to control the step size. In this case it should be understood that what is now being controlled is the error in the lower order error estimator with the hope that, since it is of one order higher, the error in the stepping formula will be even better controlled. Again, there are several possible procedures, and again the prospective user is advised to first try and understand programs professionally written before attempting to write any of his/her own.

Interpolation-Dense Output

The same methods and considerations apply here as in Subsection 6.2.

mand and Prince found that by so doing they were better able to choose the entries in the matrix a and the vectors b and $\hat{b}$ to minimize the order h^6 error terms in the stepping formula.

B.7 A 5^{th} Order PECEC Adams Routine

```
      subroutine adams5 (h,ns,nf,t,y)
c This is an N=4 PECEC Adams routine that is locally correct
c through terms of order h**5 and makes local errors of
c order h**6.
c h is the step size, and ns is the number of steps.  t is the time, and
c y is the dependent variable array.  nf is a flag that controls the mode
c of entry.  If nf = 'start', the trajectory is started with Runge Kutta.
c If nf = 'cont', the solution is continued using previous "f" values.
c ns must exceed 4 when Adams is called with nf = 'start'.
c In the next line, put in after ne the number of equations to be
c integrated.
      parameter (ne=2)
      dimension y(ne),yp(ne),yc(ne),f1(ne),f2(ne),f3(ne),
     & f4(ne),f5(ne),f6(ne)
c yp and yc are corrector arrays.  f1 through f6 form the array of
c "f" values.
      dimension a(5),am(5),b(5),bm(5)
c a,am and b,bm are coefficients used in the corrector and predictor,
c respectively.
      data (a(i), i=1,5) /-19.,106.,-264.,646.,251./
      data (b(i), i=1,5) /251.,-1274.,2616.,-2774.,1901./
      save am,bm,f1,f2,f3,f4,f5
      nsa=ns
c nsa is the number of steps to be made by Adams.
      if (nf .eq. 'cont') go to 20
c When nf = 'cont', the integration has already been started earlier,
c and "f" values are assumed to exist.  Otherwise, start with Runge Kutta.
c Set up the initial f array using Runge Kutta.
      call eval (t,y,f1)
c eval is a subroutine that evaluates ydot.
      call rk3 (h/5.,5,0,t,y)
      call eval (t,y,f2)
      call rk3 (h/5.,5,0,t,y)
      call eval (t,y,f3)
      call rk3 (h/5.,5,0,t,y)
      call eval (t,y,f4)
      call rk3 (h/5.,5,0,t,y)
      call eval (t,y,f5)
c Now go into the finite difference procedure.
      nsa=ns-4
c nsa is the number of steps to be made by Adams.  If the integration
c began with Runge Kutta, Adams has 4 fewer steps to make.
      hdiv=h/720.
      do 10 i=1,5
      am(i)=hdiv*a(i)
   10 bm(i)=hdiv*b(i)
c am and bm are used in the corrector and predictor.
   20 tint=t
c tint is the initial time for Adams.
      do 100 i=1,nsa
c Begin with predictor.
```

```
      do 30 j=1,ne
   30 yp(j)=y(j)+bm(1)*f1(j)+bm(2)*f2(j)+bm(3)*f3(j)
     & +bm(4)*f4(j)+bm(5)*f5(j)
c First evaluation.
      call eval (t+h,yp,f6)
c First use of corrector.  Here we use yp as a storage array.
      do 40 j=1,ne
      yp(j)=y(j)+am(1)*f2(j)+am(2)*f3(j)+am(3)*f4(j)
     & +am(4)*f5(j)
   40 yc(j)=yp(j)+am(5)*f6(j)
c Second evaluation.
      call eval (t+h,yc,f6)
c Second use of corrector.
      do 50 j=1,ne
   50 y(j)=yp(j)+am(5)*f6(j)
c Update table of f values.
      do 60 j=1,ne
      f1(j)=f2(j)
      f2(j)=f3(j)
      f3(j)=f4(j)
      f4(j)=f5(j)
   60 f5(j)=f6(j)
      t=tint+float(i)*h
  100 continue
      return
      end
```

Note: Here the *flag* `nf` controls the mode of entry.

B.8 A 10^{th} Order PECEC Adams Routine

```
      subroutine adams10(h,ns,nf,t,y)
c  Written by Rob Ryne, Spring 1986, based on a routine of Alex Dragt.
c  This N=9 Adams integration routine makes local truncation errors
c  at each step of order h**11.  That is, it is locally correct through
c  order h**10.  Due to round off errors, its true precision is
c  realized only when more than 64 bits are used.
c  Warning: because this is a high-order method, the step size must be
c  correspondingly small to achieve stability.  For example, for the simple
c  harmonic oscillator with unit frequency (xdoubleprime+x=0), at least
c  50 steps per oscillation are require to safely achieve stability and
c  for the error analysis based on finite-difference considerations
c  to be relevant.
      implicit double precision (a-h,o-z)
c
      character*6 nf
      parameter (ne=2)
c
      dimension y(ne),yp(ne),yc(ne),f1(ne),f2(ne),f3(ne),f4(ne),
     # f5(ne),f6(ne),f7(ne),f8(ne),f9(ne),f10(ne),f11(ne)
c

Appendix C

Baker-Campbell-Hausdorff and Zassenhaus Formulas, Bases, and Paths

The purpose of this appendix is to describe the Lie-algebraic results of Henry Frederick Baker (1866-1956), John Edward Campbell (1862-1924), and Felix Hausdorff (1868-1942), and the related results of Hans Zassenhaus (1912-1991). We also discuss differentiating the exponential function, bases for Lie algebras, and paths in Lie groups and Lie algebras.

C.1 Differentiating the Exponential Function

C.2 The Baker-Campbell-Hausdorff Formula

C.3 The Baker-Campbell-Hausdorff Series

Exercises

C.3.1. According to the BCH theorem the *exponential* function has the remarkable property that the quantity C in the relation

$$\exp(A)\exp(B) = \exp(C) \tag{C.3.1}$$

depends only on elements in the Lie algebra generated by A and B. See Section 3.7.3 and the BCH series in Section C.3 above. The purpose of this exercise is to study the properties of two other functions.

Begin with the truncated exponential function t1exp defined by

$$\mathrm{t1exp}(A) = I + A. \tag{C.3.2}$$

See (4.1.22). Show that

$$\mathrm{t1exp}(A)\mathrm{t1exp}(B) = \mathrm{t1exp}(C) \tag{C.3.3}$$

with

$$C = A + B + AB. \tag{C.3.4}$$

Evidently the degree 1 term $A + B$ is in the Lie algebra generated by A and B, but the degree 2 term AB is not.

Next consider the truncated exponential function t2exp defined by

$$\mathrm{t2exp}(A) = I + A + A^2/2!. \tag{C.3.5}$$

Show that in this case

$$\mathrm{t2exp}(A)\mathrm{t2exp}(B) = \mathrm{t2exp}(C) \tag{C.3.6}$$

with

$$C = A + B + (1/2)(AB - BA) + \cdots . \tag{C.3.7}$$

Evidently the terms explicitly displayed on the right side of (C.3.7) are in the Lie algebra generated by A and B. Show that the remaining terms, which are of degree 3 and higher, are not.

Analyticity, Aberration Expansions, and Smoothing

F.1 The Static Case

According to Poincaré's Theorem 1.3.3, trajectories will be analytic functions of the initial conditions in some domain if the right sides of the equations of motion (1.3.4) are analytic. Correspondingly, according to the results of Section 26.2, the Taylor map (7.5.5) will converge in some domain about the origin. For problems of particular interest to us the Hamiltonians, and hence the equations of motion, will involve the scalar and vector potentials ψ and $\boldsymbol{A}$ as in, for example, (1.5.29), (1.6.16), and (1.6.17). Consequently, we are interested in knowing the analytic properties of ψ and $\boldsymbol{A}$.

In the static case these potentials are determined in terms of the charge density $\rho(\boldsymbol{r})$ and the current density $\boldsymbol{j}(\boldsymbol{r})$ by the Poisson equations

$$\nabla^2\psi = -4\pi\rho, \tag{F.1.1}$$

$$\nabla^2\boldsymbol{A} = -4\pi\boldsymbol{j}/c, \tag{F.1.2}$$

which have the solutions

$$\psi(\boldsymbol{r}) = \int d^3\boldsymbol{r}'\rho(\boldsymbol{r}')/\parallel \boldsymbol{r}'-\boldsymbol{r} \parallel, \tag{F.1.3}$$

$$\boldsymbol{A}(\boldsymbol{r}) = (1/c)\int d^3\boldsymbol{r}'\boldsymbol{j}(\boldsymbol{r}')/\parallel \boldsymbol{r}'-\boldsymbol{r} \parallel . \tag{F.1.4}$$

Here the notation $\parallel\ \parallel$ indicates the Euclidean norm,

$$\parallel \boldsymbol{r}'-\boldsymbol{r} \parallel = [(x'-x)^2+(y'-y)^2+(z'-z)^2]^{1/2}. \tag{F.1.5}$$

It follows immediately from (1.1) that if $\psi(\boldsymbol{r})$ is analytic in the components x, y, z of $\boldsymbol{r}$ at some point $\boldsymbol{r}^0$, then $\rho(\boldsymbol{r})$ must also be analytic at $\boldsymbol{r}^0$. The purpose of this appendix is to show the converse: if $\rho(\boldsymbol{r})$ is analytic at some point $\boldsymbol{r}^0$, then $\psi(\boldsymbol{r})$ will also be analytic at $\boldsymbol{r}^0$. We note, with some surprise, that this is a *local* statement. Although, according to (1.3), the value of $\psi(\boldsymbol{r})$ at the point $\boldsymbol{r}$ is determined by the value of $\rho(\boldsymbol{r}')$ at *all* points $\boldsymbol{r}'$, the quantity $\rho(\boldsymbol{r}')$ need not be analytic everywhere, but only at $\boldsymbol{r}^0$, for $\psi(\boldsymbol{r})$ to be analytic at

$\boldsymbol{r}^0$. Finally, since (1.4) is analogous to (1.3), our proof will also show that if all components of $\boldsymbol{j}(\boldsymbol{r})$ are analytic at $\boldsymbol{r}^0$, then all components of $\boldsymbol{A}(\boldsymbol{r})$ will also be analytic at $\boldsymbol{r}^0$.

Before proceeding further, and so as to not raise the reader's expectations too high, we confess that the analyticity we will prove is analyticity in the vicinity of *real* points. That is, at any real point (x^0, y^0, z^0), we will be able to prove analyticity in the complex variables $(x^0 + i\tilde{x}, y^0 + i\tilde{y}, z^0 + i\tilde{z})$ for $\tilde{x}$, $\tilde{y}$, $\tilde{z}$ finite but possibly small.

Why should we be interested in this question? First, we note that if $\rho(\boldsymbol{r})$ is zero in some region, then it is automatically analytic in that region. Therefore, as a particular case, we will find that vacuum solutions to Poisson's equation (solutions to Laplace's equation) must be analytic. This particular case is in fact the most common case since we are usually interested in orbits that remain within evacuated beam pipes. However, in some cases we are interested in the behavior of orbits that pass through regions of nonzero charge and/or current densities. Examples that come to mind include plasma lenses, electron cloud lenses, lithium lenses, beam-beam effects, and space-charge effects. In these cases we may still expect to have convergent aberration expansions provided $\rho(\boldsymbol{r})$ and $\boldsymbol{j}(\boldsymbol{r})$ are analytic in the region *traversed* by all orbits of interest. We emphasize again that no analyticity assumptions need be made about the behavior of $\rho(\boldsymbol{r})$ and $\boldsymbol{j}(\boldsymbol{r})$ in regions not traversed by orbits. From a mathematical perspective, the discussion that follows will be somewhat discursive; but it will have the advantage of obtaining several interesting results along the way. For a more direct approach, see Exercises 17 and 18.

By a suitable translation, and without loss of generality, we may take $\boldsymbol{r}^0$ to be the origin. Then, by the theory of Section 26.2, the assumption that ρ is analytic implies that it has an expansion of the form

$$\rho(\boldsymbol{r}) = \sum_{ijk} c_{ijk} x^i y^j z^k \tag{F.1.6}$$

that converges in some polydisc $\mathcal{D}$ given by inequalities of the form

$$|x| < R_x, \ |y| < R_y, \ |z| < R_z. \tag{F.1.7}$$

Here we are treating x, y, z as three *complex* variables. For further discussion, it is convenient to work within a smaller domain $\mathcal{R}$ contained within $\mathcal{D}$. Let ϵ be some fixed small positive number. Define a quantity R by the rule

$$R = \text{ minimum of } (R_x - \epsilon), (R_y - \epsilon), (R_z - \epsilon). \tag{F.1.8}$$

Then we define $\mathcal{R}$ to be the closed set

$$|x| \le R, \ |y| \le R, \ |z| \le R. \tag{F.1.9}$$

We are now in a position to obtain a bound on the Taylor coefficients c_{ijk}. From the Cauchy formula

$$c_{jk\ell} = \frac{1}{(2\pi i)^3} \oint_{|x|=R} \oint_{|y|=R} \oint_{|z|=R} dxdydz \frac{\rho(x,y,z)}{x^{j+1} y^{k+1} z^{\ell+1}} \tag{F.1.10}$$

we get the result

$$|c_{jk\ell}| \le K R^{-(j+k+\ell)} \tag{F.1.11}$$

where the constant K is defined by the equation

$$K = \max |\rho(x, y, z)| \text{ for } |x| = |y| = |z| = R. \tag{F.1.12}$$

Suppose the terms in the series (1.6) are grouped together according to their total degree. Doing so gives the result

$$\rho(\boldsymbol{r}) = \sum_{D=0}^{\infty} \sum_{\alpha=1}^{N(D,3)} d_{D\alpha} h_D^\alpha(\boldsymbol{r}). \tag{F.1.13}$$

Here $h_D^\alpha(\boldsymbol{r})$ denotes a monomial of the form $x^i y^j z^k$ and of degree D (that is, $i + j + k = D$) and labelled by an index α. From (6.3.36) we know that $N(D, 3)$, the number of monomials of degree D in 3 variables, is given by the relation

$$N(D, 3) = \frac{(D + 2)!}{D!2!} = (D + 2)(D + 1)/2. \tag{F.1.14}$$

Hence, we may label the monomials of degree D in such a way that the index α ranges over the values of 1 to $N(D, 3)$, as indicated in (1.13). We note that that (1.13) is an ordering and grouping of (1.6), and hence is a permissible operation that cannot change its value for $\boldsymbol{r} \in \mathcal{R}$. See Sections 26.1 through 26.3.

We next study the relation between the monomials h_D^α, harmonic polynomials, and spherical harmonics. For the moment let x, y, and z be real. Introduce, in the standard way, spherical coordinates by the relations

$$x = r \sin\theta \cos\phi, \tag{F.1.15}$$

$$y = r \sin\theta \sin\phi, \tag{F.1.16}$$

$$z = r \cos\theta, \tag{F.1.17}$$

with r given by the relation

$$r = (x^2 + y^2 + z^2)^{1/2}. \tag{F.1.18}$$

Now consider the functions $H_\ell^m(\boldsymbol{r})$ defined by the relation

$$H_\ell^m(\boldsymbol{r}) = r^\ell Y_\ell^m(\theta, \phi) \tag{F.1.19}$$

where the Y_ℓ^m are the usual *spherical harmonics*. We observe that the H_ℓ^m are *homogeneous polynomials* of degree ℓ in the variables x, y, z. In fact, for H_ℓ^ℓ we have the relation

$$\begin{aligned} H_\ell^\ell(\boldsymbol{r}) &= r^\ell Y_\ell^\ell(\theta, \phi) = (2\ell + 1)^{1/2} \{4\pi[(2\ell)!]\}^{-1/2} r^\ell P_\ell^\ell(\cos\theta) \\ &= [(-1)^\ell/(2^\ell \ell!)]\{[(2\ell + 1)/(4\pi)][(2\ell)!]\}^{1/2} r^\ell (\sin\theta)^\ell e^{i\ell\phi} \\ &= [(-1)^\ell/(2^\ell \ell!)]\{[(2\ell + 1)/(4\pi)][(2\ell)!]\}^{1/2} (x + iy)^\ell. \end{aligned} \tag{F.1.20}$$

To see that the remaining H_ℓ^m are also homogeneous polynomials of degree ℓ we define, in the usual way, the angular momentum operator $\boldsymbol{\mathcal{L}}$ by the rule

$$\boldsymbol{\mathcal{L}} = -i\boldsymbol{r} \times \boldsymbol{\partial}. \tag{F.1.21}$$

By convention and construction the Y_ℓ^m have the property

$$\mathcal{L}_- Y_\ell^m = [(\ell+m)(\ell-m+1)]^{1/2} Y_\ell^{m-1} \tag{F.1.22}$$

where $\mathcal{L}_-$ is defined by the rule

$$\mathcal{L}_- = \mathcal{L}_x - i\mathcal{L}_y. \tag{F.1.23}$$

It is easily verified that $\boldsymbol{\mathcal{L}}$ commutes with r, and hence we also have the relation

$$\mathcal{L}_- H_\ell^m = [(\ell+m)(\ell-m+1)]^{1/2} H_\ell^{m-1}. \tag{F.1.24}$$

Moreover, we see from (1.21) and (1.23) that $\mathcal{L}_-$ maps homogeneous polynomials into homogeneous polynomials, and leaves their degrees unchanged. It follows that all the H_ℓ^m are homogeneous polynomials of degree ℓ. Finally, we see from (1.19) that the H_ℓ^m satisfy Laplace's equation,

$$\nabla^2 H_\ell^m = 0, \tag{F.1.25}$$

and therefore are entitled to be called *harmonic* polynomials.

Consider now the functions $H_\ell^{ms}(\boldsymbol{r})$ defined by the relations

$$H_\ell^{ms}(\boldsymbol{r}) = r^{2s} r^\ell Y_\ell^m = r^{2s} H_\ell^m(\boldsymbol{r}),\ s = 0, 1, 2, \cdots . \tag{F.1.26}$$

They are evidently homogeneous polynomials in x, y, z of degree D, with D given by the relation

$$D = \ell + 2s. \tag{F.1.27}$$

See (1.18). They are also linearly independent. Let us count their number for fixed D. The cases of even and odd D need to be treated separately. For even D we have the polynomials

$$r^D Y_D^m, r^2 r^{D-2} Y_{D-2}^m, \cdots r^{D-2} r^2 Y_2^m, r^D, \tag{F.1.28}$$

and their total number is

$$\begin{aligned} \text{number} &= [2D+1] + [2(D-2)+1] + \cdots + [2(2)+1] + 1 \\ &= (D+2)(D+1)/2 = N(D,3). \end{aligned} \tag{F.1.29}$$

For odd D we have the polynomials

$$r^D Y_D^m, r^2 r^{D-2} Y_{D-2}^m, \cdots r^{D-1} r Y_1^m, \tag{F.1.30}$$

and their total number is

$$\begin{aligned} \text{number} &= [2D+1] + [2(D-2)+1] + \cdots + [2(1)+1] \\ &= (D+2)(D+1)/2 = N(D,3). \end{aligned} \tag{F.1.31}$$

Comparison of (1.14), (1.29), and (1.31) shows that the number of homogeneous polynomials H_ℓ^{ms} with fixed degree D equals the number of monomials h_D^α with fixed D. Consequently, there exist expansion coefficients a and relations of the form

$$\begin{aligned} x^i y^j z^k &= h_D^\alpha(\boldsymbol{r}) = \sum_{\ell+2s=D} \sum_{m=-\ell}^{\ell} a_{m\ell s}^{D\alpha} r^{2s} r^\ell Y_\ell^m \\ &= \sum_{\ell+2s=D} \sum_{m=-\ell}^{\ell} a_{m\ell s}^{D\alpha} H_\ell^{ms}(\boldsymbol{r}). \end{aligned} \tag{F.1.32}$$

With the aid of (1.32), the series (1.13) can also be written in the form

$$\begin{aligned}\rho(\boldsymbol{r}) &= \sum_{D=0}^{\infty}\sum_{\ell+2s=D}\sum_{m=-\ell}^{\ell} b_{m\ell s} r^{2s} r^{\ell} Y_{\ell}^{m} \\ &= \sum_{D=0}^{\infty}\sum_{\ell+2s=D}\sum_{m=-\ell}^{\ell} b_{m\ell s} r^{2s} H_{\ell}^{m}(\boldsymbol{r}). \qquad \text{(F.1.33)}\end{aligned}$$

In this form we see, as a consequence of analyticity, that spherical harmonics Y_ℓ^m always occur in conjunction with powers of r of the form $r^{\ell+2s}$ with $s = 0, 1, 2, \cdots$.

The transition from the Taylor series (1.13) to what we will call the *harmonic* series (1.33) is not simply a different ordering, and therefore questions of convergence have to be examined anew. We begin by finding bounds for the polynomials $H_\ell^m(\boldsymbol{r})$. For this purpose it is convient to use the familiar expansion

$$\frac{1}{\parallel \boldsymbol{r}' - \boldsymbol{r} \parallel} = 4\pi \sum_{\ell,m} (2\ell+1)^{-1} r^{\ell} Y_\ell^m(\Omega)(r')^{-\ell-1}\overline{Y}_\ell^m(\Omega') \text{ for } r < r'. \qquad \text{(F.1.34)}$$

For real angles we note the bound

$$|Y_\ell^m(\Omega)| \leq [(2\ell+1)/4\pi]^{1/2}. \qquad \text{(F.1.35)}$$

It follows that the expansion (1.34) is absolutely convergent for $\boldsymbol{r}$ and $\boldsymbol{r}'$ real and $r < r'$. Now multiply both sides of (134) by $Y_{\ell'}^{m'}(\Omega')$, integrate over Ω', and use the orthogonality of the Y_ℓ^m to get the integral representation

$$H_\ell^m(\boldsymbol{r}) = r^\ell Y_\ell^m(\Omega) = (4\pi)^{-1}(2\ell+1)(r')^{\ell+1}\int d\Omega'\ Y_\ell^m(\Omega')/\parallel \boldsymbol{r}' - \boldsymbol{r} \parallel. \qquad \text{(F.1.36)}$$

As it stands, the representation (1.36) holds for $\boldsymbol{r}$ real and satisfying $r < r'$. We will now analytically continue it to possibly complex $\boldsymbol{r}$ while keeping $\boldsymbol{r}'$ real. There is no difficulty in extending the left side of (1.36) to complex $\boldsymbol{r}$ since it is a polynomial. The extension of the right side is also straight forward. Moreover, when the left and right sides of (1.36) are extended to complex $\boldsymbol{r}$, they will continue to agree. That is, the integral representation (1.36) is also valid for complex $\boldsymbol{r}$. See Exercise 9. Introduce the unit vector

$$\boldsymbol{e}(\Omega') = \boldsymbol{r}'/r' = \boldsymbol{e}_x \sin\theta'\cos\phi' + \boldsymbol{e}_y \sin\theta'\sin\phi' + \boldsymbol{e}_z\cos\theta'. \qquad \text{(F.1.37)}$$

Also introduce real vectors $\boldsymbol{\xi}$ and $\boldsymbol{\eta}$ and a complex vector $\boldsymbol{\zeta}$ by the relation

$$\boldsymbol{r}/r' = \boldsymbol{\xi} + i\boldsymbol{\eta} = \boldsymbol{\zeta}. \qquad \text{(F.1.38)}$$

With the aid of these definitions (1.36) can be recast in the form

$$H_\ell^m(\boldsymbol{r}) = (4\pi)^{-1}(2\ell+1)(r')^{\ell}\int d\Omega'\ Y_\ell^m(\Omega')/\parallel \boldsymbol{e}(\Omega') - \boldsymbol{\zeta} \parallel. \qquad \text{(F.1.39)}$$

Let us examine the denominator $\parallel \boldsymbol{e} - \boldsymbol{\zeta} \parallel$. It has the form

$$\parallel \boldsymbol{e} - \boldsymbol{\zeta} \parallel = [(\boldsymbol{e} - \boldsymbol{\zeta})\cdot(\boldsymbol{e} - \boldsymbol{\zeta})]^{1/2}. \qquad \text{(F.1.40)}$$

For the dot product appearing in (1.40) we find the expression

$$\begin{aligned}(\boldsymbol{e}-\boldsymbol{\zeta})\cdot(\boldsymbol{e}-\boldsymbol{\zeta}) &= \boldsymbol{e}\cdot\boldsymbol{e}-2\boldsymbol{e}\cdot\boldsymbol{\zeta}+\boldsymbol{\zeta}\cdot\boldsymbol{\zeta}\\ &= 1-2\boldsymbol{e}\cdot\boldsymbol{\zeta}+\boldsymbol{\zeta}\cdot\boldsymbol{\zeta}=(1-2\boldsymbol{e}\cdot\boldsymbol{\xi}+\boldsymbol{\xi}\cdot\boldsymbol{\xi}-\boldsymbol{\eta}\cdot\boldsymbol{\eta})\\ &+ 2i(\boldsymbol{\xi}\cdot\boldsymbol{\eta}-\boldsymbol{e}\cdot\boldsymbol{\eta}).\end{aligned} \tag{F.1.41}$$

Suppose the vectors $\boldsymbol{\xi}$ and $\boldsymbol{\eta}$ are restricted in length to satisfy the relations

$$\boldsymbol{\xi}\cdot\boldsymbol{\xi}\leq 1/16,\ \ \boldsymbol{\eta}\cdot\boldsymbol{\eta}\leq 1/16. \tag{F.1.42}$$

Then the quantities appearing in the real part of (1.41) obey the inequalities

$$|\boldsymbol{e}\cdot\boldsymbol{\xi}|\leq\parallel \boldsymbol{e}\parallel\parallel\boldsymbol{\xi}\parallel\leq 1/4, \tag{F.1.43}$$

$$-1/16\leq\boldsymbol{\xi}\cdot\boldsymbol{\xi}-\boldsymbol{\eta}\cdot\boldsymbol{\eta}\leq 1/16, \tag{F.1.44}$$

and the real part itself satisfies the inequality

$$|1-2\boldsymbol{e}\cdot\boldsymbol{\xi}+\boldsymbol{\xi}\cdot\boldsymbol{\xi}-\boldsymbol{\eta}\cdot\boldsymbol{\eta}|\geq 7/16. \tag{F.1.45}$$

From (1.41) and (1.45) it follows that $\parallel \boldsymbol{e}-\boldsymbol{\zeta}\parallel$ satisfies the inequality

$$|[\parallel \boldsymbol{e}-\boldsymbol{\zeta}\parallel]|=|[(\boldsymbol{e}-\boldsymbol{\zeta})\cdot(\boldsymbol{e}-\boldsymbol{\zeta})]^{1/2}|\geq\sqrt{7}/4. \tag{F.1.46}$$

Now use (1.35) and (1.46) in (1.39) to get the bound

$$|H_\ell^m(\boldsymbol{r})|\leq(16\pi/\sqrt{7})[(2\ell+1)/4\pi]^{3/2}(r')^\ell. \tag{F.1.47}$$

Suppose $\boldsymbol{r}$ is in the closed polydisc $\mathcal{R}$ given by (1.9). Then we have the relations

$$\xi_x=\mathrm{Re}(x)/r'\leq R/r',\ \text{etc.}; \tag{F.1.48}$$

$$\eta_x=\mathrm{Im}(x)/r'\leq R/r',\ \text{etc.} \tag{F.1.49}$$

From these relations it follows that

$$\boldsymbol{\xi}\cdot\boldsymbol{\xi}\leq 3(R/r')^2, \tag{F.1.50}$$

$$\boldsymbol{\eta}\cdot\boldsymbol{\eta}\leq 3(R/r')^2. \tag{F.1.51}$$

Finally set r' to the value

$$r'=4\sqrt{3}R. \tag{F.1.52}$$

Then the inequalities (1.42) are satisfied and (1.47) takes the final form

$$|H_\ell^m(\boldsymbol{r})|\leq(16\pi/\sqrt{7})[(2\ell+1)/4\pi]^{3/2}(4\sqrt{3})^\ell R^\ell \text{ for } \boldsymbol{r}\in\mathcal{R}. \tag{F.1.53}$$

Inspection of (1.33) shows that what we really require are bounds on the polynomials $r^{2s}H_\ell^m(\boldsymbol{r})$. From the definition (1.18) and (1.9) we find the result

$$|r^2|=|x^2+y^2+z^2|\leq|x^2|+|y^2|+|z^2|\leq 3R^2. \tag{F.1.54}$$

Consequently we find for the quantity r^{2s} the bound

$$|r^{2s}| = |r^2|^s \leq 3^s R^{2s} \leq (\sqrt{3})^{2s} R^{2s} \leq (4\sqrt{3})^{2s} R^{2s}. \tag{F.1.55}$$

It follows that the polynomials $r^{2s} H_\ell^m(\boldsymbol{r})$ have the bounds

$$|r^{2s} H_\ell^m(\boldsymbol{r})| \leq (16\pi/\sqrt{7})[(2\ell+1)/4\pi]^{3/2}(4\sqrt{3})^{\ell+2s} R^{\ell+2s}. \tag{F.1.56}$$

We next find bounds on the coefficients $b_{m\ell s}$. For each degree D we have the relation

$$\sum_{i+j+k=D} c_{ijk} x^i y^j z^k = \sum_{\ell+2s=D} \sum_{m=-\ell}^{\ell} b_{m\ell s} r^{\ell+2s} Y_\ell^m(\theta,\phi). \tag{F.1.57}$$

Multiply both sides of (1.57) by $\overline{Y}_{\ell'}^{m'}$ and integrate over solid angle to obtain the relation

$$b_{m'\ell' s'} r^D = r^D \int d\Omega \sum_{i+j+k=D} c_{ijk} (\sin\theta\cos\phi)^i (\sin\theta\sin\phi)^j (\cos\theta)^k \overline{Y}_{\ell'}^{m'}(\theta,\phi) \tag{F.1.58}$$

where s' satisfies the condition

$$\ell' + 2s' = D. \tag{F.1.59}$$

Here we have also used (1.15) through (1.17). It follows from (1.35) and (1.58) that we have the inequality

$$|b_{m'\ell' s'}| \leq 4\pi[(2\ell+1)/4\pi]^{1/2} \sum_{i+j+k=D} |c_{ijk}|. \tag{F.1.60}$$

Now use (1.11), and the fact that the number of terms appearing in the sum (1.60) is $N(D,3)$, to get the result

$$|b_{m'\ell' s'}| \leq 2\pi K[(2\ell+1)/4\pi]^{1/2}(D+2)(D+1)R^{-D}. \tag{F.1.61}$$

Let us use the results (1.56) and (1.61) to examine the convergence of the series (1.33). Suppose $\boldsymbol{r}$ is in a polydisc of the form (1.9) with R replaced by some value R'' yet to be selected. Consider the series

$$\begin{aligned}
&\sum_{D=0}^{\infty} \sum_{\ell+2s=D} \sum_{m=-\ell}^{\ell} 2\pi K[(2\ell+1)/4\pi]^{1/2}(D+2)(D+1)R^{-D}|r^{2s} H_\ell^m(\boldsymbol{r})| \\
&\leq K(2/\sqrt{7}) \sum_{D=0}^{\infty} \sum_{\ell+2s=D} \sum_{m=-\ell}^{\ell} (D+2)(D+1)(2\ell+1)^2(4\sqrt{3})^D (R''/R)^D \\
&\leq K(2/\sqrt{7}) \sum_{D=0}^{\infty} (D+2)(D+1)(4\sqrt{3})^D (R''/R)^D \sum_{\ell+2s=D} (2\ell+1)^3.
\end{aligned} \tag{F.1.62}$$

Here we have used (1.56) with R replaced by R''. Evidently the series (1.62) is convergent if R'' satisfies the inequality

$$R'' < (4\sqrt{3})^{-1} R. \tag{F.1.63}$$

We conclude that the series (1.33) converges absolutely in the polydisc

$$|x| \leq R'',\ |y| \leq R'',\ |z| \leq R'' \tag{F.1.64}$$

with R'' given by (1.63).

With these matters concerning the series (1.6) and (1.33) for $\rho(\boldsymbol{r})$ behind us, we turn to the behavior of $\psi(\boldsymbol{r})$. Break up the integration required by (1.3) into two regions by rewriting it in the form

$$\psi(\boldsymbol{r}) = \psi_<(\boldsymbol{r}) + \psi_>(\boldsymbol{r}) \tag{F.1.65}$$

where

$$\psi_<(\boldsymbol{r}) = \int\limits_{\|\boldsymbol{r}'\| \leq R'} d^3\boldsymbol{r}'\rho(\boldsymbol{r}')/\parallel \boldsymbol{r}' - \boldsymbol{r} \parallel, \tag{F.1.66}$$

$$\psi_>(\boldsymbol{r}) = \int\limits_{\|\boldsymbol{r}'\| \geq R'} d^3\boldsymbol{r}'\rho(\boldsymbol{r}')/\parallel \boldsymbol{r}' - \boldsymbol{r} \parallel . \tag{F.1.67}$$

We will examine each of the functions $\psi_<(\boldsymbol{r})$ and $\psi_>(\boldsymbol{r})$ separately.

The behavior of $\psi_>(\boldsymbol{r})$ near the origin is relatively easy to discern. By analysis similar to that of equations (1.40) through (1.46), we see that $(1/\parallel \boldsymbol{r}' - \boldsymbol{r} \parallel)$ with $\parallel \boldsymbol{r}' \parallel \geq R'$ is analytic in the components of $\boldsymbol{r}$ in a small neighborhood of the origin. Consequently, $\psi_>(\boldsymbol{r})$ is also analytic in the components of $\boldsymbol{r}$ in a small neighborhood of the origin, and this conclusion is independent of the nature of $\rho(\boldsymbol{r}')$ for $\parallel \boldsymbol{r}' \parallel \geq R'$ save for some mild distribution theoretic or integrability conditions such as, for example, that the integral (1.67) be absolutely convergent. We also observe that $(1/\parallel \boldsymbol{r}' - \boldsymbol{r} \parallel)$ with $\parallel r' \parallel \geq R'$ is harmonic in the variables $\boldsymbol{r}$ in a small neighborhood of the origin,

$$\nabla^2(1/\parallel \boldsymbol{r}' - \boldsymbol{r} \parallel) = (\partial_x^2 + \partial_y^2 + \partial_z^2)(1/\parallel \boldsymbol{r}' - \boldsymbol{r} \parallel) = 0 \text{ for } \parallel \boldsymbol{r}' \parallel \geq R' \text{ and } \boldsymbol{r} \text{ near } 0. \tag{F.1.68}$$

Consequently, $\psi_>(\boldsymbol{r})$ is also harmonic around the origin,

$$\nabla^2\psi_>(\boldsymbol{r}) = 0 \text{ for } \boldsymbol{r} \text{ near } 0. \tag{F.1.69}$$

Finding the behavior of $\psi_<(\boldsymbol{r})$ near the origin requires more work. We know that an expansion for $\rho(\boldsymbol{r}')$ of the form (1.33) converges for $\boldsymbol{r}'$ in some sufficiently small polydisc. Select the R' in (1.66) and (1.67) such that the region $\boldsymbol{r}'$ real and $\parallel \boldsymbol{r}' \parallel \leq R'$ lies within this polydisc. Then we may use the expansion (1.33) for $\rho(\boldsymbol{r}')$ in the integral (1.66) to compute $\psi_<(\boldsymbol{r})$.

Let us do this one term at a time. Define functions $\mathcal{X}_{m\ell s}(\boldsymbol{r})$ by the rule

$$\mathcal{X}_{m\ell s}(\boldsymbol{r}) = \int\limits_{\|\boldsymbol{r}'\| \leq R'} d^3\boldsymbol{r}'(r')^{2s+\ell}Y_\ell^m(\Omega')/\parallel \boldsymbol{r}' - \boldsymbol{r} \parallel . \tag{F.1.70}$$

Then, $\psi_<(\boldsymbol{r})$ will have the expansion

$$\psi_<(\boldsymbol{r}) = \sum_{D=0}^{\infty} \sum_{\ell+2s=D} \sum_{m=-\ell}^{\ell} b_{m\ell s}\mathcal{X}_{m\ell s}(\boldsymbol{r}). \tag{F.1.71}$$

The integral (1.70) can be written in the iterated form

$$\mathcal{X}_{m\ell s}(\boldsymbol{r}) = \int_0^{R'} dr'(r')^2(r')^{2s+\ell} \int d\Omega' \; Y_\ell^m(\Omega')/ \parallel \boldsymbol{r'} - \boldsymbol{r} \parallel . \tag{F.1.72}$$

The second integral in (1.72) has the value

$$\int d\Omega' \; Y_\ell^m(\Omega')/ \parallel \boldsymbol{r'} - \boldsymbol{r} \parallel = [4\pi/(2\ell+1)](r_<^\ell/r_>^{\ell+1})Y_\ell^m(\Omega), \tag{F.1.73}$$

where $r_<$ and $r_>$ are defined by the equations

$$r_< = \text{ the lesser of } r, r', \tag{F.1.74}$$

$$r_> = \text{ the greater of } r, r'. \tag{F.1.75}$$

This value can be used in (1.72) to yield the result

$$\mathcal{X}_{m\ell s}(\boldsymbol{r}) = \mathcal{X}^1_{m\ell s}(\boldsymbol{r}) + \mathcal{X}^2_{m\ell s}(\boldsymbol{r}), \tag{F.1.76}$$

where

$$\mathcal{X}^1_{m\ell s}(\boldsymbol{r}) = -4\pi[(2\ell+1)+(2s+2)]^{-1}(2s+2)^{-1}r^{2s+2}r^\ell Y_\ell^m(\theta,\phi), \tag{F.1.77}$$

$$\mathcal{X}^2_{m\ell s}(\boldsymbol{r}) = 4\pi[(2\ell+1)(2s+2)]^{-1}(R')^{2s+2}r^\ell Y_\ell^m(\theta,\phi). \tag{F.1.78}$$

We see that $\mathcal{X}_{m\ell s}(\boldsymbol{r})$ is a linear combination of the functions $r^{2s+2}r^\ell Y_\ell^m$ and $r^\ell Y_\ell^m$. From our earlier work we know that both these functions are polynomials in the components of $\boldsymbol{r}$, and are therefore entire analytic functions of the variables x, y, z.

The next thing to check is that the series (1.71) for $\psi_<(\boldsymbol{r})$ converges. Following the decomposition (1.76), we will write $\psi_<(\boldsymbol{r})$ in the form

$$\psi_<(\boldsymbol{r}) = \psi^1_<(\boldsymbol{r}) + \psi^2_<(\boldsymbol{r}) \tag{F.1.79}$$

where

$$\psi^1_<(\boldsymbol{r}) = -4\pi \sum_{D=0}^{\infty} \sum_{\ell+2s=D} \sum_{m=-\ell}^{\ell} b_{m\ell s}[(2\ell+1)+(2s+2)]^{-1}(2s+2)^{-1}r^{2s+2}r^\ell Y_\ell^m(\theta,\phi), \tag{F.1.80}$$

$$\psi^2_<(\boldsymbol{r}) = 4\pi \sum_{D=0}^{\infty} \sum_{\ell+2s=D} \sum_{m=-\ell}^{\ell} b_{m\ell s}[(2\ell+1)(2s+2)]^{-1}(R')^{2s+2}r^\ell Y_\ell^m(\theta,\phi). \tag{F.1.81}$$

It is easily verified, using the bounds (1.56) and (1.61), that both the series $\psi^1_<(\boldsymbol{r})$ and $\psi^2_<(\boldsymbol{r})$ converge, and converge absolutely, for $\boldsymbol{r}$ sufficiently near the origin and R' sufficiently small. Consequently, $\psi_<(\boldsymbol{r})$ itself is analytic in a neighborhood of the origin. We now know that both $\psi_>$ and $\psi_<$ are analytic around the origin, and hence their sum ψ is analytic about the origin, which is what we have wanted to prove.

At this point we make some observations about the functions $\psi^1_<(\boldsymbol{r})$ and $\psi^2_<(\boldsymbol{r})$. We claim that they satisfy the equations

$$\nabla^2\psi^1_<(\boldsymbol{r}) = -4\pi\rho(\boldsymbol{r}), \tag{F.1.82}$$

$$\nabla^2\psi^2_<(\boldsymbol{r}) = 0. \tag{F.1.83}$$

Since the series for $\psi^1_<$ and $\psi^2_<$ converge absolutely, the operator ∇^2 can be taken under the summation signs and allowed to act term by term. The claim (1.83) then follows immediately from (1.25). To verify (1.82) we note that the operator ∇^2 has the spherical decomposition

$$\nabla^2 = r^{-1}\partial_r^2 r - \mathcal{L}^2/r^2, \tag{F.1.84}$$

and the spherical harmonics have the property

$$\mathcal{L}^2 Y_\ell^m = \ell(\ell+1)Y_\ell^m. \tag{F.1.85}$$

It follows that

$$\begin{aligned}\nabla^2(r^{2s+2}r^\ell Y_\ell^m) &= \{[(r^{-1}\partial_r^2 r) - \ell(\ell+1)/r^2]r^{\ell+2s+2}\}Y_\ell^m\\ &= [(\ell+2s+3)(\ell+2s+2) - \ell(\ell+1)]r^{\ell+2s}Y_\ell^m\\ &= [(2\ell+1)+(2s+2)](2s+2)r^{2s}r^\ell Y_\ell^m.\end{aligned} \tag{F.1.86}$$

We see that the ℓ and s dependent multiplicative factors in (1.86) cancel like factors in the denominators appearing in (1.80), and comparison of the resulting expression for $\nabla^2\psi^1_<$ with that given in (1.33) for ρ shows that the assertion (1.82) is also correct.

Exercises

F.1.1. This section has been devoted to the rather laborious task of showing that if $\rho(\boldsymbol{r})$ is analytic in the components of $\boldsymbol{r}$ at some point $\boldsymbol{r}^0$, then the same is true for $\psi(\boldsymbol{r})$. By contrast, the converse is easy to prove. Show that if $\psi(\boldsymbol{r})$ is analytic in the components of $\boldsymbol{r}$ at some point $\boldsymbol{r}^0$, then the same is true for $\rho(\boldsymbol{r})$.

F.1.2. Consider, as examples, three possible forms for $\rho(\boldsymbol{r})$ as shown below. In each case find the corresponding $\psi(\boldsymbol{r})$, and discuss its analytic properties.

$$\begin{aligned}\rho(\boldsymbol{r}) &= \text{ constant for } \parallel \boldsymbol{r} \parallel \leq R,\\ &= 0 \text{ for } \parallel \boldsymbol{r} \parallel > R;\end{aligned} \tag{F.1.87}$$

$$\rho(\boldsymbol{r}) = a\exp(-br^2); \tag{F.1.88}$$

$$\rho(\boldsymbol{r}) = a\exp(-br). \tag{F.1.89}$$

F.1.3. Show that the electron charge density for any hydrogen atom energy eigenstate,

$$\rho(\boldsymbol{r}) = \overline{\mathcal{X}}(\boldsymbol{r})\mathcal{X}(\boldsymbol{r}), \tag{F.1.90}$$

is *not* analytic at the origin. Relate this "singular" behavior to the fact that the energy eigenstate wave function $\mathcal{X}(\boldsymbol{r})$ satisfies the Schroedinger equation

$$-[\hbar^2/(2m)]\nabla^2\mathcal{X} - (e^2/r)\mathcal{X} = E\mathcal{X}. \tag{F.1.91}$$

F.1.4. Suppose that $f(D, \boldsymbol{r})$ is a homogeneous polynomial of degree D in the components of $\boldsymbol{r}$. According to Exercise 1.5.12 it obeys the relation

$$(\boldsymbol{r}\cdot\boldsymbol{\partial})f(D,\boldsymbol{r}) = Df(D,\boldsymbol{r}). \tag{F.1.92}$$

Show that the operators $(\boldsymbol{r}\cdot\boldsymbol{\partial})$ and $\boldsymbol{\mathcal{L}}$ commute. You have provided another demonstration that $\mathcal{L}_-$ maps homogeneous polynomials into themselves and leaves their degrees unchanged.

F.1.5. Verify (1.25) directly for H_ℓ^ℓ as given by (1.20). Show that ∇^2 commutes with $\boldsymbol{\mathcal{L}}$, and hence (1.25) holds for all H_ℓ^m.

F.1.6. Verify the sums (1.29) and (1.31).

F.1.7. Verify the bound (1.35).

F.1.8. Verify (1.36) through (1.53). Verify that H_ℓ^ℓ as given by (1.20) satisfies the bound (1.53).

F.1.9. The conditions (1.42) were chosen to simplify analysis. Show that the analysis can be modified to improve the bound (1.53) and the requirement (1.63) by replacing $(4\sqrt{3})$ by a smaller factor. Verify that H_ℓ^ℓ as given by (1.20) satisfies your improved bound. Hint: Let δ be a real number in the open interval $0 < \delta < 1$. Show that if $\boldsymbol{\xi}$ and $\boldsymbol{\eta}$ satisfy the conditions

$$\boldsymbol{\xi}\cdot\boldsymbol{\xi} \le (1-\delta)^2/4,\ \boldsymbol{\eta}\cdot\boldsymbol{\eta} \le (1-\delta)^2/4, \tag{F.1.93}$$

then one has the inequality

$$|[\|\ \boldsymbol{e} - \boldsymbol{\zeta}\ \|]| \ge \delta^{1/2}. \tag{F.1.94}$$

F.1.10. Since H_ℓ^m is a homogeneous polynomial of degree ℓ, show that both sides of (1.39) can be divided by $(r')^\ell$ so that, with the aid of (1.38), it can be rewritten in the form

$$H_\ell^m(\boldsymbol{\zeta}) = (4\pi)^{-1}(2\ell+1)\int d\Omega' Y_\ell^m(\Omega')/\ \|\ \boldsymbol{e}(\Omega') - \boldsymbol{\zeta}\ \|\ . \tag{F.1.95}$$

Verify that the right side of (1.95) is analytic in the components of $\boldsymbol{\zeta}$ for $\boldsymbol{\zeta}$ sufficiently near 0, and that it has a Taylor expansion about 0 that converges absolutely for $\boldsymbol{\zeta}$ in a sufficiently small polydisc about the origin. (Here you may assume that the composition of two analytic functions is again analytic. See Section 38.2.) Show that the coefficients of this Taylor expansion can be determined from a knowledge of the values of the right side of (1.95) when $\boldsymbol{\zeta}$ is *real* and near 0. We know that both sides of (1.95) are equal when $\boldsymbol{\zeta}$ is real and near 0. (Such a set is an example of what is called a *real environment*. See Exericse 38.2.8.) It follows that both sides of (1.95) have identical Taylor coefficients. Consequently, both sides of (1.95) must also be equal when $\boldsymbol{\zeta}$ is complex and in a sufficiently small polydisc about the origin. Show, in fact, that they must be equal in the domain (1.93).

F.1.11. Verify that (1.61) is a consequence of (1.11).

F.1.12. Verify that the series (1.62) is convergent if (1.64) is satisfied.

F.1.13. Verify that if (in the static case) ρ vanishes in some region, then ψ is analytic in this region.

F.1.14. Verify (1.77) and (1.78). Show that the series (1.80) and (1.81) converge.

F.1.15. Verify (1.86) and (1.82).

F.1.16. Our discussion so far of how ψ inherits the analytic properties of ρ has taken a rather circuitous path through the territory of Taylor and harmonic series. Is there an approach that displays the inheritance directly? There is. Consider $\psi_<$ as given by (1.66). Introduce the variable $\boldsymbol{\Delta}$ by the definition

$$\boldsymbol{r}' = \boldsymbol{r} + \boldsymbol{\Delta}, \tag{F.1.96}$$

and show that (1.66) can also be written in the form

$$\psi_<(\boldsymbol{r}) = \int_{\|\boldsymbol{r}+\boldsymbol{\Delta}\|\leq R'} d^3\boldsymbol{\Delta}\ \rho(\boldsymbol{r}+\boldsymbol{\Delta})/ \parallel \boldsymbol{\Delta} \parallel . \tag{F.1.97}$$

Next introduce polar coordinates for $\boldsymbol{\Delta}$ by the relation

$$\boldsymbol{\Delta} = \Delta \boldsymbol{e}(\Omega). \tag{F.1.98}$$

Show that (1.97) can be rewritten in the form

$$\psi_<(\boldsymbol{r}) = \int d\Omega \int_0^{\tilde{\Delta}} d\Delta\ \Delta\rho(\boldsymbol{r}+\boldsymbol{\Delta}), \tag{F.1.99}$$

where $\tilde{\Delta}$ is given by the expression

$$\tilde{\Delta}(\boldsymbol{r}, \Omega, R') = -\boldsymbol{r}\cdot\boldsymbol{e}(\Omega) + \{(R')^2 + [\boldsymbol{r}\cdot\boldsymbol{e}(\Omega)]^2 - r^2\}^{1/2}. \tag{F.1.100}$$

Finally, introduce the variable τ by writing

$$\Delta = \tau\tilde{\Delta}, \tag{F.1.101}$$

and show that (1.99) can be rewritten as

$$\psi_<(\boldsymbol{r}) = \int d\Omega \int_0^1 d\tau\ \tau\tilde{\Delta}^2\rho[\boldsymbol{r} + \tau\tilde{\Delta}\boldsymbol{e}(\Omega)]. \tag{F.1.102}$$

As it stands, (1.102) may be viewed as an integral representation for $\psi_<(\boldsymbol{r})$ that is valid for small real $\boldsymbol{r}$. Now consider making $\boldsymbol{r}$ complex. Verify that $\tilde{\Delta}$ as given by (1.100) is analytic in $\boldsymbol{r}$ for $\boldsymbol{r}$ contained in a sufficiently small polydisc about 0. By hypothesis, $\rho(\boldsymbol{r})$ is also analytic in some such polydisc. Verify that the same is true for the function $\rho[\boldsymbol{r} + \tau\tilde{\boldsymbol{\Delta}}\boldsymbol{e}(\Omega)]$. Finally, show that $\psi_<(\boldsymbol{r})$ as given by (1.102) must be analytic in some such polydisc.

F.2 The Time Dependent Case

We will now sketch how the results obtained so far can be extended to the time dependent case. In the time dependent case the scalar potential satisfies the inhomogeneous wave equation

$$[\nabla^2 - (1/c^2)\partial_t^2]\psi(\boldsymbol{r}, t) = -4\pi\rho(\boldsymbol{r}, t). \tag{F.2.1}$$

Let us assume that ρ, although time dependent, has a *bounded* Fourier spectrum. That is, we assume that $\rho(\boldsymbol{r}, t)$ can be written in the form

$$\rho(\boldsymbol{r}, t) = (1/2\pi)\int_{-\omega_{\max}}^{\omega_{\max}} d\omega\tilde{\rho}(\boldsymbol{r}, \omega)\exp(-i\omega t) \tag{F.2.2}$$

where $\omega_{\max}$ is some finite frequency cutoff. Then $\psi(\boldsymbol{r}, t)$ will also have a bounded Fourier spectrum,

$$\psi(\boldsymbol{r}, t) = (1/2\pi)\int_{-\omega_{\max}}^{\omega_{\max}} d\omega\tilde{\psi}(\boldsymbol{r}, \omega)\exp(-i\omega t). \tag{F.2.3}$$

We know from (2.1) that the Fourier transform $\tilde{\psi}$ satisfies the inhomogeneous Helmholtz equation

$$(\nabla^2 + k^2)\tilde{\psi}(\boldsymbol{r}, \omega) = -4\pi\tilde{\rho}(\boldsymbol{r}, \omega) \tag{F.2.4}$$

where

$$k = \omega/c. \tag{F.2.5}$$

With the assumption of an outgoing wave boundary condition, equation (2.4) has the solution

$$\tilde{\psi}(\boldsymbol{r}, \omega) = \int d^3\boldsymbol{r}'\tilde{\rho}(\boldsymbol{r}', \omega)[\exp(ik \parallel \boldsymbol{r}' - \boldsymbol{r} \parallel)]/ \parallel \boldsymbol{r}' - \boldsymbol{r} \parallel . \tag{F.2.6}$$

We now assume that $\tilde{\rho}(\boldsymbol{r}, \omega)$, for all ω in the closed interval $[-\omega_{\max}, \omega_{\max}]$, is analytic in the components of $\boldsymbol{r}$ at some point $\boldsymbol{r}^0$. Then it can be shown that $\tilde{\psi}(\boldsymbol{r}, \omega)$ will also be analytic at $\boldsymbol{r}^0$. It follows from (2.3) that $\psi(\boldsymbol{r}, t)$ will also be analytic in the components of $\boldsymbol{r}$ at $\boldsymbol{r}^0$ for all t. Finally, again from (2.3), we see that $\psi(\boldsymbol{r}, t)$ will also be an analytic function of t for all t.

We now outline the proof of this assertion. As before, we take $\boldsymbol{r}^0$ to be the origin and break up the region of integration in (2.6) to write

$$\tilde{\psi}(\boldsymbol{r}, \omega) = \tilde{\psi}_<(\boldsymbol{r}, \omega) + \tilde{\psi}_>(\boldsymbol{r}, \omega) \tag{F.2.7}$$

where

$$\tilde{\psi}_<(\boldsymbol{r}, \omega) = \int\limits_{\|\boldsymbol{r}'\| \leq R'} d^3\boldsymbol{r}'\tilde{\rho}(\boldsymbol{r}', \omega)[\exp(ik \parallel \boldsymbol{r}' - \boldsymbol{r} \parallel)]/ \parallel \boldsymbol{r}' - \boldsymbol{r} \parallel, \tag{F.2.8}$$

$$\tilde{\psi}_>(\boldsymbol{r}, \omega) = \int\limits_{\|\boldsymbol{r}'\| \geq R'} d^3\boldsymbol{r}'\tilde{\rho}(\boldsymbol{r}', \omega)[\exp(ik \parallel \boldsymbol{r}' - \boldsymbol{r} \parallel)]/ \parallel \boldsymbol{r}' - \boldsymbol{r} \parallel . \tag{F.2.9}$$

It follows, from arguments similar to those made earlier, that $\tilde{\psi}_>(\boldsymbol{r}, \omega)$ is analytic in the components of $\boldsymbol{r}$ in a small neighborhood of the origin, and satisfies the Helmholtz equation

$$[\nabla^2 + k^2]\tilde{\psi}_>(\boldsymbol{r}, \omega) = 0 \text{ for } \boldsymbol{r} \text{ near } 0. \tag{F.2.10}$$

To study the behavior of $\tilde{\psi}_<$ we assume, as before, that R' is sufficiently small that $\tilde{\rho}(\boldsymbol{r}', \omega)$ has a convergent expansion of the form (1.33) where the coefficients $b_{m\ell s}(\omega)$ are now ω dependent. Again consider each term at a time and, in analogy to (1.78), examine the integrals

$$\tilde{\mathscr{X}}_{m\ell s}(\boldsymbol{r}, \omega) = \int_0^{R'} dr'(r')^2(r')^{2s+\ell} \int d\Omega' Y_\ell^m(\Omega')[\exp(ik \parallel \boldsymbol{r}' - \boldsymbol{r} \parallel)]/ \parallel \boldsymbol{r}' - \boldsymbol{r} \parallel . \quad \text{(F.2.11)}$$

The second integral in (2.11) has the value

$$\int d\Omega' Y_\ell^m(\Omega')[\exp(ik \parallel \boldsymbol{r}' - \boldsymbol{r} \parallel)]/ \parallel \boldsymbol{r}' - \boldsymbol{r} \parallel = 4\pi ik j_\ell(kr_<)h_\ell^1(kr_>)Y_\ell^m(\Omega). \quad \text{(F.2.12)}$$

Consequently our problem is reduced to studying the behavior of the integral

$$\int_0^{R'} dr'(r')^{\ell+2s+2} 4\pi ik j_\ell(kr_<)h_\ell^1(kr_>). \quad \text{(F.2.13)}$$

It can be shown that this integral has the same analytic behavior as the related integral

$$\int_0^{R'} dr'(r')^{\ell+2s+2}[4\pi/(2\ell+1)]r_<^\ell/r_>^{\ell+1} \quad \text{(F.2.14)}$$

for the analogous time independent case. In particular, $\tilde{\mathscr{X}}_{m\ell s}$ can be written in the form

$$\tilde{\mathscr{X}}_{m\ell s}(\boldsymbol{r}, \omega) = \tilde{\mathscr{X}}^1_{m\ell s}(\boldsymbol{r}, \omega) + \tilde{\mathscr{X}}^2_{m\ell s}(\boldsymbol{r}, \omega) \quad \text{(F.2.15)}$$

where both $\tilde{\mathscr{X}}^1$ and $\tilde{\mathscr{X}}^2$ are entire analytic functions of the variables x, y, z. Correspondingly, $\tilde{\psi}_<(\boldsymbol{r}, \omega)$ can be written in the form

$$\tilde{\psi}_<(\boldsymbol{r}, \omega) = \tilde{\psi}^1_<(\boldsymbol{r}, \omega) + \tilde{\psi}^2_<(\boldsymbol{r}, \omega) \quad \text{(F.2.16)}$$

where both $\tilde{\psi}^1_<$ and $\tilde{\psi}^2_<$ are analytic in a neighborhood about the origin, and satisfy the equations

$$(\nabla^2 + k^2)\tilde{\psi}^1_<(\boldsymbol{r}, \omega) = -4\pi\tilde{\rho}(\boldsymbol{r}, \omega), \quad \text{(F.2.17)}$$

$$(\nabla^2 + k^2)\tilde{\psi}^2_<(\boldsymbol{r}, \omega) = 0. \quad \text{(F.2.18)}$$

Exercises

F.2.1. Review Exercise 1.13. Now consider the time dependent case. Show that the frequency cutoff in (2.2) is essential to the argument. Show that if all frequencies are allowed, then the effect of singularities in ρ can *propagate*. That is, a singularity in ρ at some point $\boldsymbol{r}'$, and some time, can produce a singularity in ψ at some other point $\boldsymbol{r}$ at some later time even though ρ may be analytic at $\boldsymbol{r}$.

F.2.2. Evaluate the integral (2.13), and complete the analysis of the time dependent case.

F.2.3. Extend the method of Exercise 1.16 to the time-dependent case (2.6.

F.3 Smoothing Properties of the Laplacian Kernel

In Section 22.2 we encountered the relation

$$\boldsymbol{H}(\boldsymbol{r}) = [1/(4\pi)] \int_V d^3\boldsymbol{r}' \, \boldsymbol{F}(\boldsymbol{r}')G(\boldsymbol{r}, \boldsymbol{r}'). \tag{F.3.1}$$

See (22.2.92). It follows from the work at the beginning of this appendix that if $\boldsymbol{F}(\boldsymbol{r}')$ is analytic, then $\boldsymbol{H}(\boldsymbol{r})$ will also be analytic. Now we will assume only that $\boldsymbol{F}(\boldsymbol{r}')$ is smooth, and then study what can be said about the properties of $\boldsymbol{H}(\boldsymbol{r})$. By *smooth*, we mean that ....

Appendix H

Harmonic Functions

Section 13.2 provided cylindrical harmonic expansions for the harmonic function ψ. This appendix does the same for the gradients of ψ. It also studies the *range* of the transverse gradient operators when acting on the space of harmonic functions. In particular, given a harmonic function χ, it shows that there exists a harmonic function ψ such that $\partial_x \psi = \chi$ or a ψ such that $\partial_y \psi = \chi$. Finally, it provides representations for harmonic functions in two variables.

H.1 Representation of Gradients

We know that the harmonic function $\psi(x, y, z)$ has the representation (13.2.37). We would like to find similar representations for $\partial_x \psi(x, y, z)$, $\partial_y \psi(x, y, z)$, and $\partial_z \psi(x, y, z)$ which, of course, are also harmonic functions.

H.1.1 Low-Order Results

We will begin by finding low-order results, and then work out results to all orders. Refer to (13.2.37) to write ψ in the form

$$\psi = \psi_0 + \psi_c + \psi_s \tag{H.1.1}$$

where

$$\psi_0(x, y, z) = \sum_{\ell=0}^{\infty} (-1)^\ell \frac{1}{2^{2\ell} \ell! \ell!} C_0^{[2\ell]}(z) \rho^{2\ell}, \tag{H.1.2}$$

$$\begin{aligned}\psi_c(x, y, z) &= \sum_{m=1}^{\infty} \cos(m\phi) \sum_{\ell=0}^{\infty} (-1)^\ell \frac{m!}{2^{2\ell} \ell! (\ell + m)!} C_{m,c}^{[2\ell]}(z) \rho^{2\ell+m} \\ &= \sum_{m=1}^{\infty} \sum_{\ell=0}^{\infty} (-1)^\ell \frac{m!}{2^{2\ell} \ell! (\ell + m)!} C_{m,c}^{[2\ell]}(z) \rho^{2\ell} \Re(x + iy)^m, \end{aligned}\tag{H.1.3}$$

$$\begin{aligned}\psi_s(x,y,z) &= \sum_{m=1}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,s}^{[2\ell]}(z)\rho^{2\ell+m}\\ &= \sum_{m=1}^{\infty}\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,s}^{[2\ell]}(z)\rho^{2\ell}\Im(x+iy)^m. \qquad \text{(H.1.4)}\end{aligned}$$

Let us expand ψ through terms of third order. We can then differentiate this expansion to find the first few terms in the expansions of its gradients. Through terms of degree 3, we find for the constituents of ψ the expansions

$$\psi_0 = C_0^{[0]}(z) - (1/4)(x^2+y^2)C_0^{[2]}(z) + \cdots , \qquad \text{(H.1.5)}$$

$$\begin{aligned}\psi_c &= \Re(x+iy)C_{1,c}^{[0]}(z) + \Re(x+iy)^2C_{2,c}^{[0]}(z) + \Re(x+iy)^3C_{3,c}^{[0]}(z)\\ &-(1/8)(x^2+y^2)\Re(x+iy)C_{1,c}^{[2]}(z) + \cdots\\ &= xC_{1,c}^{[0]}(z) + (x^2-y^2)C_{2,c}^{[0]}(z) + (x^3-3xy^2)C_{3,c}^{[0]}(z) - (1/8)(x^2+y^2)xC_{1,c}^{[2]}(z) + \cdots ,\\ &= xC_{1,c}^{[0]}(z) + (x^2-y^2)C_{2,c}^{[0]}(z)\\ &+x^3[C_{3,c}^{[0]}(z) - (1/8)C_{1,c}^{[2]}(z)] - xy^2[3C_{3,c}^{[0]}(z) + (1/8)C_{1,c}^{[2]}(z)] + \cdots ,\end{aligned} \qquad \text{(H.1.6)}$$

$$\begin{aligned}\psi_s &= \Im(x+iy)C_{1,s}^{[0]}(z) + \Im(x+iy)^2C_{2,s}^{[0]}(z) + \Im(x+iy)^3C_{3,s}^{[0]}(z)\\ &-(1/8)(x^2+y^2)\Im(x+iy)C_{1,s}^{[2]}(z) + \cdots\\ &= yC_{1,s}^{[0]}(z) + 2xyC_{2,s}^{[0]}(z) + (-y^3+3x^2y)C_{3,s}^{[0]}(z) - (1/8)(x^2+y^2)yC_{1,s}^{[2]}(z) + \cdots ,\\ &= yC_{1,s}^{[0]}(z) + 2xyC_{2,s}^{[0]}(z)\\ &-y^3[C_{3,s}^{[0]}(z) + (1/8)C_{1,s}^{[2]}(z)] + x^2y[3C_{3,s}^{[0]}(z) - (1/8)C_{1,s}^{[2]}(z)] + \cdots .\end{aligned} \qquad \text{(H.1.7)}$$

Differentiating these expansions, and retaining terms through second order, give the results

$$\partial_z\psi_0 = C_0^{[1]}(z) - (1/4)(x^2+y^2)C_0^{[3]}(z) + \cdots , \qquad \text{(H.1.8)}$$

$$\partial_z\psi_c = xC_{1,c}^{[1]}(z) + (x^2-y^2)C_{2,c}^{[1]}(z) + \cdots , \qquad \text{(H.1.9)}$$

$$\partial_z\psi_s = yC_{1,s}^{[1]}(z) + 2xyC_{2,s}^{[1]}(z) + \cdots , \qquad \text{(H.1.10)}$$

$$\partial_x\psi_0 = -(1/2)xC_0^{[2]}(z) + \cdots , \qquad \text{(H.1.11)}$$

$$\begin{aligned}\partial_x\psi_c \;=\; & C_{1,c}^{[0]}(z) + 2xC_{2,c}^{[0]}(z) + 3x^2[C_{3,c}^{[0]}(z) - (1/8)C_{1,c}^{[2]}(z)]\\ & -y^2[3C_{3,c}^{[0]}(z) + (1/8)C_{1,c}^{[2]}(z)] + \cdots , \end{aligned} \qquad \text{(H.1.12)}$$

$$\partial_x\psi_s = 2yC_{2,s}^{[0]}(z) + 2xy[3C_{3,s}^{[0]}(z) - (1/8)C_{1,s}^{[2]}(z)] + \cdots , \qquad \text{(H.1.13)}$$

$$\partial_y\psi_0 = -(1/2)yC_0^{[2]}(z) + \cdots\ , \tag{H.1.14}$$

$$\partial_y\psi_c = -2yC_{2,c}^{[0]}(z) - 2xy[3C_{3,c}^{[0]}(z) + (1/8)C_{1,c}^{[2]}(z)] + \cdots\ , \tag{H.1.15}$$

$$\begin{aligned}\partial_y\psi_s \;=\;& C_{1,s}^{[0]}(z) + 2xC_{2,s}^{[0]}(z) - 3y^2[C_{3,s}^{[0]}(z) + (1/8)C_{1,s}^{[2]}(z)]\\ &+x^2[3C_{3,s}^{[0]}(z) - (1/8)C_{1,s}^{[2]}(z)] + \cdots\ .\end{aligned} \tag{H.1.16}$$

Finally, upon employing the decomposition (1.1), we find the results

$$\begin{aligned}&\partial_z\psi = C_0^{[1]}(z) + xC_{1,c}^{[1]}(z) + yC_{1,s}^{[1]}(z)\\ &+(x^2-y^2)C_{2,c}^{[1]}(z) + 2xyC_{2,s}^{[1]}(z) - (1/4)(x^2+y^2)C_0^{[3]}(z) + \cdots\\ &= C_0^{[1]}(z) + xC_{1,c}^{[1]}(z) + yC_{1,s}^{[1]}(z)\\ &+x^2[C_{2,c}^{[1]}(z) - (1/4)C_0^{[3]}(z)] - y^2[C_{2,c}^{[1]}(z) + (1/4)C_0^{[3]}(z)] + 2xyC_{2,s}^{[1]}(z) + \cdots\ ,\end{aligned} \tag{H.1.17}$$

$$\begin{aligned}&\partial_x\psi = C_{1,c}^{[0]}(z) + x[2C_{2,c}^{[0]}(z) - (1/2)C_0^{[2]}(z)] + 2yC_{2,s}^{[0]}(z)\\ &+3x^2[C_{3,c}^{[0]}(z) - (1/8)C_{1,c}^{[2]}(z)] - y^2[3C_{3,c}^{[0]}(z) + (1/8)C_{1,c}^{[2]}(z)]\\ &+2xy[3C_{3,s}^{[0]}(z) - (1/8)C_{1,s}^{[2]}(z)]\cdots\ ,\end{aligned} \tag{H.1.18}$$

$$\begin{aligned}&\partial_y\psi = C_{1,s}^{[0]}(z) - y[2C_{2,c}^{[0]}(z) + (1/2)C_0^{[2]}(z)] + 2xC_{2,s}^{[0]}(z)\\ &-3y^2[C_{3,s}^{[0]}(z) + (1/8)C_{1,s}^{[2]}(z)] + x^2[3C_{3,s}^{[0]}(z) - (1/8)C_{1,s}^{[2]}(z)]\\ &-2xy[3C_{3,c}^{[0]}(z) + (1/8)C_{1,c}^{[2]}(z)] + \cdots\ .\end{aligned} \tag{H.1.19}$$

H.1.2 Results to All Orders

Let us study the effect of the operators ∂_x, ∂_y, and ∂_z on each of the terms in (1.1). Finding the effect of ∂_z is easy because it acts only on the $C_{m,\alpha}^{[n]}(z)$ to raise the value of n by 1. The effects of ∂_x and ∂_y are more complicated. Observe that ψ_0, ψ_c, and ψ_s are sums over the "basis" functions $\rho^{2\ell}$, $\rho^{2\ell}\Re(x+iy)^m$, and $\rho^{2\ell}\Im(x+iy)^m$, respectively. We will first compute ∂_x and ∂_y of these basis functions; then compute ∂_x and ∂_y of ψ_0, ψ_c, and ψ_s; and finally compute $\partial_x\psi$ and $\partial_y\psi$ and also $\partial_z\psi$.

Transverse Gradients of $\rho^{2\ell}$

Let us begin by calculating ∂_x and ∂_y of $\rho^{2\ell}$. We find that

$$\partial_x\rho^{2\ell} = \partial_x(x^2+y^2)^\ell = \ell(x^2+y^2)^{\ell-1}2x = 2\ell\rho^{2\ell-2}\Re(x+iy) \tag{H.1.20}$$

and

$$\partial_y\rho^{2\ell} = \partial_y(x^2+y^2)^\ell = \ell(x^2+y^2)^{\ell-1}2y = 2\ell\rho^{2\ell-2}\Im(x+iy). \tag{H.1.21}$$

Transverse Gradients of $\rho^{2\ell}\Re(x+iy)^m$ and $\rho^{2\ell}\Im(x+iy)^m$

Determining the transverse gradients of $\rho^{2\ell}\Re(x+iy)^m$ and $\rho^{2\ell}\Im(x+iy)^m$ requires somewhat more work. Note that for these calculations we have $m \geq 1$. We find that

$$\begin{aligned}
&\partial_x[\rho^{2\ell}\Re(x+iy)^m] = \partial_x\{\rho^{2\ell}[(x+iy)^m + (x-iy)^m]/2\} \\
&= [\partial_x\rho^{2\ell}][(x+iy)^m + (x-iy)^m]/2 + \rho^{2\ell}\partial_x[(x+iy)^m + (x-iy)^m]/2 \\
&= 2\ell\rho^{2\ell-2}\Re(x+iy)[(x+iy)^m + (x-iy)^m]/2 + \rho^{2\ell}m[(x+iy)^{m-1} + (x-iy)^{m-1}]/2 \\
&= \ell\rho^{2\ell-2}[(x+iy) + (x-iy)][(x+iy)^m + (x-iy)^m]/2 + m\rho^{2\ell}\Re(x+iy)^{m-1} \\
&= \ell\rho^{2\ell-2}\{[(x+iy)^{m+1} + (x-iy)^{m+1}] + \rho^2[(x+iy)^{m-1} + (x-iy)^{m-1}]\}/2 \\
&+m\rho^{2\ell}\Re(x+iy)^{m-1} \\
&= \ell\rho^{2\ell-2}\Re(x+iy)^{m+1} + (\ell+m)\rho^{2\ell}\Re(x+iy)^{m-1},
\end{aligned} \tag{H.1.22}$$

$$\begin{aligned}
&\partial_x[\rho^{2\ell}\Im(x+iy)^m] = \partial_x\{\rho^{2\ell}[(x+iy)^m - (x-iy)^m]/(2i)\} \\
&= [\partial_x\rho^{2\ell}][(x+iy)^m - (x-iy)^m]/(2i) + \rho^{2\ell}\partial_x[(x+iy)^m - (x-iy)^m]/(2i) \\
&= 2\ell\rho^{2\ell-2}\Re(x+iy)[(x+iy)^m - (x-iy)^m]/(2i) + \rho^{2\ell}m[(x+iy)^{m-1} - (x-iy)^{m-1}]/(2i) \\
&= \ell\rho^{2\ell-2}[(x+iy) + (x-iy)][(x+iy)^m - (x-iy)^m]/(2i) + m\rho^{2\ell}\Im(x+iy)^{m-1} \\
&= \ell\rho^{2\ell-2}\{[(x+iy)^{m+1} - (x-iy)^{m+1}] + \rho^2[(x+iy)^{m-1} - (x-iy)^{m-1}]\}/(2i) \\
&+m\rho^{2\ell}\Im(x+iy)^{m-1} \\
&= \ell\rho^{2\ell-2}\Im(x+iy)^{m+1} + (\ell+m)\rho^{2\ell}\Im(x+iy)^{m-1},
\end{aligned} \tag{H.1.23}$$

$$\begin{aligned}
&\partial_y[\rho^{2\ell}\Re(x+iy)^m] = \partial_y\{\rho^{2\ell}[(x+iy)^m + (x-iy)^m]/2\} \\
&= [\partial_y\rho^{2\ell}][(x+iy)^m + (x-iy)^m]/2 + \rho^{2\ell}\partial_y[(x+iy)^m + (x-iy)^m]/2 \\
&= 2\ell\rho^{2\ell-2}\Im(x+iy)[(x+iy)^m + (x-iy)^m]/2 + \rho^{2\ell}im[(x+iy)^{m-1} - (x-iy)^{m-1}]/2 \\
&= \ell\rho^{2\ell-2}[(x+iy) - (x-iy)][(x+iy)^m + (x-iy)^m]/(2i) - m\rho^{2\ell}\Im(x+iy)^{m-1} \\
&= \ell\rho^{2\ell-2}\{[(x+iy)^{m+1} - (x-iy)^{m+1}] - \rho^2[(x+iy)^{m-1} - (x-iy)^{m-1}]\}/(2i) \\
&-m\rho^{2\ell}\Im(x+iy)^{m-1} \\
&= \ell\rho^{2\ell-2}\Im(x+iy)^{m+1} - (\ell+m)\rho^{2\ell}\Im(x+iy)^{m-1},
\end{aligned} \tag{H.1.24}$$

$$\begin{aligned}
&\partial_y[\rho^{2\ell}\Im(x+iy)^m] = \partial_y\{\rho^{2\ell}[(x+iy)^m - (x-iy)^m]/(2i)\} \\
&= [\partial_y\rho^{2\ell}][(x+iy)^m - (x-iy)^m]/(2i) + \rho^{2\ell}\partial_y[(x+iy)^m - (x-iy)^m]/(2i) \\
&= 2\ell\rho^{2\ell-2}\Im(x+iy)[(x+iy)^m - (x-iy)^m]/(2i) + \rho^{2\ell}im[(x+iy)^{m-1} + (x-iy)^{m-1}]/(2i) \\
&= -\ell\rho^{2\ell-2}[(x+iy) - (x-iy)][(x+iy)^m - (x-iy)^m]/2 + m\rho^{2\ell}\Re(x+iy)^{m-1} \\
&= -\ell\rho^{2\ell-2}\{[(x+iy)^{m+1} + (x-iy)^{m+1}] - \rho^2[(x+iy)^{m-1} + (x-iy)^{m-1}]\}/2 \\
&+m\rho^{2\ell}\Re(x+iy)^{m-1} \\
&= -\ell\rho^{2\ell-2}\Re(x+iy)^{m+1} + (\ell+m)\rho^{2\ell}\Re(x+iy)^{m-1}.
\end{aligned} \tag{H.1.25}$$

Transverse Gradients of ψ_0

We are now prepared to compute the transverse gradients of ψ_0. Based on (1.2), (1.20), and (1.21), we find that

$$\begin{aligned}
\partial_x\psi_0 &= \sum_{\ell=0}^{\infty}(-1)^\ell \frac{2\ell}{2^{2\ell}\ell!\ell!}C_0^{[2\ell]}(z)\rho^{2\ell-2}\Re(x+iy) \\
&= \sum_{\ell=1}^{\infty}(-1)^\ell \frac{2\ell}{2^{2\ell}\ell!\ell!}C_0^{[2\ell]}(z)\rho^{2\ell-2}\Re(x+iy) \\
&= \sum_{\ell=0}^{\infty}(-1)^{\ell+1} \frac{(2\ell+2)}{2^{2\ell+2}(\ell+1)!(\ell+1)!}C_0^{[2\ell+2]}(z)\rho^{2\ell}\Re(x+iy) \\
&= \sum_{\ell=0}^{\infty}(-1)^{\ell+1} \frac{2}{2^{2\ell+2}\ell!(\ell+1)!}C_0^{[2\ell+2]}(z)\rho^{2\ell}\Re(x+iy) \qquad \text{(H.1.26)}
\end{aligned}$$

and

$$\begin{aligned}
\partial_y\psi_0 &= \sum_{\ell=0}^{\infty}(-1)^\ell \frac{2\ell}{2^{2\ell}\ell!\ell!}C_0^{[2\ell]}(z)\rho^{2\ell-2}\Im(x+iy) \\
&= \sum_{\ell=1}^{\infty}(-1)^\ell \frac{2\ell}{2^{2\ell}\ell!\ell!}C_0^{[2\ell]}(z)\rho^{2\ell-2}\Im(x+iy) \\
&= \sum_{\ell=0}^{\infty}(-1)^{\ell+1} \frac{(2\ell+2)}{2^{2\ell+2}(\ell+1)!(\ell+1)!}C_0^{[2\ell+2]}(z)\rho^{2\ell}\Im(x+iy) \\
&= \sum_{\ell=0}^{\infty}(-1)^{\ell+1} \frac{2}{2^{2\ell+2}\ell!(\ell+1)!}C_0^{[2\ell+2]}(z)\rho^{2\ell}\Im(x+iy) \qquad \text{(H.1.27)}
\end{aligned}$$

Transverse Gradients of ψ_c and ψ_s

We are also ready to compute the transverse gradients of ψ_c and ψ_s. These results are more lengthy. Based on (1.3), (1.4), and (1.22) through (1.25), we find the following results.

Result for $\partial_x \psi_c$

$$
\begin{aligned}
\partial_x \psi_c &= \sum_{m=1}^{\infty}\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}C_{m,c}^{[2\ell]}(z)[\ell\rho^{2\ell-2}\Re(x+iy)^{m+1}+(\ell+m)\rho^{2\ell}\Re(x+iy)^{m-1}]\\
&= \sum_{m=1}^{\infty}\sum_{\ell=1}^{\infty}(-1)^{\ell}\frac{m!\ell}{2^{2\ell}\ell!(\ell+m)!}C_{m,c}^{[2\ell]}(z)\rho^{2\ell-2}\Re(x+iy)^{m+1}\\
&+\sum_{m=1}^{\infty}\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!(\ell+m)}{2^{2\ell}\ell!(\ell+m)!}C_{m,c}^{[2\ell]}(z)\rho^{2\ell}\Re(x+iy)^{m-1}\\
&= \sum_{m=1}^{\infty}\sum_{\ell=0}^{\infty}(-1)^{\ell+1}\frac{m!(\ell+1)}{2^{2\ell+2}(\ell+1)!(\ell+m+1)!}C_{m,c}^{[2\ell+2]}(z)\rho^{2\ell}\Re(x+iy)^{m+1}\\
&+\sum_{m=1}^{\infty}\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!(\ell+m)}{2^{2\ell}\ell!(\ell+m)!}C_{m,c}^{[2\ell]}(z)\rho^{2\ell}\Re(x+iy)^{m-1}\\
&= \sum_{m=1}^{\infty}\sum_{\ell=0}^{\infty}(-1)^{\ell+1}\frac{m!}{2^{2\ell+2}\ell!(\ell+m+1)!}C_{m,c}^{[2\ell+2]}(z)\rho^{2\ell}\Re(x+iy)^{m+1}\\
&+\sum_{m=1}^{\infty}\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m-1)!}C_{m,c}^{[2\ell]}(z)\rho^{2\ell}\Re(x+iy)^{m-1}\\
&= \sum_{m=1}^{\infty}\sum_{\ell=0}^{\infty}(-1)^{\ell+1}\frac{m!}{2^{2\ell+2}\ell!(\ell+m+1)!}C_{m,c}^{[2\ell+2]}(z)\rho^{2\ell}\Re(x+iy)^{m+1}\\

$$

Exercises

H.1.1. Verify (1.22) through (1.22) for selected example values of ℓ and m.

H.1.2. Verify (1.26) and (1.27).

H.1.3. Verify (1.28) through (1.31).

H.1.4. Verify (1.32) through (1.34). Show that, when expanded to low order, they yield results identical to (1.17) through (1.19).

H.1.5. Write

$$\boldsymbol{B} = \nabla\psi \tag{H.1.35}$$

to find the cylindrical coordinate results

$$B_\rho = \partial\psi/\partial\rho, \tag{H.1.36}$$

$$B_\phi = (1/\rho)\partial\psi/\partial\phi, \tag{H.1.37}$$

$$B_z = \partial\psi/\partial z. \tag{H.1.38}$$

Also invoke the relations

$$B_x = (\cos\phi)B_\rho - (\sin\phi)B_\phi \tag{H.1.39}$$

$$B_y = (\sin\phi)B_\rho + (\cos\phi)B_\phi. \tag{H.1.40}$$

Use these results to derive (1.32) through (1.34).

H.2 Range of Transverse Gradient Operators

We next enquire about the *range* of the operators ∂_x and ∂_y. Consider ∂_x. Suppose χ is some given (real) harmonic function. Can we find a (real) harmonic ψ such that either

$$\partial_x\psi = \chi \tag{H.2.1}$$

or

$$\partial_y\psi = \chi? \tag{H.2.2}$$

We will verify, by construction, that the answer is *yes*.

H.2.1 Solution of $\partial_x\psi = \chi$

Since χ is assumed (real) harmonic, it has a representation of the form

$$\begin{aligned}\chi(x,y,z) &= \sum_{\ell=0}^{\infty}(-1)^\ell\frac{1}{2^{2\ell}\ell!\ell!}B_0^{[2\ell]}(z)\rho^{2\ell}\\ &+ \sum_{m=1}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{m!}{2^{2\ell}\ell!(\ell+m)!}B_{m,c}^{[2\ell]}(z)\rho^{2\ell+m}\\ &+ \sum_{m=1}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^\ell\frac{m!}{2^{2\ell}\ell!(\ell+m)!}B_{m,s}^{[2\ell]}(z)\rho^{2\ell+m}.\end{aligned} \tag{H.2.3}$$

Evidently, we must compare (1.32) and (2.3). We must try to satisfy the pair of equations

$$\begin{aligned}
&\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!\ell!}C_{1,c}^{[2\ell]}(z)\rho^{2\ell}+\\
&+\cos(\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{2}{2^{2\ell}\ell!(\ell+1)!}[C_{2,c}^{[2\ell]}(z)-(1/4)C_{0}^{[2\ell+2]}(z)]\rho^{2\ell+1}\\
&+\sum_{m=2}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}\{(m+1)C_{m+1,c}^{[2\ell]}(z)-[1/(4m)]C_{m-1,c}^{[2\ell+2]}(z)\}\rho^{2\ell+m}\\
&\overset{?}{=}\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!\ell!}B_{0}^{[2\ell]}(z)\rho^{2\ell}+\sum_{m=1}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}B_{m,c}^{[2\ell]}(z)\rho^{2\ell+m}
\end{aligned}\tag{H.2.4}$$

and

$$\begin{aligned}
&\sin(\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{2}{2^{2\ell}\ell!(\ell+1)!}C_{2,s}^{[2\ell]}(z)\rho^{2\ell+1}\\
&+\sum_{m=2}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}\{(m+1)C_{m+1,s}^{[2\ell]}(z)-[1/(4m)]C_{m-1,s}^{[2\ell+2]}(z)\}\rho^{2\ell+m}\\
&\overset{?}{=}\sum_{m=1}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}B_{m,s}^{[2\ell]}(z)\rho^{2\ell+m}.
\end{aligned}\tag{H.2.5}$$

Here we have used (13.2.7) and (13.2.8).

Let us first work on question (2.4). Suppose we set

$$C_{1,c}^{[0]}(z)=B_{0}^{[0]}(z).\tag{H.2.6}$$

Then (2.4) becomes the question

$$\begin{aligned}
&+\cos(\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{2}{2^{2\ell}\ell!(\ell+1)!}[C_{2,c}^{[2\ell]}(z)-(1/4)C_{0}^{[2\ell+2]}(z)]\rho^{2\ell+1}\\
&+\sum_{m=2}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}\{(m+1)C_{m+1,c}^{[2\ell]}(z)-[1/(4m)]C_{m-1,c}^{[2\ell+2]}(z)\}\rho^{2\ell+m}\\
&\overset{?}{=}\sum_{m=1}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}B_{m,c}^{[2\ell]}(z)\rho^{2\ell+m}.
\end{aligned}\tag{H.2.7}$$

Note that the right side of (2.7) can be written in the form

$$\begin{aligned}&\sum_{m=1}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}B_{m,c}^{[2\ell]}(z)\rho^{2\ell+m}\\&=\cos(\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!(\ell+1)!}B_{1,c}^{[2\ell]}(z)\rho^{2\ell+1}\\&+\sum_{m=2}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}B_{m,c}^{[2\ell]}(z)\rho^{2\ell+m}.\end{aligned} \tag{H.2.8}$$

Therefore, upon equating like terms, we see that (2.7) is equivalent to the two questions

$$2[C_{2,c}^{[2\ell]}(z)-(1/4)C_{0}^{[2\ell+2]}(z)]\overset{?}{=}B_{1,c}^{[2\ell]}(z) \tag{H.2.9}$$

and

$$(m+1)C_{m+1,c}^{[2\ell]}(z)-[1/(4m)]C_{m-1,c}^{[2\ell+2]}(z)=B_{m,c}^{[2\ell]}(z)?\text{ for }m\geq 2. \tag{H.2.10}$$

We will solve (2.9) by making the stipulation

$$C_{0}^{[0]}=0, \tag{H.2.11}$$

in which case (2.9) has the solution

$$C_{2,c}^{[0]}(z)=(1/2)B_{1,c}^{[0]}(z). \tag{H.2.12}$$

Let us next rewrite (2.10) in the recursive form

$$C_{m+1,c}^{[2\ell]}(z)=[1/(m+1)]B_{m,c}^{[2\ell]}(z)+\{1/[(4m)(m+1)]\}C_{m-1,c}^{[2\ell+2]}(z)?\text{ for }m\geq 2. \tag{H.2.13}$$

In view of (2.6) and (2.12), this is a well-defined recursion relation. For example, putting $m=2$ in (2.13) gives the result

$$C_{3,c}^{[0]}(z)=(1/3)B_{2,c}^{[0]}(z)+\{1/[(8)(3)]\}C_{1,c}^{[2]}(z), \tag{H.2.14}$$

which, using (2.6), can be rewritten as

$$C_{3,c}^{[0]}(z)=(1/3)B_{2,c}^{[0]}(z)+(1/24)B_{0}^{[2]}(z). \tag{H.2.15}$$

Now put $m=3$. Doing so gives the result

$$C_{4,c}^{[0]}(z)=(1/4)B_{3,c}^{[0]}(z)+\{1/[(12)(4)]\}C_{2,c}^{[2]}(z), \tag{H.2.16}$$

which, using (2.12), can be rewritten as

$$C_{4,c}^{[0]}(z)=(1/4)B_{3,c}^{[0]}(z)+(1/96)B_{1,c}^{[2]}(z). \tag{H.2.17}$$

Finally, put $m = 4$, The result is

$$C^{[0]}_{5,c}(z) = (1/5)B^{[0]}_{4,c}(z) + \{1/[(16)(5)]\}C^{[2]}_{3,c}(z), \tag{H.2.18}$$

which, using (2.15), can be rewritten as

$$C^{[0]}_{5,c}(z) = (1/5)B^{[0]}_{4,c}(z) + (1/240)B^{[2]}_{2,c}(z) + (1/1920)B^{[4]}_{0}(z). \tag{H.2.19}$$

The pattern is now clear. All the $C^{[0]}_{m,c}(z)$ are determined in terms of the $B^{[n]}_{m,c}(z)$, and (2.4) is satisfied.

Move on to look at (2.5), which can also be written in the form

$$\begin{aligned}&\sin(\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{2}{2^{2\ell}\ell!(\ell+1)!}C^{[2\ell]}_{2,s}(z)\rho^{2\ell+1}\\ &+\sum_{m=2}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}\{(m+1)C^{[2\ell]}_{m+1,s}(z)-[1/(4m)]C^{[2\ell+2]}_{m-1,s}(z)\}\rho^{2\ell+m}\\ &\overset{?}{=}\sin(\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!(\ell+1)!}B^{[2\ell]}_{1,s}(z)\rho^{2\ell+1}\\ &+\sum_{m=2}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}B^{[2\ell]}_{m,s}(z)\rho^{2\ell+m}.\end{aligned} \tag{H.2.20}$$

Upon equating like terms in (2.20) we see that it is equivalent to the two relations

$$2C^{[2\ell]}_{2,s}(z)\overset{?}{=}B^{[2\ell]}_{1,s}(z) \tag{H.2.21}$$

and

$$(m+1)C^{[2\ell]}_{m+1,s}(z) - [1/(4m)]C^{[2\ell+2]}_{m-1,s}(z)\overset{?}{=}B^{[2\ell]}_{m,s}(z) \text{ for } m \geq 2. \tag{H.2.22}$$

The relation (2.21) has the solution

$$C^{[0]}_{2,s}(z) = (1/2)B^{[0]}_{1,s}(z), \tag{H.2.23}$$

and (2.22) can be written in the recursive form

$$C^{[2\ell]}_{m+1,s}(z)\overset{?}{=}[1/(m+1)]B^{[2\ell]}_{m,s}(z) + \{1/[(4m)(m+1)]\}C^{[2\ell+2]}_{m-1,s}(z) \text{ for } m \geq 2. \tag{H.2.24}$$

Now make the stipulation

$$C^{[0]}_{1,s}(z) = 0. \tag{H.2.25}$$

Then, for $m = 2$, we get the result

$$C^{[0]}_{3,s}(z) = (1/3)B^{[0]}_{2,s}(z). \tag{H.2.26}$$

Now put $m = 3$ to get the result

$$C^{[0]}_{4,s}(z) = (1/4)B^{[0]}_{3,s}(z) + \{1/[(12)(4)]\}C^{[2]}_{2,s}(z), \tag{H.2.27}$$

which, when combined with (2.23), gives the result

$$C_{4,s}^{[0]}(z) = (1/4)B_{3,s}^{[0]}(z) + (1/96)B_{1,s}^{[2]}(z). \tag{H.2.28}$$

To continue the calculation, put $m = 4$ to find

$$C_{5,s}^{[0]}(z) = (1/5)B_{4,s}^{[0]}(z) + \{1/[(16)(5)]\}C_{3,s}^{[2]}(z), \tag{H.2.29}$$

which, when combined with (2.26), gives the result

$$C_{5,s}^{[0]}(z) = (1/5)B_{4,s}^{[0]}(z) + (1/240)B_{2,s}^{[2]}(z). \tag{H.2.30}$$

The pattern becomes clear when $m = 5$. In this case we find that

$$C_{6,s}^{[0]}(z) = (1/6)B_{5,s}^{[0]}(z) + \{1/[(20)(6)]\}C_{4,s}^{[2]}(z), \tag{H.2.31}$$

which, when combined with (2.28), gives the result

$$C_{6,s}^{[0]}(z) = (1/6)B_{5,s}^{[0]}(z) + (1/480)B_{3,s}^{[2]}(z) + (1/11520)B_{1,s}^{[4]}(z). \tag{H.2.32}$$

We see that all the $C_{m,s}^{[0]}(z)$ are determined in terms of the $B_{m,s}^{[n]}(z)$, and (2.5) is satisfied. Thus, both (2.4) and (2.5) have been satisfied, and therefore our goal (2.1) has been met.

At this point we should comment on the stipulations (2.11) and (2.25). Evidently the stipulation (2.11) specifies that all terms of the form

$$\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!\ell!}C_0^{[2\ell]}(z)\rho^{2\ell} \tag{H.2.33}$$

are omitted from ψ. And the stipulation (2.25) specifies that all terms of the form

$$\sin(\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!(\ell+1)!}C_{1,s}^{[2\ell]}(z)\rho^{2\ell+1} \tag{H.2.34}$$

are omitted from ψ. We have seen that these terms are not needed to meet the goal (2.1), and their omission simplifies the recursion relations that specify ψ in terms of χ.

H.2.2 Solution of $\partial_y\psi = \chi$

We next address the question of whether there is a ψ such that (2.2) is satisfied. By symmetry we know that there must be such a ψ, but it is instructive to work out the details. Evidently we must compare (1.33) and (2.3). We must try to satisfy the pair of equations

$$\begin{aligned}&\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!\ell!}C_{1,s}^{[2\ell]}(z)\rho^{2\ell} + \cos(\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{2}{2^{2\ell}\ell!(\ell+1)!}C_{2,s}^{[2\ell]}(z)\rho^{2\ell+1}\\ &+\sum_{m=2}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}\{(m+1)C_{m+1,s}^{[2\ell]}(z) + [1/(4m)]C_{m-1,s}^{[2\ell+2]}(z)\}\rho^{2\ell+m}\\ &\overset{?}{=}\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!\ell!}B_0^{[2\ell]}(z)\rho^{2\ell} + \sum_{m=1}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}B_{m,c}^{[2\ell]}(z)\rho^{2\ell+m}\end{aligned} \tag{H.2.35}$$

and

$$
\begin{aligned}
&-\sin(\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{2}{2^{2\ell}\ell!(\ell+1)!}[C_{2,c}^{[2\ell]}(z)+(1/4)C_{0}^{[2\ell+2]}]\rho^{2\ell+1}\\
&-\sum_{m=2}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}\{(m+1)C_{m+1,c}^{[2\ell]}(z)+[1/(4m)]C_{m-1,c}^{[2\ell+2]}(z)\}\rho^{2\ell+2}\\
&\overset{?}{=}\sum_{m=1}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}B_{m,s}^{[2\ell]}(z)\rho^{2\ell+m}. \qquad \text{(H.2.36)}
\end{aligned}
$$

Let us first work on question (2.35). Begin by setting

$$C_{1,s}^{[0]}(z)=B_{0}^{[0]}(z). \qquad \text{(H.2.37)}$$

When this is done, (2.35) becomes

$$
\begin{aligned}
&\cos(\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{2}{2^{2\ell}\ell!(\ell+1)!}C_{2,s}^{[2\ell]}(z)\rho^{2\ell+1}\\
&+\sum_{m=2}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}\{(m+1)C_{m+1,s}^{[2\ell]}(z)+[1/(4m)]C_{m-1,s}^{[2\ell+2]}(z)\}\rho^{2\ell+m}\\
&\overset{?}{=}\cos(\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!(\ell+1)!}B_{1,c}^{[2\ell]}(z)\rho^{2\ell+1}\\
&+\sum_{m=2}^{\infty}\cos(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}B_{m,c}^{[2\ell]}(z)\rho^{2\ell+m},
\end{aligned}
\qquad \text{(H.2.38)}
$$

which is equivalent to the questions

$$2C_{2,s}^{[0]}(z)\overset{?}{=}B_{1,c}^{[0]}(z) \qquad \text{(H.2.39)}$$

and

$$(m+1)C_{m+1,s}^{[0]}(z)+[1/(4m)]C_{m-1,s}^{[2]}(z)\overset{?}{=}B_{m,c}^{[0]}(z) \text{ for } m\geq 2. \qquad \text{(H.2.40)}$$

The question (2.39) has the answer

$$C_{2,s}^{[0]}(z)=(1/2)B_{1,c}^{[0]}(z), \qquad \text{(H.2.41)}$$

and (2.40) can be written in the recursive form

$$C_{m+1,s}^{[0]}(z)\overset{?}{=}[1/(m+1)]B_{m,c}^{[0]}(z)-\{1/[(4m)(m+1)]\}C_{m-1,s}^{[2]}(z). \qquad \text{(H.2.42)}$$

We see from (2.37) and (2.41) that this recursion relation has a unique solution. Setting $m=2$ in (2.42) gives the result

$$C_{3,s}^{[0]}(z)=(1/3)B_{2,c}^{[0]}(z)-\{1/[(8)(3)]\}C_{1,s}^{[2]}(z), \qquad \text{(H.2.43)}$$

which, in view of (2.37), becomes

$$C^{[0]}_{3,s}(z) = (1/3)B^{[0]}_{2,c}(z) - (1/24)B^{[2]}_{0}(z). \tag{H.2.44}$$

Setting $m = 3$ gives

$$C^{[0]}_{4,s}(z) = (1/4)B^{[0]}_{3,c}(z) - \{1/[(12)(4)]\}C^{[2]}_{2,s}(z), \tag{H.2.45}$$

which, in view of (2.41), becomes

$$C^{[0]}_{4,s}(z) = (1/4)B^{[0]}_{3,c}(z) - (1/96)B^{[2]}_{1,c}(z). \tag{H.2.46}$$

Setting $m = 4$ gives

$$C^{[0]}_{5,s}(z) = (1/5)B^{[0]}_{3,c}(z) - \{1/[(16)(5)]\}C^{[2]}_{3,s}(z), \tag{H.2.47}$$

which, in view of (2.44), becomes

$$C^{[0]}_{5,s}(z) = (1/5)B^{[0]}_{4,c}(z) - (1/96)B^{[2]}_{2,c}(z) - (1/96)B^{[4]}_{0}(z). \tag{H.2.48}$$

Evidently we are able to find all the $C^{[0]}_{m,s}(z)$ in terms of the $B^{[n]}_{m,c}(z)$, and therefore (2.35) can be satisfied.

Now turn to satisfying (2.36), which is equivalent to the question

$$\begin{aligned}
&-\sin(\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{2}{2^{2\ell}\ell!(\ell+1)!}[C^{[2\ell]}_{2,c}(z) + (1/4)C^{[2\ell+2]}_{0}]\rho^{2\ell+1} \\
&-\sum_{m=2}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}\{(m+1)C^{[2\ell]}_{m+1,c}(z) + [1/(4m)]C^{[2\ell+2]}_{m-1,c}(z)\}\rho^{2\ell+2} \\
&\overset{?}{=}\sin(\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!(\ell+1)!}B^{[2\ell]}_{1,s}(z)\rho^{2\ell+1} \\
&+\sum_{m=2}^{\infty}\sin(m\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{m!}{2^{2\ell}\ell!(\ell+m)!}B^{[2\ell]}_{m,s}(z)\rho^{2\ell+m}.
\end{aligned} \tag{H.2.49}$$

Upon equating like terms, we find the questions

$$2[C^{[0]}_{2,c}(z) + (1/4)C^{[2]}_{0}] \overset{?}{=} -B^{[0]}_{1,s}(z) \tag{H.2.50}$$

and

$$(m+1)C^{[0]}_{m+1,c}(z) + [1/(4m)]C^{[2]}_{m-1,c}(z) \overset{?}{=} -B^{[0]}_{m,s}(z). \tag{H.2.51}$$

We again make the stipulation (2.11) so that (2.50) has the answer

$$C^{[0]}_{2,c}(z) = -(1/2)B^{[0]}_{1,s}(z). \tag{H.2.52}$$

Moreover, (2.51) is equivalent to the recursion relation

$$C^{[0]}_{m+1,c}(z) \overset{?}{=} -[1/(m+1)]B^{[0]}_{m,s}(z) - \{1/[(4m)(m+1)]\}C^{[2]}_{m-1,c}(z). \tag{H.2.53}$$

We now add the further stipulation

$$C_{1,c}^{[0]}(z)=0. \tag{H.2.54}$$

In view of (2.52) and (2.54), the recursion relation (2.53) now has a unique solution. Setting $m=2$ and using (2.54) give the result

$$C_{3,c}^{[0]}(z)=-(1/3)B_{2,s}^{[0]}(z). \tag{H.2.55}$$

Next set $m=3$ to find the result

$$C_{4,c}^{[0]}(z)=-(1/4)B_{3,s}^{[0]}(z)-\{1/[(12)(4)]\}C_{2,c}^{[2]}(z), \tag{H.2.56}$$

which, in view of (2.52), becomes the relation

$$C_{4,c}^{[0]}(z)=-(1/4)B_{3,s}^{[0]}(z)+(1/96)B_{1,s}^{[2]}(z). \tag{H.2.57}$$

Now set $m=4$ to find the result

$$C_{5,c}^{[0]}(z)=-(1/5)B_{4,s}^{[0]}(z)-\{1/[(16)(5)]\}C_{3,c}^{[2]}(z), \tag{H.2.58}$$

which, in view of (2.55), becomes the relation

$$C_{5,c}^{[0]}(z)=-(1/5)B_{4,s}^{[0]}(z)+(1/240)B_{2,s}^{[2]}(z). \tag{H.2.59}$$

Set $m=5$ to find the result

$$C_{6,c}^{[0]}(z)=-(1/6)B_{5,s}^{[0]}(z)-\{1/[(20)(6)]\}C_{4,c}^{[2]}(z), \tag{H.2.60}$$

which, in view of (2.57), becomes the relation

$$C_{6,c}^{[0]}(z)=-(1/6)B_{5,s}^{[0]}(z)+(1/480)B_{3,s}^{[2]}(z)-(1/11520)B_{1,s}^{[4]}(z). \tag{H.2.61}$$

Evidently we are able to find all the $C_{m,c}^{[0]}(z)$ in terms of the $B_{m,s}^{[n]}(z)$, and therefore (2.36) can be satisfied. Since both (2.35) and (2.36) have been satisfied, our goal (2.2) has been met.

We note that the stipulation (2.54) specifies that all terms of the form

$$\cos(\phi)\sum_{\ell=0}^{\infty}(-1)^{\ell}\frac{1}{2^{2\ell}\ell!(\ell+1)!}C_{1,c}^{[2\ell]}(z)\rho^{2\ell+1} \tag{H.2.62}$$

are omitted from ψ. We have seen that these terms [and those of (2.33)] are not needed to meet the goal (2.2), and their omission simplifies the recursion relations that specify ψ in terms of χ.

H.3 Harmonic Functions in Two Variables and Their Associated Fields

It is also useful to have representations for harmonic functions in two variables. We will consider the two cases of harmonic functions in the variable pairs x, z and y, z.

H.3.1 Harmonic Functions in x, z

Suppose $\psi(x,z)$ is a harmonic function in the two variables x, z. That is, we have the relation

$$[(\partial_x)^2 + (\partial_z)^2]\psi(x,z) = 0. \tag{H.3.1}$$

Decompose ψ into *even* and *odd* parts with respect to its x dependence,

$$\psi = \psi_{ev} + \psi_{od}. \tag{H.3.2}$$

Then, because the operation $x \to -x$ commutes with $[(\partial_x)^2 + (\partial_z)^2]$, each separate part of ψ must be harmonic,

$$[(\partial_x)^2 + (\partial_z)^2]\psi_{ev}(x,z) = 0, \tag{H.3.3}$$

$$[(\partial_x)^2 + (\partial_z)^2]\psi_{od}(x,z) = 0. \tag{H.3.4}$$

Series Representation

For the even part let us make the Ansatz

$$\begin{aligned}\psi_{ev}(x,z) &= \sum_{n=0}^{\infty}(-1)^n[1/(2n)!]x^{2n}E^{[2n]}(z)\\ &= E^{[0]}(z) - (1/2)x^2E^{[2]}(z) + (1/24)x^4E^{[4]}(z) + \cdots ,\end{aligned} \tag{H.3.5}$$

where the functions $E^{[n]}(z)$ and the meaning of the $[n]$ notation are yet to be determined. For such a ψ_{ev} to be harmonic there must be the relation

$$\begin{aligned}0 &= \nabla^2\psi_{ev}(x,z) = \partial_x^2\psi_{ev}(x,z) + \partial_z^2\psi(x,z)\\ &= [\partial_z^2E^{[0]}(z) - E^{[2]}(z)] - (1/2)x^2[\partial_z^2E^{[2]}(z) - E^{[4]}(z)] + \cdots ,\end{aligned} \tag{H.3.6}$$

from which we conclude that

$$E^{[n+2]}(z) = \partial_z^2E^{[n]}(z). \tag{H.3.7}$$

Similarly, for the odd part we make the Ansatz

$$\begin{aligned}\psi_{od}(x,z) &= \sum_{n=0}^{\infty}(-1)^n[1/(2n+1)!]x^{2n+1}O^{[2n]}(z)\\ &= xO^{[0]}(z) - (1/6)x^3O^{[2]}(z) + (1/120)x^5O^{[4]}(z) + \cdots .\end{aligned} \tag{H.3.8}$$

Now the harmonic requirement yields the result

$$\begin{aligned}0 &= \nabla^2\psi_{od}(x,z) = \partial_x^2\psi_{od}(x,z) + \partial_z^2\psi_{od}(x,z)\\ &= x[\partial_z^2O^{[0]}(z) - O^{[2]}(z)] - (1/6)x^3[\partial_z^2O^{[2]}(z) - O^{[4]}(z)] + \cdots ,\end{aligned} \tag{H.3.9}$$

from which we conclude that

$$O^{[n+2]}(z) = \partial_z^2O^{[n]}(z). \tag{H.3.10}$$

We see that in both cases the $[n]$ notation is the usual one. Thus, ψ is specified by the two functions $E^{[0]}(z)$ and $O^{[0]}(z)$. These functions may, in principle, be chosen arbitrarily. Often they are required to go to zero as $|z| \to \infty$.

Let us compute the "fields" associated with ψ_{ev} and ψ_{od}, call them $\boldsymbol{B}^{ev}$ and $\boldsymbol{B}^{od}$. We find the results

$$B_x^{ev} = \partial_x \psi_{ev} = -xE^{[2]}(z) + (1/6)x^3 E^{[4]}(z) - (1/120)x^5 E^{[6]}(z) + \cdots , \tag{H.3.11}$$

$$B_y^{ev} = \partial_y \psi_{ev} = 0, \tag{H.3.12}$$

$$B_z^{ev} = \partial_z \psi_{ev} = E^{[1]}(z) - (1/2)x^2 E^{[3]}(z) + (1/24)x^4 E^{[5]}(z) + \cdots ; \tag{H.3.13}$$

$$B_x^{od} = \partial_x \psi_{od} = O^{[0]}(z) - (1/2)x^2 O^{[2]}(z) + (1/24)x^4 O^{[4]}(z) + \cdots , \tag{H.3.14}$$

$$B_y^{od} = \partial_y \psi_{od} - 0, \tag{H.3.15}$$

$$B_z^{od} = \partial_z \psi_{od} = xO^{[1]}(z) - (1/6)x^3 O^{[3]}(z) + (1/120)x^5 O^{[5]}(z) + \cdots . \tag{H.3.16}$$

Note that, because the fields are the gradients of harmonic functions, the Cartesian components of $\boldsymbol{B}^{ev}$ and $\boldsymbol{B}^{od}$ must also be harmonic functions.

Explicit Construction from Analytic Functions

As is well known, there is an intimate connection between harmonic functions in two variables and analytic functions of a complex variable. This connection facilitates obtaining closed-form expressions for harmonic functions rather than dealing solely with power series. Let w be a complex variable written in the form

$$w = u + iv. \tag{H.3.17}$$

Suppose $f(w)$ is a *real-analytic* function. That is, f is defined, analytic, and real for w on the real axis. Such a function can be extended into the complex plane by analytic continuation. For complex arguments, decompose f into real and imaginary parts by writing

$$f(u + iv) = f_r(u, v) + if_i(u, v). \tag{H.3.18}$$

For f_r and f_i we find, by the chain rule, the result

$$[(\partial_u)^2 + (\partial_v)^2][f_r(u, v) + if_i(u, v)] = f''(u + iv)(1 + i^2) = 0. \tag{H.3.19}$$

Thus, upon equating real and imaginary parts in (H.19), we see that both f_r and f_i are harmonic.

Let us expand f as a power series in the quantity iv. From Taylor's theorem we find the result

$$\begin{aligned} f(u + iv) &= \sum_{n=0}^{\infty} f^{[n]}(u)(iv)^n/n! \\ &= \sum_{n=0}^{\infty} (-1)^n [1/(2n)!] v^{2n} f^{[2n]}(u) \\ &\quad + i \sum_{n=0}^{\infty} (-1)^n [1/(2n+1)!] v^{2n+1} f^{[2n+1]}(u). \end{aligned} \tag{H.3.20}$$

Upon comparing (H.18) and (H.20), we see that there are the relations

$$\begin{aligned} f_r(u,v) &= \sum_{n=0}^{\infty}(-1)^n[1/(2n)!]v^{2n}f^{[2n]}(u) \\ &= f^{[0]}(u)-(1/2)v^2f^{[2]}(u)+(1/24)v^4f^{[4]}(u)+\cdots \end{aligned} \tag{H.3.21}$$

and

$$\begin{aligned} f_i(u,v) &= \sum_{n=0}^{\infty}(-1)^n[1/(2n+1)!]v^{2n+1}f^{[2n+1]}(u) \\ &= vf^{[1]}(u)-(1/6)v^3f^{[3]}(u)+(1/120)v^5f^{[5]}(u)+\cdots . \end{aligned} \tag{H.3.22}$$

Observe the resemblance between the pair (H.5) and (H.8) and the pair (H.21) and (H.22). Upon making the identifications

$$z \leftrightarrow u, \tag{H.3.23}$$

$$x \leftrightarrow v, \tag{H.3.24}$$

$$E^{[0]}(z) \leftrightarrow f^{[0]}(u), \tag{H.3.25}$$

and

$$O^{[0]}(z) \leftrightarrow f^{[1]}(u), \tag{H.3.26}$$

we see that these two pairs are the same. Thus, with these identifications, we have the relations

$$\psi_{ev}(x,z)=f_r(z,x), \tag{H.3.27}$$

$$\psi_{od}(x,z)=f_i(z,x). \tag{H.3.28}$$

Note that the identifications (H.25) and (H.26) require the restrictive relation

$$O^{[0]}=E^{[1]}. \tag{H.3.29}$$

Of course, in general, ψ_{ev} and ψ_{od} need not be the real and imaginary parts of the *same* real-analytic function.

Since f_r and f_i are the real and imaginary parts of the analytic function f, they must satisfy the Cauchy-Riemann relations

$$\partial_z f_r = \partial_x f_i, \tag{H.3.30}$$

$$\partial_x f_r = -\partial_z f_i. \tag{H.3.31}$$

Consequently, if ψ_{ev} and ψ_{od} are the real and imaginary parts of the *same* real-analytic function, we have the relations

$$B_x^{ev}=\partial_x\psi_{ev}=\partial_x f_r=-\partial_z f_i=-\partial_z\psi_{od}=-B_z^{od}, \tag{H.3.32}$$

$$B_z^{ev}=\partial_z\psi_{ev}=\partial_z f_r=\partial_x f_i=\partial_x\psi_{od}=B_x^{od}. \tag{H.3.33}$$

These relations also follow from the representations (H.11) through (H.16) and the relation (H.29).

There is another application of the relation between analytic and harmonic functions that is useful. We will formulate and apply it in the subsection after the next where we discuss harmonic functions in the y,z variables. From that discussion the reader can easily infer the analogous results for harmonic functions in the variables x,z.

H.3.2 Harmonic Functions in y, z

The case of harmonic functions in the variables y, z is analogous to the x, z case. It is only necessary to make the substitution $x \to y$ in the relations found above.

Suppose $\psi(y, z)$ is a harmonic function in the two variables y, z. That is, we have the relation

$$[(\partial_y)^2 + (\partial_z)^2]\psi(y, z) = 0. \tag{H.3.34}$$

Decompose ψ into *even* and *odd* parts with respect to its y dependence,

$$\psi = \psi_{ev} + \psi_{od}. \tag{H.3.35}$$

Then, because the operation $y \to -y$ commutes with $[(\partial_y)^2 + (\partial_z)^2]$, each separate part of ψ must be harmonic,

$$[(\partial_y)^2 + (\partial_z)^2]\psi_{ev}(y, z) = 0, \tag{H.3.36}$$

$$[(\partial_y)^2 + (\partial_z)^2]\psi_{od}(y, z) = 0. \tag{H.3.37}$$

Series Representation

For the even part there is the representation

$$\begin{aligned}\psi_{ev}(y, z) &= \sum_{n=0}^{\infty}(-1)^n[1/(2n)!]y^{2n}E^{[2n]}(z)\\ &= E^{[0]}(z) - (1/2)y^2E^{[2]}(z) + (1/24)y^4E^{[4]}(z) + \cdots .\end{aligned} \tag{H.3.38}$$

For the odd part there is the representation

$$\begin{aligned}\psi_{od}(y, z) &= \sum_{n=0}^{\infty}(-1)^n[1/(2n+1)!]y^{2n+1}O^{[2n]}(z)\\ &= yO^{[0]}(z) - (1/6)y^3O^{[2]}(z) + (1/120)y^5O^{[4]}(z) + \cdots .\end{aligned} \tag{H.3.39}$$

Thus, ψ is specified by the two functions $E^{[0]}(z)$ and $O^{[0]}(z)$. These functions may, in principle, be chosen arbitrarily. Often they are required to go to zero as $|z| \to \infty$.

For the "fields" associated with ψ_{ev} and ψ_{od}, call them $\boldsymbol{B}^{ev}$ and $\boldsymbol{B}^{od}$, there are the results

$$B_x^{ev} = \partial_x\psi_{ev} = 0, \tag{H.3.40}$$

$$B_y^{ev} = \partial_y\psi_{ev} = -yE^{[2]}(z) + (1/6)y^3E^{[4]}(z) - (1/120)y^5E^{[6]}(z) + \cdots , \tag{H.3.41}$$

$$B_z^{ev} = \partial_z\psi_{ev} = E^{[1]}(z) - (1/2)y^2E^{[3]}(z) + (1/24)y^4E^{[5]}(z) + \cdots ; \tag{H.3.42}$$

$$B_x^{od} = \partial_x\psi_{od} = 0, \tag{H.3.43}$$

$$B_y^{od} = \partial_y\psi_{od} = O^{[0]}(z) - (1/2)y^2O^{[2]}(z) + (1/24)y^4O^{[4]}(z) + \cdots , \tag{H.3.44}$$

$$B_z^{od} = \partial_z\psi_{od} = yO^{[1]}(z) - (1/6)y^3O^{[3]}(z) + (1/120)y^5O^{[5]}(z) + \cdots . \tag{H.3.45}$$

Again, because the fields are the gradients of harmonic functions, the Cartesian components of $\boldsymbol{B}^{ev}$ and $\boldsymbol{B}^{od}$ must also be harmonic functions.

Explicit Construction from Analytic Functions

Suppose the functions $\psi_{ev}(y,z)$ and $\psi_{od}(y,z)$ are related to the real and imaginary parts of a real-analytic function f. Make the identifications

$$z \leftrightarrow u, \tag{H.3.46}$$

$$y \leftrightarrow v, \tag{H.3.47}$$

$$E^{[0]}(z) \leftrightarrow f^{[0]}(u), \tag{H.3.48}$$

and

$$O^{[0]}(z) \leftrightarrow f^{[1]}(u). \tag{H.3.49}$$

With these identifications, we have the relations

$$\psi_{ev}(y,z) = f_r(y,x), \tag{H.3.50}$$

$$\psi_{od}(y,z) = f_i(y,x). \tag{H.3.51}$$

The identifications (H.48) and (H.49) again require the restrictive relation

$$O^{[0]} = E^{[1]}. \tag{H.3.52}$$

But, since f_r and f_i are the real and imaginary parts of the analytic function f, they must satisfy the Cauchy-Riemann relations

$$\partial_z f_r = \partial_x f_i, \tag{H.3.53}$$

$$\partial_x f_r = -\partial_z f_i. \tag{H.3.54}$$

Thus, we have the relations

$$B_y^{ev} = -B_z^{od}, \tag{H.3.55}$$

$$B_z^{ev} = B_y^{od}. \tag{H.3.56}$$

These relations also follow from the representations (H.40) through (H.45) and the relation (H.52).

H.3.3 More About $\mathrm{B}^{od}(y,z)$ and Another Application of Analytic Function Theory

To keep the promise made in Subsection H.3.1, we now discuss another application of the relation between analytic and harmonic functions. Consider the field $\boldsymbol{B}^{od}(y,z)$ given by (H.43) through (H.45). It is a candidate magnetic field for an infinitely wide (in x) parallel-faced dipole, see Figures 1.6.1 and 1.6.2, with symmetry about the midplane $y=0$. Given a real-analytic function $f(w)$, define a related function $g(w)$ by the rule

$$g(w) = f^{[1]}(w). \tag{H.3.57}$$

Evidently g will also be real analytic. As before, employ the relation (H.17) and decompose g into real and imaginary parts by writing

$$g(u+iv) = g_r(u,v) + g_i(u,v). \tag{H.3.58}$$

In analogy to what was done for f, expand $g(u+iv)$ as a Taylor series in iv to get the relation

$$\begin{aligned} g(u+iv) &= \sum_{n=0}^{\infty} g^{[n]}(u)(iv)^n/n! \\ &= [g^{[0]}(u) - (1/2)v^2 g^{[2]}(u) + (1/24)v^4 g^{[4]}(u) + \cdots] \\ &\quad +i[vg^{[1]}(u) - (1/6)v^3 g^{[3]}(u) + (1/120)v^5 g^{[5]}(u) + \cdots]. \end{aligned} \tag{H.3.59}$$

We see that

$$g_r(u,v) = g^{[0]}(u) - (1/2)v^2 g^{[2]}(u) + (1/24)v^4 g^{[4]}(u) + \cdots \tag{H.3.60}$$

and

$$g_i(u,v) = vg^{[1]}(u) - (1/6)v^3 g^{[3]}(u) + (1/120)v^5 g^{[5]}(u) + \cdots . \tag{H.3.61}$$

Make the identifications (H.46) and (H.47) and compare the series on the right side of (H.59) with the series (H.44) and (H.45) for B_y^{od} and B_z^{od}. We see that they are analogous if we make the identification

$$O^{[0]} = g^{[0]}. \tag{H.3.62}$$

In particular, we have the relations

$$B_y^{od}(y,z) = g_r(z,y) = g^{[0]}(z) - (1/2)y^2 g^{[2]}(z) + (1/24)y^4 g^{[4]}(z) + \cdots , \tag{H.3.63}$$

$$B_z^{od}(y,z) = g_i(z,y) = yg^{[1]}(z) - (1/6)y^3 g^{[3]}(z) + (1/120)y^5 g^{[5]}(z) + \cdots . \tag{H.3.64}$$

The Cauchy-Riemann relations again hold for g_r and g_i,

$$\partial_u g_r(u,v) = \partial_v g_i(u,v), \tag{H.3.65}$$

$$\partial_v g_r(u,v) = -\partial_u g_i(u,v). \tag{H.3.66}$$

In this case, because of (H.63) and (H.64), they have the consequence

$$\partial_z B_y^{od}(y,z) = \partial_z g_r(z,y) = \partial_y g_i(y,z) = \partial_y B_z^{od}(y,z), \tag{H.3.67}$$

$$\partial_y B_y^{od}(y,z) = \partial_y g_r(z,y) = -\partial_z g_i(y,z) = -\partial_z B_z^{od}(y,z). \tag{H.3.68}$$

These relations can also be verified directly form the representations (H.63) and (H.64).

We already know that $\nabla \times \boldsymbol{B}^{od} = 0$ because $\boldsymbol{B}^{od}$ is the gradient of a scalar field. See (H.43) through (H.45). What can be said about $\nabla \cdot \boldsymbol{B}^{od}$? From the second Cauchy-Riemann relation (H.68) we see that

$$\nabla \cdot \boldsymbol{B}^{od} = \partial_y B_y^{od} + \partial_z B_z^{od} = 0, \tag{H.3.69}$$

as expected and required.

Also observe that, in complex notation, the relations (H.58), (H.63), and (H.64) can be expressed in the compact form

$$B_y^{odd}(y,z) + iB_z^{odd}(y,z) = g(z+iy). \tag{H.3.70}$$

Thus, in this application, the selection of one real-analytic function $g(w)$ specifies both components of the field for an infinitely wide parallel-faced dipole. Indeed, the application is even broader. It would also apply to an infinitely wide parallel-faced wiggler. In this case $g(u)$ would be roughly oscillatory in u. All that is required in both applications is that $g(u)$ vanish as $u \rightarrow \pm\infty$, in which case $\boldsymbol{B}^{od}(y,z)$ will vanish as $z \rightarrow \pm\infty$. Suppose, for example, that we set

$$g(u) = B \text{ bump}(u, c\ell, L) \tag{H.3.71}$$

where bump$(u, c\ell, L)$ is one of the bump functions defined in Section 11.11. These functions are real analytic, and therefore the representation (H.70) can be implemented.

There is one last item to be discussed. Namely, it would be good to have a vector potential $\boldsymbol{A}^{od}$ from which $\boldsymbol{B}^{od}$ could be derived. Consider the following Ansatz,

$$A_x^{od}(x,y,z) = 0, \tag{H.3.72}$$

$$A_y^{od}(x,y,z) = xB_z^{od}(y,z), \tag{H.3.73}$$

$$A_z^{od}(x,y,z) = -xB_y^{od}(y,z). \tag{H.3.74}$$

(Evidently, this vector potential is horizontal free.) It is easily verified that

$$(\nabla \times \boldsymbol{A}^{od})_x = \partial_y A_z^{od} - \partial_z A_y^{od} = x[-\partial_y B_y^{od}(y,z) - \partial_z B_z^{od}(y,z)] = 0 = B_x^{od}(y,z), \tag{H.3.75}$$

$$(\nabla \times \boldsymbol{A}^{od})_y = \partial_z A_x^{od} - \partial_x A_z^{od} = -\partial_x A_z^{od} = B_y^{od}(y,z), \tag{H.3.76}$$

$$(\nabla \times \boldsymbol{A}^{od})_z = \partial_x A_y^{od} - \partial_y A_x^{od} = \partial_x A_y^{od} = B_z^{od}(y,z), \tag{H.3.77}$$

as desired. Also, we find that

$$\nabla \cdot \boldsymbol{A}^{od} = \partial_y A_y^{od} + \partial_z A_z^{od} = x[\partial_y B_z^{od}(y,z) - \partial_z B_y^{od}(y,z)] = 0. \tag{H.3.78}$$

Here we have used the first Cauchy-Riemann relation (H.67). Thus, in addition to being horizontal free, the vector potential $\boldsymbol{A}^{od}(x,y,z)$ is in the Coulomb gauge. Since $\boldsymbol{A}^{od}(x,y,z)$ is in the Coulomb gauge, it follows, as is also readily verified from (H.72) through (H.74), that its Cartesian components are harmonic functions.

Note also, from its definition (H.72) through (H.74), that $\boldsymbol{A}^{od}(x,y,z)$ vanishes as $z \rightarrow \pm\infty$ if $\boldsymbol{B}^{od}(y,z)$ does so. This feature is desirable because we would like canonical and mechanical momenta to be equal in field-free regions. We also note the convenient feature that $A_y^{od}(x,y,z)$ vanishes in the midplane,

$$A_y^{od}(x, y=0, z) = xB_z^{od}(y=0,z) = 0. \tag{H.3.79}$$

See (H.64). Thus, for the design orbit which lies in the midplane, there is no difference between mechanical and canonical for the x and y components of the momentum. Finally, as in the case of the vector potentials found in Exercises 13.3.4 and 13.5.5, the vector potential is primarily in the z direction except in the fringe-field regions.

Bibliography

[1] The Ansatz (H.72) through (H.74) for $\boldsymbol{A}^{od}(x, y, z)$ is due to Peter Walstrom.

$$[f_k,[f_\ell,[f_m,[f_n,z_a]]]]J_{aa'}z_{a'}= \tag{I.2.6}$$

I.3 Application

Suppose $t^i = 0$ and $t^f = 1$ in (1.2.57) and (6.6.57). Suppose also that we confine our interest to the case where only h_3 through h_6 are possibly nonzero. Our task will be to find the Poincaré generating function F_+ corresponding to $\mathcal{M}$.

From (6.6.57) we have the result

$$F(z) = -\sum_m (m-2)h_m(z). \tag{I.3.1}$$

And from (6.6.37) we know that

$$F_+(z) = [F + (Z, Jz)]/2. \tag{I.3.2}$$

Also, by definition,

$$Z = \mathcal{M}z. \tag{I.3.3}$$

Upon combining () through () we conclude that F_+ is given by the relation

$$F_+(z) = (1/2)[(\mathcal{M}z, Jz) - \sum_m (m-2)h_m(z)]. \tag{I.3.4}$$

Our task will be to work out the implications of (). What we will find will be a homogeneous polynomial expansion for F_+.

Evidently the hard part is to find an expansion for $(\mathcal{M}z, Jz)$. Let us write

$$\mathcal{M} = \exp(-:H:) = I - :H: + :H:^2/2! - :H:^3/3! : +H:^4/4! + \cdots \tag{I.3.5}$$

where the terms retained are sufficient to compute F_+ through terms of degree 6. Let $Z^{(n)}$ be the contribution to Z made by the term $:-H:^n/n!$ in $\mathcal{M}$ and let $Y^{(n)}$ be the contribution that it makes to F_+. That is, we make the definitions

$$Z^{(n)} = [:-H:^n/n!]z \tag{I.3.6}$$

and

$$Y^{(n)}(z) = (Z^{(n)}, Jz) = ([:-H:^n/n!]z, Jz). \tag{I.3.7}$$

From the relations listed in Section 23.1 above, we easily find the results

$$Y^{(0)}(z) = (Z^{(0)}, Jz) = (z, Jz) = 0, \tag{I.3.8}$$

$$\begin{aligned} Y^{(1)}(z) &= (Z^{(1)}, Jz) = (:-H:z, Jz) = -\sum_m (:h_m:z, Jz) \\ &= \sum_m m h_m(z). \end{aligned} \tag{I.3.9}$$

It follows from the work done so far that

$$\begin{aligned} F_+(z) &= (1/2)[(\mathcal{M}z, Jz) - \sum_m (m-2)h_m(z)] \\ &= (1/2)\{[\sum_m m h_m(z)] - [\sum_m (m-2)h_m(z)] + \cdots\} = H(z) + \cdots. \end{aligned} \tag{I.3.10}$$

As already stated, we ultimately desire to have an expansion of F_+ in homogeneous polynomials. Let F_+^m denote the term in F_+ that is homogeneous of degree n. Then, based on the work done so far, we have the result

$$F_+^m = h_m + \cdots \,. \tag{I.3.11}$$

The next term we need is $Y^{(2)}(z)$. We have the result

$$Y^{(2)}(z) = (Z^{(2)}, Jz) = (:H:^2 z, Jz)/2!. \tag{I.3.12}$$

The term $:H:^2$ has the expansion

$$\begin{aligned} :H:^2 &= \sum_m \sum_n :h_m::h_n: \\ &= :h_3:^2 + :h_3::h_4: + :h_4::h_3: \\ &+ :h_4:^2 + :h_3::h_5: + :h_5::h_3: + \cdots \end{aligned} \tag{I.3.13}$$

where we have displayed only the terms that will contribute to the F_+^m for $m \leq 6$. Correspondingly, we find for $Y^{(2)}$ the result

$$\begin{aligned} Y^{(2)}(z) &= (1/2!)[(:h_3:^2 z, Jz) \\ &+ (:h_3::h_4: z, Jz) + (:h_4::h_3: z, Jz) \\ &+ (:h_4:^2 z, Jz) \\ &+ (:h_3::h_5: z, Jz) + (:h_5::h_3: z, Jz)] \\ &= (1/2!)([h_3, h_3] + [h_4, h_4] \\ &+ [h_3, h_4] + [h_4, h_3] + [h_3, h_5] + [h_5, h_3]) \\ &= (1/2)([h_3, h_4] + [h_3, h_5]). \end{aligned} \tag{I.3.14}$$

We are now able to conclude that

$$F_+^3 = h_3, \tag{I.3.15}$$

$$F_+^4 = h_4, \tag{I.3.16}$$

$$F_+^5 = h_5 + (1/4)[h_3, h_4] + \cdots \,, \tag{I.3.17}$$

$$F_+^6 = h_6 + (1/4)[h_3, h_5] + \cdots \,. \tag{I.3.18}$$

Let us move on to the term

$$Y^{(3)}(z) = (Z^{(3)}, Jz) = -(:H:^3 z, Jz)/3!. \tag{I.3.19}$$

The term $:H:^3$ has the expansion

$$\begin{aligned} :H:^3 &= \sum_\ell \sum_m \sum_n :h_\ell::h_m::h_n: \\ &= :h_3:^3 + :h_3:^2:h_4: + :h_3::h_4::h_3: + :h_4::h_3:^2 + \cdots \end{aligned} \tag{I.3.20}$$

where we have displayed only the terms that will contribute to the F_+^m for $m \leq 6$. Correspondingly, we find for $Y^{(3)}$ the result

$$\begin{aligned} Y^{(3)}(z) &= (1/2!)[(: h_3 :^3 z, Jz) \\ &+ (: h_3 :^2: h_4 : z, Jz) + (: h_3 :: h_4 :: h_3; z, Jz) + (: h_4 :: h_3 :^2 z, Jz)] \\ &= \end{aligned} \tag{I.3.21}$$

We are now able to conclude that

$$F_+^3 = h_3, \tag{I.3.22}$$

$$F_+^4 = h_4, \tag{I.3.23}$$

$$F_+^5 = h_5 + (1/4)[h_3, h_4] + (\partial h_3, JS(h_3)J\partial h_3) \tag{I.3.24}$$

$$F_+^6 = h_6 + [h_3, h_5] + (\partial h_3, JS(h_3)J\partial h_4) + (\partial h_3, JS(h_4)J\partial h_3) + \cdots . \tag{I.3.25}$$

Finally, as we will see, we need the term

$$Y^{(4)}(z) = (Z^{(4)}, Jz) = -(: H :^4 z, Jz)/3!. \tag{I.3.26}$$

The term $: H :^4$ has the expansion

$$\begin{aligned} : H :^4 &= \sum_k \sum_\ell \sum_m \sum_n : h_k :: h_\ell :: h_m :: h_n : \\ &= : h_3 :^4 + \cdots \end{aligned} \tag{I.3.27}$$

where we have again displayed only the terms that will contribute to the F_+^m for $m \leq 6$. Correspondingly, we find for $Y^{(3)}$ the result

$$Y^{(4)}(z) = (1/2!)[(: h_3 :^4 z, Jz) = \tag{I.3.28}$$

We are now able to conclude that

$$F_+^3 = h_3, \tag{I.3.29}$$

$$F_+^4 = h_4, \tag{I.3.30}$$

$$F_+^5 = h_5 + (1/4)[h_3, h_4] + (\partial h_3, JS(h_3)J\partial h_3), \tag{I.3.31}$$

$$F_+^6 = h_6 + [h_3, h_5] + (\partial h_3, JS(h_3)J\partial h_4) + (\partial h_3, JS(h_4)J\partial h_3) + . \tag{I.3.32}$$

Appendix J

Feigenbaum Cascade Denied/Achieved

Section 1.2.1 described Feigenbaum infinite period doubling cascades and mentioned that, for some maps in some parameter ranges, period doubling cascades begin but do not continue to completion. The purpose of this appendix is to provide a simple example of both incomplete and complete cascades.

J.1 Simple Map and Its Initial Bifurcations

Consider the simple one-dimensional map given by the relation

$$x_{n+1} = \mathcal{M}x_n = f(a, b; x_n) = a + bx_n/[1 + (x_n)^2] \tag{J.1.1}$$

where a and b are parameters. Figure 1.1 shows the curves $y = f(a, b; x)$ for $b = 11.5$ and selected values of a. As is evident from (1.1) and from the figure, these curves are all vertical displacements of eachother.

Also shown is the line $y = x$. Any intersection of the line $y = x$ and the curve $y = f(a, b; x)$ corresponds to a fixed point of $\mathcal{M}$. Observe that for sufficiently negative values of a there is only one intersection, and hence only one fixed point. This is the fixed point whose path is shown as a function of a in the lower left portion of the bifurcation diagram provided by Figure 1.2. Its path extends forever to the left, and has the asymptotic form

$$x_\infty \simeq a \text{ as } a \to -\infty. \tag{J.1.2}$$

Further computation shows that this fixed point is stable.

However, as a is increased slightly beyond -5, Figure 1.1 shows that there are two more intersections of the curve $y = f(a, b; x)$ with the line $y = x$. When these two intersections first occur (when the curve and line are tangent), a pair of fixed points is born together in a blue-sky bifurcation. These are the two fixed points that appear out of the blue at $a \simeq -4.8$ and $x_\infty \simeq +1$ in Figure 1.2, and move along separate paths as a is further increased. One of these fixed points (the one on the lower of the two paths) is unstable, and the other (the one on the very top path) is stable.

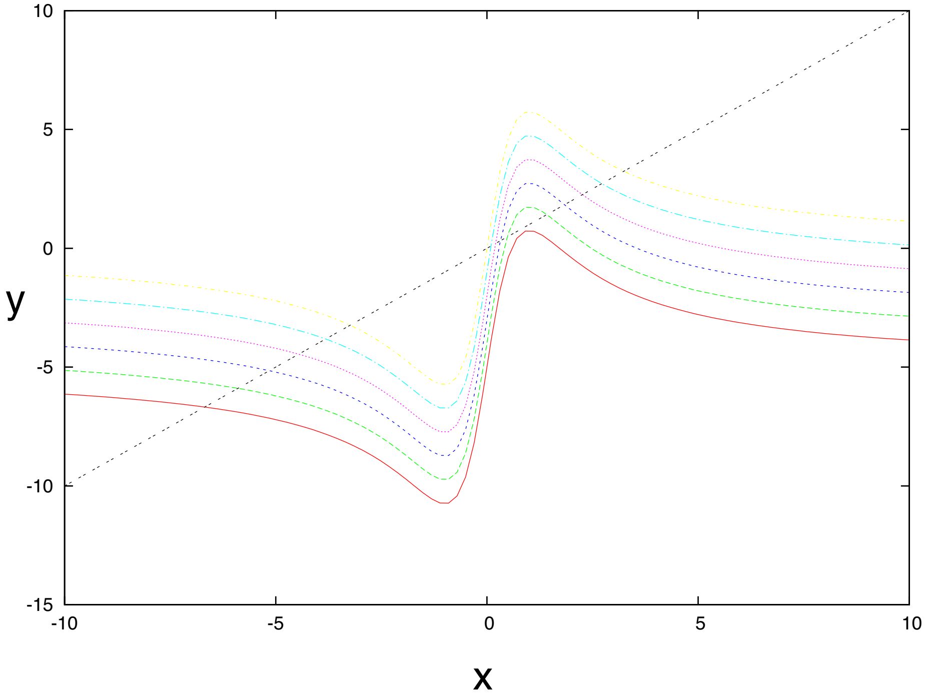

Figure J.1.1: The curves $y = f(a, b; x)$ for $b = 11.5$ and various values of $a \in [-5, 0]$. Also shown is the line $y = x$. Intersections of the line and the curve correspond to fixed points.

J.2 Complete Cascade Denied

As a is increased still further, the fixed point on the very top path begins a period doubling cascade, which we will call the *upper* cascade, at $a \simeq -4.3$ and $x \simeq +1.5$. Again see Figure 1.2. However, as is evident from the figure, the period doubling cascade does not run to completion. Instead it ceases and then begins to undo itself by successive mergers that begin at $a \simeq -3.2$ so that for $a \simeq -.8$ there is again a single fixed point. Its path extends forever to the right, and has the asymptotic form

$$x_\infty \simeq a \text{ as } a \to +\infty. \tag{J.2.1}$$

Further computation shows that this fixed point is stable.

We began our discussion with the fixed point whose path appears in the lower left side of Figure 1.2 and has the asymptotic form (1.2). Let us now follow its history as a is increased. As indicated in Figure 1.2, it too begins a period doubling cascade, which we will call the *lower* cascade, and this cascade begins at $a \simeq +.8$ and $q_\infty \simeq -2.8$. And, like the upper period doubling cascade, it also does not run to completion. Instead it stops and then undoes itself by successive mergers so that for $a \simeq +4.3$ there is again a single fixed point. This fixed point is stable. Inspection of Figure 1.2 shows that, as a is increased still further, this fixed point blue-sky merges with the unstable fixed point that came out of the blue-sky bifurcation at $a \simeq -4.8$ and $q_\infty \simeq +1$ so that they are mutually annihilated at $q_\infty \simeq -1$ when $a \simeq +4.8$.

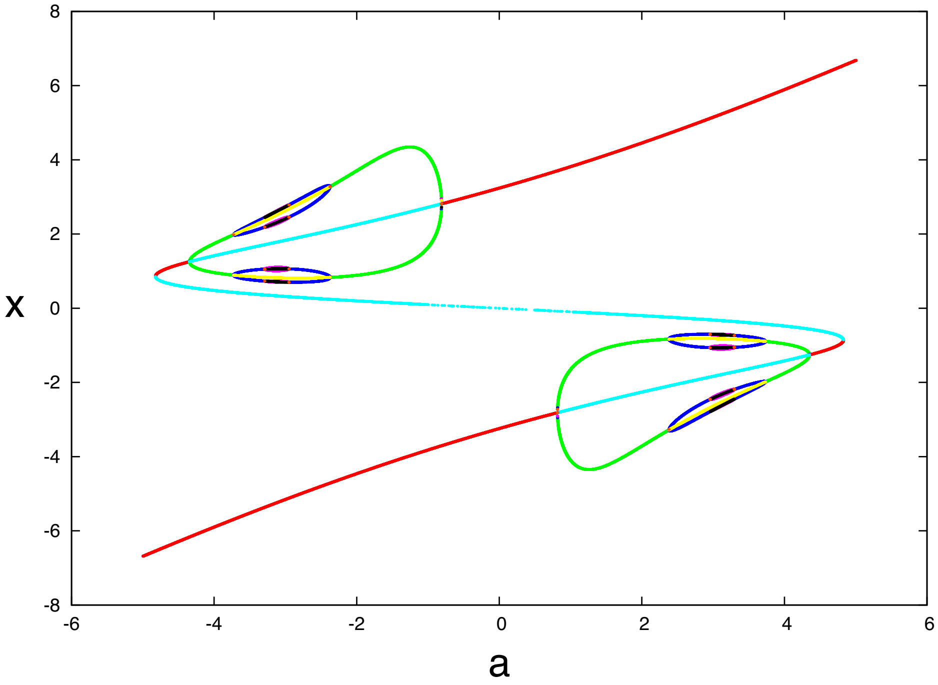

Figure J.1.2: Bifurcation diagram showing x_∞ as a function of a for the map (1.1) with $b = 11.5$ and $a \in [-5, 5]$. For $a = -5$, there is only one fixed point, and it is stable. As a is increased from this value, a blue-sky bifurcation occurs at $x_\infty \simeq +1$ when $a =\simeq -4.8$. Here a pair of fixed points, one stable and one unstable, is born. Now there are three fixed points. The one that bifurcates to larger values of x_∞ is stable, and the one that bifurcates to smaller values of x_∞ is unstable. The original fixed point persists, and remains stable. At $x_\infty \simeq +1$ and $a =\simeq +4.8$ a blue-sky merger occurs where two fixed points, one stable and the other unstable, annihilate. For a values larger than this there is only one fixed point. In between the values $a \simeq -4.8$ and $a \simeq +4.8$ there are two incomplete period-doubling cascades.

Exercises

J.2.1. Figure 2.1 displays intersections between the curve $y = f(a, b; x)$ and the line $y = x$, and we have seen how these intersections are related to the blue-sky bifurcation at $a \simeq -4.8$. Show that the blue-sky merger at $a \simeq +4.8$ can also be understood in terms of intersections between the curve $y = f(a, b; x)$ and the line $y = x$.

J.3 Complete Cascade Achieved

We have seen, from Figure 1.2, that for $b = 11.5$ the period-doubling cascades fail to run to completion. By contrast in Figure 3.1, for which $b = 11.7$, each Feigenbaum cascade runs to completion followed by a region of chaos. Then, it is fascinating to see, each cascade undoes itself by successive mergers as a is further increased until eventually there is again only the one stable fixed point.[1] Note also there that there are two visible windows of stability at $a \simeq -3.3$ and $a \simeq -3.05$. These windows contain stable period-twelve fixed points (as well as numerous unstable fixed points that do not appear because this is a Feigenbaum diagram).

[1] In fact there are dynamical systems for which a large or even infinite number of period doubling cascades followed by inverse cascades occur.

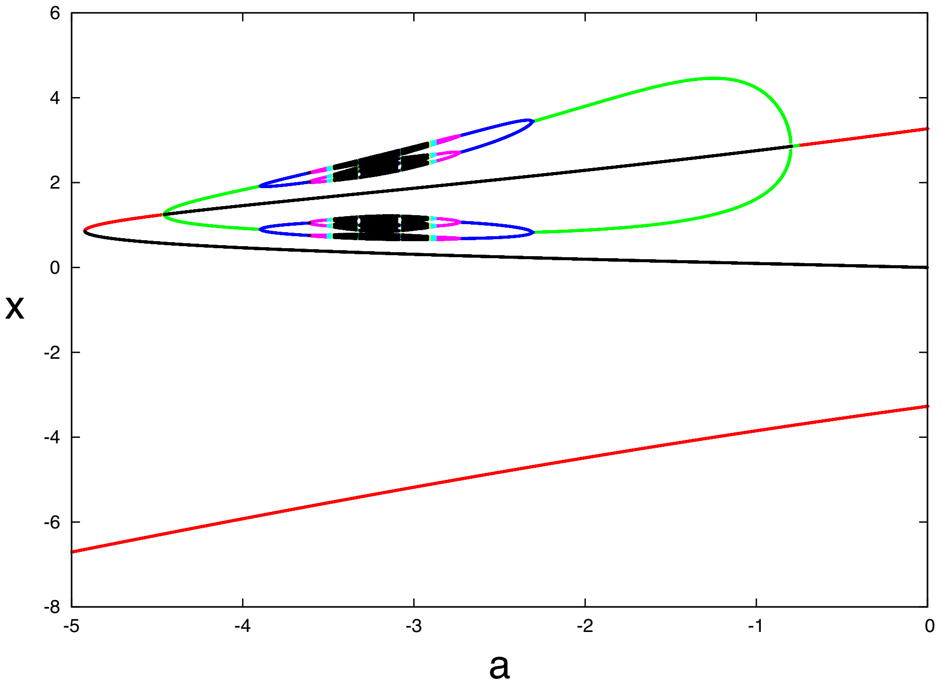

Figure J.3.1: A portion of the Feigenbaum diagram for the map (1.1) with $b = 11.7$. Also shown are the paths of all period-one fixed points, both stable and unstable. The full diagram is similar to that of Figure 1.2 except that both period-doubling cascades now run to completion. Specifically, for the upper cascade shown here, a blue-sky bifurcation again occurs and, as a is further increased, the stable fixed point begins a Feigenbaum perioding doubling cascade that now runs to completion followed by a region of chaos. But then, as a is increased still further, the cascades undoes itself until there is again only a single stable fixed point. The behavior for the lower cascade is analogous.

Appendix K

Supplement to Chapter 17

K.1 Computation of Generalized Gradients from Spinning Coil Data

A widely used method to measure the magnetic field in magnets for beam optics relies on spinning coils [*]. By using spinning coils one can achieve very accurate measurements of the angular Fourier components of the magnetic field. In this section, which is restricted to the case of straight elements, we show how it is possible using a short length (i.e. with a length shorter than the region of the magnet where the fields are z-dependent) rectangular spinning coil to recover the full z-dependent profiles of the fields and in particular the profiles of the generalized gradients that are necessary to compute accurately both the linear and nonlinear parts of the transfer map for the magnet.

We consider the case of a rectangular coil rotating in such a way that one side of the coil is always positioned along the magnetic axis of the magnet. The idea is to make repeated measurements of angular field data (integrated over the coil area) by moving the coil along the magnet axis by small steps. The Fourier transforms of the experimental data for each angular harmonic are than calculated, multiplied by a suitable kernel, and then Fourier transformed back to obtain the desired generalized gradients.

For the kind of coil we consider in this section the only relevant component of the magnetic field is B_ϕ because it is the only one generating a flux linked to the coil. It should be mentioned that tangential coils are also used for which the relevant component of the magnetic field is B_ρ. The treatment of that case would follow the same lines as for the kind of coils considered here.

The E.M.F. produced by a rectangular spinning coil (or set of coils, in a realistic setup), with barycenter positioned at z is given by

$$\mathcal{E}(z,t) = -\int_{z-\ell_c}^{z+\ell_c} dz' \int_0^R \frac{dB_\phi}{dt} d\rho, \tag{K.1.1}$$

where $2\ell_c$ is the length of coil and R is its radius. The E.M.F. can be written in terms of a Fourier series in time,

$$\mathcal{E}(z,t) = \sum_{m=0} \mathcal{E}_{m,s}(z)\sin(m\omega t) + \mathcal{E}_{m,c}(z)\cos(m\omega t), \tag{K.1.2}$$

where we assume $\mathcal{E}_{m,s}(z)$ and $\mathcal{E}_{m,c}(z)$ can be experimentally determined over a sufficient number of locations in z in the end and fringe regions where the field varies with z. The angular frequency of the spinning coil is ω.

By using (2.3) we can write B_ϕ as

$$B_\phi = \frac{1}{\rho}\frac{\partial\psi}{\partial\phi} = \sum_{m=1}^{\infty}\int_{-\infty}^{\infty} dk e^{ikz} m \frac{I_m(k\rho)}{\rho}[\hat{b}_m(k)\cos m\phi - \hat{a}_m(k)\sin m\phi]. \tag{K.1.3}$$

By substituting (5.3) into (5.1) with $\phi = \omega t$ we get

$$\mathcal{E}(z,t) = \frac{\omega}{\sqrt{2\pi}}\sum_{m=1}^{\infty}\int_{-\infty}^{\infty} dk e^{ikz}\frac{2m^2\sin k\ell_c}{k}[\hat{b}_m(k)\sin m\omega t + \hat{a}_m(k)\cos m\omega t]. \tag{K.1.4}$$

Then, by comparing (5.2) and (5.4), we find the relations

$$\mathcal{E}_{m,c}(z) = \frac{m^2\omega}{\sqrt{2\pi}}\int_{-\infty}^{\infty} dk e^{ikz}\mathcal{I}_m(kR)\frac{2\sin k\ell_c}{k}\hat{b}_m(k), \tag{K.1.5}$$

$$\mathcal{E}_{m,s}(z) = \frac{m^2\omega}{\sqrt{2\pi}}\int_{-\infty}^{\infty} dk e^{ikz}\mathcal{I}_m(kR)\frac{2\sin k\ell_c}{k}\hat{a}_m(k). \tag{K.1.6}$$

Here we have defined the new function

$$\mathcal{I}_m(kR) = \int_0^R \frac{I_m(k\rho)}{\rho}d\rho = \int_0^{kR}\frac{I_m(x)}{x}dx. \tag{K.1.7}$$

Finally use of (5.5) and (5.6) allows us to write the expression for the generalized gradients,

$$C_{m,\alpha}^{[n]}(z) = \frac{i^n}{2^{m+1}m!m^2\omega}\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} dk e^{ikz}\frac{k^{m+n+1}\tilde{\mathcal{E}}_{m,\alpha}(k)}{\mathcal{I}_m(kR)\sin k\ell_c}, \tag{K.1.8}$$

where the $\tilde{\mathcal{E}}_{m,\alpha}(k)$ are the Fourier transforms of the experimental data,

$$\tilde{\mathcal{E}}_{m,\alpha}(k) = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} dz^{-ikz}\mathcal{E}_{m,\alpha}(z). \tag{K.1.9}$$

Notice that because of the asymptotic form of the Bessel function I_m, as $k \to \infty$ the function $\mathcal{I}_m(kR)$ grows exponentially at infinity as $e^{kR}/\sqrt{k}$. Because the function $\mathcal{I}_m(kR)$ is in the denominator of the integrand in (5.8), there is again an effective cut-off in k.

The integral (5.7) for a general m cannot be carried out analytically, but it can easily be reduced to an infinite series either in the Bessel functions or, most conveniently, directly in kR:

$$\mathcal{I}_m(kR) = \frac{1}{kR}\frac{2}{m}\sum_{n=0}^{\infty}(-1)^n(m+2n+1)I_{m+2n+1}(kR), \tag{K.1.10}$$

$$\mathcal{I}_m(kR) = \sum_{\ell=0}\frac{1}{(2\ell+m)\ell!(\ell+m)!}\left(\frac{kR}{2}\right)^{m+2\ell}. \tag{K.1.11}$$

In the particular case $m = 2$ we have

$$\mathcal{I}_2(kR) = \frac{I_1(kR)}{kR} - \frac{1}{2}. \tag{K.1.12}$$

For numerical purposes use of (5.11) may be perfectly adequate (in particular if speed is not an issue). We will see later that we are often interested in values of kR that satisfy the condition $kR < 20$. For such kR values, one can obtain values for $\mathcal{I}_m(kR)$ that are accurate through 15 digits by retaining the first 30 terms in the series.

K.2 Computation of Generalized Gradients from Coil Geometry and Current Data

Spline Routines

```
!  The following are double precision versions of the subroutines
!  "spline" and "splint" used for 1-D cubic spline interpolation, found in Numerical
!  Recipes pp. 107-110.  Instructions for use:
!
! 1) Call spline(x,y,n,yp1,ypn,y2).
!
!Here x={x_k} is an array of length n containing the x-values on which the function is given, and y is
!array of the same length containing the corresponding function values {f(x_k)}.  Also, yp1 and ypn are
!the first derivatives of the function at the points x_1 and x_n, respectively.  The routine returns an
!array y2 of length n, which contains the second derivatives of the interpolating function at the
!tabulated points x_n.
!
!The subroutine spline is called only once for a given data set, to set up the array y2.
!
! 2) For a given point x at which the interpolating function is desired, call
     splint(xa,ya,y2,n,x,y).
!
!Here xa and ya are the arrays {x_n} and {f(x_n)} as above.  The array y2 is the output from the
!subroutine "spline" above.  Again, n is the number of points in x.  Finally, the double precision numb
!x is the value at which the interpolating function is to be evaluated.  The resulting value f(x) is gi
!as the double precision number y.

Mathieu-Bessel Connection Coefficients

As a consequence of the symmetry properties (13.9.40) through (13.9.43), the Fourier expansions (13.10.144) and (13.10.150) for the $\mathrm{ce}_n(v,q)$ and $\mathrm{se}_n(v,q)$ can be written in the form

$$\mathrm{ce}_{2n}(v,q) = \sum_{m=0}^{\infty} A_{2m}^{2n}(q)\cos(2mv), \tag{N.0.1}$$

$$\mathrm{ce}_{2n+1}(v,q) = \sum_{m=0}^{\infty} A_{2m+1}^{2n+1}(q)\cos[(2m+1)v], \tag{N.0.2}$$

$$\mathrm{se}_{2n+1}(v,q) = \sum_{m=0}^{\infty} B_{2m+1}^{2n+1}(q)\sin[(2m+1)v], \tag{N.0.3}$$

$$\mathrm{se}_{2n+2}(v,q) = \sum_{m=0}^{\infty} B_{2m+2}^{2n+2}(q)\sin[(2m+2)v]. \tag{N.0.4}$$

In all these relations $n = 0, 1, 2, 3, \cdots$. Put another way, the symmetry properties require that the coefficients A_m^n and B_m^n vanish unless both m and n are even or both m and n are odd.

In this appendix we will see that the same symmetry properties hold for the Mathieu-Bessel connection coefficients α_m^n and β_m^n. That is, formulas (13.9.64) and (13.9.65) can be written in the corresponding form

$$\mathrm{Ce}_{2n}(u,q)\ \mathrm{ce}_{2n}(v,q) = \sum_{m=0}^{\infty} \alpha_{2m}^{2n}(k) I_{2m}(k\rho)\cos(2m\phi), \tag{N.0.5}$$

$$\mathrm{Ce}_{2n+1}(u,q)\ \mathrm{ce}_{2n+1}(v,q) = \sum_{m=0}^{\infty} \alpha_{2m+1}^{2n+1}(k) I_{2m+1}(k\rho)\cos[(2m+1)\phi], \tag{N.0.6}$$

$$\mathrm{Se}_{2n+1}(u,q)\ \mathrm{se}_{2n+}(v,q) = \sum_{m=0}^{\infty} \beta_{2m+1}^{2n+1}(k) I_{2m+1}(k\rho)\sin[(2m+1)\phi], \tag{N.0.7}$$

$$\mathrm{Se}_{2n+2}(u,q)\,\mathrm{se}_{2n+2}(v,q)=\sum_{m=0}^{\infty}\beta_{2m+2}^{2n+2}(k)I_{2m+2}(k\rho)\sin[(2m+2)\phi]. \tag{N.0.8}$$

Moreover, there are the relations

$$\alpha_{2m}^{2n}(k)=g_c^{2n}(k)A_{2m}^{2n}(q), \tag{N.0.9}$$

$$\alpha_{2m+1}^{2n+1}(k)=g_c^{2n+1}(k)A_{2m+1}^{2n+1}(q), \tag{N.0.10}$$

$$\beta_{2m+1}^{2n+1}(k)=g_s^{2n+1}(k)B_{2m+1}^{2n+1}(q), \tag{N.0.11}$$

$$\beta_{2m+2}^{2n+2}(k)=g_s^{2n+2}(k)B_{2m+2}^{2n+2}(q), \tag{N.0.12}$$

where

$$g_c^{2n}(k)=[\mathrm{ce}_{2n}(\pi/2,q)\,\mathrm{ce}_{2n}(0,q)]/A_0^{2n}(q), \tag{N.0.13}$$

$$g_c^{2n+1}(k)=-2[\mathrm{ce}'_{2n+1}(\pi/2,q)\,\mathrm{ce}_{2n+1}(0,q)]/[kfA_1^{2n+1}(q)], \tag{N.0.14}$$

$$g_s^{2n+1}(k)=2[\mathrm{se}_{2n+1}(\pi/2,q)\,\mathrm{se}'_{2n+1}(0,q)]/[kfB_1^{2n+1}(q)], \tag{N.0.15}$$

$$g_s^{2n+2}(k)=[\mathrm{se}'_{2n+2}(\pi/2,q)\,\mathrm{se}'_{2n+2}(0,q)]/[qB_2^{2n+2}(q)]. \tag{N.0.16}$$

Here a $'$ denotes d/dv.

Appendix O

Quadratic Forms

O.1 Background

Let L be a real $m \times m$ matrix, let w be a real m-component vector, and let $(*,*)$ denote the usual real inner product. Define a quadratic form $Q(w)$ by the rule

$$Q(w) = (w, Lw). \tag{O.1.1}$$

The matrix L can be uniquely decomposed into symmetric and antisymmetric parts S and A by writing

$$L = S + A \tag{O.1.2}$$

with

$$S = (1/2)(L + L^T) \tag{O.1.3}$$

and

$$A = (1/2)(L - L^T). \tag{O.1.4}$$

Then, since only the symmetric part of L contributes to Q, we may equally well write

$$Q(w) = (w, Sw). \tag{O.1.5}$$

According to standard matrix theory, any real $m \times m$ symmetric matrix S has m real eigenvalues and m associated real eigenvectors that can arranged to form an orthonormal basis. (Note that no assumption needs to be made about the eigenvalues being distinct.) Call the eigenvalues σ_j and the associated orthonormal eigenvectors v_j. Then we may write S in the dyadic form

$$S = \sum_{j=1}^{m} \sigma_j |v_j)(v_j|. \tag{O.1.6}$$

With the aid of this representation for S we find that Q takes the form

$$Q(w) = (w, Sw) = \sum_{j=1}^{m} \sigma_j (w, v_j)(v_j, w) = \sum_{j=1}^{m} \sigma_j (w, v_j)^2. \tag{O.1.7}$$

We see that Q will be positive definite if all $\sigma_j > 0$. Conversely, since the v_j are orthonormal, it is evident that all the σ_j will be positive if Q is positive definite. Similarly, Q will be negative definite if all $\sigma_j < 0$, and conversely. Finally, Q will be indefinite if not all σ_j have the same sign or some are zero.

O.2 Effect of Small Perturbations in the Definite Case

Now suppose, for example, that Q is positive definite and that all the eigenvalues σ_j of S are substantially different from 0. Next suppose that L is slightly perturbed so that S is also slightly perturbed. Thus, we may write that

$$S = S^0 + S^1 \tag{O.2.1}$$

where S^0 is the initial S before perturbation and S^1 is a small symmetric matrix that describes the perturbation. Now the quadratic form Q becomes Q' with

$$Q'(w) = (w, [S^0 + S^1]w) = (w, S^0 w) + (w, S^1 w) = Q(w) + (w, S^1 w). \tag{O.2.2}$$

It is easy to see from (1.7) that

$$Q(w) \geq \sigma_{\min} \sum_{j=1}^{m} (w, v_j)^2 = \sigma_{\min}(w, w) = \sigma_{\min}||w||^2 \tag{O.2.3}$$

where $\sigma_{\min}$ is the smallest eigenvalue of S. Also, we have the estimate

$$|(w, S^1 w)| \leq ||w|| \, ||S^1 w|| \leq ||w|| \, ||S^1|| \, ||w|| = ||S^1|| \, ||w||^2. \tag{O.2.4}$$

It follows that Q' will also be positive definite providing

$$||S^1|| < \sigma_{\min}. \tag{O.2.5}$$

We conclude that if Q is positive definite, it will remain positive definite under small perturbations of L. Similarly, if Q is negative definite, it will remain negative definite under small perturbations of L.

Even more can be said. The *rank* of Q is defined to be the number of nonzero eigenvectors of S, and the *signature* is defined to be the number of positive eigenvalues minus the number of negative eigenvalues. It can be shown that if under a continuous change in S the rank does not change (no eigenvalue passes through the value 0), then the signature also does not change. This result follows from the fact that the eigenvalues of S are continuous functions of the matrix elements of S.

Appendix P

Parameterization of the Coset Space $GL(2n, \mathbb{R})/Sp(2n, \mathbb{R})$

P.1 Introduction

Suppose that $M \in GL(2n, \mathbb{R})$ has a symplectic polar decomposition,

$$M = QR \tag{P.1.1}$$

where Q is J-symmetric and R is symplectic.[1] We know that such a decomposition is possible for M sufficiently near the symplectic group and is unique. We know that the ordinary (orthogonal) polar decomposition can be made globally. By contrast, from counter examples, we know that symplectic polar decomposition is not possible globally. We also see that, by construction, J-symmetric matrices Q are related to the cosets $GL(2n, \mathbb{R})/Sp(2n, \mathbb{R})$. We want to find what restrictions must be imposed on M for a symplectic polar decomposition to be possible, and suspect that these restrictions are related to coset structure.

P.2 M Must Have Positive Determinant

From (1.1) we find

$$\det M = (\det Q)(\det R) = \det Q. \tag{P.2.1}$$

According to Lemma 3.6 of Section 4.3 of *Lie Methods*, any J-symmetric matrix Q can be written in the form

$$Q = JA \tag{P.2.2}$$

where A is real and antisymmetric. It follows that

$$\det Q = (\det J)(\det A) = \det A \geq 0. \tag{P.2.3}$$

Here we have used the fact that a real antisymmetric matrix cannot have a negative determinant. It follows from (1.1), (2.1), and (2.3) that, if M is to be nonsingular and have a symplectic polar decomposition, it must have positive determinant,

$$\det M > 0. \tag{P.2.4}$$

[1] We adopt the terminology of Chapter 4 of *Lie Methods* $\cdots$.

Then, from (2.1), we also have

$$\det Q > 0. \tag{P.2.5}$$

P.3 It is Sufficient to Consider $SL(2n,\mathbb{R})/Sp(2n,\mathbb{R})$

Suppose N is any matrix in $GL(2n,\mathbb{R})$ and $\det N > 0$. Define an associated matrix M by the rule

$$M = (\det N)^{-1/(2n)} N. \tag{P.3.1}$$

By construction, M will be in $SL(2n,\mathbb{R})$.

Next assume that M has the symplectic polar decomposition (1.1). Then (1.1) and (3.1) imply that

$$N = (\det N)^{1/(2n)} M = (\det N)^{1/(2n)} QR = Q'R \tag{P.3.2}$$

where

$$Q' = (\det N)^{1/(2n)} Q. \tag{P.3.3}$$

By the lemmas of Section 4.3 of *Lie Methods*, Q' will also be J-symmetric, and therefore N has a symplectic polar decomposition. Thus, it is sufficient to study whether any $M \in SL(2n,\mathbb{R})$ has a symplectic polar decomposition.

P.4 Some Symmetries

Consider the map Σ of $SL(2n,\mathbb{R})$ into itself defined by the rule

$$\Sigma(M) = J(M^T)^{-1}J^{-1}. \tag{P.4.1}$$

We will now explore the properties of Σ.

Suppose M_1 and M_2 are any two $SL(2n,\mathbb{R})$ matrices. Then we find the relation

$$\begin{aligned}\Sigma(M_1M_2) &= J[(M_1M_2)^T]^{-1}J^{-1} = J[M_2^TM_1^T]^{-1}J^{-1} \\ &= J(M_1^T)^{-1}(M_2^T)^{-1}J^{-1} = J(M_1^T)^{-1}J^{-1}J(M_2^T)^{-1}J^{-1} \\ &= \Sigma(M_1)\Sigma(M_2).\end{aligned} \tag{P.4.2}$$

Thus, Σ is a homomorphism.

Next we observe that

$$\Sigma(I) = I \tag{P.4.3}$$

and

$$\Sigma(J) = J(J^T)^{-1}J^{-1} = J(-J)^{-1}J^{-1} = JJJ^{-1} = J. \tag{P.4.4}$$

Similarly, we find

$$\Sigma(J^{-1}) = J^{-1}. \tag{P.4.5}$$

Also, there is the property

$$\Sigma(M^{-1}) = J[(M^{-1})^T]^{-1}J^{-1} = JM^TJ^{-1} = [J(M^T)^{-1}J^{-1}]^{-1} = [\Sigma(M)]^{-1}. \tag{P.4.6}$$

[This result also follows from (4.2) and (4.3).] Consequently, Σ is an isomorphism.

We claim that Σ acts as the identity map on $Sp(2n, \mathbb{R})$. That is, all elements $R \in Sp(2n, \mathbb{R})$ are fixed points of Σ. Indeed, suppose that $R \in Sp(2n, \mathbb{R})$. Then we have the result

$$RJR^T = J, \tag{P.4.7}$$

which is equivalent to the relation

$$J^{-1} = (RJR^T)^{-1} = (R^T)^{-1}J^{-1}R^{-1}, \tag{P.4.8}$$

which in turn is equivalent to the relation

$$R = J(R^T)^{-1}J^{-1} = \Sigma(R). \tag{P.4.9}$$

Note that (4.3) through (4.5) are special cases of (4.9).

Let us next find the action of Σ on any J-symmetric matrix Q. We find the result

$$\Sigma(Q) = J(Q^T)^{-1}J^{-1} = (JQ^TJ^{-1})^{-1} = Q^{-1}. \tag{P.4.10}$$

Note that (2.5) guarantees that Q^{-1} exists.

Upon combining (4.9) and (4.10) we find that the effect of Σ on any matrix M having the factorization (1.1) is given by the relation

$$\Sigma(M) = \Sigma(QR) = \Sigma(Q)\Sigma(R) = Q^{-1}R. \tag{P.4.11}$$

Finally, Σ is an involution. By calculating we find that

$$\begin{aligned} \Sigma^2(M) &= \Sigma[\Sigma(M)] = \Sigma[J(M^T)^{-1}J^{-1}] = \Sigma(J)\Sigma[(M^T)^{-1}]\Sigma(J^{-1}) \\ &= J\Sigma[(M^T)^{-1}]J^{-1} = JJ\{[(M^T)^{-1}]^T\}^{-1}J^{-1}J^{-1} \\ &= JJMJ^{-1}J^{-1} = (-I)M(-I) = M. \end{aligned} \tag{P.4.12}$$

We have found a symmetry for $SL(2n, \mathbb{R})$. We will now see that Σ produces an associated symmetry σ on the Lie algebra $s\ell(2n, \mathbb{R})$. Let B be any element in the Lie algebra $s\ell(2n, \mathbb{R})$. Let σ be the associated induced map in the Lie algebra defined by the relation

$$\Sigma[\exp(B)] = \exp[\sigma(B)]. \tag{P.4.13}$$

By calculation we find

$$\begin{aligned} \Sigma[\exp(B)] &= J\{[\exp(B)]^T\}^{-1}J^{-1} = J\{\exp(B^T)\}^{-1}J^{-1} \\ &= J\exp(-B^T)J^{-1} = \exp(-JB^TJ^{-1}). \end{aligned} \tag{P.4.14}$$

Upon comparing (4.13) and (4.14) in the vicinity of the identity, we conclude that

$$\sigma(B) = -JB^TJ^{-1}. \tag{P.4.15}$$

Let us explore the properties of σ. Any element $B \in s\ell(2n, \mathbb{R})$ can be written uniquely in the form

$$B = JS + JA \tag{P.4.16}$$

where S is symmetric, A is antisymmetric, and JA is traceless. The elements JS are a basis for $sp(2n,\mathbb{R})$, and together with the elements of the form JA form a basis for $s\ell(2n,\mathbb{R})$. Computation gives the results

$$\sigma(JS) = -J(JS)^T J^{-1} = -JS^T J^T J^{-1} = -JS(-J)J^{-1} = JS, \tag{P.4.17}$$

$$\sigma(JA) = -J(JA)^T J^{-1} = -JA^T J^T J^{-1} = JA(-J)J^{-1} = -JA. \tag{P.4.18}$$

We see from (4.17) that $sp(2n,\mathbb{R})$ is invariant under σ. That is, σ acts as the identity on $sp(2n,\mathbb{R})$. This is the local consequence of the global result that Σ acts as the identity on $Sp(2n,\mathbb{R})$. And, since σ is manifestly linear, we have

$$\sigma(B) = \sigma(JS + JA) = \sigma(JS) + \sigma(JA) = JS - JA. \tag{P.4.19}$$

From (4.16) through (4.19) we find that

$$\sigma^2(B) = \sigma[\sigma(B)] = B. \tag{P.4.20}$$

Thus, σ is an involution on $s\ell(2n,\mathbb{R})$.

P.5 Connection between Symmetries and Being J-Symmetric

A matrix Q is called J-symmetric if it satisfies the condition

$$JQ^T J^{-1} = Q, \tag{P.5.1}$$

which is equivalent to the condition

$$\sigma(Q) = -Q. \tag{P.5.2}$$

Suppose we represent Q in the form

$$Q = JX \tag{P.5.3}$$

where the properties of X are yet to be determined. Then we find

$$\sigma(Q) = \sigma(JX) = -J(JX)^T J^{-1} = -JX^T J^T J^{-1} = JX^T. \tag{P.5.4}$$

Thus, in this representation, the J-symmetric condition (5.2) yields the requirement

$$JX^T = -JX, \tag{P.5.5}$$

from which it follows that

$$X^T = -X. \tag{P.5.6}$$

That is,

$$Q = JA' \tag{P.5.7}$$

where A' is antisymmetric.

Suppose we instead represent Q in the form

$$Q = \exp(JX). \tag{P.5.8}$$

Then we find the relation

$$\begin{aligned}\sigma(Q) &= \sigma[\exp(JX)] = -J[\exp(JX)]^T J^{-1} = -J\exp[(JX)^T]J^{-1} \\ &= -J\exp(-X^T J)J^{-1} = -\exp(-JX^T).\end{aligned} \tag{P.5.9}$$

In this context requiring (5.2) produces the relation

$$\exp(JX) = \exp(-JX^T), \tag{P.5.10}$$

which again produces (5.5) and hence (5.6) and consequently

$$Q = \exp(JA) \tag{P.5.11}$$

where A is antisymmetric.

As a side comment, we have discovered, upon comparing (5.7) and (5.11), the relation

$$JA' = \exp(JA), \tag{P.5.12}$$

or,

$$A' = -J\exp(JA), \tag{P.5.13}$$

which maps antisymmetric matrices A into antisymmetric matrices A'. Keeping the first few terms in the power series we find that

$$\begin{aligned}A' &= -J[I + JA + (JA)^2/2! + (JA)^3/3! + \cdots] \\ &= -J + A - J(JA)^2/2! - J(JA)^3/3! + \cdots \\ &= -J + A + AJA/2! + AJAJA/3! + \cdots .\end{aligned} \tag{P.5.14}$$

In this form we see that *any* Taylor series in JA would have the same mapping property.

Finally, let us apply Σ to Q as given by (5.11). We find the result

$$\Sigma(Q) = \Sigma[\exp(JA)] = \exp[\sigma(JA)] = \exp(-JA) = Q^{-1} \tag{P.5.15}$$

as before.

P.6 Relation to Darboux Matrices

According to *Lie Methods* the matrix $N(M)$ is J-symmetric, and we seek a J-symmetric matrix Q such that

$$Q^2 = N(M). \tag{P.6.1}$$

Use the result of Lemma 3.6 of *Lie Methods* to write the representations

$$N(M) = JA' \tag{P.6.2}$$

and

$$Q = JA \tag{P.6.3}$$

where A' and A are antisymmetric. With these representations (6.1) becomes

$$JAJA = JA', \tag{P.6.4}$$

which yields the relation

$$A' = AJA. \tag{P.6.5}$$

Since A is assumed to be antisymmetric, (6.5) can also be written in the form

$$-A' = AJA^T, \tag{P.6.6}$$

which shows that A, if it exists, is a Darboux matrix connecting $-A'$ and J. Thus, the problem of finding Q is equivalent to showing that it is possible to find a Darboux matrix connecting $-A'$ and J that is also antisymmetric.

P.7 Some Observations on $SL(2n,\mathbb{R})/Sp(2n,\mathbb{R})$

By its nature, $SL(2n,\mathbb{R})/Sp(2n,\mathbb{R})$ is a homogeneous space. That is, $SL(2n,\mathbb{R})$ when acting on this space can send any point into any other point. See Section 5.12 for a description of group action on cosets. Between the JS and the JA there are the relations (4.3.2) through (4.3.4). Consequently $SL(2n,\mathbb{R})/Sp(2n,\mathbb{R})$ is a reductive homogeneous space. Since σ is an involution on $s\ell(2n,\mathbb{R})$ that leaves $sp(2n,\mathbb{R})$ invariant, it follows that $SL(2n,\mathbb{R})/Sp(2n,\mathbb{R})$ is a symmetric space. Moreover, at least for the cases $n = 2$ and $n = 3$ and presumably for all n, the elements of the form JA with JA traceless transform irreducibly under the action of $sp(2n,\mathbb{R})$. Therefore $SL(2n,\mathbb{R})/Sp(2n,\mathbb{R})$ is an irreducible symmetric space. For example, in the case $n = 2$ the elements of the form JA with JA traceless carry the irreducible representation $\Gamma(0,1)$ of $sp(4,\mathbb{R})$; and in the case $n = 3$ they carry the irreducible representation $\Gamma(0,1,0)$ of $sp(6,\mathbb{R})$. See the weight diagrams 27.5.4 and 27.8.4 in Chapter 27.

Digesting Goodman Notes

P.8 Action of σ on $s\ell(2n,\mathbb{R})$

Consider the action of σ on $s\ell(2n,\mathbb{R})$. First we see that, for a real symmetric matrix,

$$\sigma(S) = -JS^TJ^{-1} = -JSJ^{-1} = JSJ \tag{P.8.1}$$

so that

$$[\sigma(S)]^T = [JSJ]^T = J^TS^TJ^T = JSJ = \sigma(S). \tag{P.8.2}$$

Therefore, σ maps the space of real symmetric matrices into itself.

Next suppose B and B' are two matrices in $s\ell(2n,\mathbb{R})$. Define their inner product to be

$$(B,B') = \mathrm{tr}(BB'). \tag{P.8.3}$$

Then we find that σ preserves the inner product,

$$\begin{aligned}(\sigma(B),\sigma(B')) &= \mathrm{tr}[(-J)B^TJ^{-1}(-J)(B')^TJ^{-1}] = \mathrm{tr}[JB^T(B')^TJ^{-1}] = \mathrm{tr}[B^T(B')^T] \\ &= \mathrm{tr}[(B'B)^T] = \mathrm{tr}[B'B] = \mathrm{tr}[BB'] = (B,B'). \end{aligned} \tag{P.8.4}$$

Suppose we write for any real symmetric matrix S the decomposition

$$S = S^a + S^c \tag{P.8.5}$$

where S^a anticommutes with J and S^c commutes with J. See Section 3.8 of *Lie Methods*. Then we find that

$$\sigma(S^a) = -JS^aJ^{-1} = S^aJJ^{-1} = S^a, \tag{P.8.6}$$

and

$$\sigma(S^c) = -JS^cJ^{-1} = -S^cJJ^{-1} = -S^c. \tag{P.8.7}$$

We see that σ, which we already know is a linear operator that maps the space of real symmetric matrices into itself, has eigenvalues ±1. This is to be expected because σ is an involution.

As an application of this result, we find that

$$(S^a,S^c) = -(\sigma(S^a),\sigma(S^c)) = -(S^a,S^c) \tag{P.8.8}$$

from which it follows that

$$(S^a,S^c) = 0 \tag{P.8.9}$$

for any S^a, S^c pair.

P.9 Lie Triple System

Let S, S', and S'' be real symmetric matrices. Then we have

$$\{S',S\} = A \tag{P.9.1}$$

where A is an antisymmetric matrix. And,

$$\{S'',\{S',S\}\} = S''' \tag{P.9.2}$$

where S''' is again a symmetric matrix. Thus symmetric matrices comprise a Lie triple system.

Let S^a, $S^{a\prime}$, and $S^{a\prime\prime}$ be real symmetric matrices that anticommute with J. Then we have

$$\{S^{a\prime},S^a\} = A^c \tag{P.9.3}$$

where A^c is an antisymmetric matrix that commutes with J. And,

$$\{S^{a''}, \{S^{a'}, S^a\}\} = S^{a'''} \tag{P.9.4}$$

where $S^{a'''}$ is again a symmetric matrix that anticommutes with J. Thus symmetric matrices that anticommute with J also comprise a Lie triple system.

Similarly, it can be verified that real symmetric matrices of the form S^c comprise a Lie triple system,

$$\{S^{c''}, \{S^{c'}, S^c\}\} = S^{c'''} \tag{P.9.5}$$

where $S^{c'''}$ is again a symmetric matrix that commutes with J.

P.10 A Factorization Theorem (Theorem 1.1 of Goodman)

P.10.1 A Particular Mapping from Real Symmetric Matrices to Positive-Definite Matrices

Define for any S an associated matrix $P(S)$ by the rule

$$P(S) = \exp(S^a)\exp(S^c)\exp(S^a). \tag{P.10.1}$$

Evidently, P is real, symmetric and nonsingular. It is also positive definite because we have

$$\begin{aligned}(v, Pv) &= (v, \exp(S^a)\exp(S^c)\exp(S^a)v) = (\exp(S^a)v, \exp(S^c)\exp(S^a)v)\\ &= ([\exp(S^a)v], \exp(S^c)[\exp(S^a)v]) > 0 \text{ if } v \neq 0\end{aligned} \tag{P.10.2}$$

because $\exp(S^a)$ is symmetric and invertible and $\exp(S^c)$ is positive definite.

We will eventually see that the map (10.1) is invertible. That is, given any real symmetric positive-definite matrix P, there are (unique) matrices S^a and S^c such that (10.1) holds. Thus, (10.1) provides a factorization of any real symmetric positive-definite matrix P.

P.10.2 The Map Is Real Analytic

Evidently, by the nature of the exponential function, $P(S)$ is a real analytic function of S^a and S^c. We claim that $P(S)$ is also an analytic function of S. Note that

$$S^a = (S - J^{-1}SJ)/2 \tag{P.10.3}$$

and

$$S^c = (S + J^{-1}SJ)/2 \tag{P.10.4}$$

Therefore S^a and S^c are analytic functions of S. Since the various exponential functions appearing in (10.1) are analytic functions of their arguments, it follows that $P(S)$ is an analytic function of S.

P.10.3 Trace and Determinant Properties

From (10.3) we find

$$\begin{aligned} \mathrm{tr}(S^a) &= (1/2)[\mathrm{tr}(S) - \mathrm{tr}(J^{-1}SJ)] = (1/2)[\mathrm{tr}(S) - \mathrm{tr}(JJ^{-1}S)] \\ &= (1/2)[\mathrm{tr}(S) - \mathrm{tr}(S)] = 0. \end{aligned} \tag{P.10.5}$$

From (10.4) we find

$$\begin{aligned} \mathrm{tr}(S^c) &= (1/2)[\mathrm{tr}(S) + \mathrm{tr}(J^{-1}SJ)] = (1/2)[\mathrm{tr}(S) + \mathrm{tr}(JJ^{-1}S)] \\ &= (1/2)[\mathrm{tr}(S) + \mathrm{tr}(S)] = \mathrm{tr}(S). \end{aligned} \tag{P.10.6}$$

Now take the determinant of both sides of (10.1). So doing gives the result

$$\det[P(S)] = \exp[\mathrm{tr}(S^a)]\exp[\mathrm{tr}(S^c)]\exp[\mathrm{tr}(S^a)] = \exp[\mathrm{tr}(S)]. \tag{P.10.7}$$

P.10.4 Study of the Inverse of the Map

Conversely, it is claimed that S is an analytic function of P. If true, then, by (10.3) and (10.4), S^a and S^c are also analytic functions of P. Proceed as follows: Since P is real, symmetric, and positive definite, there is a real symmetric matrix Z such that

$$P(S) = \exp(Z) = \exp(S^a)\exp(S^c)\exp(S^a), \tag{P.10.8}$$

and Z will be analytic in P and therefore in S. What we want to do is find S^a and S^c in terms of Z.

P.10.5 Formula for S^a in terms of Z

Begin by finding S^a in terms of Z. Apply Σ to both sides of (10.8) to find the result

$$\Sigma[P(S)] = \Sigma[\exp(Z)] = \Sigma[\exp(S^a)]\Sigma[\exp(S^c)]\Sigma[\exp(S^a)], \tag{P.10.9}$$

from which it follows that

$$\exp[\sigma(Z)] = \exp[\sigma(S^a)]\exp[\sigma(S^c)]\exp[\sigma(S^a)], \tag{P.10.10}$$

from which it follows that

$$\exp[\sigma(Z)] = \exp(S^a)\exp(-S^c)\exp(S^a). \tag{P.10.11}$$

Next take inverses of both sides of (10.8) to find the relation

$$\exp(-Z) = \exp(-S^a)\exp(-S^c)\exp(-S^a), \tag{P.10.12}$$

from which it follows that

$$\exp(-S^c) = \exp(S^a)\exp(-Z)\exp(S^a). \tag{P.10.13}$$

Use (10.13) in (10.11) to get the relation

$$\exp[\sigma(Z)] = \exp(2S^a)\exp(-Z)\exp(2S^a), \tag{P.10.14}$$

which is a relation between Z and S^a.

Next show that, given Z, (10.14) has, in fact, a unique solution S^a. In particular, we want to verify the assertion

$$\exp(2S^a) = \exp(Z/2)\exp(T)\exp(Z/2) \tag{P.10.15}$$

where

$$\exp(2T) = \exp(-Z/2)\exp[\sigma(Z)]\exp(-Z/2). \tag{P.10.16}$$

Note that the right side of (10.16) is real, symmetric, and positive definite. Therefore T and consequently $\exp(T)$ are well defined (real analytic) functions of Z. Correspondingly, the right side of (10.15) is well defined, real, symmetric, and positive definite. Therefore S^a is well defined, and a real analytic function of Z. We also observe that (10.16) can be rewritten in the form

$$\exp[\sigma(Z)] = \exp(Z/2)\exp(2T)\exp(Z/2). \tag{P.10.17}$$

To prove the assertion, take (10.15) and (10.16) to be the definition of S^a. Then, using (10.15), we find that

$$\begin{aligned}&\exp(2S^a)\exp(-Z)\exp(2S^a) =\\ &\exp(Z/2)\exp(T)\exp(Z/2)\exp(-Z)\exp(Z/2)\exp(T)\exp(Z/2) =\\ &\exp(Z/2)\exp(2T)\exp(Z/2) = \exp[\sigma(Z)].\end{aligned} \tag{P.10.18}$$

Here, in the last step, we have also used (10.17). Thus, we see that (10.14) is satisfied.

P.10.6 Uniqueness of Solution for S^a

What about uniqueness? Suppose $\hat{S}^a$ also satisfies (10.14). That is, assume

$$\exp[\sigma(Z)] = \exp(2\hat{S}^a)\exp(-Z)\exp(2\hat{S}^a). \tag{P.10.19}$$

Substitute (10.19) into (10.16) to get

$$\begin{aligned}\exp(2T) &= \exp(-Z/2)\exp[\sigma(Z)]\exp(-Z/2)\\ &= \exp(-Z/2)\{\exp(2\hat{S}^a)\exp(-Z)\exp(2\hat{S}^a)\}\exp(-Z/2)\\ &= \exp(-Z/2)\{\exp(2\hat{S}^a)\exp(-Z/2)\exp(-Z/2)\exp(2\hat{S}^a)\}\exp(-Z/2)\\ &= [\exp(-Z/2)\exp(2\hat{S}^a)\exp(-Z/2)]^2.\end{aligned} \tag{P.10.20}$$

Therefore, by the uniqueness of the positive-definite square root of a positive-definite matrix, we have

$$\exp(T) = \exp(-Z/2)\exp(2\hat{S}^a)\exp(-Z/2), \tag{P.10.21}$$

which can be rewritten in the form

$$\exp(2\hat{S}^a) = \exp(Z/2)\exp(T)\exp(Z/2). \tag{P.10.22}$$

Now compare (10.15) and (10.22) to get

$$\exp(2S^a) = \exp(2\hat{S}^a), \tag{P.10.23}$$

from which it follows that

$$S^a = \hat{S}^a. \tag{P.10.24}$$

P.10.7 Verification of Expected Symmetry for S^a

Also, does the S^a just found satisfy (8.6)? Apply Σ to both sides of (10.14) to get the relation

$$\exp\{\sigma[\sigma(Z)]\} = \exp[2\sigma(S^a)]\exp[-\sigma(Z)]\exp[2\sigma(S^a)], \tag{P.10.25}$$

form which it follows by (4.20) that

$$\exp(Z) = \exp[2\sigma(S^a)]\exp[-\sigma(Z)]\exp[2\sigma(S^a)]. \tag{P.10.26}$$

Rewrite (10.26) in the form

$$\exp[-2\sigma(S^a)]\exp(Z)\exp[-2\sigma(S^a)] = \exp[-\sigma(Z)]. \tag{P.10.27}$$

Now invert both sides of (10.27) to get

$$\exp[\sigma(Z)] = \exp[2\sigma(S^a)]\exp(-Z)\exp[2\sigma(S^a)]. \tag{P.10.28}$$

Upon comparing (10.14) and (10.28) we see that S^a and $\sigma(S^a)$ obey the same equation. Therefore, from the uniqueness of the solution, we have

$$\sigma(S^a) = S^a, \tag{P.10.29}$$

which is (8.6).

P.10.8 Formula for S^c in Terms of Z

The last thing to do is, given Z, find S^c. Look at (10.8). It can be rewritten in the form

$$\exp(S^c) = \exp(-S^a)\exp(Z)\exp(-S^a). \tag{P.10.30}$$

And, since S^a is now known, we may regard (10.30) as a formula for S^c.

P.10.9 Verification of Expected Symmetry for S^c

However, it would be good to check that (8.7) holds. Apply Σ to both sides of (10.30) and manipulate to find

$$\begin{aligned}\exp[\sigma(S^c)] &= \exp[-\sigma(S^a)]\exp[\sigma(Z)]\exp[-\sigma(S^a)]\\ &= \exp(-S^a)\exp[\sigma(Z)]\exp(-S^a)\\ &= \exp(-S^a)\{\exp(2S^a)\exp(-Z)\exp(2S^a)\}\exp(-S^a)\\ &= \exp(S^a)\exp(-Z)\exp(S^a)\\ &= \exp(-S^c),\end{aligned} \tag{P.10.31}$$

from which it follows that

$$\sigma(S^c) = -S^c, \tag{P.10.32}$$

as required by (8.7). Here we used (10.14) and the relation

$$\exp(-S^c) = \exp(S^a)\exp(-Z)\exp(S^a) \tag{P.10.33}$$

which follows from (10.30).

P.10.10 Conclusion

In summary, we have learned that both S^a and S^c are real-analytic functions of Z.

P.10.11 Motivation for Mapping

Suppose P is a real, symmetric, and positive-definite matrix. Use it to define a matrix Q by the relation

$$Q = P^{-1/2}JP^{-1/2}. \tag{P.10.34}$$

(Note that Goodman defines Q by $Q = P^{1/2}JP^{-1/2}$, but presumably this is a misprint.) By calculation we find that

$$Q^T = -P^{-1/2}JP^{-1/2} = -Q. \tag{P.10.35}$$

Evidently Q is real, antisymmetric, and nonsingular. Then $\hat{P}$ given by

$$\hat{P} = Q^TQ \tag{P.10.36}$$

will be real, symmetric, and positive definite. Goodman claims that

$$P = \exp(X)\exp(Y)\exp(X) \tag{P.10.37}$$

with

$$\exp(X) = (P^{1/2}\hat{P}^{1/2}P^{1/2})^{1/2} \tag{P.10.38}$$

and

$$\exp(Y) = \exp(-X)P\exp(-X). \tag{P.10.39}$$

Let us see if this is true. Evidently (10.37) and (10.39) are logically equivalent for any matrices P, X, and Y. So, perhaps we should examine the properties of X and Y.

Evidently X is real analytic in P. Squaring both sides of (10.38) gives

$$\exp(2X) = P^{1/2}\hat{P}^{1/2}P^{1/2}. \tag{P.10.40}$$

Define Z by writing

$$\exp(Z) = P. \tag{P.10.41}$$

Evidently Z is real analytic in P and

$$\exp(Z/2) = P^{1/2}. \tag{P.10.42}$$

With this definition, (10.40) can be rewritten in the form

$$\exp(2X) = \exp(Z/2)\hat{P}^{1/2}\exp(Z/2). \tag{P.10.43}$$

Next, define T by writing

$$\exp(T) = \hat{P}^{1/2}. \tag{P.10.44}$$

Then we have the result

$$\exp(2T) = \hat{P}. \tag{P.10.45}$$

Also, (10.43) can now be written in the form

$$\exp(2X) = \exp(Z/2)\exp(T)\exp(Z/2). \tag{P.10.46}$$

Now work out an expression for $\hat{P}$. From (10.34) through (10.36) we find that

$$\begin{aligned}\hat{P} &= -P^{-1/2}JP^{-1/2}P^{-1/2}JP^{-1/2} = P^{-1/2}JP^{-1}J^{-1}P^{-1/2}\\ &= \exp(-Z/2)J\exp(-Z)J^{-1}\exp(-Z/2) = \exp(-Z/2)\exp(-JZJ^{-1})\exp(-Z/2)\\ &= \exp(-Z/2)\exp[\sigma(Z)]\exp(-Z/2).\end{aligned} \tag{P.10.47}$$

Thus, we get the result

$$\exp(2T) = \exp(-Z/2)\exp[\sigma(Z)]\exp(-Z/2). \tag{P.10.48}$$

We see that (10.46) is the counterpart to (10.22), and (10.48) is the counterpart to (10.16). Therefore we have the relations

$$X = S^a \tag{P.10.49}$$

and

$$Y = S^c. \tag{P.10.50}$$

P.11 Theorem 1.2 of Goodman Due to Mostow

Consider the triplet $\{k \in O(2n, \mathbb{R}), S^c, S^a\}$. Use it to construct $g \in GL(2n, \mathbb{R})$ by the rule

$$g = k\exp(S^c)\exp(S^a). \tag{P.11.1}$$

It is claimed that (11.1) provides an analytic isomorphism between the triplet and $GL(2n, \mathbb{R})$.

Let us pause to do a dimension count. The dimension of S^c plus the dimension of S^a is the dimension of all symetric matrices S. And the dimension of $O(2n,\mathbb{R})$ is the dimension of all antisymmetric matrices A. Taken together, these dimensions add up to the dimension of all $2n \times 2n$ matrices, which is just the dimension of $GL(2n,\mathbb{R})$.

To continue, first we verify that (11.1) is injective. That is, different triplets must yield different elements in $GL(2n,\mathbb{R})$. For suppose that two triplets yield the same element $g \in GL(2n,\mathbb{R})$,

$$g = k_1 \exp(S_1^c)\exp(S_1^a) \tag{P.11.2}$$

and

$$g = k_2 \exp(S_2^c)\exp(S_2^a). \tag{P.11.3}$$

From (11.2) we find

$$g^T g = \exp(S_1^a)\exp(S_1^c)k_1^T k_1 \exp(S_1^c)\exp(S_1^a) = \exp(S_1^a)\exp(2S_1^c)\exp(S_1^a), \tag{P.11.4}$$

and from (11.3) we find

$$g^T g = \exp(S_2^a)\exp(S_2^c)k_2^T k_1 \exp(S_2^c)\exp(S_2^a) = \exp(S_2^a)\exp(2S_2^c)\exp(S_2^a). \tag{P.11.5}$$

Thus, we have the relation

$$\exp(S_1^a)\exp(2S_1^c)\exp(S_1^a) = \exp(S_2^a)\exp(2S_2^c)\exp(S_2^a). \tag{P.11.6}$$

From Theorem 1.1 and (11.6) we conclude that

$$S_1^a = S_2^a \tag{P.11.7}$$

and

$$S_1^c = S_2^c. \tag{P.11.8}$$

Then, from (11.2) and (11.3), se see that

$$k_1 = k_2. \tag{P.11.9}$$

Next, we verify that any $g \in GL(2n,\mathbb{R})$ can be written in the form (11.1). Given any $g \in GL(2n,\mathbb{R})$, define a real symmetric positive-definite matrix P by the rule

$$P = g^T g. \tag{P.11.10}$$

Evidently P is real analytic in g. Therefore, by the factorization theorem, there are unique matrices S^a and S^c, that depend real-analytically on P and therefore real-analytically on g, such that

$$P = \exp(S^a)\exp(2S^c)\exp(S^a). \tag{P.11.11}$$

Now define k by the rule

$$k = (g^T)^{-1}\exp(S^a)\exp(S^c). \tag{P.11.12}$$

Then k is also real-analytic in g. Moreover, we find that

$$k^T = \exp(S^c)\exp(S^a)(g)^{-1}, \tag{P.11.13}$$

from which it follows that

$$\begin{aligned} k^T k &= \exp(S^c)\exp(S^a)(g)^{-1}(g^T)^{-1}\exp(S^a)\exp(S^c) \\ &= \exp(S^c)\exp(S^a)P^{-1}\exp(S^a)\exp(S^c) \\ &= \exp(S^c)\exp(S^a)\exp(-S^a)\exp(-2S^c)\exp(-S^a)\exp(S^a)\exp(S^c) \\ &= \exp(S^c)\exp(-2S^c)\exp(S^c) = I. \qquad \text{(P.11.14)} \end{aligned}$$

Therefore $k \in O(2n, \mathbb{R})$.

Finally, suppose that $g \in SL(2n, \mathbb{R})$. In this case, take the determinant of both sides of (11.1) to get the result

$$1 = \det(g) = \det(k)\exp[\mathrm{tr}(\mathrm{S^c})]\exp[\mathrm{tr}(\mathrm{S^a})] = \det(\mathrm{k})\exp[\mathrm{tr}(\mathrm{S^c})] \qquad \text{(P.11.15)}$$

where we have used (10.5). We know that

$$\det(k) = \pm 1. \qquad \text{(P.11.16)}$$

We see that, in order for (11.15) to be satisfied, we must have the relations

$$\det(k) = +1 \text{ so that } k \in SO(2n, \mathbb{R}) \qquad \text{(P.11.17)}$$

and

$$\mathrm{tr}(S^c) = 0. \qquad \text{(P.11.18)}$$

We conclude the following: Consider the triplet $\{k \in SO(2n, \mathbb{R}), S^c \text{ with } \mathrm{tr}(S^c) = 0, S^a\}$. Use it to construct $g \in SL(2n, \mathbb{R})$ by the rule

$$g = k\exp(S^c)\exp(S^a). \qquad \text{(P.11.19)}$$

Then (11.19) provides an analytic isomorphism between the triplet and $SL(2n, \mathbb{R})$.

P.12 Goodman's Work on Symplectic Polar Decomposition

Consider the group $G = SL(2n, \mathbb{R})$, and its subgroups $H = Sp(2n, \mathbb{R})$ and $K = SO(2n, \mathbb{R})$. We want to study the coset space G/H.

P.12.1 Some More Symmetry Operations

To do so it is useful to introduce some additional symmetry operations on G. The operation Σ has already been defined by (4.1). We will define two more.

Introduce the operation Θ by the rule

$$\Theta(M) = (M^T)^{-1} \qquad \text{(P.12.1)}$$

for any $M \in G$. Evidently this map preserves the condition $\det(M) = 1$, and therefore sends G unto itself. Also we find that

$$\Theta(I) = I, \qquad \text{(P.12.2)}$$

$$\Theta(J) = J, \tag{P.12.3}$$

$$\Theta(M_1M_2) = [(M_1M_2)^T]^{-1} = [(M_2^TM_1^T)]^{-1} = (M_1^T)^{-1}(M_2^T)^{-1} = \Theta(M_1)\Theta(M_2), \tag{P.12.4}$$

$$\Theta[\Theta(M)] = \{[(M^T)^{-1}]^T\}^{-1} = M. \tag{P.12.5}$$

Thus Θ, like Σ, is an isomorphism and an involution.

Next, we discover that Σ and Θ commute. From the definition of Σ we find that

$$\Sigma[\Theta(M)] = J\{[\Theta(M)]^T\}^{-1}J^{-1}. \tag{P.12.6}$$

But, from (12.1),

$$\{[\Theta(M)]^T\}^{-1} = \{[(M^T)^{-1}]^T\}^{-1} = M. \tag{P.12.7}$$

Therefore, we conclude that

$$\Sigma[\Theta(M)] = JMJ^{-1}. \tag{P.12.8}$$

Applying the symmetries in opposite order gives

$$\Theta[\Sigma(M)] = \{[\Sigma(M)]^T\}^{-1}. \tag{P.12.9}$$

But, from (4.1), we have the relations

$$[\Sigma(M)]^T = [J(M^T)^{-1}J^{-1}]^T = JM^{-1}J^{-1} \tag{P.12.10}$$

and

$$\{[\Sigma(M)]^T\}^{-1} = [JM^{-1}J^{-1}]^{-1} = JMJ^{-1}. \tag{P.12.11}$$

It follows that

$$\Theta[\Sigma(M)] = JMJ^{-1}. \tag{P.12.12}$$

We see that the right sides of (12.8) and (12.12) agree, and therefore

$$\Sigma[\Theta(M)] = \Theta[\Sigma(M)] \tag{P.12.13}$$

or, in operator notation,

$$\Sigma\Theta = \Theta\Sigma. \tag{P.12.14}$$

Next define the operation Υ as the product

$$\Upsilon = \Sigma\Theta = \Theta\Sigma. \tag{P.12.15}$$

From (12.8) or (12.2) we find that

$$\Upsilon(M) = JMJ^{-1}. \tag{P.12.16}$$

We see that Υ is also an isomorphism. And, from (12.16), we see that

$$\Upsilon[\Upsilon(M)] = J[JMJ^{-1}]J^{-1} = M, \tag{P.12.17}$$

and therefore Υ is an involution as is expected for the product of commuting involutions.

Let θ and τ be the associated induced maps in the Lie algebra defined by

$$\Theta[\exp(B)] = \exp[\theta(B)], \tag{P.12.18}$$

$$\Upsilon[\exp(B)] = \exp[\tau(B)]. \tag{P.12.19}$$

For (12.18) we find

$$\Theta[\exp(B)] = \{[\exp(B)]^T\}^{-1} = [\exp(B^T)]^{-1} = \exp(-B^T), \tag{P.12.20}$$

and conclude that

$$\theta(B) = -B^T. \tag{P.12.21}$$

For (12.19) we find

$$\Upsilon[\exp(B)] = J\exp(B)J^{-1} = \exp(JBJ^{-1}), \tag{P.12.22}$$

and conclude that

$$\tau(B) = JBJ^{-1}. \tag{P.12.23}$$

Let us check some expected relations: First, we find the results

$$\theta[\theta(B)] = \theta[-B^T] = -[-B^T]^T = B \tag{P.12.24}$$

so that θ, like σ, is an involution, as expected. Second, we find the results

$$\sigma[\theta(B)] = \sigma[-B^T] = -J[-B^T]^T J^{-1} = JBJ^{-1} = \tau(B), \tag{P.12.25}$$

$$\theta[\sigma(B)] = \theta[-JB^TJ^{-1}] = -[-JB^TJ^{-1}]^T = JBJ^{-1} = \tau(B). \tag{P.12.26}$$

Thus, we conclude that

$$\sigma\theta = \theta\sigma = \tau. \tag{P.12.27}$$

It follows that τ is also an involution, as is also obvious from (12.22). Moreover, we note the relations

$$\sigma\tau = \tau\sigma = \theta, \tag{P.12.28}$$

$$\theta\tau = \tau\theta = \sigma. \tag{P.12.29}$$

Finally we should check the effects of θ and τ on scalar products. First we see that, for a real symmetric matrix,

$$\theta(S) = -S^T = -S \tag{P.12.30}$$

so that

$$[\theta(S)]^T = -S^T = -S = \theta(S). \tag{P.12.31}$$

Therefore, θ maps the space of real symmetric matrices into itself.

Next suppose B and B' are two matrices in $s\ell(2n, \mathbb{R})$. As before, define their inner product to be

$$(B, B') = \mathrm{tr}(BB'). \tag{P.12.32}$$

Then we find that θ preserves the inner product,

$$\begin{aligned}(\theta(B), \theta(B')) &= \mathrm{tr}[(-B^T)(-B')^T)] = \mathrm{tr}[B^T(B')^T] = \mathrm{tr}[(B'B)^T] \\ &= \mathrm{tr}[B'B] = \mathrm{tr}[BB'] = (B, B').\end{aligned} \tag{P.12.33}$$

Using (12.25), because σ and θ preserve the inner product, we see that τ also preserves the inner product,

$$(\tau(B), \tau(B')) = (\sigma[\theta(B)], \sigma[\theta(B')]) = ([\theta(B)], [\theta(B')]) = (B, B'). \tag{P.12.34}$$

P.12.2 Fixed-Point Subgroups Associated with Symmetry Operations

In Section 4 we found that the fixed points of Σ comprise the subgroup $Sp(2n,\mathbb{R})$. Now we will find that the fixed points of Θ and Υ also yield subgroups of $GL(2n,\mathbb{R})$.

Suppose g is a fixed point of Θ. Then we find that

$$\Theta(g)=g \;\Leftrightarrow\; (g^T)^{-1}=g \;\Leftrightarrow\; g^Tg=I. \tag{P.12.35}$$

Thus, the fixed points of Θ comprise $SO(2n,\mathbb{R})$. [Here we have already assumed $g\in SL(2n,\mathbb{R})$ so that we know that $\det g=1$. Otherwise the fixed points of Θ comprise $O(2n,\mathbb{R})$.]

Suppose g is a fixed point of Υ. Then we find that

$$\Upsilon(g)=g \;\Leftrightarrow\; JgJ^{-1}=g \;\Leftrightarrow\; Jg=gJ. \tag{P.12.36}$$

Thus, the fixed points of Υ comprise the matrices in $GL(2n,\mathbb{R})$ that commute with J. They also obviously form a group. But what is this group?

Write g in the block form

$$g=\begin{pmatrix} a & b\\ c & d\end{pmatrix}, \tag{P.12.37}$$

where the matrices a,b,c, and d are real and $n\times n$. Then we find the results

$$Jg=\begin{pmatrix} c & d\\ -a & -b\end{pmatrix}, \tag{P.12.38}$$

and

$$gJ=\begin{pmatrix} -b & a\\ -d & c\end{pmatrix}. \tag{P.12.39}$$

Therefore, requiring that g commute with J yields the restrictions

$$c=-b \tag{P.12.40}$$

and

$$d=a. \tag{P.12.41}$$

Thus, g is of the form

$$g=\begin{pmatrix} a & b\\ -b & a\end{pmatrix}. \tag{P.12.42}$$

Next define matrices A and B by the rules

$$A=\begin{pmatrix} a & 0\\ 0 & a\end{pmatrix}, \tag{P.12.43}$$

and

$$B=\begin{pmatrix} b & 0\\ 0 & b\end{pmatrix}. \tag{P.12.44}$$

Then both A and B commute with J, and we also have the relation

$$JB = \begin{pmatrix} 0 & b \\ -b & 0 \end{pmatrix}. \tag{P.12.45}$$

Therefore, we may also write

$$g = A + JB. \tag{P.12.46}$$

Suppose g_1 and g_2 are two matrices that commute with J and we use the representation (12.46) to write

$$g_k = A_k + JB_k \tag{P.12.47}$$

Then, recalling that the A_k and B_k commute with J and that $J^2 = -I$, we find the product relation

$$g_1 g_2 = (A_1 A_2 - B_1 B_2) + J(A_1 B_2 + B_1 A_2). \tag{P.12.48}$$

We see that, in (12.47) and (12.48), the matrix J plays a role analogous to the imaginary number i.

This analogy can be made explicit using the machinery of Section 3.9 of *Lie Methods*. Suppose m is an arbitrary $n \times n$ matrix with possibly complex entries. Evidently it can be written in the form

$$m = a + ib \tag{P.12.49}$$

where a and b are real $n \times n$ matrices. Let us multiply two such matrices together. So doing gives the result

$$m_1 m_2 = (a_1 a_2 - b_1 b_2) + i(a_1 b_2 + b_1 a_2). \tag{P.12.50}$$

Note the resemblance between the pairs (12.46), (12.49) and (12.48), (12.50).

To pursue the analogy further, let W be the unitary and (complex) symplectic matrix

$$W = \frac{1}{\sqrt{2}} \begin{pmatrix} I & iI \\ iI & I \end{pmatrix}. \tag{P.12.51}$$

Here each block in W is $n \times n$. Now, as in Section 3.9 of *Lie Methods*, define an associated $2n \times 2n$ matrix $g(m)$ by the rule

$$g(m) = M(m) = W \begin{pmatrix} m & 0 \\ 0 & \overline{m} \end{pmatrix} W^{-1}. \tag{P.12.52}$$

Then it is easily verified that there are the relations

$$g(I) = I, \tag{P.12.53}$$

$$g(m_1 m_2) = g(m_1) g(m_2), \tag{P.12.54}$$

$$g(m^{-1}) = g^{-1}(m). \tag{P.12.55}$$

Also, if (12.52) is multiplied out explicitly, we find the result

$$g(m) = \begin{pmatrix} \mathrm{Re}(m) & \mathrm{Im}(m) \\ -\mathrm{Im}(m) & \mathrm{Re}(m) \end{pmatrix} = \begin{pmatrix} a & b \\ -b & a \end{pmatrix}. \tag{P.12.56}$$

It follows that $g(m)$ is real for any m.

Matrices of the form (12.49) constitute the group $SL(n,\mathbb{C})$ provided we add the condition

$$\det(m) = 1. \tag{P.12.57}$$

Now take the determinant of both sides of (12.52). Doing so gives the result

$$\begin{aligned} \det(g) &= [\det(W)][\det(m)][\det(\overline{m})][\det(W^{-1})] \\ &= [\det(m)][\det(\overline{m})] = |\det(m)|^2 \geq 0. \end{aligned} \tag{P.12.58}$$

If (12.57) holds, then from (12.58) we also have the condition

$$\det(g) = 1. \tag{P.12.59}$$

From (12.49) through (12.59) we conclude that the set of matrices $g \in SL(2n,\mathbb{R})$ that also commute with J constitutes a group that is isomorphic to $SL(n,\mathbb{C})$. More precisely, the set of matrices $g \in SL(2n,\mathbb{R})$ that also commute with J constitutes a group that is the representation $SL(n,\mathbb{C}) \oplus \overline{SL(n,\mathbb{C})}$ of $SL(n,\mathbb{C})$. If we relax the determinant condition, we conclude that the set of matrices $g \in GL(2n,\mathbb{R},+)$ that also commute with J constitutes a group that is the representation $GL(n,\mathbb{C}) \oplus \overline{GL(n,\mathbb{C})}$ of $GL(n,\mathbb{C})$.

To summarize, let G^{Σ} be the fixed-point group associated with the symmetry Σ. Then we have the result

$$G^{\Sigma} = Sp(2n,\mathbb{R}) = H. \tag{P.12.60}$$

Similarly, we have

$$G^{\Theta} = SO(2n,\mathbb{R}) = K, \tag{P.12.61}$$

and

$$G^{\Upsilon} \cong SL(n,\mathbb{C}). \tag{P.12.62}$$

Also, from Section 3.9 of *Lie Methods*, we know that

$$K \cap H = SO(2n,\mathbb{R}) \cap Sp(2n,\mathbb{R}) \cong U(n) \oplus \overline{U(n)}. \tag{P.12.63}$$

Finally, suppose

$$m = \exp(i\phi)I, \tag{P.12.64}$$

which corresponds to

$$a = \cos(\phi)I \tag{P.12.65}$$

and

$$b = \sin(\phi)I. \tag{P.12.66}$$

Then we find the result

$$g(m) = \begin{pmatrix} \cos(\phi)I & \sin(\phi)I \\ -\sin(\phi)I & \cos(\phi)I \end{pmatrix} = I\cos(\phi) + J\sin(\phi) = \exp(\phi J). \tag{P.12.67}$$

P.13 Decomposition of Lie Algebras

Denote the Lie algebras of $G = SL(2n,\mathbb{R})$, $H = Sp(2n,\mathbb{R})$, and $K = SO(2n,\mathbb{R})$ by the symbols $\mathfrak{g}$, $\mathfrak{h}$, and $\mathfrak{k}$, respectively. The effects of σ, θ, and τ on $\mathfrak{g} = sl(2n,\mathbb{R})$ have already been determined in (4.15), (12.21), and (12.23), respectively. To recapitulate, we find the results

$$\sigma(B) = -JB^TJ^{-1} = B \text{ for } B \in \mathfrak{h} \tag{P.13.1}$$

and

$$\theta(B) = -B^T = B \text{ for } B \in \mathfrak{k}. \tag{P.13.2}$$

That is, $\mathfrak{h}$ is the +1 eigenspace of σ in $\mathfrak{g}$, and $\mathfrak{k}$ (the antisymmetric matrices) is the +1 eigenspace of θ in $\mathfrak{g}$.

Define the subspace $\mathfrak{p}$ by the requirement

$$\mathfrak{p} = \{B \in \mathfrak{g} \mid \theta(B) = -B\}. \tag{P.13.3}$$

That is, $\mathfrak{p}$ consists of the symmetric traceless matrices, and is the -1 eigenspace of θ in $\mathfrak{g}$. Then we have the direct sum decomposition (±1 eigenspaces of θ)

$$\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{p}, \tag{P.13.4}$$

which is just the familiar statement that any matrix can be uniquely decomposed into antisymmetric and symmetric parts. These parts are also mutually orthogonal relative to the trace form. Indeed, we have

$$(A,S) = \mathrm{tr}(AS) = \mathrm{tr}[(AS)^T] = \mathrm{tr}(S^TA^T) = \mathrm{tr}(-SA) = \mathrm{tr}(-AS) = -(A,S) \tag{P.13.5}$$

and therefore

$$(A,S) = 0. \tag{P.13.6}$$

Here A and S are antisymmetric and symmetric matrices, respectively.

Likewise, define the subspace $\mathfrak{q}$ by the requirement

$$\mathfrak{q} = \{B \in \mathfrak{g} \mid \sigma(B) = -B\}. \tag{P.13.7}$$

Then we have the direct sum decomposition (±1 eigenspaces of σ)

$$\mathfrak{g} = \mathfrak{h} \oplus \mathfrak{q}. \tag{P.13.8}$$

We should check that these eigenspaces are also mutually orthogonal relative to the trace form. The elements of $\mathfrak{h}$ are matrices of the form JS where S is symmetric. From (4.18) we know that the elements of $\mathfrak{q}$ are matrices of the form JA where A is antisymmetric. For their inner product we find that

$$\begin{aligned}(JS,JA) &= \mathrm{tr}(JSJA) = \mathrm{tr}[(JSJA)^T] = \mathrm{tr}[A^TJ^TS^TJ^T] \\ &= \mathrm{tr}[-AJSJ] = \mathrm{tr}[-JSJA] = -(JS,JA),\end{aligned} \tag{P.13.9}$$

from which we conclude that

$$(JS,JA) = 0. \tag{P.13.10}$$

Finally, we observe that the relation (13.8) is just the assertion that every traceless matrix can be written as the sum $(JS+JA)$ where A is chosen to make JA traceless. (Note that JS is automatically traceless for any S.)

Next we can refine the decompositions (13.4) and (13.8) using both θ and σ. For example, the decomposition (13.4) used θ to decompose $\mathfrak{g}$ into $\mathfrak{k}+\mathfrak{p}$. We can now further decompose $\mathfrak{k}$ and $\mathfrak{p}$ using σ. Alternatively, the decomposition (13.8) used σ to decompose $\mathfrak{g}$ into $\mathfrak{h}+\mathfrak{q}$. We can now further decompose $\mathfrak{h}$ and $\mathfrak{q}$ using θ. These refinements are possible because θ and σ commute. The eigenspaces of θ are invariant under the action of σ, and the eigenspaces of σ are invariant under the action of θ.

Let s and s' be *sign* variables that take on the values ±1. Define subspaces $\mathfrak{g}_{ss'}$ by the requirements

$$\sigma(B)=sB \tag{P.13.11}$$

and

$$\theta(B)=s'B \tag{P.13.12}$$

for any $B\in\mathfrak{g}_{ss'}$. Then we have the direct sum decomposition

$$\mathfrak{g}=\mathfrak{g}_{1,1}\oplus\mathfrak{g}_{1,-1}\oplus\mathfrak{g}_{-1,1}\oplus\mathfrak{g}_{-1.-1}. \tag{P.13.13}$$

Also, we have the result

$$\tau(B)=ss'B \tag{P.13.14}$$

for any $B\in\mathfrak{g}_{ss'}$.

Let us examine the contents of each subspace $\mathfrak{g}_{ss'}$. Begin with $\mathfrak{g}_{1,1}$. From (4.17) we see that it must be of the form JS. From (12.23) and (13.14) we see that it must be of the form JS^c. Thus we have

$$B\in\mathfrak{g}_{1,1}\ \Leftrightarrow\ B=JS^c. \tag{P.13.15}$$

Similarly, we find that elements in $\mathfrak{g}_{1,-1}$ must be of the form JS^a,

$$B\in\mathfrak{g}_{1,-1}\ \Leftrightarrow\ B=JS^a. \tag{P.13.16}$$

Together $\mathfrak{g}_{1,1}$ and $\mathfrak{g}_{1,-1}$ span $\mathfrak{h}=sp(2n,\mathbb{R})$,

$$\mathfrak{h}=\mathfrak{g}_{1,1}\oplus\mathfrak{g}_{1,-1}. \tag{P.13.17}$$

Next consider $\mathfrak{g}_{-1,1}$. By (4.18) it must be of the form JA. By (13.14) it must be of the form JA^a where A^a is an antisymmetric matrix that anticommutes with J,

$$B\in\mathfrak{g}_{-1,1}\ \Leftrightarrow\ B=JA^a. \tag{P.13.18}$$

Finally, any $B\in\mathfrak{g}_{-1,-1}$ must be of the form JA^c where A^c is an antisymmetric matrix that commutes with J,

$$B\in\mathfrak{g}_{-1,-1}\ \Leftrightarrow\ B=JA^c. \tag{P.13.19}$$

In summary, the claim is that any matrix $B\in sl(2n,\mathbb{R})$ can be uniquely be decomposed as the sum

$$B=JS^c+JS^a+JA^a+JA^c, \tag{P.13.20}$$

which is, in fact, almost obvious upon inspection.

These elements are also mutually orthogonal. We find from (8.9) the result

$$(JS^c, JS^a) = \mathrm{tr}(JS^cJS^a) = \mathrm{tr}(S^cJJS^a) = -\mathrm{tr}(S^cS^a) = -(S^c, S^a) = 0. \tag{P.13.21}$$

From (13.10) we find the results

$$(JS^c, JA^a) = (JS^c, JA^c) = (JS^a, JA^a) = (JS^a, JA^c) = 0. \tag{P.13.22}$$

Lastly, we find

$$(JA^a, JA^c) = \mathrm{tr}(JA^aJA^c) = -\mathrm{tr}(A^aJJA^c) = \mathrm{tr}(A^aA^c) = (A^a, A^c). \tag{P.13.23}$$

But we also find

$$(JA^a, JA^c) = \mathrm{tr}(JA^aJA^c) = \mathrm{tr}(JA^aA^cJ) = \mathrm{tr}(JJA^aA^c) = -(A^a, A^c), \tag{P.13.24}$$

from which we conclude that

$$(JA^a, JA^c) = 0. \tag{P.13.25}$$

These orthogonality proofs just provided are brute force. A more elegant proof, in the style of (8.8) and (8.9), can be given based on (13.1) and (13.2) and the fact that σ and θ preserve the inner product.

Together $\mathfrak{g}_{1,1}$ and $\mathfrak{g}_{-1,1}$ span $\mathfrak{k} = so(2n, \mathbb{R})$,

$$\mathfrak{k} = \mathfrak{g}_{1,1} \oplus \mathfrak{g}_{-1,1}. \tag{P.13.26}$$

Inspection of (3.15) and (3.18) shows that

$$B \in \mathfrak{g}_{1,1} \oplus \mathfrak{g}_{-1,1} \;\Leftrightarrow\; B = JS^c + JA^a. \tag{P.13.27}$$

Matrices of the form ($B = JS^c + JA^a$) are evidently antisymmetric. It is also easily verified that matrices of the form ($JS^a + JA^c$) are symmetric. Since all the matrices appearing in (13.20), when taken together, span $g\ell(2n, \mathbb{R})$, it follows that matrices of the form ($B = JS^c + JA^a$) span the full space of antisymmetric matrices. See also (13.28) and (13.30) below.

It remains to be seen what matrices in (13.20) are traceless. We already know that JS^c and JS^a are traceless, and JA^a is also traceless because it is antisymmetric. The remaining candidate is JA^c. It contains the possibility $JJ = -I$, which is not traceless.

Finally, using the notation of intersecting sets, we may write

$$\mathfrak{g}_{1,1} = \mathfrak{h} \cap \mathfrak{k} = \text{ matrices of the form } JS^c \cong A^c, \tag{P.13.28}$$

$$\mathfrak{g}_{1,-1} = \mathfrak{h} \cap \mathfrak{p} = \text{ matrices of the form } JS^a \cong S^a, \tag{P.13.29}$$

$$\mathfrak{g}_{-1,1} = \mathfrak{q} \cap \mathfrak{k} = \text{ matrices of the form } JA^a \cong A^a, \tag{P.13.30}$$

$$\mathfrak{g}_{-1,-1} = \mathfrak{q} \cap \mathfrak{p} = \text{ matrices of the form } JA^c \cong S^c. \tag{P.13.31}$$

Here we have included the fact that various categories of matrices are are isomorphic. For example, matrices of the form JS^c are evidently antisymmetric, and commute with J. Therefore they are of the form A^c. We also note, from the discussion of the previous paragraph, that all the $\mathfrak{g}_{s,s'}$ are traceless with the possible exception of $\mathfrak{g}_{-1,-1}$.

By using these isomorphisms in (13.20), we find that any matrix $B \in s\ell(2n,\mathbb{R})$ can also be uniquely be decomposed as the sum

$$B = A^c + S^a + A^a + S^c, \tag{P.13.32}$$

which is also obvious upon inspection.

We have already noted in (13.17) that $\mathfrak{g}_{1,1}$ and $\mathfrak{g}_{1,-1}$ together span $\mathfrak{h} = sp(2n,\mathbb{R})$. They, in fact, provide the Cartan decomposition of $sp(2n,\mathbb{R})$.

Finally, Goodman makes the claims

$$\mathfrak{g}_{1,-1} = \mathfrak{h} \cap \mathfrak{p} = \{B \in \mathcal{E} \mid \mathrm{tr}B = 0\}, \tag{P.13.33}$$

$$\mathfrak{g}_{-1,-1} = \mathfrak{q} \cap \mathfrak{p} = \{B \in \mathcal{F} \mid \mathrm{tr}B = 0\}. \tag{P.13.34}$$

But, $\mathcal{E}$ is defined by the requirements

$$\mathcal{E} = \{B \mid B^T = B \text{ and } \sigma(B) = B\}, \tag{P.13.35}$$

which is equivalent to the requirements

$$\mathcal{E} = \{B \mid \theta(B) = -B \text{ and } \sigma(B) = B\}. \tag{P.13.36}$$

In our notation, these requirements simply state that

$$\mathcal{E} = \mathfrak{g}_{1,-1}. \tag{P.13.37}$$

We already know that matrices in $\mathfrak{g}_{1,-1}$ are traceless, and so (13.33) is verified. Moreover, $\mathcal{F}$ is defined by the requirements

$$\mathcal{F} = \{B \mid B^T = B \text{ and } \sigma(B) = -B\}, \tag{P.13.38}$$

which is equivalent to the requirements

$$\mathcal{F} = \{B \mid \theta(B) = -B \text{ and } \sigma(B) = -B\}. \tag{P.13.39}$$

In our notation, these requirements simply state that

$$\mathcal{F} = \mathfrak{g}_{-1,-1}. \tag{P.13.40}$$

We know from (13.19) that in this case there is a matrix that has trace, namely JJ, and therefore in this case (13.34) is also verified provided the JJ case is excluded.

P.14 Preparation for Lemma 2.1 of Goodman

Let S_d consist of all the real *diagonal* symmetric matrices s_d of the form

$$s_d = \begin{pmatrix} d & 0 \\ 0 & d \end{pmatrix} \tag{P.14.1}$$

where

$$d = \operatorname{diag}[d_1, \cdots, d_n] \text{ and } \operatorname{tr}(d) = 0. \tag{P.14.2}$$

(Goodman uses the symbol A for what we call S_d. However, we have already used A to denote antisymmetric matrices.) Then, from Section 12.2, we have the relation

$$\tau(s_d) = s_d. \tag{P.14.3}$$

And, from (12.21), we see that

$$\theta(s_d) = -s_d. \tag{P.14.4}$$

Therefore, from (12.29), we conclude that

$$\sigma(s_d) = -s_d, \tag{P.14.5}$$

and consequently

$$S_d \subset \mathfrak{g}_{-1,-1} = \mathfrak{q} \cap \mathfrak{p}. \tag{P.14.6}$$

Let S_d^+ be the open subset of S_d consisting of the matrices s_d with

$$d_1 > d_2 > \cdots > d_n. \tag{P.14.7}$$

Let S_d^{+c} be the closure of S_d^+. Then we also have the relations

$$S_d^+ \subset \mathfrak{g}_{-1,-1} = \mathfrak{q} \cap \mathfrak{p}, \tag{P.14.8}$$

and

$$S_d^{+c} \subset \mathfrak{g}_{-1,-1} = \mathfrak{q} \cap \mathfrak{p}. \tag{P.14.9}$$

Also, let D^+ be the set of matrices d of the form (14.2) with (14.7) satisfied, and let D^{+c} denote its closure.

P.15 Lemma 2.1 of Goodman

Suppose x is of the form $x = \exp(B)$ where $B \in \mathfrak{g}_{-1,-1}$. Then we know there is a matrix of the form JA^c such that

$$x = \exp(JA^c). \tag{P.15.1}$$

We may also require that JA^c be traceless. By inspection, JA^c is symmetric and commutes with J. Therefore, consistent with (13.31), there is a real traceless symmetric matrix S^c such that

$$JA^c = S^c, \tag{P.15.2}$$

and we have the relation

$$x = \exp(S^c). \tag{P.15.3}$$

It follows from (15.3) that x is real, symmetric, and positive definite.

Let us see what can be said about S^c. Since it commutes with J, by the work of Section 12.2, it must be of the form

$$S^c = \begin{pmatrix} \alpha & \beta \\ -\beta & \alpha \end{pmatrix}. \tag{P.15.4}$$

Since S^c is traceless, α must be traceless. Since S^c is symmetric, the matrices α and β must have have the properties

$$\alpha^T = \alpha, \tag{P.15.5}$$

$$\beta^T = -\beta. \tag{P.15.6}$$

Note that, by (15.6), the matrix β is traceless. Define the matrix m by the rule

$$m = \alpha + i\beta. \tag{P.15.7}$$

Then, we have the relation

$$S^c = S^c(m) = M(m) = W \begin{pmatrix} m & 0 \\ 0 & \overline{m} \end{pmatrix} W^{-1}. \tag{P.15.8}$$

We also observe that

$$m^\dagger = \alpha^T - i\beta^T = \alpha + i\beta = m \tag{P.15.9}$$

so that m is Hermitian. Since both α and β are traceless, m is also traceless.

Since m is Hermitian and traceless, there is a unitary matrix v and a matrix $d \in D^{+c}$ such that

$$m = vdv^{-1}. \tag{P.15.10}$$

Since d is real, we also have the relation

$$\overline{m} = \overline{v}d\overline{v^{-1}}. \tag{P.15.11}$$

It follows that S^c has the representation

$$S^c(m) = W \begin{pmatrix} v & 0 \\ 0 & \overline{v} \end{pmatrix} \begin{pmatrix} d & 0 \\ 0 & d \end{pmatrix} \begin{pmatrix} v^{-1} & 0 \\ 0 & \overline{v^{-1}} \end{pmatrix} W^{-1}. \tag{P.15.12}$$

Insert factors of W and W^{-1} into (15.12) to rewrite it in the form

$$S^c(m) = W \begin{pmatrix} v & 0 \\ 0 & \overline{v} \end{pmatrix} W^{-1} W \begin{pmatrix} d & 0 \\ 0 & d \end{pmatrix} W^{-1} W \begin{pmatrix} v^{-1} & 0 \\ 0 & \overline{v^{-1}} \end{pmatrix} W^{-1}. \tag{P.15.13}$$

Since d is real, we see that (15.13) can be rewritten in the form

$$S^c(m) = M(v)M(d)M(v^{-1}). \tag{P.15.14}$$

We also know, since d is real, that we have

$$M(d) = s_d, \tag{P.15.15}$$

with $s_d \in S_d^{+c}$, so that there is also the relation

$$S^c = M(v) s_d M(v^{-1}). \tag{P.15.16}$$

Define the matrix O by the rule

$$O = M(v). \tag{P.15.17}$$

Since v is unitary, O will be real, symplectic, and orthogonal. Thus we have the result

$$S^c = O s_d O^{-1}. \tag{P.15.18}$$

Finally, exponentiate both sides of (15.18). So doing gives the result

$$x = O \exp(s_d) O^{-1} \tag{P.15.19}$$

with

$$O \in SO(2n, \mathbb{R}) \cap Sp(2n, \mathbb{R} \cong U(n) \oplus \overline{U(n)}. \tag{P.15.20}$$

Note that since O is orthogonal, (15.19) can also be written in the form

$$x = O \exp(s_d) O^T, \tag{P.15.21}$$

from which we again see that x is real, symmetric, and positive definite.

Goodman claims that s_d depends analytically on x when the eigenvalues of x, which will be the quantities $\exp(d_j)$, are distinct. We will worry about proving this later. We know from (15.3) that S^c is real analytic in x, and from (15.4) through (15.7) we see that m is analytic in S^c. What remains to be shown is that the eigenvalues of m, with m Hermitian and traceless, are analytic in m under the assumption that the eigenvalues are distinct.

P.16 Preparation for Theorem 2.1 of Goodman

Let u be any $n \times n$ unitary matrix, and consider $M(u)$. From Section 3.9 of *Lie methods* we know that

$$M(u) \in SO(2n, \mathbb{R}) \cap Sp(2n, \mathbb{R}) \cong U(n) \oplus \overline{U(n)}, \tag{P.16.1}$$

and given any $M' \in SO(2n, \mathbb{R}) \cap Sp(2n, \mathbb{R})$ there is a unique $u \in U(n)$ such that

$$M(u) = M'. \tag{P.16.2}$$

Let $L \subset SO(2n, \mathbb{R}) \cap Sp(2n, \mathbb{R})$ be the subgroup of matrices g such that

$$g s_d g^{-1} = s_d \text{ for all } s_d \in S_d. \tag{P.16.3}$$

By definition for any such s_d there is a corresponding d given by (14.1) and (14.2), and we have the relation

$$s_d = M(d). \tag{P.16.4}$$

Also, given any $g \in SO(2n,\mathbb{R}) \cap Sp(2n,\mathbb{R})$, there is a unique $u \in U(n)$ such that

$$M(u) = g. \tag{P.16.5}$$

With these definitions, the relation (16.3) becomes

$$M(u)M(d)[M(u)]^{-1} = M(d) \text{ for all } d. \tag{P.16.6}$$

By the isomorphic property of M this relation is equivalent to the requirement

$$udu^{-1} = d \text{ for all } d. \tag{P.16.7}$$

All such u must be diagonal unitary matrices, and therefore have the explicit form

$$u = \text{diag}[\exp(i\phi_1), \cdots, \exp(i\phi_n)]. \tag{P.16.8}$$

Thus, we have the isomorphism

$$L \cong T^n. \tag{P.16.9}$$

Moreover, since $SO(2n,\mathbb{R})$ has rank n, L is a maximal torus in $SO(2n,\mathbb{R})$. Goodman says that this means that $SO(2n,\mathbb{R})/L$ is the flag manifold for $SO(2n,\mathbb{R})$.

By the definition of L we see from (16.3) that

$$\ell s_d \ell^{-1} = s_d \text{ for all } \ell \in L \text{ and all } s_d \in S_d. \tag{P.16.10}$$

It follows that

$$\ell \exp(s_d)\ell^{-1} = \exp(\ell s_d \ell^{-1}) = \exp(s_d). \tag{P.16.11}$$

Introduce the notation

$$\hat{s}_d = \exp(s_d). \tag{P.16.12}$$

Then, for future use, we have the relation

$$\ell \hat{s}_d = \hat{s}_d \ell \text{ for all } \ell \in L \text{ and all } \hat{s}_d \in \exp(S_d). \tag{P.16.13}$$

Also, we see directly that

$$\ell \in SO(2n,\mathbb{R}) \cap Sp(2n,\mathbb{R}) \tag{P.16.14}$$

since ℓ is of the form $M(u)$ with u given by (16.8).

For insight, let us work out the explicit matrix form of ℓ. We have the relation

$$\ell = M(u) = \begin{pmatrix} \text{Re}(u) & \text{Im}(u) \\ -\text{Im}(u) & \text{Re}(u) \end{pmatrix} = \begin{pmatrix} C & S \\ -S & C \end{pmatrix}. \tag{P.16.15}$$

Here C and S are $n \times n$ diagonal matrices given by the relations

$$C = \begin{pmatrix} \cos(\phi_1) & & & \\ & \cos(\phi_2) & & \\ & & \ddots & \\ & & & \cos(\phi_n) \end{pmatrix}, \tag{P.16.16}$$

$$S = \begin{pmatrix} \sin(\phi_1) & & & \\ & \sin(\phi_2) & & \\ & & \ddots & \\ & & & \sin(\phi_n) \end{pmatrix}. \tag{P.16.17}$$

P.17 Theorem 2.1 of Goodman

Recall that $G = SL(2n, \mathbb{R})$, $H = Sp(2n, \mathbb{R})$, and $K = SO(2n, \mathbb{R})$. Goodman claims that any $g \in G$ has the decomposition

$$g = k\hat{s}_d h \tag{P.17.1}$$

where $k \in K$, $h \in H$, and $\hat{s}_d \in \exp(S_d^{+c})$.

The argument goes as follows. Recall that, according to Theorem 1.2, every $g \in SL(2n, \mathbb{R})$ has the factorization

$$g = k \exp(S^c) \exp(S^a) \tag{P.17.2}$$

with $k \in SO(2n, \mathbb{R})$ and $\mathrm{tr}(S^c) = 0$. Also, we know from (15.3) and (15.20) that there is the representation

$$\exp(S^c) = O \exp(s_d) O^T, \tag{P.17.3}$$

so that we also have the factorization

$$g = kO \exp(s_d) O^T \exp(S^a). \tag{P.17.4}$$

Rewrite this relation in the form

$$g = [kO][\exp(s_d)][O^T \exp(S^a)]. \tag{P.17.5}$$

Note from (13.29) that $S^a \in \mathfrak{g}_{1,-1} = \mathfrak{h} \cap \mathfrak{p}$ and $S^a \cong JS^a$. Therefore,

$$\exp(S^a) \in Sp(2n, \mathbb{R}). \tag{P.17.6}$$

Also O is in both $SO(2n, \mathbb{R})$ and $Sp(2n, \mathbb{R})$. Consequently there are the following group relations,

$$kO \in SO(2n, \mathbb{R}), \tag{P.17.7}$$

$$O^T \exp(S^a) \in Sp(2n, \mathbb{R}). \tag{P.17.8}$$

Define group elements k', $\hat{s}_d$, and h by the rules

$$k' = kO, \tag{P.17.9}$$

$$\hat{s}_d = \exp(s_d), \tag{P.17.10}$$

$$h = O^T \exp(S^a). \tag{P.17.11}$$

Then, we may write

$$g = k'\hat{s}_d h, \tag{P.17.12}$$

which is a factorization of the form (17.1).

Consider the map

$$(K, S_d) \mapsto G \tag{P.17.13}$$

given by the rule

$$g(k, s_d) = k[\exp(s_d)]. \tag{P.17.14}$$

Then, we find that

$$g(k\ell,s_d)=k\ell[\exp(s_d)]=k[\exp(s_d)]\ell \tag{P.17.15}$$

where we have used (16.12). Also we know that

$$\ell\in SO(2n,\mathbb{R})\cap Sp(2n,\mathbb{R}) \tag{P.17.16}$$

and therefore

$$\ell\in Sp(2n,\mathbb{R}). \tag{P.17.17}$$

Thus, we may write (17.15) in the form

$$g(k\ell,s_d)=k\ell[\exp(s_d)]=k[\exp(s_d)]\ell=g(k,s_d)h \tag{P.17.18}$$

with

$$h=\ell \text{ and } h\in Sp(2n,\mathbb{R}). \tag{P.17.19}$$

We see that $g(k\ell,s_d)$ and $g(k,s_d)$ are in the same coset in the coset space G/H,

$$g(k\ell,s_d)\sim g(k,s_d) \bmod Sp(2n,\mathbb{R}). \tag{P.17.20}$$

Also, we know that $k\ell$ and k are in the same coset in the coset space K/L,

$$k\ell\sim k \bmod L. \tag{P.17.21}$$

Therefore (17.14) provides a map

$$(K/L,S_d)\mapsto G/H. \tag{P.17.22}$$

But, by (17.1), we know that every element of G/H can be obtained in this way. Thus, we conjecture that there is a correspondence of the form

$$[K/L]\times S_d^{+c}\leftrightarrow G/H. \tag{P.17.23}$$

Let us check dimensions. We want to check the relation

$$\dim K-\dim L+\dim S_d^{+c}=\dim G-\dim H. \tag{P.17.24}$$

We have the counts

$$\dim K=n(2n-1), \tag{P.17.25}$$

$$\dim L=n, \tag{P.17.26}$$

$$\dim S_d^{+c}=n-1, \tag{P.17.27}$$

$$\dim H=n(2n+1), \tag{P.17.28}$$

$$\dim G=(2n)^2-1. \tag{P.17.29}$$

Therefore we have to check the relation

$$n(2n-1)-n+(n-1)=[(2n)^2-1]-n(2n+1)? \tag{P.17.30}$$

A little algebra shows that both sides of (17.30) simplify to the expression $(2n^2 - n - 1)$ so that the relation does indeed hold.

We still have to check uniqueness. Suppose (k_1, s_{d1}) and (k_2, s_{d2}) are sent to g_1 and g_2 under (17.14),

$$k_1[\exp(s_{d1})] = g_1, \tag{P.17.31}$$

$$k_2[\exp(s_{d2})] = g_2. \tag{P.17.32}$$

Also suppose that

$$g_2 \sim g_1 \bmod H. \tag{P.17.33}$$

Then, we want to show that

$$k_2 \sim k_1 \bmod L \tag{P.17.34}$$

and

$$s_{d2} = s_{d1}. \tag{P.17.35}$$

Suppose (17.33) holds. Then there is an $h \in H$ such that

$$g_2 = g_1 h, \tag{P.17.36}$$

and therefore, from (17.31) and (17.32), there is the relation

$$k_2[\exp(s_{d2})] = k_1[\exp(s_{d1})]h. \tag{P.17.37}$$

To be continued.

Application to Dragt's Symplectic Polar Decompostion

P.18 Search for Counter Examples

In view of the results of the previous section, we will also get elements g' in all possible cosets $GL(2n, \mathbb{R})/Sp(2n, \mathbb{R})$ by the the rule

$$g'(k, s'_d) = ks'_d \tag{P.18.1}$$

where s'_d is of the form (14.1) but d is no longer required to be traceless. Comparison of this rule with (17.14) shows that we may get some overlap by this procedure, but (18.1) appears easier to work with.

The search for counter examples can be begun with the case $k = I$ for which

$$g'(I, s'_d) = Is'_d = s'_d, \tag{P.18.2}$$

and we have found counter examples in the 4 × 4 matrix context. They demonstrate that symplectic polar decomposition of a matrix M is not possible globally even with the restriction $\det(M) > 0$. See Section 4.3.5 of *Lie Methods*.

We can next examine the case $s'_d = I$ for which the g' are matrices of the form

$$g'(k, I) = k. \tag{P.18.3}$$

When k is in the vicinity of the identity, g' will be near the identity, and therefore have a symplectic polar decomposition. But what happens when we consider all $k \in SO(2n,\mathbb{R})$? Exercise 4.3.19 of *Lie Methods* studies a particular one-parameter subgroup of $SO(4,\mathbb{R})$ and shows that for all such elements symplectic polar decomposition is always possible, but the ray$\lambda^2 N(M)$ need not always intersect the unit ball around I. Exercise 4.3.22 shows that all elements of $SO(4,\mathbb{R})$ have symplectic polar decompositions.

Let H be the subgroup consisting of all elements $g \in GL(2n,\mathbb{R},+)$ such that

$$\{g, J\} = 0. \tag{P.18.4}$$

We know that H is isomorphic to $GL(n,\mathbb{C})$. Exercise 4.3.21 shows that all elements of H have symplectic polar decompositions.

We should now think about more general elements of $GL(4,\mathbb{R})$. For example, Exercise 4.3.20 describes a one parameter closed path of elements that includes elements that do and do not have symplectic polar decompositions. It would be interesting to see where the decomposition first fails.

Also, suppose symplectic polar decomposition is possible for some matrix M. What can be said about matrices in the neighborhood of M? Similarly, suppose symplectic polar decomposition is impossible for some matrix M. What can be said then about matrices in the neighborhood of M? What is the nature of the transition from having to not having a symplectic polar decomposition?

Appendix Q

Improving Convergence of Fourier Representation

Q.1 Introduction

Suppose $f(u)$ is a function defined on the interval $u \in [0, 2\pi]$, and suppose f is continuous and has a continuous first derivative. What can be said about a Fourier representation of f over this interval? We observe that, by definition, a Fourier series produces a periodic function, and straight-forward application of Fourier's theorem to f produces a function with period 2π. But, f may not have a periodic extension unless some kind of singularity (say a discontinuity in f or one of its derivatives) is introduced at the points $u = 0, \pm 2\pi, \pm 4\pi, \cdots$. For example, if $f(0) \neq f(2\pi)$, the periodic extension of f cannot be continuous. The net effect of this discontinuity is that in this case the Fourier coefficients of f can fall off no faster than $(1/n)$ for large n. In Section 14.5 we saw that this situation can be improved somewhat by doubling the domain of definition for f and imposing an *evenness* condition on its extension. The net result is a modified Fourier representation over the domain $[-2\pi, 2\pi]$ whose coefficients fall off like $(1/n)^2$. The purpose of this appendix is to describe and apply a further trick that makes it possible to obtain a Fourier-like representation for which the coefficients fall off still faster.

Begin by writing f in the form

$$f(u) = c + [d/(2\pi)]u + g(u) \tag{Q.1.1}$$

where

$$c = f(0) \text{ and } d = f(2\pi) - f(0). \tag{Q.1.2}$$

Then the function $g(u)$ is also defined for $u \in [0, 2\pi]$, is continuous, and has a continuous first derivative. Moreover, it has the property

$$g(0) = g(2\pi) = 0. \tag{Q.1.3}$$

Extend g to the interval $[-2\pi, 0]$ by requiring that g be odd,

$$g(u) = -g(-u) \text{ for } u \in [-2\pi, 0]. \tag{Q.1.4}$$

Then, because of (1.3) and (1.4), the extended g is continuous at $u = 0$. Moreover, we find that

$$g(-2\pi) = -g(2\pi) = 0. \tag{Q.1.5}$$

Finally, from (1.4) we find that

$$g'(u) = g'(-u) \;\; \text{for} \;\; u \in [-2\pi, 0], \tag{Q.1.6}$$

from which it follows that the extended g' is continuous at $u = 0$. Thus, g has now been defined for $u \in [-2\pi, 2\pi]$, and is continuous and has a continuous first derivative in the open interval $u \in (-2\pi, 2\pi)$.

Further extend g to the full interval $u \in (-\infty, \infty)$ by requiring that g be periodic with period 4π,

$$g(u + 4\pi) = g(u). \tag{Q.1.7}$$

We will now see that this extension results in a g that is also continuous and has a continuous first derivative at the points $u = \pm 2\pi$ and their 4π periodic extensions. Thus the net result is that, by these extensions, g has been defined everywhere and is continuous and has a continuous first derivative everywhere. Let us check first the case $u = 2\pi$. From the definitions so far we have the relations

$$g(2\pi + \epsilon) = g(-2\pi + \epsilon) = -g(2\pi - \epsilon). \tag{Q.1.8}$$

In view of (1.3) and (1.8), continuity at $u = 2\pi$ has been established. Also, using periodicity and (1.6), we have the relations

$$g'(2\pi + \epsilon) = g'(-2\pi + \epsilon) = g'(2\pi - \epsilon), \tag{Q.1.9}$$

from which it follows that g has a continuous first derivative at $u = 2\pi$. Similarly, we find that

$$g(-2\pi - \epsilon) = g(2\pi - \epsilon) = -g(-2\pi + \epsilon) \tag{Q.1.10}$$

and

$$g'(-2\pi - \epsilon) = g'(2\pi - \epsilon) = g'(-2\pi + \epsilon), \tag{Q.1.11}$$

from which it follows that g is continuous and has a continuous first derivative at $u = -2\pi$.

We are now ready to invoke the results of Fourier. Since g is 4π periodic, it has an expansion over the interval $u \in [-2\pi, 2\pi]$ of the form

$$g(u) = \sum_{n=0}^{\infty} a_n \cos(nu/2) + \sum_{n=1}^{\infty} b_n \sin(nu/2). \tag{Q.1.12}$$

Since g is odd, all the a_n must vanish, and we are left with

$$g(u) = \sum_{n=1}^{\infty} b_n \sin(nu/2). \tag{Q.1.13}$$

The coefficients b_n are given by the integrals

$$b_n = [1/(2\pi)] \int_{-2\pi}^{2\pi} du \; g(u) \sin(nu/2) = (1/\pi) \int_{0}^{2\pi} du \; g(u) \sin(nu/2). \tag{Q.1.14}$$

Note that the integrals on the far right side of (1.14) depend only on the knowledge of g, and hence f, in the original interval $u \in [0, 2\pi]$. Finally, since g will generally have a discontinuous second derivative at the points $u = 0, \pm 2\pi, \pm 4\pi, \cdots$, the coefficients b_n will generally fall off according to the rule

$$b_n \sim (1/n)^3 \;\text{ as }\; n \to \infty. \tag{Q.1.15}$$

The net result of our efforts is that f has the representation

$$f(u) = c + [d/(2\pi)]u + \sum_{n=1}^{\infty} b_n \sin(nu/2) \tag{Q.1.16}$$

with the coefficients b_n obeying (1.15).

Consider the function $h(v)$ defined by

$$h(v) = f(v + \pi). \tag{Q.1.17}$$

It is defined on the interval $v \in [-\pi, \pi]$. According to (1.16) it has the expansion

$$\begin{aligned} h(v) &= c + [d/(2\pi)](v + \pi) + \sum_{n=1}^{\infty} b_n \sin[n(v + \pi)/2] \\ &= [h(\pi) + h(-\pi)]/2 + \{[h(\pi) - h(-\pi)]/(2\pi)\}v + \sum_{n=1}^{\infty} b_n \sin[n(v + \pi)/2]. \end{aligned} \tag{Q.1.18}$$

Appendix R

Abstract Lie Group Theory

The purpose of this appendix is to show that the Jacobi identity in a Lie algebra is related to the assumed associativity of group multiplication in the corresponding Lie group. When a Lie group is realized in terms of matrices, the associative condition for group multiplication is automatically satisfied because matrix multiplication is associative. Correspondingly, the Jacobi identity is readily verified for Lie algebras realized in terms of matrices with the Lie product taken to be the matrix commutator. Treating the case of an abstract Lie group requires somewhat more effort.

$\exp[(t_1 + t_2)X] = [\exp(t_1X)][\exp(t_2X)]$.

Appendix S

Mathematica Realization of TPSA and Taylor Map Computation

S.1 Background

The forward integration method (Section 10.12.4) for computing Taylor maps can be implemented by a code employing the tools of *automatic differentiation* (AD) described by Neidinger [1].[1] In this approach arrays of Taylor coefficients of various functions are referred to as AD variables or *pyramids* since, as will be seen, they have a hyper-pyramidal structure. Generally the first entry in the array will be the value of the function about some expansion point, and the remaining entries will be the higher-order Taylor coefficients about the expansion point and truncated beyond some specified order. Such truncated Taylor expansions are also commonly called *jets*. Recall Section 7.5.

In our application elements in these arrays will be addressed and manipulated with the aid of scalar indices and associated look-up and look-back tables generated at run time. We have also replaced the original APL implementation of Neidinger with a code written in the language of *Mathematica* (Version 6, or 7) [2,3]. Where necessary, for those unfamiliar with the details of *Mathematica*, we will explain the consequences of various *Mathematica* commands. Recall that we wish to integrate equations of the form

$$\dot{z}_a = f_a(\boldsymbol{z}, t), \quad a = 1, m \tag{S.1.1}$$

and their associated complete variational equations. The inputs to the code are the right sides (RS) of (1.1). Other input parameters are the number of variables m, the desired order of the Taylor map p, and the *initial* conditions $(z_a^d)^i$ for the design solution.

Various AD tools for describing and manipulating pyramids are outlined in Section S.2. There we show how pyramid operations are encoded in the case of polynomial RS, as needed, for example, for the Duffing equation. For brevity, we omit the cases of rational, fractional power, and transcendental RS. These cases can also be handled using various methods based on functional identities and known Taylor coefficients, or the differential equations that such

[1] Some authors refer to AD as *truncated power series algebra* (TPSA) since AD algorithms arise from manipulating multivariable truncated power series. Other authors refer to AD as *Differential Algebra* (DA). There is a substantial literature on this subject. See the Web site http://www.autodiff.org/.

functions obey along with certain recursion relations [1]. In Section S.3, based on the work of Section S.2, we in effect obtain and integrate numerically the complete variational equations (10.12.36) in pyramid form, i.e. valid for any map order and any number of variables. Section S.4 treats the specific case of the Duffing equation. A final Section S.5 describes in more detail the relation between integrating equations for pyramids and the complete variational equations.

S.2 AD Tools

This section describes how arithmetic expressions representing $f_a(\boldsymbol{z}, t)$, the right sides of (1.1) where $\boldsymbol{z}$ denotes the dependent variables, are replaced with expressions for arrays (pyramids) of Taylor coefficients. These pyramids in turn constitute the input to our code. Such an ad-hoc replacement, according to the problem at hand, as opposed to operator overloading where the kind of operation depends on the type of its argument, is also the approach taken in [1,4,5].

Let u, v, w be general arithmetic expressions, i.e. scalar-valued functions of $\boldsymbol{z}$. They contain various arithmetic operations such as addition/subtraction ($\pm$), multiplication ($*$), and raising to a power ($\wedge$). (They may also entail the computation of various transcendental functions such as the sine function, etc. However, as stated earlier, for simplicity we will omit these cases.) The arguments of these operations may be a constant, a single variable or multiple variables z_a, or even some other expression. The idea of AD is to redefine the arithmetic operations in such a way (see Definition 1), that all functions u, v, w can be consistently replaced with the arrays of coefficients of their Taylor expansions. For example, by redefining the usual product of numbers ($*$) and introducing the pyramid operation `PROD`, $u * v$ is replaced with `PROD[U,V]`.

We use upper typewriter font for pyramids (`U,V,...`) and for operations on pyramids (`PROD, POW, ...`). Everywhere, equalities written in typewriter fonts have equivalent *Mathematica* expressions. That is, they have associated realizations in *Mathematica* and directly correspond to various operations and commands in *Mathematica*. In effect, our code operates entirely on pyramids. However, as we will see, any pyramid expression contains, as its first entry, its usual arithmetic counterpart.

We begin with a description of our method of monomial labeling. In brief, we list all monomials in a polynomial in some sequence, and label them by where they occur in the list. Next follow Definition 1 and the recipes for encoding operations on pyramids. Subsequently, by using Definition 2, which simply states the rule by which an arithmetic expression is replaced with its pyramid counterpart, we show how a general expression can be encoded by using only the pyramids of a constant and those of the various variables involved.

S.2.1 Labeling Scheme

A monomial $G_{\boldsymbol{j}}(\boldsymbol{z})$ in m variables is of the form

$$G_{\boldsymbol{j}}(\boldsymbol{z}) = (z_1)^{j_1}(z_2)^{j_2}\cdots(z_m)^{j_m}. \tag{S.2.1}$$

Here we have introduced an exponent vector $\boldsymbol{j}$ by the rule

$$\boldsymbol{j} = (j_1, j_2, \cdots j_m). \tag{S.2.2}$$

Evidently $\boldsymbol{j}$ is an m-tuple of non-negative integers. The degree of $G_{\boldsymbol{j}}(\boldsymbol{z})$, denoted by $|\boldsymbol{j}|$, is given by the sum of exponents,

$$|\boldsymbol{j}| = j_1 + j_2 + \cdots + j_m. \tag{S.2.3}$$

The set of all exponents for monomials in m variables with degree less than or equal to p will be denoted by Γ_m^p,

$$\Gamma_m^p = \{\boldsymbol{j} \mid |\boldsymbol{j}| \leq p\}. \tag{S.2.4}$$

According to Section 32.1, this set has $L(m,p)$ entries with $L(m,p)$ given by a binomial coefficient,

$$L(m,p) = S_0(m,p) = \binom{p+m}{p}. \tag{S.2.5}$$

With this notation, a Taylor series expansion (about the origin) of a scalar-valued function u of m variables $\boldsymbol{z} = (z_1, z_2, \ldots z_m)$, truncated beyond terms of degree p, can be written in the form

$$u(\boldsymbol{z}) = \sum_{\boldsymbol{j} \,\in\, \Gamma_m^p} \mathtt{U}(\boldsymbol{j})\; G_{\boldsymbol{j}}(\boldsymbol{z}). \tag{S.2.6}$$

Assuming that m and p are fixed input variables, we will often simply write Γ and L. Here, for now, $\mathtt{U}$ simply denotes an array of numerical coefficients. When employed in code that has symbolic manipulation capabilities, each $\mathtt{U}(\boldsymbol{j})$ may also be a symbolic quantity.

To proceed, what is needed is some way of listing monomials systematically. With such a list, as described in Subsections 32.3.3 and 32.3.4, we may assign a label r to each monomial based on where it appears in the list. We will use a variant of *modified glex sequencing*, the only change being that we will begin the list with the monomial of degree 0. For example, Table 2.1 shows a list of monomials in three variables. As one goes down the list, first the monomial of degree $D = 0$ appears, then the monomials of degree $D = 1$, etc. Within each group of monomials of fixed degree the individual monomials appear in descending lex order. Note that Table 2.1 is similar to Table 32.2.4 except that it begins with the monomial of degree 0. Other possible listings include ascending true glex order in which monomials appear in ascending lex order within each group of degree D, and lex order for the whole monomial list as in [1].

Table S.2.1: A labeling scheme for monomials in three variables.

With the aid of the scalar index r the relation (2.6) can be rewritten in the form

$$u(\boldsymbol{z}) = \sum_{r=1}^{L(m,p)} \mathtt{U}(r) G_r(\boldsymbol{z}), \tag{S.2.7}$$

because (by construction and with fixed m) for each positive integer r there is a unique exponent $\boldsymbol{j}(r)$, and for each $\boldsymbol{j}$ there is a unique r. Here $\mathtt{U}$ may be viewed as a vector with entries $\mathtt{U}(\mathtt{r})$, and $G_r(\boldsymbol{z})$ denotes $G_{\boldsymbol{j}(r)}(\boldsymbol{z})$.

Consider, in an m-dimensional space, the points defined by the heads of the vectors $\boldsymbol{j} \in \Gamma_m^p$. See (2.4). Figure 2.1 displays them in the case $m = 3$ and $p = 4$. Evidently they form a grid that lies on the surface and interior of what can be viewed as an m-dimensional *pyramid* in m-dimensional space. At each grid point there is an associated coefficient $\mathtt{U}(\mathtt{r})$.

Because of its association with this pyramidal structure, we will refer to the entire set of coefficients in (2.6) or (2.7) as the *pyramid* $\mathtt{U}$ of $u(\boldsymbol{z})$.

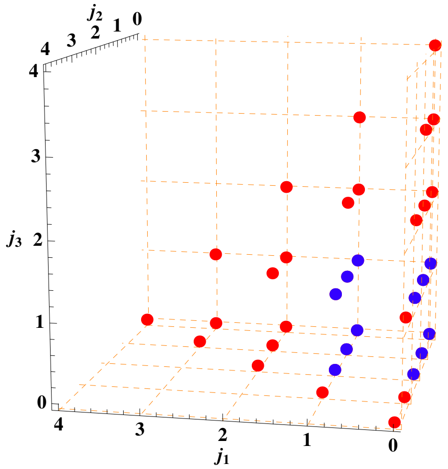

Figure S.2.1: A grid of points representing the set Γ_3^4. For future reference a subset of Γ_3^4, called a *box*, is shown in blue.

S.2.2 Implementation of Labeling Scheme

We have seen that use of modified glex sequencing, for any specified number of variables m, provides a labeling rule such that for each positive integer r there is a unique exponent $\boldsymbol{j}(r)$, and for each $\boldsymbol{j}$ there is a unique r. That is, there is a invertible function $r(\boldsymbol{j})$ that provides a 1-to-1 correspondence between the positive integers and the exponent vectors $\boldsymbol{j}$. To proceed further, it would be useful to have this function and its inverse in more explicit form.

From the work of Subsection 32.2.6, we already know a formula for $r(\boldsymbol{j})$ based on the Giorgilli formula (32.2.15),

$$r(\boldsymbol{j}) = r(j_1, \cdots j_m) = 1 + i(j_1, \cdots j_m). \tag{S.2.8}$$

Below is simple *Mathematica* code that implements this formula (which we call *Gfor*) in the case of three variables, and evaluates it for selected exponents $\boldsymbol{j}$. Observe that these evaluations agree with results in Table 2.1.

```
Gfor[j1_, j2_, j3_] := (
s1 = j3; s2 = 1 + j3 + j2; s3 = 2 + j3 + j2 + j1;
t1 = Binomial[s1, 1]; t2 = Binomial[s2, 2]; t3 = Binomial[s3, 3];
r = 1 + t1 + t2 + t3; r
)
Gfor[0, 0, 0]
Gfor[1, 0, 0]
Gfor[2, 0, 1]
Gfor[1, 2, 1]
1
2
13
28
```

(S.2.9)

For the inverse relation we have found it convenient to introduce a rectangular matrix associated with the set Γ_m^p. By abuse of notation, it will also be called Γ. It has $L(m,p)$ rows and m columns with entries

$$\Gamma_{r,a} = j_a(r). \tag{S.2.10}$$

For example, looking a Table 2.1, we see (when $m = 3$) that $\Gamma_{1,1} = 0$ and $\Gamma_{17,2} = 3$. Indeed, if the first and last columns of Table 2.1 are removed, what remains (when $m = 3$) is the matrix $\Gamma_{r,a}$. In the language of Subsection 32.2.9, Γ is a *look up table* that, given r, produces the associated $\boldsymbol{j}$. In our *Mathematica* implementation Γ is the matrix GAMMA with elements GAMMA[[r, a]].

The matrix GAMMA is constructed using the *Mathematica* code illustrated below,

```
Needs["Combinatorica`"];
m = 3; p = 4;
GAMMA = Compositions[0, m];
Do[GAMMA = Join[GAMMA, Reverse[Compositions[d, m]]], {d, 1, p, 1}];
L = Length[GAMMA]
r = 17; a = 2;
GAMMA[[r]]
GAMMA[[r, a]]
35
{0, 3, 0}
3
```

(S.2.11)

It employs the *Mathematica* commands Compositions, Reverse, and Join.

We will now describe the ingredients of this code and illustrate the function of each:

- The command Needs["Combinatorica‘"]; loads a combinatorial package.

- The command Compositions[i, m] produces, as a list of arrays (a rectangular array), all *compositions* (under addition) of the integer i into m integer parts. Furthermore, the compositions appear in *ascending* lex order. For example, the command Compositions[0, 3] produces the single row

  $$\begin{array}{ccc} 0 & 0 & 0 \end{array} \tag{S.2.12}$$

  As a second example, the command Compositions[1, 3] produces the rectangular array

  $$\begin{array}{ccc} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{array} \tag{S.2.13}$$

  As a third example, the command Compositions[2, 3] produces the rectangular array

  $$\begin{array}{ccc} 0 & 0 & 2 \\ 0 & 1 & 1 \\ 0 & 2 & 0 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \\ 2 & 0 & 0 \end{array} \tag{S.2.14}$$

- The command Reverse acts on the list of arrays, and reverses the order of the list while leaving the arrays intact. For example, the nested sequence of commands Reverse[Compositions[1, 3]] produces the rectangular array

  $$\begin{array}{ccc} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{array} \tag{S.2.15}$$

  As a second example, the nested sequence of commands Reverse[Compositions[2, 3]] produces the rectangular array

  $$\begin{array}{ccc} 2 & 0 & 0 \\ 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 2 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 2 \end{array} \tag{S.2.16}$$

  Now the compositions appear in *descending* lex order.

- Look, for example, at Table 2.1. We see that the exponents j_a for the $r = 1$ entry are those appearing in (2.12). Next, exponents for the $r = 2$ through $r = 4$ entries are those appearing in (2.15). Following them, the exponents for the $r = 5$ through $r = 10$ entries, are those appearing in (2.16), etc. Evidently, to produce the exponent list of Table 2.1, what we must do is successively *join* various lists. That is what the *Mathematica* command `Join` accomplishes.

We are now ready to describe how `GAMMA` is constructed:

- The second line in (2.11) sets the values of m and p. They are assigned the values $m = 3$ and $p = 4$ for this example, which will construct `GAMMA` for the case of Table 2.1. The third line in (2.11) initially sets `GAMMA` to a row of m zeroes. The fourth line is a `Do` loop that successively redefines `GAMMA` by generating and joining to it successive descending lex order compositions. The net result is the exponent list of Table 2.1.

- The quantity $L = L(m, p)$ is obtained by applying the *Mathematica* command `Length` to the the rectangular array `GAMMA`.

- The last 6 lines of (2.11) illustrate that L is computed properly and that the command `GAMMA[[r, a]]` accesses the array `GAMMA` in the desired fashion. Specifically, in this example, we find from (2.5) that $L(3, 4) = 35$ in agreement with the *Mathematica* output for L. Moreover, `GAMMA[[17]]` produces the exponent array $\{0, 3, 0\}$, in agreement with the $r = 17$ entry in Table 2.1, and `GAMMA[[17, 2]]` produces $\Gamma_{17,2} = 3$, as expected.

S.2.3 Pyramid Operations: General Procedure

Here we *derive* the pyramid operations in terms of $\boldsymbol{j}$-vectors by using the ordering previously described, and provide scripts to *encode* them in the r-representation (2.7).

Definition 1. Suppose that $w(\boldsymbol{z})$ arises from carrying out various *arithmetic operations* on $u(\boldsymbol{z})$ and $v(\boldsymbol{z})$, and the associated pyramids `U` and `V` are known. The corresponding pyramid operation on `U` and `V` is so defined that it yields the pyramid `W` of $w(\boldsymbol{z})$.

Here we assume that u, v, w are polynomials such as (2.6).

S.2.4 Pyramid Operations: Scalar Multiplication and Addition

We begin with the operations of scalar multiplication and addition, which are easy to define and implement. If

$$w(\boldsymbol{z}) = c\, u(\boldsymbol{z}), \tag{S.2.17}$$

then

$$\mathtt{W}(r) = c\, \mathtt{U}(r), \tag{S.2.18}$$

and we write

$$\mathtt{W} = c\, \mathtt{U}. \tag{S.2.19}$$

If

$$w(\boldsymbol{z}) = u(\boldsymbol{z}) + v(\boldsymbol{z}), \tag{S.2.20}$$

then

$$\mathtt{W}(r) = \mathtt{U}(r) + \mathtt{V}(r), \tag{S.2.21}$$

and we write

$$\mathtt{W} = \mathtt{U} + \mathtt{V}. \tag{S.2.22}$$

In both cases all operations are performed coordinate-wise (as for vectors).

Implementation of scalar multiplication and vector addition is easy in *Mathematica* because, as the example below illustrates, it has built in vector routines. There we define two vectors, multiply them by scalars, and add the resulting vectors.

```
Unprotect[V];
U = {1, 2, 3};
V = {4, 5, 6};
W = .1U + .2V
{.9, 1.2, 1.5}                                   (S.2.23)
```

Since V is a "protected" symbol in the *Mathematica* language, and, for purposes of illustration, we wish to use it as an ordinary vector variable, it must first be unprotected as in line 1 above. The last line shows that the *Mathematica* output is indeed the desired result.

S.2.5 Pyramid Operations: Background for Polynomial Multiplication

The operation of polynomial multiplication is more involved. Now we have the relation

$$w(\boldsymbol{z}) = u(\boldsymbol{z}) * v(\boldsymbol{z}), \tag{S.2.24}$$

and we want to encode

$$\mathtt{W} = \mathtt{PROD}[\mathtt{U}, \mathtt{V}]. \tag{S.2.25}$$

Shown below is *Mathematica* code that implements this operation,

$$\mathtt{PROD}[\mathtt{U\_}, \mathtt{V\_}] := \mathtt{Table}[\mathtt{U}[[\mathtt{B}[[\mathtt{k}]]]] \cdot \mathtt{V}[[\mathtt{Brev}[[\mathtt{k}]]]], \{\mathtt{k}, \mathtt{1}, \mathtt{L}, \mathtt{1}\}]; \tag{S.2.26}$$

Our next task is to describe and explain the ingredients in (2.26).

Let us write $u(\boldsymbol{z})$ in the form (2.6), but with a change of dummy indices, so that it has the representation

$$u(\boldsymbol{z}) = \sum_{\boldsymbol{i} \,\in\, \Gamma_m^p} \mathtt{U}(\boldsymbol{i})\; G_{\boldsymbol{i}}(\boldsymbol{z}). \tag{S.2.27}$$

Similarly, write $v(\boldsymbol{z})$ in the form

$$v(\boldsymbol{z}) = \sum_{\boldsymbol{j} \,\in\, \Gamma_m^p} \mathtt{V}(\boldsymbol{j})\; G_{\boldsymbol{j}}(\boldsymbol{z}). \tag{S.2.28}$$

Then there is the result

$$u(\boldsymbol{z}) * v(\boldsymbol{z}) = \sum_{\boldsymbol{i} \,\in\, \Gamma_m^p} \; \sum_{\boldsymbol{j} \,\in\, \Gamma_m^p} \mathtt{U}(\boldsymbol{i})\mathtt{V}(\boldsymbol{j}) G_{\boldsymbol{i}}(\boldsymbol{z}) * G_{\boldsymbol{j}}(\boldsymbol{z}). \tag{S.2.29}$$

From (2.1) we observe that

$$\begin{aligned} G_{\boldsymbol{i}}(\boldsymbol{z}) * G_{\boldsymbol{j}}(\boldsymbol{z}) &= (z_1)^{i_1}(z_2)^{i_2}\cdots(z_m)^{i_m} * (z_1)^{j_1}(z_2)^{j_2}\cdots(z_m)^{j_m} \\ &= (z_1)^{i_1+j_1}(z_2)^{i_2+j_2}\cdots(z_m)^{i_m+j_m} = G_{\boldsymbol{i}+\boldsymbol{j}}(\boldsymbol{z}). \end{aligned} \tag{S.2.30}$$

Therefore, we may also write

$$u(\boldsymbol{z}) * v(\boldsymbol{z}) = \sum_{\boldsymbol{i}\,\in\,\Gamma_m^p}\ \sum_{\boldsymbol{j}\,\in\,\Gamma_m^p} \mathtt{U}(\boldsymbol{i})\mathtt{V}(\boldsymbol{j})G_{\boldsymbol{i}+\boldsymbol{j}}(\boldsymbol{z}). \tag{S.2.31}$$

Now we see that there are two complications. First, there may be terms on the right side of (2.31) whose degree is higher than p and therefore need not be computed. Second, there are generally many terms on the right side of (2.31) that contribute to a given monomial term in $w(\boldsymbol{z}) = u(\boldsymbol{z}) * v(\boldsymbol{z})$. Suppose we write

$$w(\boldsymbol{z}) = \sum_{\boldsymbol{k}} \mathtt{W}(\boldsymbol{k})\ G_{\boldsymbol{k}}(\boldsymbol{z}). \tag{S.2.32}$$

Upon comparing (2.31) and (2.32) we conclude that there is the multidimensional *Cauchy* product rule

$$\mathtt{W}(\boldsymbol{k}) = \sum_{\boldsymbol{i}+\boldsymbol{j}=\boldsymbol{k}} \mathtt{U}(\boldsymbol{i})\mathtt{V}(\boldsymbol{j}) = \sum_{\boldsymbol{j}\le\boldsymbol{k}} \mathtt{U}(\boldsymbol{k}-\boldsymbol{j})\mathtt{V}(\boldsymbol{j}). \tag{S.2.33}$$

Here, by $\boldsymbol{j} \le \boldsymbol{k}$, we mean that the sum ranges over all $\boldsymbol{j}$ such that $j_a \le k_a$ for all $a \in [1, m]$. That is,

$$\boldsymbol{j} \le \boldsymbol{k} \ \Leftrightarrow\ j_a \le k_a \text{ for all } a \in [1, m]. \tag{S.2.34}$$

Evidently, to implement the relation (2.33) in terms of r labels, we need to describe the exponent relation $\boldsymbol{j} \le \boldsymbol{k}$ in terms of r labels. Suppose $\boldsymbol{k}$ is some exponent vector with label $r(\boldsymbol{k})$ as, for example, in Table 2.1. Introduce the notation

$$k = r(\boldsymbol{k}). \tag{S.2.35}$$

This notation may be somewhat confusing because k is not the norm of the vector $\boldsymbol{k}$, but rather the label associated with $\boldsymbol{k}$. However, this notation is very convenient. Now, given a label k, we can find $\boldsymbol{k}$. Indeed, from (2.10), we have the result

$$k_a = \Gamma_{k,a}. \tag{S.2.36}$$

Having found $\boldsymbol{k}$, we define a set of exponents B_k by the rule

$$B_k = \{\boldsymbol{j} | \boldsymbol{j} \le \boldsymbol{k}\}. \tag{S.2.37}$$

This set of exponents is called the k^{th} *box*. Note that the heads of the vectors $\boldsymbol{j}$ that satisfy (2.37) for some fixed vector $\boldsymbol{k}$ do indeed lie within some hyper-rectangular volume (box). For example (when $m = 3$), suppose $k = 28$. Then we see from Table 2.1 that $\boldsymbol{k} = (1, 2, 1)$. Table 2.2 lists, in modified glex order, all the vectors in B_{28}, i.e. all vectors $\boldsymbol{j}$ such that

Table S.2.2: The vectors in $B_{28} = \{\boldsymbol{j} | \boldsymbol{j} \leq (1,2,1)\}$.

r	j_1	j_2	j_3	D
1	0	0	0	0
2	1	0	0	1
3	0	1	0	1
4	0	0	1	1
6	1	1	0	2
7	1	0	1	2
8	0	2	0	2
9	0	1	1	2
14	1	2	0	3
15	1	1	1	3
18	0	2	1	3
28	1	2	1	4

$\boldsymbol{j} \leq (1,2,1)$. These are the vectors whose heads are shown in blue in Figure 2.1. Finally, with this notation, we can rewrite (2.33) in the form

$$\mathtt{W}(\boldsymbol{k}) = \sum_{\boldsymbol{j} \in B_k} \mathtt{U}(\boldsymbol{k} - \boldsymbol{j}) \mathtt{V}(\boldsymbol{j}). \tag{S.2.38}$$

What can be said about the vectors $(\boldsymbol{k} - \boldsymbol{j})$ as $\boldsymbol{j}$ ranges over B_ℓ? Table 2.3 lists, for example, the vectors $\boldsymbol{j} \in B_{28}$ and the associated vectors $\boldsymbol{i}$ with $\boldsymbol{i} = (\boldsymbol{k} - \boldsymbol{j})$. Also listed are the labels $r(\boldsymbol{j})$ and $r(\boldsymbol{i})$. Compare columns 2,3,4, which specify the $\boldsymbol{j} \in B_{28}$, with columns 5,6,7, which specify the associated $\boldsymbol{i}$ vectors. We see that every vector that appears in the $\boldsymbol{j}$ list also occurs somewhere in the $\boldsymbol{i}$ list, and vice versa. This to be expected because the operation of multiplication is commutative: we can also write (2.33) in the form

$$\mathtt{W}(\boldsymbol{k}) = \sum_{\boldsymbol{j} \in B_k} \mathtt{U}(\boldsymbol{j}) \mathtt{V}(\boldsymbol{k} - \boldsymbol{j}). \tag{S.2.39}$$

We also observe the more remarkable feature that the two lists are *reverses* of each other: running down the $\boldsymbol{j}$ list gives the same vectors as running up the $\boldsymbol{i}$ list, and vice versa. This feature is a consequence of our ordering procedure.

As indicated earlier, what we really want is a version of (2.33) that involves labels instead of exponent vectors. Looking at Table 2.3, we see that this is easily done. We may equally well think of B_k as containing a collection of labels $r(\boldsymbol{j})$, and we may introduce a *reversed* array $Brev_k$ of *complementary* labels $r^c(\boldsymbol{j})$ where

$$r^c(\boldsymbol{j}) = r(\boldsymbol{i}). \tag{S.2.40}$$

That is, for example, B_{28} would consist of the first column of Table 2.3 and $Brev_{28}$ would consist of the last column of Table 2.3. Finally, we have already introduced k as being the label associated with $\boldsymbol{k}$. We these understandings in mind, we may rewrite (2.33) in the label form

$$\mathtt{W}(k) = \sum_{r \in B_k} \mathtt{U}(r^c)\mathtt{V}(r) = \sum_{r \in B_k} \mathtt{U}(r)\mathtt{V}(r^c). \tag{S.2.41}$$

This is the rule $\mathtt{W} = \mathtt{PROD}[\mathtt{U},\mathtt{V}]$ for multiplying pyramids. In the language of Section 32.7, B_k and $Brev_k$, when taken together, provide a *look back table* that, given k, look back to find all monomial pairs with labels r, r^c which produce, when multiplied, the monomial with label k.

Table S.2.3: The vectors $\boldsymbol{j}$ and $\boldsymbol{i} = (\boldsymbol{k} - \boldsymbol{j})$ for $\boldsymbol{j} \in B_{28}$ and $k_a = \Gamma_{28,a}$.

$r(\boldsymbol{j})$	j_1	j_2	j_3	i_1	i_2	i_3	$r(\boldsymbol{i})$
1	0	0	0	1	2	1	28
2	1	0	0	0	2	1	18
3	0	1	0	1	1	1	15
4	0	0	1	1	2	0	14
6	1	1	0	0	1	1	9
7	1	0	1	0	2	0	8
8	0	2	0	1	0	1	7
9	0	1	1	1	1	0	6
14	1	2	0	0	0	1	4
15	1	1	1	0	1	0	3
18	0	2	1	1	0	0	2
28	1	2	1	0	0	0	1

S.2.6 Pyramid Operations: Implementation of Multiplication

The code shown below in (2.42) illustrates how B_k and $Brev_k$ are constructed using *Mathematica.*

```
JSK[list_, K_] :=
Position[Apply[And, Thread[#1<=#2&[#,K]]]& /@ list, True]//Flatten;
B = Table[JSK[GAMMA, GAMMA[[k]]], {k, 1, L}];
Brev = Reverse /@ B;                                        (S.2.42)
```

As before, some explanation is required. The main tasks are to implement the $\boldsymbol{j} \leq \boldsymbol{k}$ operation (2.34) and then to employ this implementation. We will begin by implementing the $\boldsymbol{j} \leq \boldsymbol{k}$ operation. Several steps are required, and each of them is described briefly below:

- When *Mathematica* is presented with a statement of the form $j <= k$, with j and k being *integers*, it replies with the answer True or the answer False. (Here $j <= k$

denotes $j \leq k$.) Two sample *Mathematica* runs are shown below:

```
3 <= 4
True                                        (S.2.43)
```

```
5 <= 4
False                                       (S.2.44)
```

- A *Mathematica* function can be constructed that does the same thing. It takes the form

```
#1 <= #2 & [j, k]                           (S.2.45)
```

Here the symbols #1 and #2 set up two *slots* and the symbol & means the operation to its left is to be regarded as a function and is to be applied to the arguments to its right by inserting the arguments into the slots. Below is a *Mathematica* run illustrating this feature.

```
j = 3; k = 4;
#1 <= #2 & [j, k]
True                                        (S.2.46)
```

Observe that the output of this run agrees with that of (2.43).

- The same operation can be performed on pairs of *arrays* (rather than pairs of numbers) in such a way that corresponding entries from each array are compared, with the output then being an array of True and False answers. This is done using the *Mathematica* command Thread. Below is a *Mathematica* run illustrating this feature.

```
j = {1, 2, 3}; k = {4, 5, 1};
Thread[#1 <= #2 & [j, k]]
{True, True, False}                         (S.2.47)
```

Note that the first two answers in the output array are True because the statements $1 \leq 4$ and $2 \leq 5$ are true. The last answer in the output array is False because the statement $3 \leq 1$ is false.

- Suppose, now, that we are given two arrays $\boldsymbol{j}$ and $\boldsymbol{k}$ and we want to determine if $\boldsymbol{j} \leq \boldsymbol{k}$ in the sense of (2.34). This can be done by *applying* the logical And operation (using the *Mathematica* command Apply) to the True/False output array described above. Below is a *Mathematica* run illustrating this feature.

```
j = {1, 2, 3}; k = {4, 5, 1};
Apply[And, Thread[#1 <= #2 & [j, k]]]
False                                       (S.2.48)
```

Note that the output answer is False because at least one of the entries in the output array in (2.47) is False. The output answer would be True if, and only if, all entries in the output array in (2.47) were True.

- Now that the $\boldsymbol{j} \le \boldsymbol{k}$ operation has been defined for two exponent arrays, we would like to construct a related operator/function, to be called `JSK`. (Here the letter `S` stands for *smaller than or equal to*.) It will depend on the exponent array $\boldsymbol{k}$, and its task will be to search a list of exponent arrays to find those $\boldsymbol{j}$ within it that satisfy $\boldsymbol{j} \le \boldsymbol{k}$. The first step in this direction is to slightly modify the function appearing in (2.48). Below is a *Mathematica* run that specifies this modified function and illustrates that it has the same effect.

```
j = {1, 2, 3}; k = {4, 5, 1};
Apply[And, Thread[#1 <= #2 & [#, k]]] & [j]
False                                                  (S.2.49)
```

  Comparison of the functions in (2.48) and (2.49) reveals that what has been done is to replace the argument j in (2.48) by a slot `#`, then follow the function by the character `&`, and finally add the symbols [j]. What this modification does is to redefine the function in such a way that it acts on what follows the second `&`.

- The next step is to extend the function appearing in (2.49) so that it acts on a list of exponent arrays. To do this, we replace the symbols [j] by the symbols `/@ list`. The symbols `/@` indicate that what stands to their left is to act on what stands to their right, and what stands to their right is a list of exponent arrays. The result of this action will be a list of True/False results with one result for each exponent array in the list. Below is a *Mathematica* run that illustrates how the further modified function acts on lists.

```
k = {4, 5, 1};
ja = {3, 4, 1}; jb = {1, 2, 3}; jc = {1, 2, 1};
list = {ja, jb, jc};
Apply[And, Thread[#1 <= #2 & [#, k]]] & /@ list
{True, False, True}                                    (S.2.50)
```

  Observe that the output answer list is $\{\text{True}, \text{False}, \text{True}\}$ because $\{3, 4, 1\} \le \{4, 5, 1\}$ is True, $\{1, 2, 3\} \le \{4, 5, 1\}$ is False, and $\{1, 2, 1\} \le \{4, 5, 1\}$ is True.

- What we would really like to know is where the True items are in the list, because that will tell us where the $\boldsymbol{j}$ that satisfy $\boldsymbol{j} \le \boldsymbol{k}$ reside. This can be accomplished by use of the *Mathematica* command `Position` in conjunction with the result True. Below is a *Mathematica* run that illustrates how this works.

```
k = {4, 5, 1};
ja = {3, 4, 1}; jb = {1, 2, 3}; jc = {1, 2, 1};
list = {ja, jb, jc};
Position[Apply[And, Thread[#1 <= #2 & [#, k]]] & /@ list, True]
{{1}, {3}}                                             (S.2.51)
```

Note that the output is an array of positions in the list for which $\boldsymbol{j} \leq \boldsymbol{k}$. There is, however, still one defect. Namely, the output array is an array of single-element subarrays, and we would like it to be simply an array of location numbers. This defect can be remedied by appending the *Mathematica* command `Flatten`, preceded by `//`, to the instruction string in (2.51). The *Mathematica* run below illustrates this modification.

```
k = {4,5,1};
ja = {3,4,1}; jb = {1,2,3}; jc = {1,2,1};
list = {ja,jb,jc};
Position[Apply[And,Thread[#1 <= #2 & [#,k]]] & /@ list,True]//Flatten
{1, 3}                                                          (S.2.52)
```

Now the output is a simple array containing the positions in the list for which $\boldsymbol{j} \leq \boldsymbol{k}$.

- The last step is to employ the ingredients in (2.52) to define the operator `JSK[list,k]`. The *Mathematica* run below illustrates how this can be done.

```
k = {4,5,1};
ja = {3,4,1}; jb = {1,2,3}; jc = {1,2,1};
list = {ja,jb,jc};
JSK[list_,k_] :=
Position[Apply[And,Thread[#1 <= #2 & [#,k]]] & /@ list,True]//Flatten;
JSK[list, k]
{1, 3}                                                          (S.2.53)
```

Lines 4 and 5 above define the operator `JSK[list,k]`, line 6 invokes it, and line 7 displays its output, which agrees with the output of (2.52).

- With the operator `JSK[list,k]` in hand, we are prepared to construct tables B and *Brev* that will contain the B_k and the $Brev_k$. The *Mathematica* run below illustrates how this can be done.

```
B = Table[JSK[GAMMA,GAMMA[[k]]],{k,1,L,1}];
Brev = Reverse /@ B;
B[[8]]
Brev[[8]]
B[[28]]
Brev[[28]]
{1,3,8}
{8,3,1}
{1,2,3,4,6,7,8,9,14,15,18,28}
{28,18,15,14,9,8,7,6,4,3,2,1}                        (S.2.54)
```

The first line employs the *Mathematica* command `Table` in combination with an implied Do loop to produce a two-dimensional array `B`. Values of k in the range $[1, L]$ are selected sequentially. For each k value the associated exponent array $\boldsymbol{k}(k) =$ `GAMMA[[k]]` is obtained. The operator `JSK` then searches the full `GAMMA` array to find the list of r values associated with the $\boldsymbol{j} \leq \boldsymbol{k}$. All these r values are listed in a row. Thus, the array `B` consists of list of L rows, of varying width. The rows are labeled by $k \in [1, L]$, and in each row are the r values associated with the $\boldsymbol{j} \leq \boldsymbol{k}$. In the second line the *Mathematica* command `Reverse` is applied to `B` to produce a second array called `Brev`. Its rows are the reverse of those in `B`. For example, as the *Mathematica* run illustrates, `B[[8]]`, which is the 8^{th} row of `B`, contains the list $\{1, 3, 8\}$, and `Brev[[8]]` contains the list $\{8, 3, 1\}$. Inspection of the $r = 8$ monomial in Table 2.1, that with exponents $\{0, 2, 0\}$, shows that it has the monomials with exponents {0,0,0}, {0,1,0}, and {0,2,0} as factors. And further inspection of Table 2.1 shows that the exponents of these factors have the r values $\{1, 3, 8\}$. Similarly `B[[28]]`, which is the 28^{th} row of B, contains the same entries that appear in the first column of Table 2.3. And `Brev[[28]]`, which is the 28^{th} row of *Brev*, contains the same entries that appear in the last column of Table 2.3.

Finally, we need to explain how the arrays B and *Brev* can be employed to carry out polynomial multiplication. This can be done using the *Mathematica* dot product command:

- The exhibit below shows a simple *Mathematica* run that illustrates the use of the dot product command.

```
Unprotect[V];
U = {.1, .2, .3, .4, .5, .6, .7, .8};
V = {1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 1.7, 1.8};
U.V
u = {1, 3, 5};
v = {6, 4, 2};
U[[u]]
V[[v]]
U[[u]].V[[v]]
5.64
{.1, .3, .5}
{1.6, 1.4, 1.2}
1.18
```

(S.2.55)

As before, `V` must be unprotected. See line 1. The rest of the first part this run (lines 2 through 4) defines two vectors `U` and `V` and then computes their dot product. Note that if we multiply the entries in `U` and `V` pairwise and add, we get the result

$$.1 \times 1.1 + .2 \times 1.2 + \cdots + .8 \times 1.8 = 5.64,$$

which agrees with the *Mathematica* result for $\mathtt{U}\cdot\mathtt{V}$. See line 10.

The second part of this *Mathematica* run, lines 5 through 9, illustrates a powerful feature of the *Mathematica* language. Suppose, as illustrated, we define two arrays `u` and `v` of integers, and use these arrays as *arguments* for the vectors by writing `U[[u]]` and `V[[v]]`. Then *Mathematica* uses the integers in the two arrays `u` and `v` as labels to select the corresponding entries in `U` and `V`, and from these entries it makes new corresponding vectors. In this example, the 1^{st}, 3^{rd}, and 5^{th} entries in `U` are .1, .3, and .5. And the 6^{th}, 4^{th}, and 2^{nd} entries in `V` are 1.6, 1.4, and 1.2. Consequently, we find that

$$\mathtt{U}[[\mathtt{u}]] = \{.1, .3, .5\},$$

$$\mathtt{V}[[\mathtt{v}]] = \{1.6, 1.4, 1.2\},$$

in agreement with lines 11 and 12 of the *Mathematica* results. Correspondingly, we expect that $\mathtt{U}[[\mathtt{u}]]\cdot\mathtt{V}[[\mathtt{v}]]$ will have the value

$$\mathtt{U}[[\mathtt{u}]]\cdot\mathtt{V}[[\mathtt{v}]] = .1\times 1.6 + .3\times 1.4 + .5\times 1.2 = 1.18,$$

in agreement with the last line of the *Mathematica* output.

- Now suppose, as an example, that we set $k = 8$ and use `B[[k]]` and `Brev[[k]]` in place of the arrays `u` and `v`. The *Mathematica* fragment below shows what happens when this is done.

```
k = 8;
B[[k]]
Brev[[k]]
U[[B[[k]]]]
V[[Brev[[k]]]]
U[[B[[k]]]] · V[[Brev[[k]]]]
{1, 3, 8}
{8, 3, 1}
{.1, .3, .8}
{1.8, 1.3, 1.1}
1.45                                   (S.2.56)
```

From (2.54) we see that $\mathtt{B}[[8]] = \{1, 3, 8\}$ and $\mathtt{Brev}[[8]] = \{8, 3, 1\}$ in agreement with lines 7 and 8 of the *Mathematica* output above. Also, the 1^{st}, 3^{rd}, and 8^{th} entries in `U` are .1, .3, and .8. And the 8^{th}, 3^{rd}, and 1^{st} entries in `V` are 1.8, 1.3, and 1.1. Therefore we expect the results

$$\mathtt{U}[[\mathtt{B}[[\mathtt{k}]]]] = \{.1, .3, .8\},$$

$$\mathtt{V}[[\mathtt{Brev}[[\mathtt{k}]]]] = \{1.8, 1.3, 1.1\},$$

$$\mathtt{U}[[\mathtt{B}[[\mathtt{k}]]]]\cdot\mathtt{V}[[\mathtt{Brev}[[\mathtt{k}]]]] = .1\times 1.8 + .3\times 1.3 + .8\times 1.1 = 1.45,$$

in agreement with the last three lines of (2.56).

- Finally, suppose we carry out the operation $\texttt{U[[B[[k]]]]}\cdot\texttt{V[[Brev[[k]]]]}$ for all $k \in [1, L]$ and put the results together in a Table with entries labeled by k. According to (2.41), the result will be the pyramid for the product of the two polynomials whose individual pyramids are `U` and `V`. The *Mathematica* fragment (2.26), which is displayed again below, shows how this can be done to define a *product* function, called `PROD`, that acts on general pyramids `U` and `V`, using the command Table with an implied Do loop over k.

$$\texttt{PROD[U\_, V\_] := Table[U[[B[[k]]]]} \cdot \texttt{V[[Brev[[k]]]], \{k, 1, L, 1\}];}$$

Let us verify that this whole multiplication procedure works for a simple example. For the sake of brevity, we will consider the case of $m = 2$ variables and work through terms of degree $p = 3$. In this case pyramids have the modest length $L(2, 3) = 10$. Table 2.4 provides a labeling scheme for monomials in two variables using our standard modified glex sequencing.

Table S.2.4: A labeling scheme for monomials in two variables.

r	j_1	j_2
1	0	0
2	1	0
3	0	1
4	2	0
5	1	1
6	0	2
7	3	0
8	2	1
9	1	2
10	0	3
.	.	.
.	.	.

Suppose, for example, that u and v are the functions

$$u(\boldsymbol{z}) = 1 + 2z_1 + 3z_2 + 4z_1z_2 \tag{S.2.57}$$

and

$$v(\boldsymbol{z}) = 5 + 6z_1 + 7z_2^2. \tag{S.2.58}$$

From Table 2.4 we find that the corresponding pyramids `U` and `V` are

$$\texttt{U} = \{1, 2, 3, 0, 4, 0, 0, 0, 0, 0\} \tag{S.2.59}$$

and

$$\texttt{V} = \{5, 6, 0, 0, 0, 7, 0, 0, 0, 0\}. \tag{S.2.60}$$

Polynomial multiplication gives the result

$$\begin{aligned} w(\boldsymbol{z}) &= u(\boldsymbol{z}) * v(\boldsymbol{z}) \\ &= 5 + 16z_1 + 15z_2 + 12z_1^2 + 38z_1z_2 + 7z_2^2 + 24z_1^2z_2 + 14z_1z_2^2 + 21z_2^3 + 28z_1z_2^3. \end{aligned} \tag{S.2.61}$$

Correspondingly, through terms of degree 3, the pyramid $\mathtt{W} = \mathtt{PROD}[\mathtt{U}, \mathtt{V}]$ is given by

$$\mathtt{W} = \{5, 16, 15, 12, 38, 7, 0, 24, 14, 21\}. \tag{S.2.62}$$

Below is an execution of a *Mathematica* program illustrating the use of the product function for the polynomials u and v given by (2.57) and (2.58).

```
Clear["Global‘ * "];
Needs["Combinatorica‘"];
m = 2; p = 3;
GAMMA = Compositions[0, m];
Do[GAMMA = Join[GAMMA, Reverse[Compositions[d, m]]], {d, 1, p, 1}];
L = Length[GAMMA]
JSK[list_, k_] :=
Position[Apply[And, Thread[#1 <= #2 & [#, k]]] & /@ list, True]//Flatten;
B = Table[JSK[GAMMA, GAMMA[[r]]], {r, 1, L, 1}];
Brev = Reverse/@ B;
PROD[U_, V_] := Table[U[[B[[k]]]].V[[Brev[[k]]]], {k, 1, L, 1}];
U = {1, 2, 3, 0, 4, 0, 0, 0, 0, 0};
V = {5, 6, 0, 0, 0, 7, 0, 0, 0, 0};
10
PROD[U, V]
{5, 16, 15, 12, 38, 7, 0, 24, 14, 21}                                    (S.2.63)
```

The first 11 lines of the code set up the necessary arrays and define the product function in pyramid form. The next two lines specify the pyramids U and V given in (2.59) and (2.60). The third line from the bottom, which results from the command in line 6, illustrates that indeed $L(2, 3) = 10$. The final two lines show that use of the product function when applied to the pyramids U and V does indeed product the pyramid W given by (2.62).

S.2.7 Pyramid Operations: Implementation of Powers

With operation of multiplication in hand, it is easy to implement the operation of raising a pyramid to a power. The code shown below in (2.64) demonstrates how this can be done.

$$\begin{aligned}&\mathtt{POWER[U\_,0] := C1;}\\&\mathtt{POWER[U\_,1] := U;}\\&\mathtt{POWER[U\_,2] := PROD[U,U];}\\&\mathtt{POWER[U\_,3] := PROD[U,POWER[U,2]];}\\&\ldots\end{aligned}\qquad\text{(S.2.64)}$$

Here C1 is the pyramid for the Taylor series having *one* as its *constant* term and all other terms zero,

$$\mathtt{C1} = \{\mathtt{1,0,0,0},\cdots\}.\qquad\text{(S.2.65)}$$

It can be set up by the *Mathematica* code

$$\mathtt{C1 = Table[KroneckerDelta[k,1],\{k,1,L,1\}];}\qquad\text{(S.2.66)}$$

which employs the Table command, the Kronecker delta function, and an implied Do loop over k. This code should be executed before executing (2.64), but after the value of L has been established.

S.2.8 Replacement Rule and Automatic Differentiation

Definition 2. The transformation $A(\boldsymbol{z}) \rightsquigarrow \mathtt{A}$ means replacement of every real variable z_a in the *arithmetic expression* $A(\boldsymbol{z})$ with an associated pyramid, and of every operation on real variables in $A(\boldsymbol{z})$ with the associated operation on pyramids.

Automatic differentiation is based on the following corollary: if $A(\boldsymbol{z}) \rightsquigarrow \mathtt{A}$, then $\mathtt{A}$ is the pyramid of $A(\boldsymbol{z})$.

For simplicity, we will begin our discussion of the replacement rule with examples involving only a single variable z. In this case monomial labeling, the relation between labels and exponents, is given directly by the simple rules

$$r(j) = 1 + j \text{ and } j(r) = r - 1.\qquad\text{(S.2.67)}$$

See Table 2.5.

As a first example, consider the expression

$$A = 2 + 3(z * z).\qquad\text{(S.2.68)}$$

We have agreed to consider the case $m = 1$. Suppose we also set $p = 2$, in which case $L = 3$. In ascending glex order, see Table 2.5, the pyramid for A is then

$$2 + 3z^2 \rightsquigarrow \mathtt{A} = (2, 0, 3).\qquad\text{(S.2.69)}$$

Now imagine that A was not such a simple polynomial, but some complicated expression. Then the pyramid $\mathtt{A}$ could be generated by computing derivatives of A at $z = 0$ and dividing

Table S.2.5: A labeling scheme for monomials in one variable.

r	j
1	0
2	1
3	2
4	3
.	.
.	.

them by the appropriate factorials. Automatic differentiation offers another way to find $\mathtt{A}$. Assume that all operations in the arithmetic expression A have been encoded according to *Definition 1*. For our example, these are + and $\mathtt{PROD}$. Let $\mathtt{C1}$ and $\mathtt{Z}$ be the pyramids associated with 1 and z,

$$1 \rightsquigarrow \mathtt{C1} = (1, 0, 0), \tag{S.2.70}$$

$$z \rightsquigarrow \mathtt{Z} = (\mathtt{0}, \mathtt{1}, \mathtt{0}). \tag{S.2.71}$$

The quantity $2+3z^2$ results from performing various arithmetic operations on 1 and z. *Definition 1* says that the pyramid of $2+3z^2$ is identical to the pyramid obtained by performing the same operations on the pyramids $\mathtt{C1}$ and $\mathtt{Z}$. That is, suppose we replace 1 and z with their associated pyramids $\mathtt{C1}$ and $\mathtt{Z}$, and also replace $*$ with $\mathtt{PROD}$. Then, upon evaluating $\mathtt{PROD}$, multiplying by the appropriate scalar coefficients, and summing, the result will be the same pyramid $\mathtt{A}$,

$$2\ \mathtt{C1} + 3\ \mathtt{PROD}[\mathtt{Z}, \mathtt{Z}] = \mathtt{A}. \tag{S.2.72}$$

In this way, by knowing only the basic pyramids $\mathtt{C1}$ and $\mathtt{Z}$ (prepared beforehand), one can compute the pyramid of an arbitrary $A(z)$. Finally, in contrast to numerical differentiation, all numerical operations involved are accurate to machine precision. *Mathematica* code that implements (2.72) will be presented shortly in (2.73).

Frequently, if $A(z)$ is some complicated expression, the replacement rule will result in a long chain of nested pyramid operations. At every step in the chain the present pyramid, the pyramid resulting from the previous step, will be combined with some other pyramid to produce a new pyramid. Each such operation has two arguments (the present pyramid and some other pyramid), and *Definition 1* applies to each step in the chain. Upon evaluating all pyramid operations, the final result will be the pyramid of $A(z)$.

By using the replacement operation the above procedure can be represented as:

$$1 \rightsquigarrow \mathtt{C1}, \quad z \rightsquigarrow \mathtt{Z}, \quad A \rightsquigarrow \mathtt{A}.$$

The following general recipe then applies: In order to derive the pyramid associated with some arithmetic expression, apply the $\rightsquigarrow$ rule to all its variables, or parts, and replace all operations with operations on pyramids. Here "apply the $\rightsquigarrow$ rule" to something means replace that something with the associated pyramid. And the term "parts" means subexpressions. *Definition 1* guarantees that the result will be the same pyramid $\mathtt{A}$ no matter how we split the arithmetic expression A into subexpressions. It is only necessary to recognize, in case of using subexpressions, that one pyramid expression should be viewed as a function of another.

For illustration, suppose we regard the A given by (2.68) to be the composition of two functions, $F(z) = 2 + 3z$ and $G(z) = z^2$, so that $A(z) = F(G(z))$. Instead of associating a constant and a single variable with their respective pyramids, let us now associate whole subexpressions. In addition, let us label the pyramid expressions on the right of ⇝ with with some names, F and G:

$$2 + 3z \rightsquigarrow 2\ \mathtt{C1} + 3\ \mathtt{Z} = \mathtt{F[Z]}$$

$$z^2 \rightsquigarrow \mathtt{PROD[Z,Z]} = \mathtt{G[Z]}$$

$$A(z) \rightsquigarrow \mathtt{F[G[Z]]} = \mathtt{A}.$$

We have indicated the explicit dependence on Z. It is important to note that F[Z] is a pyramid *expression* prior to executing any the pyramid operations, i.e it is not yet a pyramid, but is simply the result of formal replacements that follow the association rule.

Mathematica code for the simple example (2.72) is shown below,

```
C1 = {1, 0, 0};
Z = {0, 1, 0};
2 C1 + 3 PROD[Z, Z]
{2, 0, 3}                                    (S.2.73)
```

Note that the result (2.73) agrees with (2.69). This example does not use any nested expressions. We will now illustrate how the same results can be obtained using nested expressions.

We begin by displaying a simple *Mathematica* program/execution, that employs ordinary variables, and uses *Mathematica*'s intrinsic abilities to handle nested expressions. The program/execution is

```
f[z_] := 2 + 3z;
g[z_] := z^2;
f[g[z]]
2 + 3z^2                                     (S.2.74)
```

With *Mathematica* the underscore in z_ indicates that z is a dummy variable name, and the symbols := indicate that f is defined with a delayed assignment. That is what is done in line one above. The same is done in line two for g. Line three requests evaluation of the nested function $f(g(z))$, and the result of this evaluation is displayed in line four. Note that the result agrees with (2.68).

With this background, we are ready to examine a program with analogous nested pyramid operations. The same comments apply regarding the use of underscores and delayed assignments. The program is

```
C1 = {1, 0, 0};
Z = {0, 1, 0};
F[Z_] := 2 C1 + 3 Z;
G[Z_] := PROD[Z, Z];
F[G[Z]]
{2, 0, 3}                                        (S.2.75)
```

Note that line (2.75) agrees with line (2.73), and is consistent with line (2.69).

S.2.9 Taylor Rule

We close this section with an important consequence of the replacement rule and nested operations, which we call the *Taylor* rule. We begin by considering functions of a single variable. Suppose the function $G(x)$ has the special form

$$G(x) = z^d + x \tag{S.2.76}$$

where z^d is some constant. Let F be some other function. Consider the composite (nested) function A defined by

$$A(x) = F(G(x)) = F(z^d + x). \tag{S.2.77}$$

Then, assuming the necessary analyticity and by the chain rule, A evidently has a Taylor expansion in x about the origin of the form

$$\begin{aligned} A &= A(0) + A'(0)x + (1/2)A''(0)x^2 + \cdots \\ &= F(z^d) + F'(z^d)x + (1/2)F''(z^d)x^2 + \cdots . \end{aligned} \tag{S.2.78}$$

We conclude that if we know the Taylor expansion of A about the origin, then we also know the Taylor expansion of F about z^d, and vice versa. Suppose, for example, that

$$F(z) = 1 + 2z + 3z^2 \tag{S.2.79}$$

and

$$z^d = 4. \tag{S.2.80}$$

Then there is the result

$$A(x) = F(G(x)) = F(z^d + x) = 1 + 2(4 + x) + 3(4 + x)^2 = 57 + 26x + 3x^2. \tag{S.2.81}$$

We now show that this same result can be obtained using pyramids. The *Mathematica* fragment below illustrates how this can be done.

```
C1 = {1, 0, 0};
X = {0, 1, 0};
zd = 4;
F[Z_] := 1 C1 + 2 Z + 3 PROD[Z, Z];
G[X_] := zd C1 + X;
F[G[X]]
{57, 26, 3}                                      (S.2.82)
```

Note that (2.82) agrees with (2.81). See also Table 2.5.

Let us also illustrate the Taylor rule in the two-variable case. Let $F(z_1, z_2)$ be some function of two variables. Introduce the functions $G(x_1)$ and $H(x_1)$ having the special forms

$$G(x_1) = z_1^d + x_1, \tag{S.2.83}$$

$$H(x_2) = z_2^d + x_2, \tag{S.2.84}$$

where z_1^d and z_2^d are some constants. Consider the function A defined by

$$A(x_1, x_2) = F(G(x_1), H(x_2)) = F(z_1^d + x_1, z_2^d + x_2). \tag{S.2.85}$$

Then, again assuming the necessary analyticity and by the chain rule, A evidently has a Taylor expansion in x_1 and x_2 about the origin $(0, 0)$ of the form

$$\begin{aligned} A &= A(0,0) + [\partial_1 A(0,0)]x_1 + [\partial_2 A(0,0)]x_2 \\ &\quad +(1/2)[(\partial_1)^2 A(0,0)]x_1^2 + [\partial_1\partial_2 A(0,0)]x_1x_2 + (1/2)[(\partial_2)^2 A(0,0)]x_2^2 + \cdots \\ &= F(z_1^d, z_2^d) + [\partial_1 F(z_1^d, z_2^d)]x_1 + [\partial_2 F(z_1^d, z_2^d)]x_2 \\ &\quad +(1/2)[(\partial_1)^2 F(z_1^d, z_2^d)]x_1^2 + [\partial_1\partial_2 AF(z_1^d, z_2^d)]x_1x_2 + (1/2)[(\partial_2)^2 A(F(z_1^d, z_2^d))]x_2^2 + \cdots \end{aligned} \tag{S.2.86}$$

where

$$\partial_1 = \partial/\partial x_1, \ \ \partial_2 = \partial/\partial x_2 \tag{S.2.87}$$

when acting on A, and

$$\partial_1 = \partial/\partial z_1, \ \ \partial_2 = \partial/\partial z_2 \tag{S.2.88}$$

when acting on F. We conclude that if we know the Taylor expansion of A about the origin $(0, 0)$, then we also know the Taylor expansion of F about (z_1^d, z_2^d), and vice versa.

As a concrete example, suppose that

$$F(z_1, z_2) = 1 + 2z_1 + 3z_2 + 4z_1^2 + 5z_1z_2 + 6z_2^2 \tag{S.2.89}$$

and

$$z_1^d = 7, \ \ z_2^d = 8. \tag{S.2.90}$$

Then, hand calculation shows that $F(G(x_1), H(x_2))$ takes the form

$$\begin{aligned} F(z_1^d + x_1, z_2^d + x_2) &= F(G(x_1), H(x_2)) \\ &= 899 + 98x_1 + 4x_1^2 + 134x_2 + 5x_1x_2 + 6x_2^2. \end{aligned} \tag{S.2.91}$$

Below is a *Mathematica* execution that finds the same result,

$$\begin{array}{l}
\texttt{F}[\texttt{z1}\_,\texttt{z2}\_] := 1 + 2\ \texttt{z1} + 3\ \texttt{z2} + 4\ \texttt{z1}^2 + 5\ \texttt{z1}\ \texttt{z2} + 6\ \texttt{z2}^2\\
\texttt{G}[\texttt{x1}\_] := \texttt{zd1} + \texttt{x1};\\
\texttt{H}[\texttt{x2}\_] := \texttt{zd2} + \texttt{x2};\\
\texttt{zd1} = 7;\\
\texttt{zd2} = 8;\\
\texttt{A} = \texttt{F}[\texttt{G}[\texttt{x1}],\texttt{H}[\texttt{x2}]]\\
\texttt{Expand}[\texttt{A}]\\
1 + 2\ (7 + x1) + 4\ (7 + x1)^2 + 3\ (8 + x2) + 5\ (7 + x1)\ (8 + x2) + 6\ (8 + x2)^2\\
899 + 98\ x1 + 4\ x1^2 + 134\ x2 + 5\ x1\ x2 + 6\ x2^2
\end{array} \tag{S.2.92}$$

The calculation above dealt with the case of a function of two ordinary variables. We now illustrate, for the same example, that there is an analogous result for pyramids. Following the replacement rule, we should make the substitutions

$$z_1^d + x_1 \rightsquigarrow \texttt{zd1 C1} + \texttt{X1}, \tag{S.2.93}$$

$$z_2^d + x_2 \rightsquigarrow \texttt{zd2 C1} + \texttt{X2}, \tag{S.2.94}$$

$$\begin{array}{l}
1 + 2\ z_1 + 3\ z_2 + 4\ z_1^2 + 5\ z_1\ z_2 + 6\ z_2^2 \rightsquigarrow\\
\texttt{C1} + 2\ \texttt{Z1} + 3\ \texttt{Z2} + 4\ \texttt{PROD}[\texttt{Z1},\texttt{Z1}] + 5\ \texttt{PROD}[\texttt{Z1},\texttt{Z2}] + 6\ \texttt{PROD}[\texttt{Z2},\texttt{Z2}].
\end{array} \tag{S.2.95}$$

The *Mathematica* fragment below, executed for the case $m = 2$ and $p = 2$, in which case $L = 6$, illustrates how the analogous result is obtained using pyramids,

$$\begin{array}{l}
\texttt{C1} = \{\texttt{1},\texttt{0},\texttt{0},\texttt{0},\texttt{0},\texttt{0}\};\\
\texttt{X1} = \{\texttt{0},\texttt{1},\texttt{0},\texttt{0},\texttt{0},\texttt{0}\};\\
\texttt{X2} = \{\texttt{0},\texttt{0},\texttt{1},\texttt{0},\texttt{0},\texttt{0}\};\\
\texttt{F}[\texttt{Z1}\_,\texttt{Z2}\_] := \texttt{C1} + 2\ \texttt{Z1} + 3\ \texttt{Z2} + 4\ \texttt{PROD}[\texttt{Z1},\texttt{Z1}] + 5\ \texttt{PROD}[\texttt{Z1},\texttt{Z2}]\\
+6\ \texttt{PROD}[\texttt{Z2},\texttt{Z2}];\\
\texttt{G}[\texttt{X1}\_] := \texttt{z01 C1} + \texttt{X1};\\
\texttt{H}[\texttt{X2}\_] := \texttt{z02 C1} + \texttt{X2};\\
\texttt{zd1} = 7;\\
\texttt{zd2} = 8;\\
\texttt{F}[\texttt{G}[\texttt{X1}],\texttt{H}[\texttt{X2}]]\\
\{899, 98, 134, 4, 5, 6\}
\end{array} \tag{S.2.96}$$

Note that, when use is made of Table 2.4, the last line of (2.96) agrees with (2.91) and the last line of (2.92).

S.3 Numerical Integration and Replacement Rule

S.3.1 Numerical Integration

Consider the set of differential equations (1.1). As described in Chapter 2, a standard procedure for their numerical integration from an initial time $t^i = t^0$ to some final time t^f is to divide the time axis into a large number of steps N, each of small duration h, thereby introducing successive times t^n defined by the relation

$$t^n = t^0 + nh \ \text{ with } \ n = 0, 1, \cdots, N. \tag{S.3.1}$$

By construction, there will also be the relation

$$Nh = t^f - t^i. \tag{S.3.2}$$

The goal is to compute the vectors $\boldsymbol{z}^n$, where

$$\boldsymbol{z}^n = \boldsymbol{z}(t^n), \tag{S.3.3}$$

starting from the vector $\boldsymbol{z}^0$. The vector $\boldsymbol{z}^0$ is assumed given as a set of definite numbers, i.e. the initial conditions at t^0.

If we assume for the solution piece-wise analyticity in t, or at least sufficient differentiability in t (which will be the case if the f_a are piece-wise analytic or at least have sufficient differentiability in t), we may convert the set of differential equations (1.1) into a set of recursion relations for the $\boldsymbol{z}^n$ in such a way that the $\boldsymbol{z}^n$ obtained by solving the recursion relations differ from the true $\boldsymbol{z}^n$ by only small truncation errors of order h^m. (Here m is *not* the number of variables, but rather some fixed integer describing the accuracy of the integration method.) One such procedure, a fourth-order *Runge Kutta* (RK4) method, is the set of marching/recursion rules

$$\boldsymbol{z}^{n+1} = \boldsymbol{z}^n + \frac{1}{6}(\boldsymbol{a} + 2\boldsymbol{b} + 2\boldsymbol{c} + \boldsymbol{d}) \tag{S.3.4}$$

where, at each step,

$$\begin{aligned} \boldsymbol{a} &= h\boldsymbol{f}(\boldsymbol{z}^n, t^n), \\ \boldsymbol{b} &= h\boldsymbol{f}(\boldsymbol{z}^n + \frac{1}{2}\boldsymbol{a}, t^n + \frac{1}{2}h), \\ \boldsymbol{c} &= h\boldsymbol{f}(\boldsymbol{z}^n + \frac{1}{2}\boldsymbol{b}, t^n + \frac{1}{2}h), \\ \boldsymbol{d} &= h\boldsymbol{f}(\boldsymbol{z}^n + \boldsymbol{c}, t^n + h). \end{aligned} \tag{S.3.5}$$

Thanks to the genius of Runge and Kutta, the relations (3.4) and (3.5) have been constructed in such a way that the method is locally (at each step) correct through order h^4, and makes local truncation errors of order h^5. Recall Section 2.3.2

In the case of a single variable, and therefore a single differential equation, the relations (3.4) and (3.5) may be encoded in the *Mathematica* form shown below. Here `Zvar` is the dependent variable, `t` is the time, `Zt` is a temporary variable, `tt` is a temporary time, and ns is the number of integration steps. The program employs a Do loop over i so that the operations (3.4) and (3.5) are carried out ns times.

```
RK4 := (
   t0 = t;
Do[
   Aa = h F[Zvar, t];
   Zt = Zvar + (1/2)Aa;
   tt = t + h/2;
   Bb = h F[Zt, tt];
   Zt = Zvar + (1/2)Bb;
   Cc = h F[Zt, tt];
   Zt = Zvar + Cc;
   tt = t + h;
   Dd = h F[Zt, tt];
   Zvar = Zvar + (1/6)(Aa + 2 Bb + 2 Cc + Dd);
   t = t0 + i h;,
   {i, 1, ns, 1}
   ]
 )
```

(S.3.6)

S.3.2 Replacement Rule, Single Equation/Variable Case

We now make what, for our purposes, is a fundamental observation: The operations that occur in the Runge Kutta recursion rules (3.4) and (3.5) and realized in the code above can be extended to pyramids by application of the replacement rule. In particular, the dependent variable $\boldsymbol{z}$ can be replaced by a pyramid, and the various operations involved in the recursion rules can be replaced by pyramid operations. Indeed if we look at the code above, apart from the evaluation of F, we see that the quantities Zvar, Zt, Aa, Bb, Cc, and Dd can be viewed, if we wish, as pyramids since the only operations involved are scalar multiplication and addition. The only requirement for a pyramidal interpretation of the RK4 *Mathematica* code is that the right side of the differential equation, F[∗, ∗], be defined for pyramids. Finally, we remark that the features that make it possible to interpret the RK4 *Mathematica* code either in terms of ordinary variables or pyramidal variables will hold for *Mathematica* realizations of many other familiar numerical integration methods including other forms of Runge Kutta, predictor-corrector methods, and extrapolation methods.

To make these ideas concrete, and to understand their implications, let us begin with a simple example. Suppose, in the single variable case, that the right side of the differential equation has the simple form

$$f(z,t) = -2tz^2. \tag{S.3.7}$$

The differential equation with this right side can be integrated analytically to yield the solution

$$z(t) = z^0/[1 + z^0(t - t^0)^2]. \tag{S.3.8}$$

In particular, for the case $t^0 = 0$, $z^0 = 1$, and $t = 1$, there is the result

$$z(1) = z^0/[1 + z^0] = 1/2. \tag{S.3.9}$$

Let us also integrate the differential equation with the right side (3.7) numerically. Shown below is the result of running the associated *Mathematica* Runge Kutta code for this case.

```
Clear["Global`*"];
F[Z_, t_] := −2 t Z^2;
h = .1;
ns = 10;
t = 0;
Zvar = 1.;
RK4;
t
Zvar
1.
0.500001
```

(S.3.10)

Note that the last line of (3.10) agrees with (3.9) save for a “1” in the last entry. As expected, and as experimentation shows, this small difference, due to accumulated truncation error, becomes even smaller if `h` is decreased (and correspondingly, `ns` is increased).

Suppose we expand the solution (3.9) about the design initial condition $z^{d0} = 1$ by replacing z^0 by $z^{d0} + x$ and expanding the result in a Taylor series in x about the point x=0. Below is a *Mathematica* run that performs this task.

```
zd0 = 1;
Series[(zd0 + x)/(1 + zd0 + x), {x, 0, 5}]
```

$$\frac{1}{2} + \frac{x}{4} - \frac{x^2}{8} + \frac{x^3}{16} - \frac{x^4}{32} + \frac{x^5}{64} + O[x]^6$$

(S.3.11)

We will now see that the same Taylor series can be obtained by the operation of numerical integration applied to pyramids. The *Mathematica* code below shows, for our example differential equation, the application of numerical integration to pyramids.

```
Clear["Global` * "];
Needs["Combinatorica`"];
m = 1; p = 5;
GAMMA = Compositions[0, m];
Do[GAMMA = Join[GAMMA, Reverse[Compositions[d, m]]], {d, 1, p, 1}];
L = Length[GAMMA];
JSK[list_, k_] :=
Position[Apply[And, Thread[#1 <= #2 & [#, k]]] & /@ list, True]//Flatten;
B = Table[JSK[GAMMA, GAMMA[[r]]], {r, 1, L, 1}];
Brev = Reverse/@ B;
PROD[U_, V_] := Table[U[[B[[k]]]].V[[Brev[[k]]]], {k, 1, L, 1}];
F[Z_, t_] := −2 t PROD[Z, Z];
h = .01;
ns = 100;
t = 0;
zd0 = 1;
C1 = {1, 0, 0, 0, 0, 0};
X = {0, 1, 0, 0, 0, 0};
Zvar = zd0 C1 + X;
RK4;
t
Zvar
1.
{0.5, 0.25, −0.125, 0.0625, −0.03125, 0.015625}                (S.3.12)
```

The first 11 lines of the code set up what should be by now the familiar procedure for labeling and multiplying pyramids. In particular, $m = 1$ because we are dealing with a single variable, and $p = 5$ since we wish to work through fifth order. The line

$$\texttt{F[Z\_, t\_] := -2 t PROD[Z, Z]} \tag{S.3.13}$$

defines F[∗, ∗] for the case of pyramids, and is the result of applying the replacement rule to the right side of f as given by (3.7),

$$-\,2\,t\,z^2 \rightsquigarrow -2\ \texttt{t PROD[Z, Z]}. \tag{S.3.14}$$

Lines 13 through 15 play the same role as lines 3 through 5 in (3.10) except that, in order to improve numerical accuracy, the step size `h` has been decreased and correspondingly the number of steps `ns` has been increased. Lines 16 through 19 now initialize `Zvar` as a pyramid with a constant part `zd0` and first-order monomial part with coefficient 1,

$$\texttt{Zvar = zd0 C1 + X}. \tag{S.3.15}$$

These lines are the pyramid equivalent of line 6 in (3.10). Finally lines 20 through 22 are the same as lines 7 through 9 in (3.10). In particular, the line `RK4` in (3.10) and the line `RK4` in (3.12) refer to exactly the *same* code, namely that in (3.6).

Let us now compare the outputs of (3.10) and (3.12). Comparing the penultimate lines in each we see that the final time $t = 1$ is the same in each case. Comparing the last lines shows that the output `Zvar` for (3.12) is a pyramid whose first entry agrees with the last line of (3.10). Finally, all the entries in the pyramid output agree with the Taylor coefficients in the expansion (3.11). We see, in the case of numerical integration (of a single differential equation), that replacing the dependent variable by a pyramid, with the initial value of the pyramid given by (3.15), produces a Taylor expansion of the final condition in terms of the initial condition.

What accounts for this near miraculous result? It's the Taylor rule described described in Subsection 2.9. We have already learned that to expand some function $F(z)$ about some point z^d we must evaluate $F(z^d + x)$. See (2.77). We know that the final $Zvar$, call it $Zvar^{\rm fin}$, is an analytic function of the initial $Zvar$, call it $Zvar^{\rm in}$, so that we may write

$$Zvar^{\rm fin} = Zvar^{\rm fin}(Zvar^{\rm in}) = g(Zvar^{\rm in}) \tag{S.3.16}$$

where g is the function that results from following the trajectory from $t = t^{\rm in}$ to $t = t^{\rm fin}$. Therefore, by the Taylor rule, to expand $Zvar^{\rm fin}$ about $Zvar^{\rm in} = z^{d0}$, we must evaluate $Zvar^{\rm fin}(z^{d0} + x)$. That, with the aid of pyramids, is what the code (3.12) accomplishes.

S.3.3 Multi Equation/Variable Case

Because of *Mathematica's* built-in provisions for handling arrays, the work of the previous section can easily be extended to the case of several differential equations. Consider, as an example, the two-variable case for which $\boldsymbol{f}$ has the form

$$\begin{aligned} f_1(\boldsymbol{z}, t) &= -z_1^2, \\ f_2(\boldsymbol{z}, t) &= +2z_1z_2. \end{aligned} \tag{S.3.17}$$

The differential equations associated with this $\boldsymbol{f}$ can be solved in closed form to yield, with the understanding that $t^0 = 0$, the solution

$$\begin{aligned} z_1(t) &= z_1^0/(1 + tz_1^0), \\ z_2(t) &= z_2^0(1 + tz_1^0)^2. \end{aligned} \tag{S.3.18}$$

For the final time $t = 1$ we find the result

$$\begin{aligned} z_1(1) &= z_1^0/(1 + z_1^0), \\ z_2(1) &= z_2^0(1 + z_1^0)^2. \end{aligned} \tag{S.3.19}$$

Let us expand the solution (3.19) about the design initial conditions

$$\begin{aligned} z_1^{d0} &= 1, \\ z_2^{d0} &= 2, \end{aligned} \tag{S.3.20}$$

by writing

$$\begin{aligned} z_1^0 &= z_1^{d0} + x_1 = 1 + x_1, \\ z_2^0 &= z_2^{d0} + x_2 = 2 + x_2. \end{aligned} \tag{S.3.21}$$

Doing so gives the results

$$\begin{aligned} z_1(1) &= (1+x_1)/(2+x_1) = (2+x_1-1)/(2+x_1) = 1 - 1/(2+x_1) = \\ &= 1 - (1/2)(1+x_1/2)^{-1} = 1 - (1/2)[1 - x_1/2 + (x_1/2)^2 - (x_1/2)^3 + \cdots \\ &= (1/2) + (1/4)x_1 - (1/8)x_1^2 + (1/16)x_1^3 + \cdots , \end{aligned} \tag{S.3.22}$$

$$\begin{aligned} z_2(1) &= (2+x_2)(2+x_1)^2 \\ &= 8 + 8x_1 + 4x_2 + 2x_1^2 + 4x_1x_2 + x_1^2x_2. \end{aligned} \tag{S.3.23}$$

We will now explore how this same result can be obtained using the replacement rule applied to the operation of numerical integration. As before, we will label individual monomials by an integer r. Recall that Table 2.5 shows our standard modified glex sequencing applied to the case of two variables.

The *Mathematica* code below shows, for our two-variable example differential equation, the application of numerical integration to pyramids. Before describing the code in some detail, we take note of the bottom two lines. When interpreted with the aid of Table 2.4, we see that the penultimate line of (3.24) agrees with (3.22), and the last line of (3.24) nearly agrees with (3.23). The only discrepancy is that for the monomial with label $r = 7$ in the last line of (3.24). In the *Mathematica* output it has the value -1.16563×10^{-7} while, according to (3.23), the true value should be zero. This small discrepancy arises from the truncation error inherent in the RK4 algorithm, and becomes smaller as the step size `h` is decreased (and `ns` is correspondingly increased), or if some more accurate integration algorithm is used. We conclude that, with the use of pyramids, it is also possible in the two-variable case to obtain Taylor expansions of the final conditions in terms of the initial conditions. Indeed, what is involved is again the Taylor rule applied, in this instance, to the case of two variables.

```
Clear["Global‘ * "];
Needs["Combinatorica‘"];
m = 2; p = 3;
GAMMA = Compositions[0, m];
Do[GAMMA = Join[GAMMA, Reverse[Compositions[d, m]]], {d, 1, p, 1}];
L = Length[GAMMA];
JSK[list_, k_] :=
Position[Apply[And, Thread[#1 <= #2 & [#, k]]] & /@ list, True]//Flatten;
B = Table[JSK[GAMMA, GAMMA[[r]]], {r, 1, L, 1}];
Brev = Reverse/@ B;
PROD[U_, V_] := Table[U[[B[[k]]]].V[[Brev[[k]]]], {k, 1, L, 1}];
F[Z_, t_] := {−PROD[Z[[1]], Z[[1]]], 2. PROD[Z[[1]], Z[[2]]]};
h = .01;
ns = 100;
t = 0;
zd0 = {1., 2.};
C1 = Table[KroneckerDelta[k, 1], {k, 1, L, 1}];
X[1] = Table[KroneckerDelta[k, 2], {k, 1, L, 1}];
X[2] = Table[KroneckerDelta[k, 3], {k, 1, L, 1}];
Zvar = {zd0[[1]] C1 + X[1], zd0[[2]] C1 + X[2]};
RK4;
t
Zvar
1.
{{0.5, 0.25, 0., −0.125, 0., 0., 0.0625, 0., 0., 0, },
  {8., 8., 4., 2., 4., 0., −1.16563 × 10^-7, 1., 0., 0.}}                (S.3.24)
```

Let us compare the structures of the routines for the single variable case and multi (two) variable case as illustrated in (3.12) and (3.24). The first difference occurs at line 3 where the number of variables m and the maximum degree p are specified. In (3.24) m is set to 2 because we wish to treat the case of two variables, and p is set to 3 simply to limit the lengths of the output arrays. The next difference occurs in line 12 where the right side `F` of the differential equation is specified. The major feature of the definition of `F` in (3.24) is that it is specified as two pyramids because the right side of the definition has the structure $\{*, *\}$ where each item $*$ is an instruction for computing a pyramid. In particular, the two pyramids are those for the two components of $\boldsymbol{f}$ as given by (3.17) and use of the replacement rule,

$$-z_1^2 \rightsquigarrow -\texttt{PROD[Z[[1]], Z[[1]]]}, \tag{S.3.25}$$

$$2z_1z_2 \rightsquigarrow 2.\,\texttt{PROD[Z[[1]],Z[[2]]]}. \qquad (S.3.26)$$

The next differences occur in lines 16 through 20 of (3.24). In line 16, since specification of the initial conditions now requires two numbers, see (3.20), zd0 is specified as a two-component array. In lines 17 and 18 of (3.12) the pyramids C1 and X are set up explicitly for the case $p = 5$. By contrast, in lines 17 through 19 of (3.24), the pyramids C1, X[1], and X[2] are set up for general p with the aid of the Table command and the Kronecker delta function. Recall (2.66) and observe from Tables 2.1, 2.4, and 2.5 that, no matter what the values of m and p, the constant monomial has the label $r = 1$ and the monomial x_1 has the label $r = 2$. Moreover, as long as $m \geq 2$ and no matter what the value of p, the x_2 monomial has the label $r = 3$. Finally, compare line 19 in (3.12) with line 20 in (3.24), both of which define the initial Zvar. We see that the difference is that in (3.12) Zvar is defined as a single pyramid while in (3.24) it is defined as a pair of pyramids of the form $\{*, *\}$. Most remarkably, all other corresponding lines in (3.12) and (3.24) are the same. In particular, the *same* RK4 code, namely that given by (3.6), is used in the scalar case (3.10), the single pyramid case (3.12), and the two-pyramid case (3.24). This multi-use is possible because of the convenient way in which *Mathematica* handles arrays.

We conclude that the pattern for the multivariable case is now clear. Only the following items need to be specified in an m dependent way:

- The value of m.

- The entries in F with entries entered as an array $\{*, *, \cdots\}$ of m pyramids.

- The design initial condition array zd0.

- The pyramids for C1 and X[1] through X[m].

- The entries for the initial Zvar specified as an array

  {zd0[[1]] C1 + X[1], zd0[[2]] C1 + X[2], $\cdots$, zd0[[m]] C1 + X[m]} of m pyramids.

S.4 Duffing Equation Application

Let us now apply the methods just developed to the case of the Duffing equation with parameter dependence as described by the relations (10.12.133) through (10.12.138). *Mathematica* code for this purpose is shown below. By looking at the final lines that result from executing this code, we see that the final output is an array of the form $\{\{*\}, \{*\}, \{*\}\}$. That is, the final output is an array of three pyramids. This is what we expect, because now we are dealing with three variables. See line 3 of the code, which sets $m = 3$. Also, for convenience of viewing, results are calculated and displayed only through third order as a consequence of setting $p = 3$.

```
Clear["Global‘*"];
Needs["Combinatorica‘"];
m = 3; p = 3;
GAMMA = Compositions[0, m];
Do[GAMMA = Join[GAMMA, Reverse[Compositions[d, m]]], {d, 1, p, 1}];
L = Length[GAMMA];
JSK[list_, k_] :=
Position[Apply[And, Thread[#1 <= #2 & [#, k]]] & /@ list, True]//Flatten;
B = Table[JSK[GAMMA, GAMMA[[r]]], {r, 1, L, 1}];
Brev = Reverse/@ B;
PROD[U_, V_] := Table[U[[B[[k]]]].V[[Brev[[k]]]], {k, 1, L, 1}];
POWER[U_, 2] := PROD[U, U];
POWER[U_, 3] := PROD[U, POWER[U, 2]];
C0 = Table[0, {k, 1, L, 1}];
F[Z_, t_] := {Z[[2]],
-2. beta PROD[Z[[3]], Z[[2]]] - PROD[POWER[Z[[3]], 2], Z[[1]]]-
POWER[Z[[1]], 3] - eps Sin[t] POWER[Z[[3]], 3],
C0};
ns = 100;
t = 0;
h = (2Pi)/ns;
beta = .1; eps = 1.5;
zd0 = {.3, .4, .5};
C1 = Table[KroneckerDelta[k, 1], {k, 1, L, 1}];
X[1] = Table[KroneckerDelta[k, 2], {k, 1, L, 1}];
X[2] = Table[KroneckerDelta[k, 3], {k, 1, L, 1}];
X[3] = Table[KroneckerDelta[k, 4], {k, 1, L, 1}];
Zvar = {zd0[[1]] C1 + X[1], zd0[[2]] C1 + X[2], zd0[[3]] C1 + X[3]};
RK4;
t
Zvar
```

$$
\begin{array}{l}
2\pi \\

\end{array}
\tag{S.4.1}
$$

The first unusual fragments in the code are lines 12 and 13, which define functions that implement the calculation of second and third powers of pyramids. Recall Subsection 2.7. The first new fragment is line 14, which defines the pyramid `C0` with the aid of the Table command and an implied Do loop. As a result of executing this code, `C0` is an array of L zeroes. The next three lines, lines 15 through 18, define `F`, which specifies the right sides of equations (10.12.133) through (10.12.135). See (10.12.136) through (10.12.138). The right side of `F` is of the form $\{*, *, *\}$, an array of three pyramids. By looking at (10.12.136) and recalling the replacement rule, we see that the first pyramid should be `Z[[2]]`,

$$z_2 \rightsquigarrow \texttt{Z[[2]]}. \tag{S.4.2}$$

The second pyramid on the right side of `F` is more complicated. It arises by applying the replacement rule to the right side of (10.12.137) to obtain the associated pyramid,

$$
\begin{array}{l}
-\,2\beta z_3 z_2 - z_3^2 z_1 - z_1^3 - \epsilon z_3^3 \sin t \rightsquigarrow \\
-2.\,\texttt{beta}\ \texttt{PROD[Z[[3]], Z[[2]]]} - \texttt{PROD[POWER[Z[[3]], 2], Z[[1]]]} - \\
\texttt{POWER[Z[[1]], 3]} - \texttt{eps}\ \texttt{Sin[t]}\ \texttt{POWER[Z[[3]], 3]}.
\end{array}
\tag{S.4.3}
$$

The third pyramid on the right side of F is simplicity itself. From (10.12.138) we see that this pyramid should be the result of applying the replacement rule to the number 0. Hence, this pyramid is `C0`,

$$0 \rightsquigarrow \texttt{C0} = \{\texttt{0}, \texttt{0}, \cdots, \texttt{0}\}. \tag{S.4.4}$$

The remaining lines of the code require little comment. Line 20 sets the initial time to 0, and line 21 defines h in such a way that the final value of t will be 2π. Line 22 establishes the parameter values $\beta = .1$ and $\epsilon = 1.5$, which are those for Figure 1.4.9. Line 23 specifies that the design initial condition is

$$z_1(0) = z_1^{d0} = .3,\ z_2(0) = z_2^{d0} = .4,\ z_3(0) = z_3^{d0} = .5 = \sigma, \tag{S.4.5}$$

and consequently

$$\omega = 1/\sigma = 2. \tag{S.4.6}$$

See (10.12.104). Also, it follows from (10.12.103) and (10.12.106) that

$$q(0) = \omega Q(0) = \omega z_1(0) = (2)(.3) = .6, \tag{S.4.7}$$

$$q'(0) = \omega^2 \dot{Q}(0) = \omega^2 z_2(0) = (2^2)(.4) = 1.6. \tag{S.4.8}$$

Next, lines 24 through 28 specify that the expansion is to be carried out about the initial conditions (7.124). Finally, line 29 invokes the `RK4` code given by (3.6). That is, as before, *no* modifications are required in the integration code.

A few more comments about the output are appropriate. Line 32 shows that the final time t is indeed 2π, as desired. The remaining output lines display the three pyramids that specify the final value of `Zvar`. From the first entry in each pyramid we see that

$$z_1(2\pi) = -0.0493158, \tag{S.4.9}$$

$$z_2(2\pi) = 0.439713, \tag{S.4.10}$$

$$z_3(2\pi) = .5, \tag{S.4.11}$$

when there are no deviations in the initial conditions. The remaining entries in the pyramids are the coefficients in the Taylor series that describe the changes in the final conditions that occur when changes are made in the initial conditions (including the parameter σ). We are, of course, particularly interested in the first two pyramids. The third pyramid has entries only in the first place and the fourth place, and these entries are the same as those in the third pyramid pyramid for `Zvar` at the start of the integration, namely those in `zd0[3] C1 + X[3]`. The fact that the third pyramid in `Zvar` remains constant is the expected consequence of (10.12.138).

At this point we should also describe how the $\mathcal{M}_8$ employed in Section 22.12 was actually computed. It could have been computed by setting $p = 8$ in (4.1) and specifying a small step size h and a great number of steps ns to insure good accuracy. Of course, when $p = 8$, the pyramids are large. Therefore, one does not usually print them out, but rather writes them to files or sends them directly to other programs for further use.

However, rather than using RK4 in (4.1), we replaced it with an adaptive 4-5th order Runge-Kutta-Fehlberg routine that dynamically adjusts the time step h during the course of integration to achieve a specified local accuracy, and we required that the error at each step be no larger than 10^{-12}. (Recall Subsection 2.1.1.) Like the RK4 routine, the Runge-Kutta-Fehlberg routine, when implemented in *Mathematica*, has the property that it can integrate any number of equations both in scalar variable and pyramid form without any changes in the code.[2]

S.5 Relation to the Complete Variational Equations

At this point it may not be obvious to the reader that the use of pyramids in integration routines to obtain Taylor expansions is the same as integrating the complete variational equations. We now show that the integration of pyramid equations is equivalent to the forward integration of the complete variational equations. For simplicity, we will examine the single variable case with no parameter dependence. The reader who has mastered this case should be able to generalize the results obtained to the general case.

[2] A *Mathematica* version of this code is available from Dobrin Kaltchev (kaltchev@triumf.ca) upon request.

In the single variable case with no parameter dependence (1.1) becomes

$$\dot{z} = f(z,t). \tag{S.5.1}$$

Let $z^d(t)$ be some design solution and introduce a deviation variable ζ by writing

$$z = z^d + \zeta. \tag{S.5.2}$$

Then the equation of motion (5.1) takes the form

$$\dot{z}^d + \dot{\zeta} = f(z^d + \zeta, t). \tag{S.5.3}$$

Also, the relations (10.12.14) and (10.12.15) take the form

$$f(z^d + \zeta, t) = f(z^d, t) + g(z^d, t, \zeta) \tag{S.5.4}$$

where g has an expansion of the form

$$g(z^d, t, \zeta) = \sum_{j=1}^{\infty} g^j(t)\zeta^j. \tag{S.5.5}$$

Finally, (10.12.16) and (10.12.17) become

$$\dot{z}^d = f(z^d, t), \tag{S.5.6}$$

$$\dot{\zeta} = g(z^d, t, \zeta) = \sum_{j=1}^{\infty} g^j(t)\zeta^j, \tag{S.5.7}$$

and (10.12.18) becomes

$$\zeta = \sum_{j=1}^{\infty} h^j(t)(\zeta_i)^j. \tag{S.5.8}$$

Insertion of (5.8) into both sides of (5.7) and equating like powers of ζ_i now yields the set of differential equations

$$\dot{h}^{j''}(t) = \sum_{j=1}^{\infty} g^j(t) U_j^{j''}(h^s) \text{ with } j, j'' \geq 1 \tag{S.5.9}$$

where the (universal) functions $U_j^{j''}(h^s)$ are given by the relations

$$\left(\sum_{j'=1}^{\infty} h^{j'}(\zeta_i)^{j'} \right)^j = \sum_{j''=1}^{\infty} U_j^{j''}(h^s)(\zeta_i)^{j''}. \tag{S.5.10}$$

The equations (5.6) and (5.9) are to be integrated from $t = t^{\text{in}} = t^0$ to $t = t^{\text{fin}}$ with the initial conditions

$$z^d(t^0) = z^{d0}, \tag{S.5.11}$$

$$h^1(t^0) = 1, \tag{S.5.12}$$

$$h^{j''}(t^0) = 0 \text{ for } j'' > 1. \tag{S.5.13}$$

Let us now consider the numerical integration of pyramids. Upon some reflection, we see that the numerical integration of pyramids is equivalent to finding the numerical solution to a differential equation with pyramid arguments. For example, in the single-variable case, let $\texttt{Zvar}(t)$ be the pyramid appearing in the integration process. Then, its integration is equivalent to solving numerically the pyramid differential equation

$$(d/dt)\texttt{Zvar}(t) = \texttt{F}(\texttt{Zvar}, t). \tag{S.5.14}$$

We now work out the consequences of this observation. By the inverse of the replacement rule, we may associate a Taylor series with the pyramid $\texttt{Zvar}(t)$ by writing

$$\texttt{Zvar}(t) \rightsquigarrow c_0(t) + \sum_{j\geq 1} c_j(t)x^j. \tag{S.5.15}$$

By (5.15) it is intended that the entries in the pyramid $\texttt{Zvar}(t)$ be used to construct a corresponding Taylor series with variable x. In view of (3.15), there are the initial conditions

$$c_0(t_0) = z^d(t_0), \tag{S.5.16}$$

$$c_1(t_0) = 1, \tag{S.5.17}$$

$$c_j(t_0) = 0 \text{ for } j > 1. \tag{S.5.18}$$

We next seek the differential equations that determine the time evolution of the $c_j(t)$. Under the inverse replacement rule, there is also the correspondence

$$(d/dt)\texttt{Zvar}(t) \rightsquigarrow \dot{c}_0(t) + \sum_{j\geq 1} \dot{c}_j(t)x^j. \tag{S.5.19}$$

We have found a representation for the left side of (5.14). We need to do the same for the right side. That is, we need the Taylor series associated with the pyramid $\texttt{F}(\texttt{Zvar}, t)$. By the inverse replacement rule, it will be given by the relation

$$\texttt{F}(\texttt{Zvar}, t) \rightsquigarrow f(\sum_{j\geq 0} c_j(t)x^j, t). \tag{S.5.20}$$

Here it is understood that the right side of (5.20) is to be expanded in a Taylor series about $x = 0$. From (5.4), (5.5), and (5.10) we have the relations

$$\begin{aligned} f(\sum_{j\geq 0} c_j(t)x^j, t) &= f(c_0(t)) + g(c_0(t), t, \sum_{j\geq 1} c_j(t)x^j) \\ &= f(c_0(t)) + \sum_{k\geq 1} g^k(t)(\sum_{j\geq 1} c_j(t)x^j))^k \\ &= f(c_0(t)) + \sum_{k\geq 1} g^k(t) \sum_{j\geq 1} U_k^j(c_\ell)x^j. \end{aligned} \tag{S.5.21}$$

Therefore, there is the inverse replacement rule

$$\mathtt{F(Zvar},t) \rightsquigarrow f(c_0(t)) + \sum_{k\geq 1} g^k(t) \sum_{j\geq 1} U_k^j(c_\ell)x^j. \tag{S.5.22}$$

Upon comparing like powers of x in (5.19) and (5.22), we see that the pyramid differential equation (5.14) is equivalent to the set of differential equations

$$\dot{c}_0(t) = f(c_0(t)), \tag{S.5.23}$$

$$\dot{c}_j(t) = \sum_{k\geq 1} g^k(t)U_k^j(c_\ell). \tag{S.5.24}$$

Finally, compare the initial conditions (5.11) through (5.13) with the initial conditions (5.16) through (5.18), and compare the differential equations (5.6) and (5.9) with the differential equations (5.23) and (5.24). We conclude that that there must be the relations

$$c_0(t) = z^d(t), \tag{S.5.25}$$

$$c_j(t) = h^j(t) \text{ for } j \geq 1. \tag{S.5.26}$$

We have verified, in the single variable case, that the use of pyramids in integration routines is equivalent to the solution of the complete variational equations using forward integration. As stated earlier, verification of the analogous m-variable result is left to the reader.

We also observe the wonderful convenience that, when pyramid operations are implemented and employed, it is not necessary to explicitly work out the forcing terms $g_a^r(t)$ of Subsection 10.12.1 and the universal functions $U_r^{r''}(h_n^s)$ of Subsection 10.12.3, nor is it necessary to explicitly set up the complete variational equations (10.12.36). All these complications are handled implicitly and automatically by the pyramid routines.

S.6 Acknowledgment

Dobrin Kaltchev made major contributions to the work of this appendix.

Exercises

S.6.1. Verify, in the general m variable case, that the use of pyramids in integration routines is equivalent to the solution of the complete variational equations using forward integration.

Appendix T

Quadrature and Cubature Formulas

T.1 Quadrature Formulas

T.1.1 Introduction

Suppose we wish to integrate some function $f(x)$ over some (finite) interval. Without loss of generality, by suitable translation and scaling, we may take this interval to be $[0, 1]$. A *quadrature* formula is a set of k *sampling points* x_i in the interval $[0, 1]$ and *weights* w_i such that

$$\int_0^1 dx\ f(x) \simeq \sum_{i=1}^{k} w_i f(x_i). \tag{T.1.1}$$

The challenge is to select the sampling points and weights in such a way that the approximation (1.1) is optimal and to define what is meant by *optimal.* From the *Weierstrass* approximation theorem we know that the monomials are dense on any bounded domain. Also, according to Taylor's theorem, monomials are the building blocks for analytic functions. Therefore, for our purposes, we will define optimal to mean that the relation (1.1) is to hold exactly for polynomials in x of as high a degree as possible. That is, for a given set of sampling points, we select the w_i in such a way that

$$\sum_{i=1}^{k} w_i (x_i)^\ell = \int_0^1 dx\ x^\ell = 1/(\ell + 1) \tag{T.1.2}$$

for $\ell = 0, 1, 2, \cdots$ up to as large an ℓ value (for a given k) as possible.

At this point some discussion is required. Suppose we reason as follows: Let m be an integer with $m \geq 0$. Assume $f(x)$ is a polynomial of maximum degree m. It will then have

$$k = m + 1 \tag{T.1.3}$$

coefficients in its Taylor series representation, and these coefficients can be found by sampling the value of f at k different points x_i on the interval $[0, 1]$. Put another way, suppose we are given k values $v_1, v_2, \cdots, v_k$. Then $f(x)$ is the unique polynomial of degree m whose graph passes through the points $\{x_i, v_i\}$. Now, with the coefficients known, the Taylor series can be integrated to determine the left side of (1.1). Thus, with a knowledge of f at k sampling

sampling points, it is in principle possible to integrate exactly polynomials of degree $\ell \leq m$ with m given by $m = k - 1$.

We next observe that once the k sampling points have been determined, the k weights w_i are uniquely determined. Let $L_i(x)$, called the *Lagrange* polynomial, be the degree m polynomial that takes on the value 1 at the sampling point x_i and has the value 0 at all the other sampling points,

$$L_i(x_j) = \delta_{ij}. \tag{T.1.4}$$

It is given by the construction

$$L_i(x) = \left[\prod_{j \neq i}(x - x_j)\right] \Big/ \left[\prod_{j \neq i}(x_i - x_j)\right]. \tag{T.1.5}$$

Evidently there are k such polynomials. Also, as a result of (1.4), it follows that $f(x)$ given by

$$f(x) = \sum_{i=1}^{k} v_i L_i(x) \tag{T.1.6}$$

has the property

$$f(x_j) = v_j. \tag{T.1.7}$$

Moreover, we see that

$$\int_0^1 dx\ f(x) = \sum_i v_i \int_0^1 dx\ L_i(x). \tag{T.1.8}$$

Therefore, in view of (1.7) and the desire (1.1), we make the definition

$$w_i = \int_0^1 dx\ L_i(x) \tag{T.1.9}$$

to achieve the result

$$\int_0^1 dx\ f(x) = \sum_i w_i f(x_i). \tag{T.1.10}$$

We conclude that given k sampling points, there are k weights w_i, uniquely determined by (1.9), such that (1.2) holds for $\ell \leq m$ with $m = k - 1$.

Given the k sampling points x_i, and the associated weights w_i, can it happen that (1.2) also holds for some ℓ values with $\ell > m$, i.e. $\ell > k - 1$? Let $\ell_{\max}$ be the largest integer for which (1.2) holds. More precisely, we require that (1.2) holds for $\ell \leq \ell_{\max}$, but not for $\ell = \ell_{\max} + 1$. We will see that exactly how large $\ell_{\max}$ can be depends on how the sampling points are chosen. In particular, we will learn that there is a unique optimum sampling procedure (called Legendre Gauss) for which $\ell_{\max}$ has the optimum value

$$\ell_{\max} = 2k - 1. \tag{T.1.11}$$

Upon combining (1.3) and (1.11) we see that for any sampling procedure there is the range relation

$$k - 1 \leq \ell_{\max} \leq 2k - 1. \tag{T.1.12}$$

Put another way, if $\ell_{\max}$ is specified, we will see that there can be sampling procedures such that (1.2) holds for all $\ell \leq \ell_{\max}$ with $k < \ell_{\max} + 1$. Indeed, if $\ell_{\max}$ is odd, k can be as small as $k_{\min}$ with

$$k_{\min} = (\ell_{\max} + 1)/2. \tag{T.1.13}$$

Since we know that $\ell_{\max}+1$ sampling points are necessary to determine the Taylor coefficients of a polynomial of degree $\ell_{\max}$, how can it be that we can exactly integrate over the interval $[0, 1]$ such polynomials using just k sampling points with $k < \ell_{\max} + 1$? The answer is that the *only* thing we want to know is the value of the integral over the *fixed* interval $[0, 1]$, and *not* the values of the individual Taylor coefficients. What happens is that the value of the integral depends only on the value of a certain combination of the Taylor coefficients, and the value of this combination can be found by sampling the function at fewer than $\ell_{\max} + 1$ points providing these points are judiciously chosen. See Exercise 1.2.

T.1.2 Newton Cotes

One sampling option is to space the x_i evenly with $x_1 = 0$ and $x_k = 1$,

$$x_i = (i - 1)/(k - 1). \tag{T.1.14}$$

Doing so gives the family of *Newton-Cotes* quadrature formulas.[1] For example, for the case $k = 3$, the sampling points are

$$(x_1, x_2, x_3) = (0, 1/2, 1), \tag{T.1.15}$$

the associated weights are found, using (1.9), to be

$$(w_1, w_2, w_3) = (1/6, 4/6, 1/6), \tag{T.1.16}$$

thereby yielding the celebrated *Simpson's rule* 1-4-1 formula

$$\int_0^1 dx\ f(x) \simeq (1/6)f(0) + (4/6)f(1/2) + (1/6)f(1). \tag{T.1.17}$$

In this case (1.2) holds for $\ell = 0, 1, 2,$ and 3; and errors first begin to appear for $\ell \geq 4$. For $\ell = 4$ the sum on the left side of (1.2) has the value

$$\sum_{i=1}^{3} w_i(x_i)^4 = 1/(4 + 1) + 4!/[90(2^5)] = 1/5 + 4!/2880. \tag{T.1.18}$$

Correspondingly, assuming that f is sufficiently differentiable, use of Newton Cotes gives (for the case $k = 3$) the approximation

$$\int_0^1 dx\ f(x) = (1/6)f(0) + (4/6)f(1/2) + (1/6)f(1) - (1/2880)f^{(4)}(\xi) \tag{T.1.19}$$

[1] Newton's student Roger Cotes urged and inspired Newton to write a second and enlarged edition of his *Principia*, and wrote the preface to this edition. He died of a violent fever at the early early age of 33. At Cotes' death Newton remarked, "If he had lived we would have known something." It is interesting to note that several years before Euler wrote his famous formula $\exp(i\theta) = \cos\theta + i \sin\theta$, Cotes wrote the inverse relation $\log(\cos\theta + i \sin\theta) = i\theta$.

where $\xi \in [0,1]$.

As a second example, for the case $k = 4$ the sampling points are

$$(x_1, x_2, x_3, x_4) = (0, 1/3, 2/3, 1), \tag{T.1.20}$$

the associated weights are found to be

$$(w_1, w_2, w_3, w_4) = (1/8, 3/8, 3/8, 1/8), \tag{T.1.21}$$

and we have the equally celebrated Simpson's 3/8 rule

$$\begin{aligned}\int_0^1 dx\ f(x) &= (1/8)f(0) + (3/8)f(1/3) + (3/8)f(2/3) + (1/8)f(1) \\ &\quad -(1/6480)f^{(4)}(\xi)\end{aligned} \tag{T.1.22}$$

where again $\xi \in [0,1]$.

Table 1.1 lists $\ell_{\max}$ as a function of k for Newton Cotes.[2] Evidently, when k is odd, there is no increase in order when using instead the next even value of k. Doing so does result in a decrease in the coefficient in the error term, but this decrease is fairly modest. For this reason, odd values of k are frequently preferred. Note that for even k the entries in the Table take the floor value $\ell_{\max} = k - 1$ guaranteed by (1.12), and beat this value for odd k.

Table T.1.1: Maximum Order $\ell_{\max}$ for k Newton-Cotes Sampling Points.

k	1	2	3	4	5	6	7	8	9	10
$\ell_{\max}$	1	1	3	3	5	5	7	7	9	9

T.1.3 Legendre Gauss

Another appealing sampling option is not to space the x_i evenly, but rather to select them in such a way that (for a fixed k) the number of successive ℓ values for which (1.2) holds is maximized. This choice produces the family of *Legendre-Gauss* quadrature formulas. Legendre-Gauss quadrature is most naturally described in terms of the interval $[-1,1]$. It can be shown that the *Legendre* polynomial $P_k(x)$ has k distinct zeroes on the interval $[-1,1]$, and it is these zeroes that are used in k-sampling point Legendre-Gauss quadrature.

Three examples of Legendre Gauss are given below. For ease of comparison with Newton-Cotes quadrature, we have transformed Legendre-Gauss results to the interval $[0,1]$.

For $k = 3$, the (transformed) Legendre-Gauss sampling points are given by

$$(x_1, x_2, x_3) = (1/2 - \sqrt{15}/10,\ 1/2,\ 1/2 + \sqrt{15}/10). \tag{T.1.23}$$

[2] Strictly speaking, for the Newton-Cotes we have been describing, the $k = 1$ table entry is meaningless. However, it does apply in the case of *open* Newton Cotes. See Exercise 1.1.

The corresponding weights, calculated using (1.9), are given by

$$(w_1, w_2, w_3) = (5/18,\ 8/18,\ 5/18). \tag{T.1.24}$$

Correspondingly, there is the formula

$$\int_0^1 dx f(x) \simeq (5/18)f(1/2 - \sqrt{15}/10) + (8/18)f(1/2) + (5/18)f(1/2 + \sqrt{15}/10). \tag{T.1.25}$$

In this case (1.2) holds for $\ell = 0$ through 5, but not $\ell = 6$. Therefore $\ell_{\max} = 5$. And for $\ell = 6$ the sum on the left side of (1.2) has the value

$$\sum_{i=1}^{3} w_i (x_i)^6 = 1/7 - 6!/2016000. \tag{T.1.26}$$

Correspondingly, again assuming that f is sufficiently differentiable, use of Legendre Gauss gives (for the case $k = 3$) the approximation

$$\begin{aligned} \int_0^1 dx\ f(x) \quad &= \quad (5/18)f(1/2 - \sqrt{15}/10) + (8/18)f(1/2) + (5/18)f(1/2 + \sqrt{15}/10) \\ &\quad +(1/2016000)f^{(6)}(\xi). \end{aligned} \tag{T.1.27}$$

As another example, consider the case $k = 2$. Then there is the formula

$$\int_0^1 dx\ f(x) \simeq (1/2)f(1/2 - \sqrt{3}/6) + (1/2)f(1/2 + \sqrt{3}/6). \tag{T.1.28}$$

It corresponds to sampling points and weights given by the rules

$$(x_1, x_2) = (1/2 - \sqrt{3}/6, 1/2 + \sqrt{3}/6), \tag{T.1.29}$$

$$(w_1, w_2) = (1/2, 1/2). \tag{T.1.30}$$

In this case (1.2) holds for $\ell = 0$ through 3, but not for $\ell = 4$. That is, $\ell_{\max} = 3$. For $\ell = 4$ the sum on the left side of (1.2) has the value

$$\sum_{i=1}^{2} w_i (x_i)^4 = 1/5 - 4!/4320. \tag{T.1.31}$$

Correspondingly, use of Legendre Gauss gives (for the case $k = 2$) the approximation

$$\int_0^1 dx\ f(x) = (1/2)f(1/2 - \sqrt{3}/6) + (1/2)f(1/2 + \sqrt{3}/6) + (1/4320)f^{(4)}(\xi). \tag{T.1.32}$$

Compare (1.32), Legendre Gauss for $k = 2$, with (1.19), Newton Cotes for $k = 3$. They are of the same order, but Legendre Gauss has a somewhat smaller error coefficient. Thus, Legendre Gauss for $k = 2$ not only requires one less evaluation of f than Newton Cotes for $k = 3$, it is also slightly more accurate.

Finally, consider the case $k = 1$. It has sampling point and weight given by

$$x_1 = 1/2, \tag{T.1.33}$$

$$w_1 = 1, \tag{T.1.34}$$

and yields the midpoint rule

$$\int_0^1 dx\ f(x) \simeq f(1/2). \tag{T.1.35}$$

In this case (1.2) holds for $\ell = 0$ and 1, but not for $\ell = 2$. Therefore $\ell_{\max} = 1$. And for $\ell = 2$ the sum on the left side of (1.2) has the value

$$w_1(x_1)^2 = 1/3 - 2!/24. \tag{T.1.36}$$

Correspondingly, use of Legendre Gauss gives (for the case $k = 1$) the approximation

$$\int_0^1 dx\ f(x) = f(1/2) + (1/24)f^{(2)}(\xi). \tag{T.1.37}$$

It can be shown that for Legendre Gauss the relation (1.11) holds. Moreover, for a given k value, there is no sampling procedure with larger $\ell_{\max}$ than that of Legendre Gauss. All other sampling-point choices yield a smaller value of $\ell_{\max}$. Comparison of Table 1.1 and (1.11) shows that, with increasing k, Legendre Gauss rapidly becomes far more efficient than Newton Cotes.

T.1.4 Clenshaw Curtis

Like Legendre Gauss, *Clenshaw-Curtis* quadrature is most naturally described on the interval $[-1, 1]$. It uses the *Chebyshev* points as sampling points. For $k = 1$ the Chebyshev point is 0.[3] For $k = 2$ the Chebyshev points are ∓ 1, and for $k = 3$ the Chebyshev points are $\{-1, 0, 1\}$. For $k \geq 2$ select k equally spaced angles θ_i with $\theta_1 = -\pi$ and $\theta_k = \pi$,

$$\theta_i = -\pi + 2\pi(i-1)/(k-1). \tag{T.1.38}$$

For $k \geq 2$ the Chebyshev points are given by the rule

$$x_i = \cos(\theta_i). \tag{T.1.39}$$

Let $T_{k-1}(x)$ be the Chebyshev polynomial of degree $k-1$. It can be shown, for $k \geq 2$, that T_{k-1} has k extrema on the interval $[-1, 1]$ (all of which are ∓ 1). Moreover, for $k \geq 2$, these extrema are the k Chebyshev sampling points defined by (1.38) and (1.39).

Evidently for $k \leq 3$ the Chebyshev points, when transformed to the interval $[0, 1]$, are the same as the sampling points for Newton Cotes, and therefore Table 1 provides the value of $\ell_{\max}$ in these cases. It can be shown that in fact Table 1 provides the correct value of

[3] Some authors omit this point since it is really a Chebyshev point of the second kind.

$\ell_{\max}$ for Clenshaw Curtis in all cases. That is, Table 1 holds for both Newton Cotes and Clenshaw Curtis.[4]

Although the order of Clenshaw-Curtis quadrature is the same as that for Newton Cotes, and therefore much less that that of Legendre Gauss, its use has two advantages. First, if the value of $k-1$ is doubled, thereby doubling the order, essentially half of the sampling points are the same as before. Therefore, in the same spirit as embedded Runge Kutta, it is relatively easy to devise adaptive integration schemes. A second advantage, as described in the next subsection, has to do with convergence.

T.1.5 Convergence

What happens in the limit $k \to \infty$? For the interval $[-1, 1]$ it can be shown that Newton-Cotes quadrature converges to the correct result providing $f(x)$ is *analytic* in a disk centered about $x = 0$ and having radius slightly larger than 1; and is divergent if f fails to be analytic in the open unit disk centered about $x = 0$. (The case where f has singularities on the boundary of this open unit disk requires a more refined analysis.)[5] When the interval is $[0, 1]$, this result for convergence translates to the requirement that f be analytic in a disk centered about $x = 1/2$ and having radius slightly larger than $1/2$.

By contrast, and working in the interval $[-1, 1]$, Legendre-Gauss quadrature is guaranteed to converge under the much less restrictive condition that $f(x)$ simply be *sufficiently smooth* for $x \in [-1, 1]$. An adequate condition for sufficiently smooth, which is generally realized in practice, is that $f(x)$ be *Lipschitz* continuous for $x \in [-1, 1]$. Correspondingly, when transformed to the interval $[0, 1]$, Legendre-Gauss quadrature is guaranteed to converge if $f(x)$ is sufficiently smooth for $x \in [0, 1]$.

The reason for this difference is that Taylor series on the interval $[-1, 1]$ converge in disks about $x = 0$ whereas Legendre polynomial expansions in the interval $[-1, 1]$ converge in ellipses (sometimes called *Bernstein* ellipses) with foci at $x = \mp 1$.

Although for a given k Clenshaw-Curtis quadrature has relatively low order (the same as Newton Cotes) compared to Legendre Gauss, its convergence properties are similar to those for Legendre Gauss. It too, when transformed to the interval $[0, 1]$, is guaranteed to converge under the much less restrictive condition that $f(x)$ simply be sufficiently smooth for $x \in [0, 1]$.

What can be said about Legendre-Gauss and Clenshaw-Curtis convergence in the case that f is analytic? Again it is most convenient to employ the interval $[-1, 1]$ with the understanding that the results obtained for this interval can be easily be transformed to the interval $[0, 1]$. Let ρ be a real number with $\rho > 1$. Consider the points z in the complex plane given by the rule

$$z = \rho \exp(i\phi) \tag{T.1.40}$$

[4] From (1.38) and (1.39) it follows that the Chebyshev points are symmetrically distributed about $x = 0$. Correspondingly the weights for the points $\mp x_i$ are the same. Therefore, by symmetry, Clenshaw Curtis is exact (yields the value 0) for all odd-degree monomials.

[5] Runge considered the function $f(x) = 1/(1 + 25x^2)$, now called the Runge function, on the interval $x \in [-1, 1]$ and showed that Newton-Cotes quadrature diverges for this example. Note that Runge's f is analytic on this interval, but has poles at the points $x = \pm i/5$, and these poles lie inside the unit disk centered about the origin.

with $\phi \in [0, 2\pi)$. Evidently they lie on a circle about the origin with radius ρ. Next consider points w related to points z by the rule

$$w = (1/2)(z + z^{-1}). \tag{T.1.41}$$

It can be verified that the image of the circle (1.40) under the transformation (1.41) is an ellipse in the complex plane (a Bernstein ellipse E_ρ) with foci ∓ 1,

$$\text{semi-major axis } = (1/2)(\rho + 1/\rho), \tag{T.1.42}$$

and

$$\text{semi-minor axis } = (1/2)(\rho - 1/\rho). \tag{T.1.43}$$

Suppose f is analytic on $[-1, 1]$ and that it can be analytically continued (see Figure 32.4.9) into the interior of some E_ρ without encountering a singularity, and also suppose that there are no singularities on the boundary (E_ρ itself). Then it can be shown that for large k the error in Legendre-Gauss quadrature must go to zero at least as fast as

$$\text{Legendre-Gauss quadrature error} \sim \exp[-2k \log(\rho)].$$

And for Clenshaw-Curtis quadrature the error must go to zero at least as fast as

$$\text{Clenshaw-Curtis quadrature error} \sim \exp[-k \log(\rho)].$$

Thus, in both cases, the error goes to zero *exponentially* with increasing k. And the larger the value of ρ can be without there being singularities inside or on E_ρ, the more rapid the exponential decrease.

Exercises

T.1.1. The sampling option (1.14) involves use of the endpoints 0 and 1, and for this reason is more precisely called *closed* Newton Cotes. It is also possible to employ a sampling procedure, called *open* Newton Cotes, for which the x_i are still equally spaced but the endpoints are not used. Consider, for example, the case $k = 3$ and the two equally spaced sampling procedures

$$(x_1, x_2, x_3) = (0, 1/2, 1) \text{ closed Newton Cotes}, \tag{T.1.44}$$

and

$$(x_1, x_2, x_3) = (1/4, 1/2, 3/4) \text{ open Newton Cotes}. \tag{T.1.45}$$

For $k = 3$ open Newton Cotes the weights are

$$(w_1, w_2, w_3) = (2/3, -1/3, 2/3). \tag{T.1.46}$$

Show that, just as for the case of closed Newton Cotes, (1.2) holds for $k = 3$ open Newton Cotes when $\ell = 0, 1, 2, 3$. Show that, for $k = 3$ open Newton Cotes,

$$\sum_{i=1}^{3} w_i (x_i)^4 = 1/(4 + 1) + (14)(4!)/[45(4^5)] = 1/5 + (4!)(7/23040). \tag{T.1.47}$$

Correspondingly, assuming that f is sufficiently differentiable, use of $k = 3$ open Newton Cotes gives the approximation

$$\int_0^1 dx\ f(x) = (2/3)f(1/4) - (1/3)f(1/2) + (2/3)f(3/4) + (7/23040)f^{(4)}(\xi) \qquad \text{(T.1.48)}$$

where $\xi \in [0, 1]$.

For $k = 4$ open Newton Cotes the sampling points are

$$(x_1, x_2, x_3, x_4) = (1/5, 2/5, 3/5, 4/5), \qquad \text{(T.1.49)}$$

and the weights are

$$(w_1, w_2, w_3, w_4) = (11/24, 1/24, 1/24, 11/24). \qquad \text{(T.1.50)}$$

Correspondingly, assuming that f is sufficiently differentiable, use of $k = 4$ open Newton Cotes gives the approximation

$$\begin{aligned} \int_0^1 dx\ f(x) \quad &= \quad (11/24)f(1/5) + (1/24)f(2/5) + (1/24)f(3/5) + (11/24)f(4/5) \\ &\quad +(19/90000)f^{(4)}(\xi) \qquad \text{(T.1.51)} \end{aligned}$$

where again $\xi \in [0, 1]$.

It can be shown that, for a given value of k, both closed and open Newton Cotes have the same $\ell_{\max}$. Thus Table 1.1 holds for both open and closed Newton Cotes. Comparison of (1.19) and (1.48) shows that for $k = 3$ the error coefficient for open Newton Cotes is slightly smaller than that for closed Newton Cotes. This case is an anomaly. For $k \geq 4$ closed Newton Cotes has a smaller error coefficient than open Newton Cotes. Finally, we remark that $k = 1$ Legendre Gauss my also be viewed as being $k = 1$ open Newton Cotes.

T.1.2. Consider quadrature on the interval $[-1, 1]$. Let $f(x)$ be the third-order polynomial

$$f(x) = a + bx + cx^2 + dx^3. \qquad \text{(T.1.52)}$$

Verify that

$$\int_{-1}^1 dx\ f(x) = 2a + (2/3)c. \qquad \text{(T.1.53)}$$

Observe that the right side of (1.53) is a particular linear combination of the Taylor coefficients for f, and the value of the integral on the left side of (1.53) depends only on the value of this particular combination.

The $k = 2$ Legendre-Gauss sampling points and weights on the interval $[-1, 1]$ are

$$(x_1, x_2) = (-1/\sqrt{3}, 1/\sqrt{3}), \qquad \text{(T.1.54)}$$

$$(w_1, w_2) = (1, 1). \qquad \text{(T.1.55)}$$

Verify that

$$\sum_{i=1}^{2} w_i f(x_i) = 2a + (2/3)c, \qquad \text{(T.1.56)}$$

and therefore $k = 2$ Legendre-Gauss quadrature is exact for all polynomials of degree 3 or less. Verify that Legendre Gauss is the unique $k = 2$ quadrature rule with this property. Also verify that $k = 2$ Legendre-Gauss quadrature fails for x^4.

T.1.3. There is another way of viewing quadrature formulas that is more akin to the numerical integration of differential equations. Consider the single-variable differential equation

$$dy/dt = g(t) \tag{T.1.57}$$

with the initial condition

$$y(0) = 0. \tag{T.1.58}$$

Note that g does not depend on y, and therefore (1.57) has the immediate solution

$$y(t) = \int_0^t dt' g(t'). \tag{T.1.59}$$

Suppose, in the spirit of a local stepping formula, we wish to compute $y(h)$ through some order in h. From (1.59) we find

$$y(h) = \int_0^h dt g(t). \tag{T.1.60}$$

Bring the right side of (1.60) to the $\int_0^1$ standard form by making the change of variable and definition

$$t = xh, \tag{T.1.61}$$

$$f(x) = g(xh). \tag{T.1.62}$$

Show that (1.60) then becomes

$$y(h) = h \int_0^1 dx f(x). \tag{T.1.63}$$

Suppose the right side of (1.63) is evaluated using Newton Cotes with k odd. Show that there is the result

$$y(h) = h \sum_{i=1}^{k} w_i f(x_i) + c_{k+1} h f^{k+1}(\xi) \tag{T.1.64}$$

where c_{k+1} is a coefficient that can be read off from formulas such as (1.19) and (1.48). Finally, show that

$$f^{k+1}(\xi) = h^{k+1} g^{k+1}(\tau), \tag{T.1.65}$$

where $\tau \in [0, h]$, so that (1.64) becomes

$$y(h) = h \sum_{i=1}^{k} w_i g(x_i h) + c_{k+1} h^{k+2} g^{k+1}(\tau), \; k \text{ odd.} \tag{T.1.66}$$

We see that, for k function evaluations with k odd, Newton Cotes provides a stepping formula with local error of order h^{k+2}, and therefore local accuracy through terms of order h^{k+1}.

Suppose the right side of (1.63) is evaluated using Newton Cotes with k even. Show that then there is the result

$$y(h) = h \sum_{i=1}^{k} w_i f(x_i) + c_k h f^k(\xi) \tag{T.1.67}$$

where c_k is a coefficient that can be read off from formulas such as (1.22) and (1.51). Finally, show that

$$f^k(\xi) = h^k g^k(\tau), \tag{T.1.68}$$

where $\tau \in [0, h]$, so that (1.67) becomes

$$y(h) = h \sum_{i=1}^{k} w_i g(x_i h) + c_k h^{k+1} g^k(\tau),\ k \text{ even.} \tag{T.1.69}$$

We see that, for k function evaluations with k even, Newton Cotes provides a stepping formula with local error of order h^{k+1}, and therefore local accuracy through terms of order h^k.

Suppose, instead, that the right side of (1.63) is evaluated using Legendre Gauss. Then there is the result

$$y(h) = h \sum_{i=1}^{k} w_i f(x_i) + c_{2k} h f^{2k}(\xi) \tag{T.1.70}$$

where c_{2k} is a coefficient that can be read off from formulas such as (1.27), (1.32), and (1.37). Now show that

$$f^{2k}(\xi) = h^{2k} g^{2k}(\tau), \tag{T.1.71}$$

where $\tau \in [0, h]$, so that (1.70) becomes

$$y(h) = h \sum_{i=1}^{k} w_i g(x_i h) + c_{2k} h^{2k+1} g^{2k}(\tau). \tag{T.1.72}$$

We see that, for k function evaluations, Legendre Gauss provides a stepping formula with local error of order h^{2k+1}, and therefore local accuracy through terms of order h^{2k}.

T.1.4. Verify that E_ρ given by (1.40) and (1.41) is indeed an ellipse with the advertised properties.

T.2 Cubature Formulas

T.2.1 Introduction

Cubature formulas extend the concept of qudrature formulas to the case of domains D having dimension greater than one. All such formulas are called cubature formulas, no matter what the dimension of D, as long as this dimension is greater than one.

Let D be some domain having dimension m. Label points within D by m-dimensional vectors

$$x = (x_1, x_2, \cdots, x_m), \tag{T.2.1}$$

and let $f(x)$ be a function defined on D. Then a cubature formula is a set of k sampling points in D, now call them x^i, and weights w^i such that

$$\int_D d^m x\ f(x) \simeq \sum_{i=1}^{k} w^i f(x^i). \tag{T.2.2}$$

Again the challenge is to select the sampling points and weights in such a way that the approximation (2.2) is optimal and to define what is meant by optimal. Results are known for some standard domains. For our purposes, we are interested in the cases where D is either a square, rectangle, or S^2 (the surface of a 2-sphere).

T.2.2 Cubature on a Square

The unit m-cube, denoted by C^m, is defined to be the domain

$$-1 \leq x_c \leq 1 \quad c = 1, \cdots, m. \tag{T.2.3}$$

A variety of cubature formulas are known for the C^m for all m. We will be particularly interested in the case C^2, which we call the unit square.

Let P_{j_1,j_2} denote the monomial

$$P_{j_1,j_2}(x) = x_1^{j_1} x_2^{j_2}. \tag{T.2.4}$$

It has degree

$$\hat{d} = j_1 + j_2. \tag{T.2.5}$$

From the work of Exercise 7.10.2 we know that the number of such monomials of degree 0 through d is given by

$$S_0(2, d) = (2 + d)!/(2!d!). \tag{T.2.6}$$

See (7.10.17). For convenience, the values of $S_0(2, d)$ are tabulated below for the first few values of d.

Table T.2.1: $S_0(2, d)$ as a Function of d.

d	0	1	2	3	4	5	6	7
$S_0(2, d)$	1	3	6	10	15	21	28	36

Let D be the domain C^2. Again, because of the results of Weierstrass and Taylor, as our definition of optimal we will seek k sampling points x^i and weights w^i such that

$$\int_D d^2x \; P_{j_1,j_2}(x) = \sum_{i=1}^{k} w^i P_{j_1,j_2}(x^i) \tag{T.2.7}$$

for all monomials of degree less than or equal to d. We note that the left side of (2.7) is easily evaluated to give the result

$$\int_D d^2x \; P_{j_1,j_2}(x) = 4/[(j_1 + 1)(j_2 + 1)] \quad j_1, j_2 \text{ both even,} \tag{T.2.8}$$

$$= 0 \quad \text{otherwise.} \tag{T.2.9}$$

Observe that, for the 2-dimensional case, the specification of each sampling point x^i requires 2 values. Consequently, the specification of k sampling points and k weights involves the specification of $2k + k = 3k$ values. On the other hand, there are $S_0(2, d)$ conditions of the form (2.7) that need to be met. Therefore naive counting suggests that (2.7) can be satisfied providing

$$3k \geq S_0(2, d). \tag{T.2.10}$$

For example, for the case $d = 5$, we see from Table 2.1 that (2.10) yields the requirement

$$3k \geq 21, \text{ or } k \geq 7. \tag{T.2.11}$$

We note that a formula that works for $d = 5$ can be constructed by converting the integral over the unit square into two iterated integrals, and these integrals (since they must be exact for single-variable monomials of degrees 0 through 5) can each be approximated using $[-1, 1]$ variants of the 3-point Legendre-Gauss formula (1.25). Doing so produces what is called a *product* cubature fromula, and evidently has $k = 3 \times 3 = 9$.

Remarkably, for the unit square and $d = 5$, there are two cubature formulas for which $k = 7$. *Stroud*, in his book on the approximate calculation of multiple integrals, refers to them as $^*C^2$:5-1 and $^*C^2$:5-2. In these formulas several sampling points have the same weight. The formulas are described below. Each description consists of weights and the sampling points having these weights. Also shown, in Figures 2.1 and 2.2, are the locations of the sampling points in the x_1, x_2 plane. Note that all sampling points lie *within* the unit square, a feature that is essential for our purposes; and all have positive weights, a feature that is numerically desirable.

The Unit Square Cubature Formula $^*C^2$:5-1

weights	points
8/7	$(0, 0)$
20/36	$(\pm r, \pm s)$
20/63	$(0, \pm t)$

$$\begin{aligned} r &= \sqrt{3/5} \simeq .775 \\ s &= \sqrt{1/3} \simeq .577 \\ t &= \sqrt{14/15} \simeq .966 \end{aligned} \tag{T.2.12}$$

The Unit Square Cubature Formula $^*C^2$:5-2

weights	points
$8/7$	$(0,0)$
$100/168$	$\pm\,(r,r)$
$20/48$	$\pm\,(s,-t)$
$20/48$	$\pm\,(t,-s)$

$$\begin{aligned} r &= \sqrt{7/15} \simeq .683 \\ s &= [(7+\sqrt{24})/15]^{1/2} \simeq .891 \\ t &= [(7-\sqrt{24})/15]^{1/2} \simeq .374 \end{aligned} \tag{T.2.13}$$

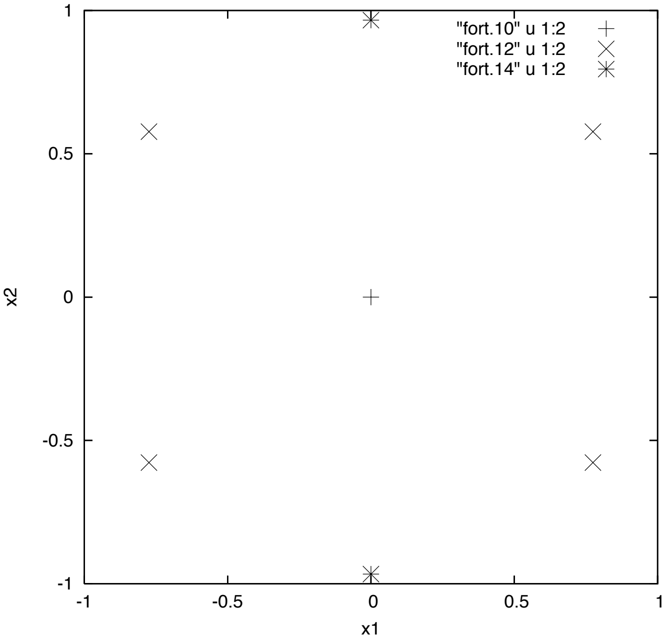

Figure T.2.1: Sampling points for $^*C^2$:5-1

Rough Error Analysis

Analysis of the errors involved with the use of cubature formulas is a complicated subject. However, one simple thing that can be done is to see how well (2.7) works for monomials having degree $d+1$ when the method has been constructed to work for monomials having degrees less than or equal to d. For example, for the two unit-square $d=5$ and $k=7$ cubature formulas we have been discussing, we can examine how well they work for monomials of degree $5+1=6$.

Observe, for these two unit-square cubature formulas, that the $(0,0)$ sampling point does not contribute to the result for any first or higher degree monomial. With regard to the other sampling points, the sampling points for each weight are symmetrically arranged in

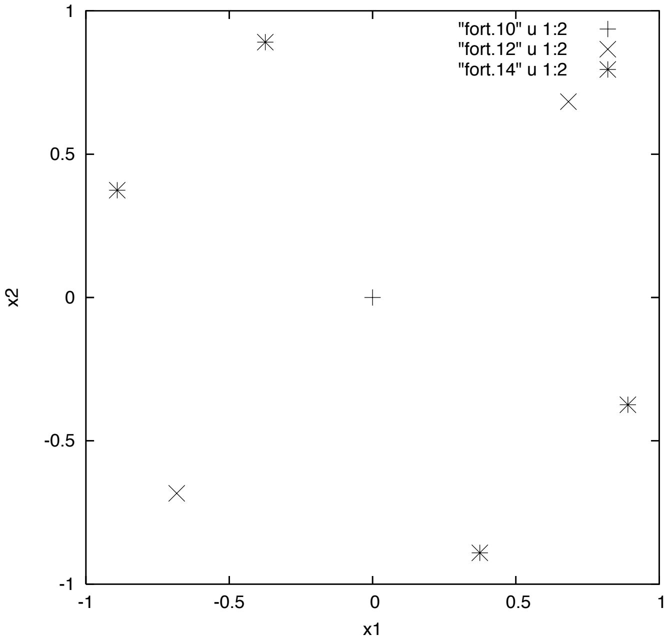

Figure T.2.2: Sampling points for ${}^*C^2$:5-2

such a way that their net contribution for any monomial $x_1^{j_1}x_2^{j_2}$ is identically zero if either j_1 or j_2 is odd, but not both are odd. Therefore these cubature formulas automatically satisfy (2.7) and (2.9) exactly for this subset of monomials,

$$\sum_{i=1}^{5} w^i P_{j_1,j_2}(x^i) = \int_D d^2x\ P_{j_1,j_2}(x) = 0 \quad \text{if either } j_1 \text{ or } j_2 \text{ is odd, but not both are odd.} \tag{T.2.14}$$

Note that, by this symmetry, (2.7) is automatically satisfied for *all* odd degree polynomials.

With regard to monomials of degree 6, we need to examine the performance of the methods (2.12) and (2.13) separately. Comparison of Figures 2.1 and 2.2 shows that the sampling points for the method (2.12) are more symmetrically arranged. In particular, for this method we have the stronger result that for all monomials

$$\sum_{i=1}^{5} w^i P_{j_1,j_2}(x^i) = 0 \quad \text{if either } j_1 \text{ or } j_2 \text{ is odd, or both are odd.} \tag{T.2.15}$$

Therefore this cubature formula automatically satisfies (2.9) exactly for all monomials of any degree if either j_1 or j_2 is odd, or both are odd. What remains to be examined for monomials of degree 6 are the cases x_1^6, $x_1^4x_2^2$, $x_1^2x_2^4$, and x_2^6, for which, according to (2.8), the exact results are 4/7, 4/15, 4/15, and 4/7, respectively. Numerical calculations show that, for ${}^*C^2$:5-1, there are the results

$$\sum_{i=1}^{5} w^i P_{6,0}(x^i) = 4/7 - .0914\cdots = (4/7)(1 - .16\cdots), \tag{T.2.16}$$

$$\sum_{i=1}^{5} w^i P_{4,2}(x^i) = 4/15 + 0, \tag{T.2.17}$$

$$\sum_{i=1}^{5} w^i P_{2,4}(x^i) = 4/15 - .1185\cdots = (4/15)(1 - .44\cdots), \tag{T.2.18}$$

$$\sum_{i=1}^{5} w^i P_{0,6}(x^i) = 4/7 + .0271\cdots = (4/7)(1 + .05\cdots). \tag{T.2.19}$$

Surprisingly, (2.17) shows that ${}^*C^2$:5-1 is exact for $x_1^4 x_2^2$! We conclude, with regard to monomials of degrees 0 through 7, that ${}^*C^2$:5-1 is exact for all such monomials save for the monomials x_1^6, $x_1^2 x_2^4$, and x_2^6 where it makes errors of approximately 16%, 44%, and 5%, respectively.

For ${}^*C^2$:5-2, the sampling points are less symmetrically arranged so that a larger number of degree 6 monomials need to be considered separately. Numerical calculations show that there are the results

$$\sum_{i=1}^{5} w^i P_{6,0}(x^i) = 4/7 - .032\cdots = (4/7)(1 - .06\cdots), \tag{T.2.20}$$

$$\sum_{i=1}^{5} w^i P_{5,1}(x^i) = 0 - .059\cdots, \tag{T.2.21}$$

$$\sum_{i=1}^{5} w^i P_{4,2}(x^i) = 4/15 - .059\cdots = (4/15)(1 - .22\cdots), \tag{T.2.22}$$

$$\sum_{i=1}^{5} w^i P_{3,3}(x^i) = 0 + .059\cdots, \tag{T.2.23}$$

$$\sum_{i=1}^{5} w^i P_{2,4}(x^i) = 4/15 - .059\cdots = (4/15)(1 - .22\cdots), \tag{T.2.24}$$

$$\sum_{i=1}^{5} w^i P_{1,5}(x^i) = 0 - .059\cdots, \tag{T.2.25}$$

$$\sum_{i=1}^{5} w^i P_{0,6}(x^i) = 4/7 - .032\cdots = (4/7)(1 - .06\cdots). \tag{T.2.26}$$

We conclude, with regard to monomials of degrees 0 through 7, that ${}^*C^2$:5-2 is exact for all such monomials save for all the monomials of degree 6 where it makes the errors indicated above.

Finally, comparison of (2.16) through (2.19) for ${}^*C^2$:5-1 with (2.20) through (2.26) for ${}^*C^2$:5-2 shows that, save for the case $x_1^2 x_2^4$, ${}^*C^2$:5-1 generally makes smaller errors than ${}^*C^2$:5-2, and therefore might be slightly preferred.

T.2.3 Cubature on a Rectangle

Let $R(a, b)$ be a rectangle with sides $2a$ and $2b$ parameterized by coordinates ξ_1, ξ_2 such that

$$\xi_1 \in [-a, a], \quad \xi_2 \in [-b, b]. \tag{T.2.27}$$

Let $g(\xi)$ be some function defined on $R(a, b)$ and suppose we wish to evaluate the integral

$$\int_{R(a,b)} d^2\xi \; g(\xi). \tag{T.2.28}$$

Our goal is to find k sampling points ξ^i and k weights $\bar{w}^i$ such that

$$\int_{R(a,b)} d^2\xi \; g(\xi) \simeq \sum_{i=1}^{k} \bar{w}^i g(\xi^i). \tag{T.2.29}$$

Introduce new variables x_1, x_2 by the rules

$$\xi_1 = ax_1, \quad \xi_2 = bx_1 \tag{T.2.30}$$

so that (2.30) maps C^2 into $R(a, b)$. See (2.3). Then there is the relation

$$\int_{R(a,b)} d^2\xi \; g(\xi) = ab \int_{C^2} d^2x \; f(x) \tag{T.2.31}$$

where

$$f(x) = g(ax_1, bx_2). \tag{T.2.32}$$

From (2.2) we have the approximation

$$\int_{C^2} d^2x \; f(x) \simeq \sum_{i=1}^{k} w^i f(x^i). \tag{T.2.33}$$

It follows that

$$\int_{R(a,b)} d^2\xi \; g(\xi) \simeq ab \sum_{i=1}^{k} w^i f(x^i) = ab \sum_{i=1}^{k} w^i g(ax_1^i, bx_2^i). \tag{T.2.34}$$

We conclude that (2.29) holds providing we make the definitions

$$\bar{w}^i = abw^i, \tag{T.2.35}$$

$$\xi_1^i = ax_1^i, \quad \xi_2^i = bx_2^i. \tag{T.2.36}$$

Exercises

T.2.1. The purpose of this exercise is to study how the accuracy of a cubature formula depends on the size of the integration domain and the analytic properties of the function being integrated. For simplicity, we will consider the case (2.29), cubature on a rectangle.

Suppose that g has a Taylor expansion of the form

$$g(\xi) = \sum_{j_1,j_2} g_{j_1,j_2}\xi_1^{j_1}\xi_2^{j_2}. \tag{T.2.37}$$

Rearrange this expansion into one in homogenous polynomials by writing

$$g(\xi) = \sum_{\ell} P_\ell(\xi) \tag{T.2.38}$$

where

$$P_\ell(\xi) = \sum_{j_1+j_2=\ell} g_{j_1,j_2}\xi_1^{j_1}\xi_2^{j_2}. \tag{T.2.39}$$

Since we will be employing cubature formulas that are exact for polynomials through degree d, let use rewrite (2.38) in the form

$$g(\xi) = \sum_{\ell=0}^{d} P_\ell(\xi) + \Delta(\xi) \tag{T.2.40}$$

where

$$\Delta(\xi) = \sum_{\ell=d+1}^{\infty} P_\ell(\xi) = \sum_{\ell=d+1}^{\infty}\sum_{j_1+j_2=\ell} g_{j_1,j_2}\xi_1^{j_1}\xi_2^{j_2}. \tag{T.2.41}$$

In a moment, we will treat Δ as an error term. First, assuming suitable analyticity for g, use the Cauchy bound (33.2.18) on Taylor coefficients to show that, for $\xi \in R(a,b)$, Δ has the bound

$$|\Delta(\xi)| \le \sum_{\ell=d+1}^{\infty}\sum_{j_1+j_2=\ell} |g_{j_1,j_2}||\xi_1^{j_1}||\xi_2^{j_2}| \le L \tag{T.2.42}$$

where

$$L = K\sum_{\ell=d+1}^{\infty}\sum_{j_1+j_2=\ell} (a/R_1')^{j_1}(b/R_2')^{j_2}. \tag{T.2.43}$$

Verify that the series for L converges, when $a < R_1'$ and $b < R_2'$, by showing that there is the relation

$$\begin{aligned}\sum_{\ell=d+1}^{\infty}\sum_{j_1+j_2=\ell} (a/R_1')^{j_1}(b/R_2')^{j_2} \;&\le\; \sum_{\ell=0}^{\infty}\sum_{j_1+j_2=\ell} (a/R_1')^{j_1}(b/R_2')^{j_2} = \sum_{j_1,j_2}(a/R_1')^{j_1}(b/R_2')^{j_2} \\ &=\; [1/(1-a/R_1')][1/(1-b/R_2')].\end{aligned} \tag{T.2.44}$$

Therefore, L is well defined.

Next, from (2.40), verify the relations

$$\int_{R(a,b)} d^2\xi\ g(\xi) = \int_{R(a,b)} d^2\xi\ \sum_{\ell=0}^{d} P_\ell(\xi) + \int_{R(a,b)} d^2\xi\ \Delta(\xi), \tag{T.2.45}$$

$$\sum_{i=1}^{k} \bar{w}^i g(\xi^i) = \sum_{i=1}^{k} \bar{w}^i \sum_{\ell=0}^{d} P_\ell(\xi^i) + \sum_{i=1}^{k} \bar{w}^i \Delta(\xi^i). \tag{T.2.46}$$

Show that, by the construction of the sampling points ξ^i and the weights $\bar{w}^i$, there must be the relation

$$\int_{R(a,b)} d^2\xi\ \sum_{\ell=0}^{d} P_\ell(\xi) = \sum_{i=1}^{k} \bar{w}^i \sum_{\ell=0}^{d} P_\ell(\xi^i). \tag{T.2.47}$$

Then subtract (2.46) from (2.45) to show that

$$\int_{R(a,b)} d^2\xi\ g(\xi) - \sum_{i=1}^{k} \bar{w}^i g(\xi^i) = \int_{R(a,b)} d^2\xi\ \Delta(\xi) - \sum_{i=1}^{k} \bar{w}^i \Delta(\xi^i). \tag{T.2.48}$$

Consequently, verify that there is the inequality

$$|\int_{R(a,b)} d^2\xi\ g(\xi) - \sum_{i=1}^{k} \bar{w}^i g(\xi^i)| \le |\int_{R(a,b)} d^2\xi\ \Delta(\xi)| + |\sum_{i=1}^{k} \bar{w}^i \Delta(\xi^i)|. \tag{T.2.49}$$

To continue, verify the bounds

$$|\int_{R(a,b)} d^2\xi\ \Delta(\xi)| \le 4abL, \tag{T.2.50}$$

$$|\sum_{i=1}^{k} \bar{w}^i \Delta(\xi^i)| \le 4abL. \tag{T.2.51}$$

Thus, show that there is the final inequality

$$|\int_{R(a,b)} d^2\xi\ g(\xi) - \sum_{i=1}^{k} \bar{w}^i g(\xi^i)| \le 8abL. \tag{T.2.52}$$

Your challenge is to determine how the error term L depends on the dimensions of the rectangle $R(a,b)$. To this end suppose a and b are scaled by a common factor of σ,

$$a(\sigma) = \sigma a_1, \quad b(\sigma) = \sigma b_1 \tag{T.2.53}$$

so that $R(a,b)$ is what we may call the original rectangle $R(a_1,b_1)$ when $\sigma = 1$, and $R(a,b)$ becomes ever smaller as $\sigma \to 0$.

Based on (2.43), define $L(\sigma)$ by writing

$$L(\sigma) = K \sum_{\ell=d+1}^{\infty} \sum_{j_1+j_2=\ell} (\sigma a_1/R_1')^{j_1} (\sigma b_1/R_2')^{j_2}. \tag{T.2.54}$$

Show that

$$\begin{aligned} L(\sigma) &= \sigma^{d+1}K\sum_{\ell=d+1}^{\infty}\sigma^{\ell-d-1}\sum_{j_1+j_2=\ell}(a_1/R_1')^{j_1}(b_1/R_2')^{j_2} \\ &= \sigma^{d+1}K' + O(\sigma^{d+2}) \end{aligned} \tag{T.2.55}$$

where

$$K' = K\sum_{j_1+j_2=d+1}(a_1/R_1')^{j_1}(b_1/R_2')^{j_2}. \tag{T.2.56}$$

Insert (2.55) into (2.52) to obtain the inequality

$$|\int_{R(a,b)} d^2\xi\ g(\xi) - \sum_{i=1}^{k}\bar{w}^i g(\xi^i)| \le 8\sigma^2 a_1 b_1 L(\sigma) = \sigma^{d+3}8a_1b_1K' + O(\sigma^{d+4}). \tag{T.2.57}$$

We expect that each of the two terms on the left side of (2.57) scales as σ^2. You have shown that their difference, the error, scales as σ^{d+3}. Therefore, the *relative* error scales as σ^{d+1}.

T.2.2. Review Exercise 2.1. The purpose of this exercise is to find a more refined error bound for the specific case of the cubature formula ${}^*C^2$:5-1 by exploiting the relations (2.16) through (2.19). Define two linear functionals I and Q by the rules

$$I[g] = \int_{R(a,b)} d^2\xi\ g(\xi), \tag{T.2.58}$$

$$Q[g] = \sum_{i=1}^{5}\bar{w}^i g(\xi^i). \tag{T.2.59}$$

Show, when ${}^*C^2$:5-1 is used in (2.35) and (2.36), that

$$Q[P_{j_1,j_2}] = I[P_{j_1,j_2}] \tag{T.2.60}$$

for all P_{j_1,j_2} having degree less than 6, and also for all P_{j_1,j_2} having degree 7.

Monomials of degree 6 need to be treated separately. With reference to (2.16) through (2.19), define constants $\lambda_{6,0}$ etc. by the rules

$$\lambda_{6,0} = .0914\cdots, \tag{T.2.61}$$

$$\lambda_{2,4} = .1185\cdots, \tag{T.2.62}$$

$$\lambda_{0,6} = .0271\cdots. \tag{T.2.63}$$

Show that, when ${}^*C^2$:5-1 is used in (2.35) and (2.36), there are the results

$$Q[P_{6,0}] = I[P_{6,0}] - a^7b\lambda_{6,0}, \tag{T.2.64}$$

$$Q[P_{2,4}] = I[P_{2,4}] - a^3b^5\lambda_{2,4}, \tag{T.2.65}$$

$$Q[P_{0,6}] = I[P_{0,6}] + ab^7\lambda_{0,6}, \tag{T.2.66}$$

and that (2.60) holds for all the remaining monomials of degree 6.

Using the machinery just developed show that, when ${}^*C^2$:5-1 is used in (2.35) and (2.36), there is the result

$$\int_{R(a,b)} d^2\xi \; g(\xi) \;=\; \sum_{i=1}^{5} \bar{w}^i g(\xi^i) + ab[\lambda_{6,0}g_{6,0}a^6 + \lambda_{2,4}g_{2,4}a^2b^4 - \lambda_{0,6}g_{0,6}b^6] + O(\sigma^{10}). \tag{T.2.67}$$

Note that

$$g_{6,0} = (1/6!)g^{[6,0]}(0,0), \;\; g_{2,4} = (1/2!)(1/4!)g^{[2,4]}(0,0), \;\; g_{0,6} = (1/6!)g^{[0,6]}(0,0). \tag{T.2.68}$$

Show that (2.67) can also be written in the form

$$\int_{R(a,b)} d^2\xi \; g(\xi) \;=\; \sum_{i=1}^{5} \bar{w}^i g(\xi^i) + \sigma^8 a_1 b_1[\lambda_{6,0}g_{6,0}a_1^6 + \lambda_{2,4}g_{2,4}a_1^2b_1^4 - \lambda_{0,6}g_{0,6}b_1^6] + O(\sigma^{10}). \tag{T.2.69}$$

Therefore, for the case where ${}^*C^2$:5-1 is used in (2.35) and (2.36), you have found an exact result for the $O(\sigma^{d+3})$ term in (2.57) and have shown that the $O(\sigma^{d+4})$ term, in fact, vanishes.

Examination of (2.67) and (2.68) indicates that there is still some freedom left in the choice of orientation of the sampling point scheme and the aspect ratio of the rectangle $R(a,b)$. In some cases it may be possible to minimize the leading error term in (2.67) by exploiting this freedom. Suppose that something is known about the relative sizes of the terms $g_{6,0}$, $g_{4,2}$, $g_{2,4}$, and $g_{0,6}$. If, for example, $g_{4,2}$ is much smaller than $g_{2,4}$, then it might be advantageous to rotate the sampling points shown in Figure 2.1 by 90° so that the cubature formula error no longer involves $g_{2,4}$ but instead involves $g_{4,2}$. With regard to the aspect ratio of $R(a,b)$, in the case that (2.67) is employed and assuming that $g_{6,0}$ and $g_{0,6}$ are comparable, it might be advantageous to use rectangles for which $a < b$ since $\lambda_{6,0} > \lambda_{0,6}$. Obviously, when contemplating this strategy, attention should also be paid to the size of the $\lambda_{2,4}g_{2,4}a^2b^4$ error term.

Appendix U

Rotational Classification and Properties of Polynomials and Analytic/Polynomial Vector Fields

U.1 Introduction

Suppose $\boldsymbol{A}(\boldsymbol{r})$ is an analytic vector field in three dimensions. That is, suppose there are three component functions $A_x(\boldsymbol{r})$, $A_y(\boldsymbol{r})$, and $A_z(\boldsymbol{r})$, all of which are analytic in some common domain in the variables x, y, and z. Without loss of generality, we may take this domain to be centered on the origin. Doing so brings us to the notationally easier problem of studying polynomial vector fields, vector fields whose components are polynomials in the variables x, y, and z. In this appendix we will study how to use $SO(3)$, the rotation group in 3 dimensions, as a tool for labeling/classifying both such polynomials and such polynomial vector fields. We will also study some of their properties.

U.2 Polynomials and Spherical Polynomials

U.2.1 Polynomials

The first step in studying multi-variable polynomials is to decompose them into homogeneous polynomials. According to (7.3.40) the number of monomials of degree n in $d = 3$ variables is given by $N(n, 3)$. And, according to (7.10.17), the total number of monomials in $d = 3$ variables having degrees 0 through n is given by $S_0(n, 3)$. Table 2.1 below shows values of $N(n, 3)$ and $S_0(n, 3)$ for various values of n. Also shown are the quantities $3N(n, 3)$ and $3S_0(n, 3)$. The quantity $3N(n, 3)$ is the number of parameters required to specify 3 homogeneous polynomials of degree n in $d = 3$ variables. And the quantity $3S_0(n, 3)$ is the number of parameters required to specify a $d = 3$ dimensional vector field in $d = 3$ variables through terms of degree n. Thus, for example, to specify a 3-dimensional vector field through terms of degree $n = 4$ requires $3S_0(4, 3) = 105$ parameters. Finally, the table displays $S_B(n)$, the number of parameters required to specify a source-free magnetic field through terms of degree n. See (2.7). Thus, for example, to specify a source-free magnetic field through terms of degree $n = 4$ requires requires $S_B(4) = 35$ parameters. Note that the requirement that the field be source free, namely divergence and curl free, reduces the parameter count substantially even for modest values of n.

Table U.2.1: $N(n,3)$, $S_0(n,3)$, $3N(n,3)$, $3S_0(n,3)$, and $S_B(n)$ as functions of n.

n	$N(n,3)$	$S_0(n,3)$	$3N(n,3)$	$3S_0(n,3)$	$S_B(n)$
0	1	1	3	3	3
1	3	4	9	12	8
2	6	10	18	30	15
3	10	20	30	60	24
4	15	35	45	105	35
5	21	56	63	168	48
6	28	84	84	252	63
7	36	120	108	360	80
8	45	165	135	495	99

U.2.2 Spherical Polar Coordinates and Harmonic Polynomials

Introduce spherical polar coordinates in the usual way as in Section 15.2.2:

$$r^2 = x^2 + y^2 + z^2, \tag{U.2.1}$$

$$x = r\sin(\theta)\cos(\phi), \tag{U.2.2}$$

$$y = r\sin(\theta)\sin(\phi), \tag{U.2.3}$$

$$z = r\cos\theta. \tag{U.2.4}$$

Let $Y_\ell^m(\theta,\phi)$ denote the usual *spherical* harmonics,

$$\begin{aligned} Y_\ell^m(\theta,\phi) &= \{[(2\ell+1)(\ell-m)!]/[4\pi(\ell+m)!]\}^{1/2} P_\ell^m(\cos\theta)\exp(im\phi) \\ &\quad \text{with } -\ell \le m \le \ell. \end{aligned} \tag{U.2.5}$$

Here the P_ℓ^m are the usual associated Legendre functions. Consider the functions

$$H_\ell^m(\boldsymbol{r}) = r^\ell Y_\ell^m(\theta,\phi). \tag{U.2.6}$$

They are homogeneous polynomials of degree ℓ in the variables x, y, and z. They are also harmonic functions, and are variously called *harmonic polynomials* or *solid* harmonics. For a given ℓ there are $2\ell+1$ such polynomials as m ranges over $-\ell \le m \le \ell$.

At this point we are prepared to compute $S_B(n)$. Evidently a source-free magnetic field homogeneous of degree ℓ results from the gradient of a harmonic polynomial of degree $\ell+1$, and there are $2(\ell+1)+1 = 2\ell+3$ such harmonic polynomials. Therefore we have the result

$$S_B(n) = \sum_{\ell=0}^{n}(2\ell+3) = 3\sum_{\ell=0}^{n}1 + 2\sum_{\ell=0}^{n}\ell = 3(n+1)+2(n/2)(n+1) = (n+1)(n+3). \tag{U.2.7}$$

U.2.3 Examples of Harmonic Polynomials and Missing Homogeneous Polynomials

Continuing with the discussion of harmonic polynomials we find, for example, the results

$$H_0^0(\boldsymbol{r}) = 1/\sqrt{4\pi}; \tag{U.2.8}$$

$$\begin{aligned}
H_1^1(\boldsymbol{r}) &= \sqrt{3/(4\pi)}(-1/\sqrt{2})(x+iy) = -\sqrt{3/(8\pi)}(x+iy),\\
H_1^0(\boldsymbol{r}) &= \sqrt{3/(4\pi)}z,\\
H_1^{-1}(\boldsymbol{r}) &= \sqrt{3/(4\pi)}(1/\sqrt{2})(x-iy) = \sqrt{3/(8\pi)}(x-iy);
\end{aligned} \tag{U.2.9}$$

$$\begin{aligned}
H_2^2(\boldsymbol{r}) &= \sqrt{15/(32\pi)}(x+iy)^2,\\
H_2^1(\boldsymbol{r}) &= -\sqrt{15/(8\pi)}(x+iy)z,\\
H_2^0(\boldsymbol{r}) &= \sqrt{5/(16\pi)}(2z^2-x^2-y^2),\\
H_2^{-1}(\boldsymbol{r}) &= \sqrt{15/(8\pi)}(x-iy)z,\\
H_2^{-2}(\boldsymbol{r}) &= \sqrt{15/(32\pi)}(x-iy)^2.
\end{aligned} \tag{U.2.10}$$

Note that there is one function for the case $\ell = 0$, three functions for the case $\ell = 1$, and five functions in the case $\ell = 2$. Comparison of this function count with the first thee lines of Table 2.1 shows that all the homogeneous monomials of degrees 0 and 1 have been accounted for, but one homogenous polynomial of degree 2 is missing. This missing polynomial is evidently proportional to $r^2 = x^2 + y^2 + z^2$, and may be taken to be $r^2 H_0^0(\boldsymbol{r})$.[1]

What about the case $n = 3$? There are the polynomials $H_3^m(\boldsymbol{r})$, and there are $2\ell + 1 = 7$ such polynomials when $\ell = 3$. But from Table 2.1 we see that there should be, in total, ten polynomials when $n = 3$. What are the remaining three? The remaining three third-degree polynomials can be taken to be the polynomials $r^2 H_1^m(\boldsymbol{r})$.

U.2.4 Spherical Polynomials

The general picture should now be clear. Form the functions $S_{n\ell}^m(\boldsymbol{r})$, which we will call *spherical polynomials*, by the rule

$$S_{n\ell}^m(\boldsymbol{r}) = r^n Y_\ell^m(\theta,\phi) \text{ with } \ell = n, n-2, \cdots, 0 \text{ for } n \text{ even}, \tag{U.2.11}$$

$$S_{n\ell}^m(\boldsymbol{r}) = r^n Y_\ell^m(\theta,\phi) \text{ with } \ell = n, n-2, \cdots, 1 \text{ for } n \text{ odd}. \tag{U.2.12}$$

So doing produces polynomials of degree n, and these polynomials form a basis for the set of all polynomials of degree n. But still more can be said. The functions Y_ℓ^m have well-defined transformation properties under rotations, and r is unchanged by rotations. It follows that the $S_{n\ell}^m(\boldsymbol{r})$ have the same transformation properties as the Y_ℓ^m.

Listed below, for possible future use, are the spherical polynomials for the cases $n = 0$, $n = 1$, and $n = 2$:

$$S_{00}^0(\boldsymbol{r}) = 1/\sqrt{4\pi}; \tag{U.2.13}$$

[1] Note that quantities of the form $r^{2k} = (x^2 + y^2 + x^2)^k$ are *polynomials* in the variables x, y, and z.

$$\begin{aligned}
&S_{11}^{1}(\boldsymbol{r}) = -\sqrt{3/(8\pi)}(x+iy),\\
&S_{11}^{0}(\boldsymbol{r}) = \sqrt{3/(4\pi)}z,\\
&S_{11}^{-1}(\boldsymbol{r}) = \sqrt{3/(8\pi)}(x-iy);
\end{aligned} \tag{U.2.14}$$

$$S_{20}^{0}(\boldsymbol{r}) = 1/\sqrt{4\pi}(x^2+y^2+z^2); \tag{U.2.15}$$

$$\begin{aligned}
&S_{22}^{2}(\boldsymbol{r}) = \sqrt{15/(32\pi)}(x+iy)^2,\\
&S_{22}^{1}(\boldsymbol{r}) = -\sqrt{15/(8\pi)}(x+iy)z,\\
&S_{22}^{0}(\boldsymbol{r}) = \sqrt{5/(16\pi)}(2z^2-x^2-y^2),\\
&S_{22}^{-1}(\boldsymbol{r}) = \sqrt{15/(8\pi)}(x-iy)z,\\
&S_{22}^{-2}(\boldsymbol{r}) = \sqrt{15/(32\pi)}(x-iy)^2.
\end{aligned} \tag{U.2.16}$$

U.3 Analytic/Polynomial Vector Fields and Spherical Polynomial Vector Fields

With the $S_{n\ell}^{m}(\boldsymbol{r})$ in hand, we next turn to the problem of classifying/labeling all vector fields whose components are polynomials in x, y, and z. Our construction will be analogous to that for vector spherical harmonics.

U.3.1 Vector Spherical Harmonics

Define a spherical basis $\boldsymbol{e}_{\pm 1}$, $\boldsymbol{e}_0$ by the rule

$$\begin{aligned}
&\boldsymbol{e}_{+1} = -(1/\sqrt{2})(\boldsymbol{e}_x + i\boldsymbol{e}_y),\\
&\boldsymbol{e}_0 = \boldsymbol{e}_z,\\
&\boldsymbol{e}_{-1} = (1/\sqrt{2})(\boldsymbol{e}_x - i\boldsymbol{e}_y).
\end{aligned} \tag{U.3.1}$$

Note the resemblance between (3.1) and (2.9) and (2.14).[2] Indeed, suppose we define three functions $r_m(\boldsymbol{r})$ by the rules

$$\begin{aligned}
&r_{+1}(\boldsymbol{r}) = \boldsymbol{r}\cdot\boldsymbol{e}_{+1} = -(1/\sqrt{2})(x+iy),\\
&r_0(\boldsymbol{r}) = \boldsymbol{r}\cdot\boldsymbol{e}_0 = z,\\
&r_{-1}(\boldsymbol{r}) = \boldsymbol{r}\cdot\boldsymbol{e}_{-1} = (1/\sqrt{2})(x-iy).
\end{aligned} \tag{U.3.2}$$

Then (2.13) can be rewritten in the form

$$S_{11}^{m}(\boldsymbol{r}) = \sqrt{3/(4\pi)}\; r_m(\boldsymbol{r}) = \sqrt{3/(4\pi)}\; \boldsymbol{r}\cdot\boldsymbol{e}_m. \tag{U.3.3}$$

[2] Note also that the basis (3.1) differs slightly from that of Exercise 3.7.22, which was selected to make the $so(3)$ structure constants real.

Moreover, we have the relation

$$\begin{aligned} r_{-1}(\boldsymbol{r})\boldsymbol{e}_{+1} + r_{+1}(\boldsymbol{r})\boldsymbol{e}_{-1} &= -(1/2)[(x-iy)(\boldsymbol{e}_x + i\boldsymbol{e}_y) + (x+iy)(\boldsymbol{e}_x - i\boldsymbol{e}_y)] \\ &= -x\boldsymbol{e}_x - y\boldsymbol{e}_y. \end{aligned} \tag{U.3.4}$$

It follows that there is the relation

$$-r_{-1}(\boldsymbol{r})\boldsymbol{e}_{+1} + r_0(\boldsymbol{r})\boldsymbol{e}_0 - r_{+1}(\boldsymbol{r})\boldsymbol{e}_{-1} = x\boldsymbol{e}_x + y\boldsymbol{e}_y + z\boldsymbol{e}_z = \boldsymbol{r}. \tag{U.3.5}$$

But, we have digressed. The *vector spherical harmonics* $\boldsymbol{Y}_{\ell J}^M(\theta,\phi)$ are defined by the rules

$$\boldsymbol{Y}_{\ell J}^M(\theta,\phi) = \sum_{m_1,m_2} C_{m_1 m_2 M}^{\ell 1 J} Y_\ell^{m_1}(\theta,\phi)\boldsymbol{e}_{m_2}. \tag{U.3.6}$$

Here the $C_{m_1 m_2 M}^{\ell 1 J}$ denote the *Clebsch-Gordan* coefficients that couple the angular momenta ℓ and 1 to produce angular momentum J.[3] In particular, there are *range* rules:

$$\text{when } \ell = 0, \text{ then } J = 1; \tag{U.3.7}$$

$$\text{when } \ell > 0, \text{ then } J \text{ can have the values } J = \ell-1, \ell, \ell+1. \tag{U.3.8}$$

The particular Clebsch-Gordan coefficients needed for our purposes are given by the relations

$$C_{M-1,1,M}^{\ell,1,\ell+1} = \sqrt{(\ell+M)(\ell+M+1)/[(2\ell+1)(2\ell+2)]}, \tag{U.3.9}$$

$$C_{M,0,M}^{\ell,1,\ell+1} = \sqrt{(\ell-M+1)(\ell+M+1)/[(2\ell+1)(\ell+1)]}, \tag{U.3.10}$$

$$C_{M+1,-1,M}^{\ell,1,\ell+1} = \sqrt{(\ell-M)(\ell-M+1)/[(2\ell+1)(2\ell+2)]}; \tag{U.3.11}$$

$$C_{M-1,1,M}^{\ell,1,\ell} = -\sqrt{(\ell+M)(\ell-M+1)/[2\ell(\ell+1)]}, \tag{U.3.12}$$

$$C_{M,0,M}^{\ell,1,\ell} = M/\sqrt{\ell(\ell+1)}, \tag{U.3.13}$$

$$C_{M+1,-1,M}^{\ell,1,\ell} = \sqrt{(\ell-M)(\ell+M+1)/[2\ell(\ell+1)]}; \tag{U.3.14}$$

$$C_{M-1,1,M}^{\ell,1,\ell-1} = \sqrt{(\ell-M)(\ell-M+1)/[2\ell(2\ell+1)]}, \tag{U.3.15}$$

$$C_{M,0,M}^{\ell,1,\ell-1} = -\sqrt{(\ell-M)(\ell+M)/[\ell(2\ell+1)]}, \tag{U.3.16}$$

$$C_{M+1,-1,M}^{\ell,1,\ell-1} = \sqrt{(\ell+M+1)(\ell+M)/[2\ell(2\ell+1)]}. \tag{U.3.17}$$

[3] Note that we write the subscripts on the vector spherical harmonics and elsewhere in the order ℓJ, the same order in which they appear in the Clebsch-Gordan coefficients. Thus, the last lower index and the upper index are *paired* and obey the rule $-J \le M \le J$. Many authors employ the opposite order, namely $J\ell$. We also remark that the Clebsch-Gordan coefficients are also sometimes called *Wigner* or vector-addition coefficients. Finally, we use the more compact notation $C_{m_1 m_2 M}^{\ell 1 J}$ for what some authors write as $C(\ell 1 J; m_1 m_2 M)$.

U.3.2 Spherical Polynomial Vector Fields

In a corresponding manner, we define *spherical polynomial vector fields* $\boldsymbol{S}_{n\ell J}^M(\boldsymbol{r})$ by the rule

$$\begin{aligned}\boldsymbol{S}_{n\ell J}^M(\boldsymbol{r}) &= \sum_{m_1,m_2} C_{m_1 m_2 M}^{\ell 1 J} S_{n\ell}^{m_1}(\boldsymbol{r})\boldsymbol{e}_{m_2} \\ &= r^n \sum_{m_1,m_2} C_{m_1 m_2 M}^{\ell 1 J} Y_\ell^{m_1}(\theta,\phi)\boldsymbol{e}_{m2} = r^n \mathbf{Y}_{\ell J}^M(\theta,\phi). \qquad \text{(U.3.18)}\end{aligned}$$

Note that by construction the components of $\boldsymbol{S}_{n\ell J}^M(\boldsymbol{r})$ are polynomial (analytic) functions of the variables x, y, and z.

For convenience, Table 3.1 lists the allowed values of the triplets $n\ell J$ in accord with the relations (2.10), (2.11), (3.7), and (3.8). And, of course, M lies in the range $-J \leq M \leq J$.

Table U.3.1: Allowed values of $n\ell J$

n	ℓ	J
0	0	1
1	1	0
1	1	1
1	1	2
2	0	1
2	2	1
2	2	2
2	2	3
3	1	0
3	1	1

3	3	2
3	3	3
3	3	4
·	·	·
·	·	·

U.3.3 Examples of and Counting Spherical Polynomial Vector Fields

Let us work out a first few examples. The simplest are those for $n = 0$. In this case we must have $\ell = 0$, see (2.10), and $J = 1$, see (3.7). For the $\boldsymbol{S}_{001}^M$ we find from (3.18) the results

$$\boldsymbol{S}_{001}^M(\boldsymbol{r}) = C_{0MM}^{011} S_{00}^0(\boldsymbol{r})\boldsymbol{e}_M. \qquad \text{(U.3.19)}$$

From (3.9) through (3.11) we see that all the C_{0MM}^{011} have value 1, and $S_{00}^0(\boldsymbol{r})$ is given by (2.12). Therefore, there is the final result

$$\boldsymbol{S}_{001}^M(\boldsymbol{r}) = (1/\sqrt{4\pi})\boldsymbol{e}_M. \qquad \text{(U.3.20)}$$

Note that M can take the three values $-1, 0, +1$ corresponding to the fact that a constant vector field has 3 constant components.

The next simplest case is $n = 1$. Then we must have $\ell = 1$, see (2.11), and there are the possibilities $J = 0, 1, 2$. See (3.8). For the case $J = 0$ we find from (3.18) the result

$$\boldsymbol{S}^0_{110}(\boldsymbol{r}) = C^{110}_{-1,1,0} S^{-1}_{11}(\boldsymbol{r})\boldsymbol{e}_{+1} + \ C^{110}_{000} S^0_{11}(\boldsymbol{r})\boldsymbol{e}_0 + \ C^{110}_{1,-1,0} S^1_{11}(\boldsymbol{r})\boldsymbol{e}_{-1}. \tag{U.3.21}$$

From (3.15) through (3.17) we see that the required Clebsch-Gordan coefficients have the values

$$C^{110}_{-1,1,0} = \sqrt{1/3}, \tag{U.3.22}$$

$$C^{110}_{000} = -\sqrt{1/3}, \tag{U.3.23}$$

$$C^{110}_{1,-1,0} = \sqrt{1/3}. \tag{U.3.24}$$

Also, the required $S^m_{11}(\boldsymbol{r})$ can be written in the form (3.3). Therefore, (3.21) can be rewritten in the final form

$$\boldsymbol{S}^0_{110}(\boldsymbol{r}) = [\sqrt{1/3}][\sqrt{3/(4\pi)}][r_{-1}(\boldsymbol{r})\boldsymbol{e}_{+1} - r_0(\boldsymbol{r})\boldsymbol{e}_0 + r_{+1}(\boldsymbol{r})\boldsymbol{e}_{-1}] = -\sqrt{1/(4\pi)}\ \boldsymbol{r}. \tag{U.3.25}$$

Here we have used (3.5).

For the case $J = 1$ we find from (3.18) and (3.3) the results

$$\boldsymbol{S}^M_{111}(\boldsymbol{r}) = \sum_{m_1,m_2} C^{111}_{m_1 m_2 M} S^{m_1}_{11}(\boldsymbol{r})\boldsymbol{e}_{m_2} = \sqrt{3/(4\pi)} \sum_{m_1,m_2} C^{111}_{m_1 m_2 M} r_{m_1}(\boldsymbol{r})\boldsymbol{e}_{m_2}. \tag{U.3.26}$$

It follows that

$$\boldsymbol{S}^1_{111}(\boldsymbol{r}) = [\sqrt{3/(4\pi)}][C^{111}_{011} r_0(\boldsymbol{r})\boldsymbol{e}_{+1} + C^{111}_{101} r_{+1}(\boldsymbol{r})\boldsymbol{e}_0], \tag{U.3.27}$$

$$\boldsymbol{S}^0_{111}(\boldsymbol{r}) = [\sqrt{3/(4\pi)}][C^{111}_{-1,1,0} r_{-1}(\boldsymbol{r})\boldsymbol{e}_{+1} + C^{111}_{000} r_0(\boldsymbol{r})\boldsymbol{e}_0 + C^{111}_{1,-1,0} r_{+1}(\boldsymbol{r})\boldsymbol{e}_{-1}], \tag{U.3.28}$$

$$\boldsymbol{S}^{-1}_{111}(\boldsymbol{r}) = [\sqrt{3/(4\pi)}][C^{111}_{-1,0,-1} r_{-1}(\boldsymbol{r})\boldsymbol{e}_0 + C^{111}_{0,-1,-1} r_0(\boldsymbol{r})\boldsymbol{e}_{-1}]. \tag{U.3.29}$$

In this case the relevant Clebsch-Gordan coefficients are given by the following relations:

$$C^{111}_{011} = -1/\sqrt{2}, \tag{U.3.30}$$

$$C^{111}_{101} = 1/\sqrt{2}, \tag{U.3.31}$$

see (3.12) and (3.13);

$$C^{111}_{-1,1,0} = -1/\sqrt{2}, \tag{U.3.32}$$

$$C^{111}_{000} = 0, \tag{U.3.33}$$

$$C^{111}_{1,-1,0} = 1/\sqrt{2}, \tag{U.3.34}$$

see (3.12) through (3.14);

$$C^{111}_{-1,0,-1} = -1/\sqrt{2}, \tag{U.3.35}$$

$$C^{111}_{0,-1,-1} = 1/\sqrt{2}, \tag{U.3.36}$$

see (3.13) and (3.14). Consequently, the relations (3.27) through (3.29) can be rewritten in the form

$$\boldsymbol{S}^{1}_{111}(\boldsymbol{r}) = [\sqrt{3/(8\pi)}][-r_0(\boldsymbol{r})\boldsymbol{e}_{+1} + r_{+1}(\boldsymbol{r})\boldsymbol{e}_0], \tag{U.3.37}$$

$$\boldsymbol{S}^{0}_{111}(\boldsymbol{r}) = [\sqrt{3/(8\pi)}][-r_{-1}(\boldsymbol{r})\boldsymbol{e}_{+1} + r_{+1}(\boldsymbol{r})\boldsymbol{e}_{-1}], \tag{U.3.38}$$

$$\boldsymbol{S}^{-1}_{111}(\boldsymbol{r}) = [\sqrt{3/(8\pi)}][-r_{-1}(\boldsymbol{r})\boldsymbol{e}_0 + r_0(\boldsymbol{r})\boldsymbol{e}_{-1}]. \tag{U.3.39}$$

After a little struggle, we recognize that the expressions appearing on the right sides of (3.37) through (3.39) can be written more compactly in terms of the vector cross product. Doing so, we find the neat result

$$\boldsymbol{S}^{M}_{111}(\boldsymbol{r}) = -i[\sqrt{3/(8\pi)}][\boldsymbol{r} \times \boldsymbol{e}_M]. \tag{U.3.40}$$

In retrospect, the cross-product result we have found should not be too surprising since we have, in effect, been combining two spin 1 objects to produce another spin 1 object, and that is just what the vector cross product operation does.

We also note, in view of (3.20), that there is the relation

$$\boldsymbol{S}^{M}_{111}(\boldsymbol{r}) = -i[\sqrt{3/2}][\boldsymbol{r} \times \boldsymbol{S}^{M}_{001}(\boldsymbol{r})]. \tag{U.3.41}$$

Finally, consider the case $J = 2$. Now, from (3.18) and (3.3), we find that

$$\boldsymbol{S}^{M}_{112}(\boldsymbol{r}) = \sum_{m_1,m_2} C^{112}_{m_1 m_2 M} S^{m_1}_{11}(\boldsymbol{r})\boldsymbol{e}_{m_2} = \sqrt{3/(4\pi)} \sum_{m_1,m_2} C^{112}_{m_1 m_2 M} r_{m_1}(\boldsymbol{r})\boldsymbol{e}_{m_2}. \tag{U.3.42}$$

It follows that

$$\boldsymbol{S}^{2}_{112}(\boldsymbol{r}) = [\sqrt{3/(4\pi)}][C^{112}_{112} r_1(\boldsymbol{r})\boldsymbol{e}_1], \tag{U.3.43}$$

$$\boldsymbol{S}^{1}_{112}(\boldsymbol{r}) = [\sqrt{3/(4\pi)}][C^{112}_{011} r_0(\boldsymbol{r})\boldsymbol{e}_1 + C^{112}_{101} r_1(\boldsymbol{r})\boldsymbol{e}_0], \tag{U.3.44}$$

$$\boldsymbol{S}^{0}_{112}(\boldsymbol{r}) = [\sqrt{3/(4\pi)}][C^{112}_{-1,1,0} r_{-1}(\boldsymbol{r})\boldsymbol{e}_1 + C^{112}_{000} r_0(\boldsymbol{r})\boldsymbol{e}_0 + C^{112}_{1,-1,0} r_1(\boldsymbol{r})\boldsymbol{e}_{-1}], \tag{U.3.45}$$

$$\boldsymbol{S}^{-1}_{112}(\boldsymbol{r}) = [\sqrt{3/(4\pi)}][C^{112}_{-1,0,-1} r_{-1}(\boldsymbol{r})\boldsymbol{e}_0 + C^{112}_{0,-1,-1} r_0(\boldsymbol{r})\boldsymbol{e}_{-1}], \tag{U.3.46}$$

$$\boldsymbol{S}^{-2}_{112}(\boldsymbol{r}) = [\sqrt{3/(4\pi)}][C^{112}_{-1,-1,-2} r_{-1}(\boldsymbol{r})\boldsymbol{e}_{-1}]. \tag{U.3.47}$$

To complete this calculation we need the Clebsch-Gordan coefficient values listed below:

$$C^{112}_{112} = 1, \tag{U.3.48}$$

see (3.9);

$$C^{112}_{011} = 1/\sqrt{2}, \tag{U.3.49}$$

$$C^{112}_{101} = 1/\sqrt{2}, \tag{U.3.50}$$

see (3.9) and (3.10);

$$C^{112}_{-1,1,0} = 1/\sqrt{6}, \tag{U.3.51}$$

$$C^{112}_{000} = \sqrt{2/3} = 2/\sqrt{6}, \tag{U.3.52}$$

$$C^{112}_{1,-1,0} = 1/\sqrt{6}, \tag{U.3.53}$$

see (3.9) through (3.11);

$$C^{112}_{-1,0,-1} = 1/\sqrt{2}, \tag{U.3.54}$$

$$C^{112}_{0,-1,-1} = 1/\sqrt{2}, \tag{U.3.55}$$

see (3.10) and (3.11);

$$C^{112}_{-1,-,1-2} = 1, \tag{U.3.56}$$

see (3.11)).

Putting everything together gives the final results

$$\begin{aligned} \boldsymbol{S}^2_{112}(\boldsymbol{r}) &= [\sqrt{3/(4\pi)}][C^{112}_{112} r_1(\boldsymbol{r})\boldsymbol{e}_1] = [\sqrt{3/(4\pi)}] r_1(\boldsymbol{r})\boldsymbol{e}_1 \\ &= [\sqrt{3/(16\pi)}](x+iy)(\boldsymbol{e}_x + i\boldsymbol{e}_y), \end{aligned} \tag{U.3.57}$$

$$\begin{aligned} \boldsymbol{S}^1_{112}(\boldsymbol{r}) &= [\sqrt{3/(4\pi)}][C^{112}_{011} r_0(\boldsymbol{r})\boldsymbol{e}_1 + C^{112}_{101} r_1(\boldsymbol{r})\boldsymbol{e}_0] \\ &= [\sqrt{3/(8\pi)}][r_0(\boldsymbol{r})\boldsymbol{e}_1 + r_1(\boldsymbol{r})\boldsymbol{e}_0] \\ &= -[\sqrt{3/(16)\pi)}][z(\boldsymbol{e}_x + i\boldsymbol{e}_y) + (x+iy)\boldsymbol{e}_z], \end{aligned} \tag{U.3.58}$$

$$\begin{aligned} \boldsymbol{S}^0_{112}(\boldsymbol{r}) &= [\sqrt{3/(4\pi)}][C^{112}_{-1,1,0} r_{-1}(\boldsymbol{r})\boldsymbol{e}_1 + C^{112}_{000} r_0(\boldsymbol{r})\boldsymbol{e}_0 + C^{112}_{1,-1,0} r_1(\boldsymbol{r})\boldsymbol{e}_{-1}] \\ &= [\sqrt{1/(8\pi)}][r_{-1}(\boldsymbol{r})\boldsymbol{e}_1 + 2r_0(\boldsymbol{r})\boldsymbol{e}_0 + r_1(\boldsymbol{r})\boldsymbol{e}_{-1}] \\ &= [\sqrt{1/(8\pi)}](-x\boldsymbol{e}_x - y\boldsymbol{e}_y + 2z\boldsymbol{e}_z), \end{aligned} \tag{U.3.59}$$

$$\begin{aligned} \boldsymbol{S}^{-1}_{112}(\boldsymbol{r}) &= [\sqrt{3/(4\pi)}][C^{112}_{-1,0,-1} r_{-1}(\boldsymbol{r})\boldsymbol{e}_0 + C^{112}_{0,-1,-1} r_0(\boldsymbol{r})\boldsymbol{e}_{-1}] \\ &= [\sqrt{3/(8\pi)}][r_{-1}(\boldsymbol{r})\boldsymbol{e}_0 + r_0(\boldsymbol{r})\boldsymbol{e}_{-1}] \\ &= [\sqrt{3/(16\pi)}][(x-iy)\boldsymbol{e}_z + z(\boldsymbol{e}_x - i\boldsymbol{e}_y)], \end{aligned} \tag{U.3.60}$$

$$\begin{aligned} \boldsymbol{S}^{-2}_{112}(\boldsymbol{r}) &= [\sqrt{3/(4\pi)}][C^{112}_{-1,-1,-2} r_{-1}(\boldsymbol{r})\boldsymbol{e}_{-1}] = [\sqrt{3/(4\pi)}] r_{-1}(\boldsymbol{r})\boldsymbol{e}_{-1} \\ &= [\sqrt{3/(16\pi)}](x-iy)(\boldsymbol{e}_x - i\boldsymbol{e}_y). \end{aligned} \tag{U.3.61}$$

Let us do a count of the $n = 1$ spherical polynomial vector fields we have found. Observe that, when considering all $n = 1$ cases, there are $1 + 3 + 5 = 9$ possibilities, which is to be expected: When $n = 1$, $N(1, 3) = 3$. See table 2.1. Moreover there are three components to be specified, and therefore there are $3N(1, 3) = 9$ parameters to be specified.

At this point the dubious reader may wonder at our counting calculations because complex numbers require two real numbers for their specification, and we appear to be working over the complex field. Should, therefore, all our counts be doubled? The answer is *no* because in our case there are implicit built-in constraints. Let * denote complex conjugation. Then, for the vectors $\boldsymbol{e}_m$, there are the conjugation relations

$$(\boldsymbol{e}_m)^* = (-1)^m \boldsymbol{e}_{-m}. \tag{U.3.62}$$

And for the functions Y_ℓ^m there are the conjugation relations

$$[Y_\ell^m(\theta,\phi)]^* = (-1)^m Y_l^{-m}(\theta,\phi). \tag{U.3.63}$$

Finally, since the Clebsch-Gordan coefficients are real and satisfy the relation

$$C^{j_1 j_2 j_3}_{m_1 m_2 m_3} = (-1)^{j_1+j_2-j_3} C^{j_1 j_2 j_3}_{-m_1,-m_2,-m_3}, \tag{U.3.64}$$

it follows from (3.18) and (3.62) through (3.64) that the $\boldsymbol{S}^M_{n\ell J}(\boldsymbol{r})$ satisfy the conjugation relations

$$[\boldsymbol{S}^M_{n\ell J}(\boldsymbol{r})]^* = (-1)^{\ell+J-M+1}\boldsymbol{S}^{-M}_{n\ell J}(\boldsymbol{r}). \tag{U.3.65}$$

U.4 Independence/Orthogonality/Integral Properties of Spherical Polynomials and Spherical Polynomial Vector Fields

The spherical polynomials $S^m_{n\ell}(\boldsymbol{r})$ and $S^{m'}_{n'\ell'}(\boldsymbol{r})$ are evidently linearly independent if their degrees n and n' differ. What can be said if $n = n'$? The spherical harmonics have the orthogonality properties

$$\int d\Omega\ [Y_\ell^m(\theta,\phi)]^* Y_{\ell'}^{m'}(\theta,\phi) = \delta_{\ell\ell'}\delta_{mm'}. \tag{U.4.1}$$

Here

$$\int d\Omega = \int_0^\pi \sin(\theta)d\theta \int_0^{2\pi} d\phi. \tag{U.4.2}$$

It follows from (2.9), (2.10), and (4.1) that the various $S^m_{n\ell}(\boldsymbol{r})$ are all linearly independent.

The spherical polynomial vector fields $\boldsymbol{S}^M_{n\ell J}(\boldsymbol{r})$ and $\boldsymbol{S}^{M'}_{n'\ell' J'}(\boldsymbol{r})$ are also evidently linearly independent if their degrees n and n' differ. What can be said if $n = n'$? The vector spherical harmonics have the orthogonality properties

$$\int d\Omega\ [\boldsymbol{Y}^M_{\ell J}(\theta,\phi)]^* \cdot \boldsymbol{Y}^{M'}_{\ell' J'}(\theta,\phi) = \delta_{\ell\ell'}\delta_{JJ'}\delta_{MM'}. \tag{U.4.3}$$

It follows from (3.18) and (4.3) that the various $\boldsymbol{S}^M_{n\ell J}(\boldsymbol{r})$ are all linearly independent.

U.5 Differential Properties of Spherical Polynomials and Spherical Polynomial Vector Fields

The purpose of the section is to list various effects of the differential operator ∇ when acting on spherical polynomials and spherical polynomial vector fields.

U.5.1 Gradient Action on Spherical Polynomials

We begin with the action of ∇ on spherical polynomials. Suppose $f(r)$ is any function of r, and suppose $\ell \geq 1$. Then it can be shown that

$$\begin{aligned}\nabla[f(r)Y_\ell^m(\theta,\phi)] &= \sqrt{\ell/(2\ell+1)}\{f'(r)+[(\ell+1)/r]f(r)\}\boldsymbol{Y}^m_{\ell-1,\ell}(\theta,\phi)\\ &\quad -\sqrt{(\ell+1)/(2\ell+1)}\{f'(r)-(\ell/r)f(r)\}\boldsymbol{Y}^m_{\ell+1,\ell}(\theta,\phi).\end{aligned} \tag{U.5.1}$$

For the case of the spherical polynomial functions $S^m_{n\ell}(\boldsymbol{r})$ we have

$$f(r)=r^n. \tag{U.5.2}$$

See (2.10) and (2.11). It follows (again supposing $\ell \geq 1$) that

$$\begin{aligned}\nabla S^m_{n\ell}(\boldsymbol{r}) &= \sqrt{\ell/(2\ell+1)}(n+\ell+1)\boldsymbol{S}^m_{n-1,\ell-1,\ell}(\boldsymbol{r})\\ &\quad -\sqrt{(\ell+1)/(2\ell+1)}(n-\ell)\boldsymbol{S}^m_{n-1,\ell+1,\ell}(\boldsymbol{r}).\end{aligned} \tag{U.5.3}$$

What about the special case $\ell = 0$? Then n must be even. So we write

$$n=2k. \tag{U.5.4}$$

Also we must have $m=0$. If $\ell=0$, we might imagine evaluating (5.3) with the first term omitted since it contains $\sqrt{\ell}$. Doing so gives the result

$$\nabla S^0_{2k,0}(\boldsymbol{r}) = -2k\boldsymbol{S}^0_{2k-1,1,0}(\boldsymbol{r}). \tag{U.5.5}$$

This result is, in fact, correct, and can be verified directly. See Exercise 6.11.

We close this subsection by observing that a special case of (5.3) is the relation

$$\nabla S^m_{nn}(\boldsymbol{r}) = \sqrt{n(2n+1)}\boldsymbol{S}^m_{n-1,n-1,n}(\boldsymbol{r}). \tag{U.5.6}$$

U.5.2 Divergence Action on Spherical Polynomial Vector Fields

We continue with the case of spherical polynomial vector fields. Suppose again that $f(r)$ is any function of r. Then (assuming $\ell \geq 1$) it can be shown that

$$\nabla\cdot[f(r)\boldsymbol{Y}^M_{\ell,J}(\theta,\phi)] = \sqrt{J/(2J+1)}\{f'(r)-[(J-1)/r]f(r)\}Y^M_J(\theta,\phi) \text{ when } J=\ell+1, \tag{U.5.7}$$

$$\nabla\cdot[f(r)\boldsymbol{Y}^M_{\ell,J}(\theta,\phi)] = 0 \text{ when } J=\ell, \tag{U.5.8}$$

$$\nabla\cdot[f(r)\boldsymbol{Y}^M_{\ell,J}(\theta,\phi)] = -\sqrt{(J+1)/(2J+1)}\{f'(r)+[(J+2)/r]f(r)\}Y^M_J(\theta,\phi) \text{ when } J=\ell-1. \tag{U.5.9}$$

For the case of the spherical polynomial vector fields $\boldsymbol{S}^M_{n,\ell,J}(\boldsymbol{r})$ the relation (5.2) again holds. It follows (again assuming $\ell \geq 1$) that

$$\nabla\cdot\boldsymbol{S}^M_{n,\ell,J}(\boldsymbol{r}) = \sqrt{J/(2J+1)}(n-J+1)S^M_{n-1,J}(\boldsymbol{r}) \text{ when } J=\ell+1, \tag{U.5.10}$$

$$\nabla \cdot \boldsymbol{S}^M_{n,\ell,J}(\boldsymbol{r}) = 0 \text{ when } J = \ell, \tag{U.5.11}$$

$$\nabla \cdot \boldsymbol{S}^M_{n,\ell,J}(\boldsymbol{r}) = -\sqrt{(J+1)/(2J+1)}(n+J+2)S^M_{n-1,J}(\boldsymbol{r}) \text{ when } J = \ell - 1. \tag{U.5.12}$$

What about the special case $\ell = 0$? Then we must have $J = 1$. Moreover n must be even so that (5.4) again holds. Evidently when $\ell = 0$ and $J = 1$ the conditions relating J and ℓ in (5.11) and (5.12) do not hold. However, the condition in (5.10) does hold and so we might speculate that (5.10) should be evaluated with $J = 1$ to give the result

$$\nabla \cdot \boldsymbol{S}^M_{2k,0,1}(\boldsymbol{r}) = (\sqrt{1/3})2kS^M_{2k-1,1}(\boldsymbol{r}). \tag{U.5.13}$$

This speculation is correct, and can be proved directly. See Exercise 6.13.

U.5.3 Curl Action on Spherical Polynomial Vector Fields

It can also be shown (assuming $\ell \geq 1$) that

$$\begin{aligned}\nabla \times [f(r)\boldsymbol{Y}^M_{\ell,J}(\theta,\phi)] &= i\sqrt{(J+1)/(2J+1)}\{f'(r) - [(J-1)/r]f(r)\}\boldsymbol{Y}^M_{J,J}(\theta,\phi)\\ &\quad \text{when } J = \ell + 1,\end{aligned} \tag{U.5.14}$$

$$\begin{aligned}\nabla \times [f(r)\boldsymbol{Y}^M_{\ell,J}(\theta,\phi)] &= i\sqrt{(J+1)/(2J+1)}\{f'(r) + [(J+1)/r]f(r)\}\boldsymbol{Y}^M_{J-1,J}(\theta,\phi)\\ &\quad +i\sqrt{J/(2J+1)}\{f'(r) - (J/r)f(r)\}\boldsymbol{Y}^M_{J+1,J}(\theta,\phi)\\ &\quad \text{when } J = \ell,\end{aligned} \tag{U.5.15}$$

$$\begin{aligned}\nabla \times [f(r)\boldsymbol{Y}^M_{\ell,J}(\theta,\phi)] &= i\sqrt{J/(2J+1)}\{f'(r) + [(J+2)/r]f(r)\}\boldsymbol{Y}^M_{J,J}(\theta,\phi)\\ &\quad \text{when } J = \ell - 1.\end{aligned} \tag{U.5.16}$$

For the case of the spherical polynomial vector fields $\boldsymbol{S}^M_{n,\ell J}(\boldsymbol{r})$ the relation (5.2) remains true. It follows (again assuming $\ell \geq 1$) that there are the relations:

$$\begin{aligned}&\nabla \times \boldsymbol{S}^M_{n,\ell,J}(\boldsymbol{r}) = i\sqrt{(J+1)/(2J+1)}(n-J+1)\boldsymbol{S}^M_{n-1,J,J}(\boldsymbol{r})\\ &\text{when } J = \ell + 1. \text{ Equivalently, we have}\\ &\nabla \times \boldsymbol{S}^M_{n,\ell,\ell+1}(\boldsymbol{r}) = i\sqrt{(\ell+2)/(2\ell+3)}(n-\ell)\boldsymbol{S}^M_{n-1,\ell+1,\ell+1}(\boldsymbol{r}),\end{aligned} \tag{U.5.17}$$

$$\begin{aligned}&\nabla \times \boldsymbol{S}^M_{n,\ell,J}(\boldsymbol{r}) = i\sqrt{(J+1)/(2J+1)}(n+J+1)\boldsymbol{S}^M_{n-1,J-1,J}(\boldsymbol{r})\\ &\qquad\qquad +i\sqrt{J/(2J+1)}(n-J)\boldsymbol{S}^M_{n-1,J+1,J}(\boldsymbol{r})\\ &\text{when } J = \ell. \text{ Equivalently, we have}\\ &\nabla \times \boldsymbol{S}^M_{n,\ell,\ell}(\boldsymbol{r}) = i\sqrt{(\ell+1)/(2\ell+1)}(n+\ell+1)\boldsymbol{S}^M_{n-1,\ell-1,\ell}(\boldsymbol{r})\\ &\qquad\qquad +i\sqrt{\ell/(2\ell+1)}(n-\ell)\boldsymbol{S}^M_{n-1,\ell+1,\ell}(\boldsymbol{r}),\end{aligned} \tag{U.5.18}$$

$$\begin{aligned}&\nabla \times \boldsymbol{S}^M_{n,\ell,J}(\boldsymbol{r}) = i\sqrt{J/(2J+1)}(n+J+2)\boldsymbol{S}^M_{n-1,J,J}(\boldsymbol{r})\\ &\text{when } J = \ell - 1. \text{ Equivalently, we have}\\ &\nabla \times \boldsymbol{S}^M_{n,\ell,\ell-1}(\boldsymbol{r}) = i\sqrt{(\ell-1)/(2\ell-1)}(n+\ell+1)\boldsymbol{S}^M_{n-1,\ell-1,\ell-1}(\boldsymbol{r}).\end{aligned} \tag{U.5.19}$$

Again we must consider the special case $\ell = 0$, in which case $J = 1$ and (5.4) holds. The conditions relating J and ℓ associated with (5.18) and (5.19) do not hold in this case, but the one associated with (5.17) does hold. We therefore speculate that (5.17) should be employed in the case $\ell = 0$ and $J = 1$ to give the result

$$\nabla \times \boldsymbol{S}^{M}_{2k,0,1}(\boldsymbol{r}) = i(\sqrt{2/3})(2k)\boldsymbol{S}^{M}_{2k-1,1,1}(\boldsymbol{r}). \tag{U.5.20}$$

This speculation is also correct, and can be proved directly. See Exercise 6.17.

Note that in all cases there is the pleasant fact that the $\nabla\times$ operator *preserves* the top index and the last bottom index, the M and J indices, on $\boldsymbol{S}^{M}_{n,\ell,J}$. It can be shown that there are *total* angular momentum operators $\mathscr{J}_1$, $\mathscr{J}_2$, and $\mathscr{J}_3$, and this preservation is a consequence of the fact that the operator $\nabla\times$ commutes with the total angular momentum operators.

We close this subsection by observing that a special case of (5.18) is the relation

$$\nabla \times \boldsymbol{S}^{M}_{n,n,n}(\boldsymbol{r}) = i\sqrt{(n+1)(2n+1)}\boldsymbol{S}^{M}_{n-1,n-1,n}(\boldsymbol{r}). \tag{U.5.21}$$

U.6 Multiplicative Properties of Spherical Polynomials and Spherical Polynomial Vector Fields

This section deals with the effects of multiplication by $\boldsymbol{r}$.

U.6.1 Ordinary Multiplication

We begin with the case of spherical polynomials and consider ordinary multiplication. Suppose $\ell \geq 1$. Then it can be shown that

$$\boldsymbol{r}Y^{m}_{\ell}(\theta,\phi) = \sqrt{\ell/(2\ell+1)}\; r\boldsymbol{Y}^{m}_{\ell-1,\ell}(\theta,\phi) - \sqrt{(\ell+1)/(2\ell+1)}\; r\boldsymbol{Y}^{m}_{\ell+1,\ell}(\theta,\phi). \tag{U.6.1}$$

In view of (3.18), it follows (again supposing $\ell \geq 1$) that

$$\boldsymbol{r}S^{m}_{n\ell}(\boldsymbol{r}) = \sqrt{\ell/(2\ell+1)}\; \boldsymbol{S}^{m}_{n+1,\ell-1,\ell}(\boldsymbol{r}) - \sqrt{(\ell+1)/(2\ell+1)}\; \boldsymbol{S}^{m}_{n+1,\ell+1,\ell}(\boldsymbol{r}). \tag{U.6.2}$$

What about the special case $\ell = 0$? Then n must be even. So we write

$$n = 2k. \tag{U.6.3}$$

Also we must have $m = 0$. If $\ell = 0$, we might imagine evaluating (6.1) with the first term omitted since it contains $\sqrt{\ell}$. Doing so gives the result

$$\boldsymbol{r}S^{0}_{2k,0}(\boldsymbol{r}) = -\boldsymbol{S}^{0}_{2k+1,1,0}(\boldsymbol{r}). \tag{U.6.4}$$

This result is, in fact, correct, and can be verified directly. See Exercise 6.23.

U.6.2 Dot Product Multiplication

We continue with the case of spherical polynomial vector fields, and consider the case of dot product multiplication. Assume that $\ell \geq 1$. Then it can be shown that

$$\boldsymbol{r} \cdot \boldsymbol{Y}_{\ell,J}^M(\theta,\phi) = \sqrt{J/(2J+1)}\, rY_J^M(\theta,\phi) \text{ when } J = \ell + 1, \tag{U.6.5}$$

$$\boldsymbol{r} \cdot \boldsymbol{Y}_{\ell,J}^M(\theta,\phi) = 0 \text{ when } J = \ell, \tag{U.6.6}$$

$$\boldsymbol{r} \cdot \boldsymbol{Y}_{\ell,J}^M(\theta,\phi) = -\sqrt{(J+1)/(2J+1)}\, rY_J^M(\theta,\phi) \text{ when } J = \ell - 1. \tag{U.6.7}$$

It follows from (3.18), again assuming $\ell \geq 1$, that

$$\boldsymbol{r} \cdot \boldsymbol{S}_{n,\ell,J}^M(\boldsymbol{r}) = \sqrt{J/(2J+1)}\, S_{n+1,J}^M(\boldsymbol{r}) \text{ when } J = \ell + 1, \tag{U.6.8}$$

$$\boldsymbol{r} \cdot \boldsymbol{S}_{n,\ell,J}^M(\boldsymbol{r}) = 0 \text{ when } J = \ell, \tag{U.6.9}$$

$$\boldsymbol{r} \cdot \boldsymbol{S}_{n,\ell,J}^M(\boldsymbol{r}) = -\sqrt{(J+1)/(2J+1)}\, S_{n+1,J}^M(\boldsymbol{r}) \text{ when } J = \ell - 1. \tag{U.6.10}$$

What about the special case $\ell = 0$? Then we must have $J = 1$. Moreover n must be even so that (5.4) again holds. Evidently when $\ell = 0$ and $J = 1$ the conditions relating J and ℓ in (6.9) and (6.10) do not hold. However, the condition in (6.8) does hold and so we might speculate that (6.8) should be evaluated with $J = 1$ to give the result

$$\boldsymbol{r} \cdot \boldsymbol{S}_{2k,0,1}^M(\boldsymbol{r}) = \sqrt{1/3}\, S_{2k+1,1}^M(\boldsymbol{r}). \tag{U.6.11}$$

This speculation is correct, and can be proved directly. See Exercise 6.25.

U.6.3 Cross Product Multiplication

Lastly, we consider the case of cross product multiplication of spherical polynomial vector fields. It can also be shown (assuming $\ell \geq 1$) that

$$\begin{aligned}\boldsymbol{r} \times \boldsymbol{Y}_{\ell,J}^M(\theta,\phi) &= i\sqrt{(J+1)/(2J+1)}\, r\boldsymbol{Y}_{J,J}^M(\theta,\phi) \\ &\quad \text{when } J = \ell + 1,\end{aligned} \tag{U.6.12}$$

$$\begin{aligned}\boldsymbol{r} \times \boldsymbol{Y}_{\ell,J}^M(\theta,\phi) &= i\sqrt{(J+1)/(2J+1)}\, r\boldsymbol{Y}_{J-1,J}^M(\theta,\phi) \\ &\quad + i\sqrt{J/(2J+1)}\, r\boldsymbol{Y}_{J+1,J}^M(\theta,\phi) \\ &\quad \text{when } J = \ell,\end{aligned} \tag{U.6.13}$$

$$\begin{aligned}\boldsymbol{r} \times \boldsymbol{Y}_{\ell,J}^M(\theta,\phi)] &= i\sqrt{J/(2J+1)}\, r\boldsymbol{Y}_{J,J}^M(\theta,\phi) \\ &\quad \text{when } J = \ell - 1.\end{aligned} \tag{U.6.14}$$

It follows from (3.18), again assuming $\ell \geq 1$, that there are the following results:

$\boldsymbol{r} \times \boldsymbol{S}_{n,\ell,J}^M(\boldsymbol{r}) = i\sqrt{(J+1)/(2J+1)}\boldsymbol{S}_{n+1,J,J}^M(\boldsymbol{r})$
when $J = \ell + 1$. Equivalently, we have

$$\boldsymbol{r} \times \boldsymbol{S}_{n,\ell,\ell+1}^M(\boldsymbol{r}) = i\sqrt{(\ell+2)/(2\ell+3)}\boldsymbol{S}_{n+1,\ell+1,\ell+1}^M(\boldsymbol{r}), \tag{U.6.15}$$

$$\boldsymbol{r} \times \boldsymbol{S}^M_{n,\ell,J}(\boldsymbol{r}) = i\sqrt{(J+1)/(2J+1)}\boldsymbol{S}^M_{n+1,J-1,J}(\boldsymbol{r})$$
$$+i\sqrt{J/(2J+1)}\boldsymbol{S}^M_{n+1,J+1,J}(\boldsymbol{r})$$

when $J = \ell$. Equivalently, we have

$$\boldsymbol{r} \times \boldsymbol{S}^M_{n,\ell,\ell}(\boldsymbol{r}) = i\sqrt{(\ell+1)/(2\ell+1)}\boldsymbol{S}^M_{n+1,\ell-1,\ell}(\boldsymbol{r})$$
$$+i\sqrt{\ell/(2\ell+1)}\boldsymbol{S}^M_{n+1,\ell+1,\ell}(\boldsymbol{r}), \qquad \text{(U.6.16)}$$

$$\boldsymbol{r} \times \boldsymbol{S}^M_{n,\ell,J}(\boldsymbol{r}) = i\sqrt{J/(2J+1)}\boldsymbol{S}^M_{n+1,J,J}(\boldsymbol{r})$$

when $J = \ell - 1$. Equivalently, we have

$$\boldsymbol{r} \times \boldsymbol{S}^M_{n,\ell,\ell-1}(\boldsymbol{r}) = i\sqrt{(\ell-1)/(2\ell-1)}\boldsymbol{S}^M_{n+1,\ell-1,\ell-1}(\boldsymbol{r}). \qquad \text{(U.6.17)}$$

Again we must consider the special case $\ell = 0$, in which case $J = 1$ and (5.4) holds. The conditions relating J and ℓ associated with (6.16) and (6.17) do not hold in this case, but the one associated with (6.15) does hold. We therefore speculate that (6.15) should be employed in the case $\ell = 0$ and $J = 1$ to give the result

$$\boldsymbol{r} \times \boldsymbol{S}^M_{2k,0,1}(\boldsymbol{r}) = i(\sqrt{2/3})\boldsymbol{S}^M_{2k+1,1,1}(\boldsymbol{r}). \qquad \text{(U.6.18)}$$

This speculation is also correct, and can be proved directly. See Exercise 6.27.

Note that in all cases there is also the pleasant fact that the $\boldsymbol{r}\times$ operator also preserves the top index and the last bottom index, the M and J indices, on $\boldsymbol{S}^M_{n,\ell,J}$.

We close this subsection by making two useful observations. The first observation is that a special case of (6.15) yields the relation

$$\boldsymbol{S}^M_{nnn}(\boldsymbol{r}) = [-i\sqrt{(2n+1)/(n+1)}][\boldsymbol{r} \times \boldsymbol{S}^M_{n-1,n-1,n}(\boldsymbol{r})]. \qquad \text{(U.6.19)}$$

To verify this claim, evaluate (6.15) for the case

$$n = n' - 1 \qquad \text{(U.6.20)}$$

and

$$\ell = n' - 1; \qquad \text{(U.6.21)}$$

from which it follows that

$$\ell + 1 = n' \qquad \text{(U.6.22)}$$

and

$$(\ell+2)/(2\ell+3) = (n'+1)/(2n'+1). \qquad \text{(U.6.23)}$$

So doing gives the result

$$\boldsymbol{r} \times \boldsymbol{S}^M_{n'-1,n'-1,n'}(\boldsymbol{r}) = i\sqrt{(n'+1)/(2n'+1)}\boldsymbol{S}^M_{n'n'n'}(\boldsymbol{r}), \qquad \text{(U.6.24)}$$

from which (6.19) follows. Note that (3.41) is special case of (6.19).

The second observation is that combining (5.6) and (6.19) gives the relation

$$\begin{aligned}\boldsymbol{S}^M_{nnn}(\boldsymbol{r}) &= [-i\sqrt{(2n+1)/(n+1)}][\boldsymbol{r} \times \boldsymbol{S}^M_{n-1,n-1,n}(\boldsymbol{r})] \\ &= [-i/\sqrt{n(n+1)}][\boldsymbol{r} \times \nabla S^M_{nn}(\boldsymbol{r})]. \end{aligned} \qquad \text{(U.6.25)}$$

Note that if we define an *orbital* angular momentum operator $\boldsymbol{L}$ by the rule

$$\boldsymbol{L} = \boldsymbol{r} \times \nabla, \tag{U.6.26}$$

then (6.25) can be written in the form

$$\boldsymbol{S}^M_{nnn}(\boldsymbol{r}) = [-i/\sqrt{n(n+1)}]\boldsymbol{L}S^M_{nn}(\boldsymbol{r}). \tag{U.6.27}$$

Exercises

U.6.1. Cognizant of the relation between ℓ and n given by (2.10) and (2.11) and the rule $-\ell \leq m \leq \ell$, count how many $S^m_{n\ell}$ there are for a given n. Show the result agrees with $N(n, 3)$.

U.6.2. Verify (3.3) through (3.5).

U.6.3. Verify (3.19) and (3.20).

U.6.4. Verify (3.21) through (3.25).

U.6.5. Verify (3.26) through (3.41).

U.6.6. Verify (3.42) through (3.61).

U.6.7. Verify (3.65) given (3.18), (3.62), (3.63), and (3.65). Verify (3.65) directly for the cases $\boldsymbol{S}^M_{001}$, $\boldsymbol{S}^0_{110}$, $\boldsymbol{S}^M_{111}$, and $\boldsymbol{S}^M_{112}$ worked out explicitly in Subsection 3.3.

U.6.8. Recall the relation between n, ℓ, and J given by (2.10), (2.11), (3.3), and (3.4). See Table 3.1. Recall also the rule $-J \leq M \leq J$. Count how many $\boldsymbol{S}^M_{n\ell J}$ there are for a given n. Show the result agrees with $3N(n, 3)$.

U.6.9. Show that

$$\int d\Omega\ S^m_{n\ell} = \sqrt{4\pi}\ r^n \delta_{\ell 0}\delta_{m0}. \tag{U.6.28}$$

Recall Exercise 16.1.1.

U.6.10. Given (5.1) and (5.2), derive (5.3). Verify (5.6).

U.6.11. Show from the definition (2.10) that

$$S^0_{2k,0}(\boldsymbol{r}) = (1/\sqrt{4\pi})(x^2 + y^2 + z^2)^k. \tag{U.6.29}$$

Show from the definition (3.18) and the result (3.25) that

$$\boldsymbol{S}^0_{2k-1,1,0}(\boldsymbol{r}) = (-1/\sqrt{4\pi})(x^2 + y^2 + z^2)^{k-1}\boldsymbol{r} = (-1/\sqrt{4\pi})\ r^{2k-2}\boldsymbol{r}. \tag{U.6.30}$$

Verify (5.5) by direct computation.

U.6.12. Given (5.2) and (5.8) through (5.9), derive (5.10) through (5.12).

U.6.13. Show from the definition (2.11) that

$$S^M_{2k-1,1}(\boldsymbol{r}) = r^{2k-2} S^M_{11}(\boldsymbol{r}). \tag{U.6.31}$$

Show from the definition (3.18) and the relation (3.20) that

$$\boldsymbol{S}^M_{2k,0,1}(\boldsymbol{r}) = r^{2k}\boldsymbol{S}^M_{001}(\boldsymbol{r}) = (1/\sqrt{4\pi}) r^{2k}\boldsymbol{e}_M. \tag{U.6.32}$$

Verify (5.13) by direct computation. Hint: Use (3.3).

U.6.14. Verify that $S^m_{nn}(\boldsymbol{r})$ is a harmonic polynomial. Verify, using the rules (5.3) and (5.5) and (5.9) through (5.12), that

$$\nabla \cdot [\nabla S^m_{nn}(\boldsymbol{r})] = 0, \tag{U.6.33}$$

as expected.

U.6.15. Show that

$$\nabla^2 S^m_{n\ell} = [n(n+1) - \ell(\ell+1)] S^m_{n-2,\ell}. \tag{U.6.34}$$

U.6.16. Given (5.2) and (5.14) through (5.16), derive (5.17) through (5.19). Verify (5.21).

U.6.17. Show from the definition (3.18) and the relation (3.40) that

$$\boldsymbol{S}^M_{2k-1,1,1}(\boldsymbol{r}) = -i\sqrt{3/(4\pi)}\, r^{2k-2}\boldsymbol{r} \times \boldsymbol{e}_M. \tag{U.6.35}$$

Review Exercise 6.13. Using the results (6.32) and (6.35) for $\boldsymbol{S}^M_{2k,0,1}$ and $\boldsymbol{S}^M_{2k-1,1,1}$, verify (5.20) by direct computation.

U.6.18. Using the rules (5.3) and (5.5) and (5.17) through (5.20), verify that

$$\nabla \times [\nabla S^m_{n\ell}(\boldsymbol{r})] = 0, \tag{U.6.36}$$

as expected.

U.6.19. Using the rules (5.10) through (5.13) and (5.17) through (5.20), verify that

$$\nabla \cdot [\nabla \times \boldsymbol{S}^M_{n\ell J}(\boldsymbol{r})] = 0, \tag{U.6.37}$$

as expected.

U.6.20. Verify the relations

$$\nabla \times \boldsymbol{S}^0_{110}(\boldsymbol{r}) = 0, \tag{U.6.38}$$

$$\nabla \times \boldsymbol{S}^M_{111}(\boldsymbol{r}) = i\sqrt{6}\boldsymbol{S}^M_{001}(\boldsymbol{r}), \tag{U.6.39}$$

$$\nabla \times \boldsymbol{S}^M_{112}(\boldsymbol{r}) = 0. \tag{U.6.40}$$

U.6.21. Show that

$$\nabla \times \boldsymbol{S}_{201}^{M}(\boldsymbol{r}) = i\sqrt{8/3}\boldsymbol{S}_{111}^{M}(\boldsymbol{r}), \tag{U.6.41}$$

$$\nabla \times \boldsymbol{S}_{223}^{M}(\boldsymbol{r}) = 0, \tag{U.6.42}$$

$$\nabla \times \boldsymbol{S}_{222}^{M}(\boldsymbol{r}) = i\sqrt{15}\boldsymbol{S}_{112}^{M}(\boldsymbol{r}), \tag{U.6.43}$$

$$\nabla \times \boldsymbol{S}_{221}^{M}(\boldsymbol{r}) = i\sqrt{25/3}\boldsymbol{S}_{111}^{M}(\boldsymbol{r}). \tag{U.6.44}$$

Show that

$$\nabla \times \nabla \times \boldsymbol{S}_{201}^{M}(\boldsymbol{r}) = i\sqrt{8/3}\nabla \times \boldsymbol{S}_{111}^{M}(\boldsymbol{r}) = -4\boldsymbol{S}_{001}^{M}(\boldsymbol{r}), \tag{U.6.45}$$

$$\nabla \times \nabla \times \boldsymbol{S}_{223}^{M}(\boldsymbol{r}) = 0, \tag{U.6.46}$$

$$\nabla \times \nabla \times \boldsymbol{S}_{222}^{M}(\boldsymbol{r}) = i\sqrt{15}\nabla \times \boldsymbol{S}_{112}^{M}(\boldsymbol{r}) = 0 \tag{U.6.47}$$

$$\nabla \times \nabla \times \boldsymbol{S}_{221}^{M}(\boldsymbol{r}) = i\sqrt{25/3}\nabla \times \boldsymbol{S}_{111}^{M}(\boldsymbol{r}) = -\sqrt{50}\, \boldsymbol{S}_{001}^{M}(\boldsymbol{r}). \tag{U.6.48}$$

U.6.22. Given (6.1), derive (6.2).

U.6.23. Verify (6.4) using (2.10) and (3.25).

U.6.24. Given (6.5) through (6.7), derive (6.8) through (6.10).

U.6.25. Review Exercise 6.13. Verify (6.11) using (6.32), (3.3), and (2.11).

U.6.26. Given (6.12) through (6.14), derive (6.15) through (6.17).

U.6.27. Review Exercise 6.13. Verify (6.18) using (6.32), (3.40), (3.18), and (2.11).

U.6.28. Verify the steps that connect (6.14) to (6.19).

U.6.29. Verify that combining (5.6) and (6.19) yields (6.25).

Appendix V

PROT without and in the Presence of a Magnetic Field

V.1 The Case of No Magnetic Field

The material to be covered in this section is standard fare with results known through at least third order, but not yet completely documented.

V.2 The Constant Magnetic Field Case

V.2.1 Preliminaries

Recall from Exercise 1.6.2 that the Hamiltonian for charged-particle motion in an electromagnetic field, when employing cylindrical coordinates with the angle ϕ as the independent variable, is given by the relation

$$K = -\rho[(p_t + q\psi)^2/c^2 - m^2c^2 - (p_\rho - qA_\rho)^2 - (p_y - qA_y)^2]^{1/2} - q\rho A_\phi. \tag{V.2.1}$$

Assume that $\psi = 0$ in accord with the desire that there be no electric field. Also stipulate that $\boldsymbol{A}$ have the components

$$A_\rho = 0, \tag{V.2.2}$$

$$A_y = 0, \tag{V.2.3}$$

$$A_\phi = -(\rho/2)B. \tag{V.2.4}$$

According to Exercise 1.5.8 this choice for $\boldsymbol{A}$ results in a constant magnetic field

$$\boldsymbol{B} = B\boldsymbol{e}_y. \tag{V.2.5}$$

With these provisos it follows that K takes the form

$$K = -\rho[(p_t/c)^2 - m^2c^2 - p_\rho^2 - p_y^2]^{1/2} + q(\rho^2/2)B. \tag{V.2.6}$$

Note that (1.5.49) can be written in the vector/matrix form

$$\begin{pmatrix} A_\phi \\ A_\rho \end{pmatrix} = \begin{pmatrix} \cos\phi & -\sin\phi \\ \sin\phi & \cos\phi \end{pmatrix} \begin{pmatrix} A_z \\ A_x \end{pmatrix}, \tag{V.2.7}$$

from which it follows immediately that there is the inverse relation

$$\begin{pmatrix} A_z \\ A_x \end{pmatrix} = \begin{pmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{pmatrix} \begin{pmatrix} A_\phi \\ A_\rho \end{pmatrix}. \tag{V.2.8}$$

Upon combining (1.2) through (1.4), (1.8), and (1.5.33), we see that there is the relation

$$\boldsymbol{A} = (B/2)(-x\boldsymbol{e}_z + z\boldsymbol{e}_x). \tag{V.2.9}$$

Evidently, $\boldsymbol{A}$ is in the Poincaré-Coulomb gauge.

V.2.2 Dimensionless Variables and Limiting Hamiltonian

Change to new scaled variables by writing

$$\rho = \rho_0\ell + \xi\ell, \tag{V.2.10}$$

$$p_\rho = P_\xi p_0, \tag{V.2.11}$$

$$y = Y\ell, \tag{V.2.12}$$

$$p_y = P_y p_0, \tag{V.2.13}$$

$$t = \tau\ell/c, \tag{V.2.14}$$

$$p_t = p_t^0 + P_\tau p_0 c. \tag{V.2.15}$$

Here ℓ is a scale length and p_0 is the design momentum. [Note that the variable Y in (2.12) is not to be confused with the Y associated with the $\boldsymbol{R}$ of Section 15.9.] Correspondingly, there are the Poisson bracket relations

$$[\xi, P_\xi] = (p_0\ell)^{-1}[\rho, p_\rho], \tag{V.2.16}$$

$$[Y, P_y] = (p_0\ell)^{-1}[y, p_y], \tag{V.2.17}$$

$$[\tau, P_\tau] = (p_0\ell)^{-1}[t, p_t]. \tag{V.2.18}$$

Let $\tilde{K}$ be the new Hamiltonian for these new variables. It is given by the relation

$$\tilde{K} = \lambda\ell\{-(\rho_0+\xi)[(p_t^0 + P_\tau p_0 c)^2/c^2 - m^2c^2 - p_0^2P_\xi^2 - p_0^2P_y^2]^{1/2} + (qB\ell/2)(\rho_0+\xi)^2\}, \tag{V.2.19}$$

or, equivalently,

$$\tilde{K} = \lambda\ell p_0\{-(\rho_0+\xi)[(p_t^0 p_0^{-1}c^{-1} + P_\tau)^2 - m^2c^2/p_0^2 - P_\xi^2 - P_y^2]^{1/2} + [qB\ell/(2p_0)](\rho_0+\xi)^2\}. \tag{V.2.20}$$

Here

$$\lambda = (\ell p_0)^{-1}. \tag{V.2.21}$$

Observe that there are the relations

$$p_0 = \gamma m v_0 = \gamma\beta mc, \tag{V.2.22}$$

$$p_t^0 = -\gamma mc^2. \tag{V.2.23}$$

It follows that there are the relations

$$m^2c^2/p_0^2 = m^2c^2/(\beta\gamma mc)^2 = 1/(\beta\gamma)^2, \tag{V.2.24}$$

$$p_t^0/(p_0c) = -(\gamma mc^2)/(\gamma\beta mc^2) = -1/\beta. \tag{V.2.25}$$

Consequently, $\tilde{K}$ can also be written on the form

$$\tilde{K} = -(\rho_0 + \xi)[(-1/\beta + P_\tau)^2 - (\beta\gamma)^{-2} - P_\xi^2 - P_y^2]^{1/2} + (b/2)(\rho_0 + \xi)^2 \tag{V.2.26}$$

where

$$b = qB\ell/p_0. \tag{V.2.27}$$

We also observe that

$$1/\beta^2 - 1/(\beta\gamma)^2 = 1. \tag{V.2.28}$$

It follows that $\tilde{K}$ can also be written as

$$\tilde{K} = -(\rho_0 + \xi)[1 - 2P_\tau/\beta + P_\tau^2 - P_\xi^2 - P_y^2]^{1/2} + (b/2)(\rho_0 + \xi)^2. \tag{V.2.29}$$

Finally, we take the limit $\rho_0 \to 0$ to obtain the limiting Hamiltonian

$$\tilde{K}^{\text{lim}} = -\xi[1 - 2P_\tau/\beta + P_\tau^2 - P_\xi^2 - P_y^2]^{1/2} + (b/2)\xi^2. \tag{V.2.30}$$

V.2.3 Design Trajectory

Evidently P_y and P_τ are integrals of motion and vanish on the design trajectory. Therefore the variables ξ, P_ξ *on* the *design trajectory* are governed by the Hamiltonian

$$\tilde{K}^{\text{dt}} = -\xi[1 - P_\xi^2]^{1/2} + (b/2)\xi^2. \tag{V.2.31}$$

Correspondingly, the associated equations of motion for these variables on the design trajectory are given by the relations

$$\xi' = \partial\tilde{K}^{\text{dt}}/\partial P_\xi = \xi P_\xi[1 - P_\xi^2]^{-1/2}, \tag{V.2.32}$$

$$P_\xi' = -\partial\tilde{K}^{\text{dt}}/\partial\xi = [1 - P_\xi^2]^{1/2} - b\xi. \tag{V.2.33}$$

They have the particular solution

$$\xi = 0, \tag{V.2.34}$$

$$P_\xi(\phi) = \sin\Delta, \tag{V.2.35}$$

where

$$\Delta = \phi - \phi^{\text{in}}. \tag{V.2.36}$$

We will take (2.34) through (2.36) to be the ξ, P_ξ results for the design trajectory. Note that the design trajectory does not depend on b. That is, it does not depend on the magnetic field.

As assumed earlier, and consistent with the full equations of motion associated with the full Hamiltonian (2.30), the remaining variables on the design trajectory vanish,

$$Y = P_y = \tau = P_\tau = 0. \tag{V.2.37}$$

It follows, from (2.34) through (2.37), that all the variables save P_ξ are deviation variables.

V.2.4 Deviation Variables

To proceed further we wish to replace ξ and P_ξ by deviation variables, which we will call $\hat{\xi}$ and $\hat{P}_\xi$, so that all variables are deviation variables. This is simply done by making the definitions

$$\xi = \hat{\xi}, \tag{V.2.38}$$

$$P_\xi = \sin\Delta + \hat{P}_\xi, \tag{V.2.39}$$

and leaving all other variables in peace. The relations (2.38) and (2.39) are a canonical transformation and can be obtained from the F_2 generating function given by

$$F_2(\xi, \hat{P}_\xi) = \xi(\sin\Delta + \hat{P}_\xi). \tag{V.2.40}$$

Indeed, employing the standard machinery (6.5.5) yields the results

$$P_\xi = \partial F_2/\partial\xi = \sin\Delta + \hat{P}_\xi, \tag{V.2.41}$$

$$\hat{\xi} = \partial F_2/\partial\hat{P}_\xi = \xi, \tag{V.2.42}$$

as desired.

V.2.5 Deviation Variable Hamiltonian

We may regard the deviation variables as new variables. Associated with the use of these new variables will be a new Hamiltonian H given by the relation

$$H = \tilde{K}^{\text{lim}} + \partial F_2/\partial\phi = \tilde{K}^{\text{lim}} + \xi\cos\Delta = \tilde{K}^{\text{lim}} + \hat{\xi}\cos\Delta. \tag{V.2.43}$$

Use of (2.43) yields the result

$$H = -\hat{\xi}[1 - 2P_\tau/\beta + P_\tau^2 - (\hat{P}_\xi + \sin\Delta)^2 - P_y^2]^{1/2} + (b/2)\hat{\xi}^2 + \hat{\xi}\cos\Delta, \tag{V.2.44}$$

or

$$H = -\hat{\xi}[1 - \sin^2\Delta - 2P_\tau/\beta + P_\tau^2 - \hat{P}_\xi^2 - 2\hat{P}_\xi\sin\Delta - P_y^2]^{1/2} + (b/2)\hat{\xi}^2 + \hat{\xi}\cos\Delta, \tag{V.2.45}$$

or

$$H = -\hat{\xi}[\cos^2\Delta - 2P_\tau/\beta + P_\tau^2 - \hat{P}_\xi^2 - 2\hat{P}_\xi\sin\Delta - P_y^2]^{1/2} + (b/2)\hat{\xi}^2 + \hat{\xi}\cos\Delta. \tag{V.2.46}$$

V.2.6 Computation of Transfer Map

Our aim is to find the transfer map associated with H. According to Section 10.4, this entails expanding H in terms of homogeneous polynomials,

$$H = H_0 + H_1 + H_2 + H_3 + H_4 + \cdots . \tag{V.2.47}$$

So doing gives for H_0 through H_2 the results

$$H_0 = 0, \tag{V.2.48}$$

$$H_1 = 0, \tag{V.2.49}$$

$$H_2 = \hat{\xi}P_\tau/(\beta\cos\Delta) + \hat{\xi}\hat{P}_\xi\tan\Delta + (b/2)\hat{\xi}^2. \tag{V.2.50}$$

Note that H_1 vanishes as expected. That is, the design trajectory is given by the relations (2.37) supplemented by the relations

$$\hat{\xi} = \hat{P}_\xi = 0. \tag{V.2.51}$$

Linear Part of Transfer Map

The first step is to find $\mathcal{R}$, the linear part of the transfer map. This requires solving the equations of motion associated with H_2. They read

$$\hat{\xi}' = \partial H_2/\partial\hat{P}_\xi = \hat{\xi}\tan\Delta, \tag{V.2.52}$$

$$\hat{P}_\xi' = -\partial H_2/\partial\hat{\xi} = -\hat{P}_\xi\tan\Delta - P_\tau/(\beta\cos\Delta) - b\hat{\xi}, \tag{V.2.53}$$

$$Y' = \partial H_2/\partial P_y = 0, \tag{V.2.54}$$

$$P_y' = -\partial H_2/\partial Y = 0, \tag{V.2.55}$$

$$\tau' = \partial H_2/\partial P_\tau = \hat{\xi}/(\beta\cos\Delta), \tag{V.2.56}$$

$$P_\tau' = -\partial H_2/\partial\tau = 0. \tag{V.2.57}$$

The solutions to (2.54), (2.55), and (2.57) can be written immediately,

$$Y(\phi) = Y^{\text{in}}, \tag{V.2.58}$$

$$P_Y(\phi) = P_Y^{\text{in}}, \tag{V.2.59}$$

$$P_\tau(\phi) = P_\tau^{\text{in}}. \tag{V.2.60}$$

The solution to (2.52), which is less trivial, is

$$\hat{\xi}(\phi) = \hat{\xi}^{\text{in}}/\cos\Delta. \tag{V.2.61}$$

The results (2.60) and (2.61) can now be inserted into (2.53) to yield the differential equation

$$\hat{P}_\xi' = -\hat{P}_\xi\tan\Delta - P_\tau^{\text{in}}/(\beta\cos\Delta) - b\hat{\xi}^{\text{in}}/\cos\Delta = -\hat{P}_\xi\tan\Delta - (b\hat{\xi}^{\text{in}} + P_\tau^{\text{in}}/\beta)/\cos\Delta. \tag{V.2.62}$$

It has the solution

$$\hat{P}_\xi(\phi) = \hat{P}_\xi^{\text{in}}\cos\Delta - (b\hat{\xi}^{\text{in}} + P_\tau^{\text{in}}/\beta)\sin\Delta. \tag{V.2.63}$$

Finally, insertion of (2.61) into (2.56) yields the differential equation

$$\tau' = \hat{\xi}^{\text{in}}/(\beta\cos^2\Delta). \tag{V.2.64}$$

It has the solution

$$\tau(\phi) = \tau^{\text{in}} + \hat{\xi}^{\text{in}}(1/\beta)\tan\Delta. \tag{V.2.65}$$

From these solutions we can read off the matrix R associated with $\mathcal{R}$. From (2.58) through (2.61), (2.63), and (2.65) we see that there is the vector/matrix relation

$$\begin{pmatrix} \hat{\xi}(\phi) \\ \hat{P}_\xi(\phi) \\ Y(\phi) \\ P_y(\phi) \\ \tau(\phi) \\ P_\tau(\phi) \end{pmatrix} = \begin{pmatrix} 1/\cos\Delta & 0 & 0 & 0 & 0 & 0 \\ -b\sin\Delta & \cos\Delta & 0 & 0 & 0 & -(1/\beta)\sin\Delta \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ (1/\beta)\tan\Delta & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \hat{\xi}^{\rm in} \\ \hat{P}_\xi^{\rm in} \\ Y^{\rm in} \\ P_y^{\rm in} \\ \tau^{\rm in} \\ P_\tau^{\rm in} \end{pmatrix}. \tag{V.2.66}$$

The matrix R is the matrix appearing in (2.66).

Nonlinear Parts of Transfer Map

To compute the nonlinear parts of the transfer map it is necessary to continue the expansion (2.47) begun in (2.48) through (2.50) to find H_3, $H_4 \cdots$ and to then apply the machinery of Section 10.5 to find the associated f_3, $f_4 \cdots$. For example, one finds from (2.46) and (2.47) the result

$$H_3 = . \tag{V.2.67}$$

Exercises

V.2.1. Verify that the solutions given by (2.34) through (2.36) do indeed satisfy the differential equations (2.32) and (2.33).

V.2.2. Verify the expansion (2.48) through (2.50).

V.2.3. Verify that the solutions (2.58) through (2.61), (2.63), and (2.65) do indeed satisfy the differential equations (2.52) through (2.57).

V.2.4. Verify that R, the matrix appearing in (1.65), is symplectic.

V.2.5. Verify (2.67).

V.3 The Inhomogeneous Field Case

The work so far has dealt with the case of a constant magnetic field. We now consider the general case.

V.3.1 Vector Potential for the General Inhomogeneous Field Case

We begin by expanding the vector potential in the Poincaré-Coulomb gauge and in homogeneous polynomials employing Cartesian coordinates and Cartesian unit vectors. That is we write

$$\boldsymbol{A}(\boldsymbol{r}) = \boldsymbol{A}^{\min 1}(\boldsymbol{r}) + \boldsymbol{A}^{\min 2}(\boldsymbol{r}) + \boldsymbol{A}^{\min 3}(\boldsymbol{r}) + \cdots . \tag{V.3.1}$$

For $\boldsymbol{A}^{\min 1}(\boldsymbol{r})$ we use (2.9) to account for the constant part of the magnetic field and write

$$\boldsymbol{A}^{\min 1}(\boldsymbol{r}) = (B/2)(-x\boldsymbol{e}_z + z\boldsymbol{e}_x). \tag{V.3.2}$$

For example, in the case of a magnetic monopole doublet, there is the result

$$\boldsymbol{A}^{\min 1}(\boldsymbol{r}) = [ga/(X_0^2 + Z_0^2 + a^2)^{3/2}](-z\boldsymbol{e}_x + x\boldsymbol{e}_z), \tag{V.3.3}$$

and there is the relation

$$B = -2[ga/(X_0^2 + Z_0^2 + a^2)^{3/2}]. \tag{V.3.4}$$

And, for the same example and again employing Cartesian coordinates and Cartesian unit vectors, there is the result

$$\begin{gathered}\boldsymbol{A}^{\min 2}(\boldsymbol{r}) = [-2ga/(X_0^2 + Z_0^2 + a^2)^{5/2}] \times \\ [(Z_0y^2 - Z_0z^2 - X_0xz)\boldsymbol{e}_x + (X_0yz - Z_0xy)\boldsymbol{e}_y + (X_0x^2 + Z_0xz - X_0y^2)\boldsymbol{e}_z].\end{gathered} \tag{V.3.5}$$

See (15.9.7) and (15.9.8) in Section 15.9. For other examples the $\boldsymbol{A}^{\min n}(\boldsymbol{r})$ with $n \geq 2$ will be different, but still homogeneous of degree n. We will continue to assume that the constant part of the magnetic field is of the form (2.5), and therefore (3.2) will always be assumed to hold.

V.3.2 Transition to Cylindrical Coordinates

Next, as in Exercise 1.5.4, introduce polar coordinates in the x, z plane by the relations

$$x = \rho \ \cos \ \phi, \tag{V.3.6}$$

$$z = \rho \ \sin \ \phi.$$

That is, we will again employ the cylindrical coordinates ρ, y, ϕ and also the unit vectors $\boldsymbol{e}_\rho, \boldsymbol{e}_y, \boldsymbol{e}_\phi$ of Exercise 1.5.4. See (3.6) and (1.5.52) through (1.5.54). Let us express $\boldsymbol{A}$ in terms of these cylindrical coordinates and unit vectors.

Begin, for example, with (3.2). With the aid of (3.6) and (1.5.53) the relation (3.2) can be rewritten in the form

$$\begin{aligned}\boldsymbol{A}^{\min 1}(\boldsymbol{r}) &= -(B/2)\rho(-\sin\phi\ \boldsymbol{e}_x + \cos\phi\ \boldsymbol{e}_z) \\ &= -(B/2)\rho\boldsymbol{e}_\phi.\end{aligned} \tag{V.3.7}$$

Since $\boldsymbol{e}_\rho, \boldsymbol{e}_y, \boldsymbol{e}_\phi$ form an orthonormal triad, it follows from (1.5.44) and (3.2) that there are the results

$$A_\rho^{\min 1}(\boldsymbol{r}) = \boldsymbol{e}_\rho \cdot \boldsymbol{A}^{\min 1}(\boldsymbol{r}) = 0, \tag{V.3.8}$$

$$A_y^{\min 1}(\boldsymbol{r}) = \boldsymbol{e}_y \cdot \boldsymbol{A}^{\min 1}(\boldsymbol{r}) = 0, \tag{V.3.9}$$

$$A_\phi^{\min 1}(\boldsymbol{r}) = \boldsymbol{e}_\phi \cdot \boldsymbol{A}^{\min 1}(\boldsymbol{r}) = -(B/2)\rho, \tag{V.3.10}$$

which are to be expected in accord with (2.2) through (2.4) and (2.9).

As a second illustrative example, let us work on (3.5), which would be the $\boldsymbol{A}^{\min 2}(\boldsymbol{r})$ in the case of a magnetic monopole doublet. With the aid of (3.6) it takes the form

$$\begin{gathered}\boldsymbol{A}^{\min 2}(\boldsymbol{r}) = [-2ga/(X_0^2 + Z_0^2 + a^2)^{5/2}] \times \\ \{[Z_0 y^2 - \rho^2(Z_0 \sin^2\phi - X_0 \cos\phi \sin\phi)]\boldsymbol{e}_x + [\rho y(X_0 \sin\phi - Z_0 \cos\phi)]\boldsymbol{e}_y \\ +[\rho^2(X_0 \cos^2\phi + Z_0 \cos\phi \sin\phi) - X_0 y^2 \boldsymbol{e}_z\}.\end{gathered} \tag{V.3.11}$$

From (1.5.35), the definitions (1.5.44), and (3.11) there are the results

$$\begin{gathered}A_\rho^{\min 2}(\boldsymbol{r}) = \boldsymbol{e}_\rho \cdot \boldsymbol{A}^{\min 2}(\boldsymbol{r}) = [-2ga/(X_0^2 + Z_0^2 + a^2)^{5/2}] \times \\ \{[\cos\phi\ \boldsymbol{e}_x + \sin\phi\ \boldsymbol{e}_z] \cdot [Z_0 y^2 \boldsymbol{e}_x - \rho^2(Z_0 \sin^2\phi - X_0 \cos\phi \sin\phi)\boldsymbol{e}_x] \\ +[\cos\phi\ \boldsymbol{e}_x + \sin\phi\ \boldsymbol{e}_z] \cdot [\rho^2(X_0 \cos^2\phi + Z_0 \cos\phi \sin\phi)\boldsymbol{e}_z - X_0 y^2 \boldsymbol{e}_z]\} \\ = [-2ga/(X_0^2 + Z_0^2 + a^2)^{5/2}] \times \\ \{(\cos\phi)[Z_0 y^2 - \rho^2(Z_0 \sin^2\phi - X_0 \cos\phi \sin\phi)] \\ +(\sin\phi)[\rho^2(X_0 \cos^2\phi + Z_0 \cos\phi \sin\phi) - X_0 y^2]\},\end{gathered} \tag{V.3.12}$$

$$A_y^{\min 2}(\boldsymbol{r}) = \boldsymbol{e}_y \cdot \boldsymbol{A}^{\min 2}(\boldsymbol{r}) = [-2ga/(X_0^2 + Z_0^2 + a^2)^{5/2}][\rho y(X_0 \sin\phi - Z_0 \cos\phi)], \tag{V.3.13}$$

$$\begin{gathered}A_\phi^{\min 2}(\boldsymbol{r}) = \boldsymbol{e}_\phi \cdot \boldsymbol{A}^{\min 2}(\boldsymbol{r}) = [-2ga/(X_0^2 + Z_0^2 + a^2)^{5/2}] \times \\ \{[-\sin\phi\ \boldsymbol{e}_x + \cos\phi\ \boldsymbol{e}_z] \cdot [Z_0 y^2 \boldsymbol{e}_x - \rho^2(Z_0 \sin^2\phi - X_0 \cos\phi \sin\phi)\boldsymbol{e}_x] \\ +[-\sin\phi\ \boldsymbol{e}_x + \cos\phi\ \boldsymbol{e}_z] \cdot [\rho^2(X_0 \cos^2\phi + Z_0 \cos\phi \sin\phi)\boldsymbol{e}_z - X_0 y^2 \boldsymbol{e}_z]\} \\ = [-2ga/(X_0^2 + Z_0^2 + a^2)^{5/2}] \times \\ \{-(\sin\phi)[Z_0 y^2 - \rho^2(Z_0 \sin^2\phi - X_0 \cos\phi \sin\phi)] \\ +(\cos\phi)[\rho^2(X_0 \cos^2\phi + Z_0 \cos\phi \sin\phi) - X_0 y^2]\}.\end{gathered} \tag{V.3.14}$$

V.3.3 Dimensionless Variables and Limiting Vector Potential

We now make the substitutions (2.10) through (2.15) and take the limit $\rho_0 \to 0$ to obtain the limiting vector potential whose components we will denote by letters with breve marks $\breve{}$ above. So doing yields for the constant part of the magnetic field the limiting result

$$\breve{A}_\phi^{\min 1} = -\ell(B/2)\xi. \tag{V.3.15}$$

And for the leading term of the nonconstant part of the magnetic field, again taking for illustrative purposes the magnetic monopole doublet example, there are the results

$$\begin{gathered}\breve{A}_\rho^{\min 2} = \ell^2[-2ga/(X_0^2 + Z_0^2 + a^2)^{5/2}] \times \\ \{(\cos\phi)[Z_0 Y^2 - \xi^2(Z_0 \sin^2\phi - X_0 \cos\phi \sin\phi)] \\ +(\sin\phi)[\xi^2(X_0 \cos^2\phi + Z_0 \cos\phi \sin\phi) - X_0 Y^2]\},\end{gathered} \tag{V.3.16}$$

$$\breve{A}_y^{\min 2} = \ell^2[-2ga/(X_0^2 + Z_0^2 + a^2)^{5/2}][\xi Y(X_0 \sin\phi - Z_0 \cos\phi)], \tag{V.3.17}$$

$$\begin{gathered}\breve{A}_\phi^{\min 2} = \ell^2[-2ga/(X_0^2 + Z_0^2 + a^2)^{5/2}] \times \\ \{-(\sin\phi)[Z_0 Y^2 - \xi^2(Z_0 \sin^2\phi - X_0 \cos\phi \sin\phi)] \\ +(\cos\phi)[\xi^2(X_0 \cos^2\phi + Z_0 \cos\phi \sin\phi) - X_0 Y^2]\}.\end{gathered} \tag{V.3.18}$$

V.3.4 Computation of Limiting Hamiltonian in Dimensionless Variables

At this point we are again ready to compute $\tilde{K}^{\text{lim}}$, but this time with possible inhomogeneity in the magnetic field included. Let us introduce the notation

$$\breve{\boldsymbol{A}}^{\text{min non}} = \breve{\boldsymbol{A}}^{\text{min 2}} + \breve{\boldsymbol{A}}^{\text{min 3}} + \breve{\boldsymbol{A}}^{\text{min 4}} + \cdots \tag{V.3.19}$$

to denote the *nonlinear* part of the vector potential. We now find for the limiting Hamiltonian the result

$$\begin{aligned}\tilde{K}^{\text{lim}} &= -\xi[1 - 2P_\tau/\beta + P_\tau^2 - (P_\xi - \mathcal{A}_\rho^{\text{min non}})^2 - (P_y - \mathcal{A}_y^{\text{min non}})^2]^{1/2} \\ &\quad +(b/2)\xi^2 - \xi\mathcal{A}_\phi^{\text{min non}}\end{aligned} \tag{V.3.20}$$

where

$$\mathcal{A}_\rho^{\text{min non}} = (q/p_0)\breve{A}_\rho^{\text{min non}}, \tag{V.3.21}$$

$$\mathcal{A}_y^{\text{min non}} = (q/p_0)\breve{A}_y^{\text{min non}}, \tag{V.3.22}$$

$$\mathcal{A}_\phi^{\text{min non}} = (q/p_0)\breve{A}_\phi^{\text{min non}}. \tag{V.3.23}$$

V.3.5 Deviation Variable Hamiltonian

Introduce, as before, deviation variables $(\hat{\xi}, \tau, Y; \hat{P}_\xi, P_\tau, P_y)$ with $\hat{\xi}$ and $\hat{P}_\xi$ defined by (2.38) and (2.39). Doing so, and employing the rule (2.43), yields the new Hamiltonian

$$\begin{aligned}H &= -\hat{\xi}[1 - 2P_\tau/\beta + P_\tau^2 - (\sin\Delta + \hat{P}_\xi - \hat{\mathcal{A}}_\rho^{\text{min non}})^2 - (P_y - \hat{\mathcal{A}}_y^{\text{min non}})^2]^{1/2} \\ &\quad + (b/2)\hat{\xi}^2 - \hat{\xi}\hat{\mathcal{A}}_\phi^{\text{min non}} + \hat{\xi}\cos\Delta.\end{aligned} \tag{V.3.24}$$

Here we have used the notation $\hat{\mathcal{A}}_\rho^{\text{min non}}$ to indicate that the variable ξ in $\mathcal{A}_\rho^{\text{min non}}$ has been replaced by $\hat{\xi}$, etc. For example, in the case of a magnetic monopole doublet, there are the results

$$\begin{aligned}\hat{\mathcal{A}}_\rho^{\text{min 2}} &= (q/p_0)\ell^2[-2ga/(X_0^2 + Z_0^2 + a^2)^{5/2}] \times \\ &\{(\cos\phi)[Z_0Y^2 - \hat{\xi}^2(Z_0\sin^2\phi - X_0\cos\phi\sin\phi)] \\ &+(\sin\phi)[\hat{\xi}^2(X_0\cos^2\phi + Z_0\cos\phi\sin\phi) - X_0Y^2]\},\end{aligned} \tag{V.3.25}$$

$$\hat{\mathcal{A}}_y^{\text{min 2}} = (q/p_0)\ell^2[-2ga/(X_0^2 + Z_0^2 + a^2)^{5/2}][\hat{\xi}Y(X_0\sin\phi - Z_0\cos\phi)], \tag{V.3.26}$$

$$\begin{aligned}\hat{\mathcal{A}}_\phi^{\text{min 2}} &= (q/p_0)\ell^2[-2ga/(X_0^2 + Z_0^2 + a^2)^{5/2}] \times \\ &\{-(\sin\phi)[Z_0Y^2 - \hat{\xi}^2(Z_0\sin^2\phi - X_0\cos\phi\sin\phi)] \\ &+(\cos\phi)[\hat{\xi}^2(X_0\cos^2\phi + Z_0\cos\phi\sin\phi) - X_0Y^2]\}.\end{aligned} \tag{V.3.27}$$

V.3.6 Expansion of Deviation Variable Hamiltonian and Computation of Transfer Map

As done before in Subsection 2.6, we expand H in terms of homogeneous polynomials. Begin by observing that there is the relation

$$1-(\sin\Delta+\hat{P}_\xi-\hat{\mathcal{A}}_\rho^{\text{min non}})^2 =$$
$$\cos^2\Delta-\hat{P}_\xi^2-(\hat{\mathcal{A}}_\rho^{\text{min non}})^2-2(\sin\Delta)\hat{P}_\xi+2(\sin\Delta)\hat{\mathcal{A}}_\rho^{\text{min non}}+2\hat{P}_\xi\hat{\mathcal{A}}_\rho^{\text{min non}}. \tag{V.3.28}$$

Consequently H, as given by (3.24), can be rewritten in the form

$$\begin{aligned} H &= -\hat{\xi}[\cos^2\Delta-2P_\tau/\beta+P_\tau^2-\hat{P}_\xi^2-(\hat{\mathcal{A}}_\rho^{\text{min non}})^2 \\ &\quad -2(\sin\Delta)\hat{P}_\xi+2(\sin\Delta)\hat{\mathcal{A}}_\rho^{\text{min non}}+2\hat{P}_\xi\hat{\mathcal{A}}_\rho^{\text{min non}} \\ &\quad -P_y^2+2P_y\hat{\mathcal{A}}_y^{\text{min non}}-(\hat{\mathcal{A}}_y^{\text{min non}})^2]^{1/2} \\ &\quad +(b/2)\hat{\xi}^2-\hat{\xi}\hat{\mathcal{A}}_\phi^{\text{min non}}+\ \hat{\xi}\cos\Delta. \end{aligned} \tag{V.3.29}$$

We are now prepared to expand H in the form (2.47). Compare (2.46) and (3.29). Since $\hat{\mathcal{A}}_\rho^{\text{min non}}$ and $\hat{\mathcal{A}}_y^{\text{min non}}$ consist entirely of terms of degree 2 and higher, and $\hat{\xi}\hat{\mathcal{A}}_\phi^{\text{min non}}$ consists entirely of terms of degree 3 and higher, it follows that they make *no* contribution to H_0 through H_2. {Note that the term of the form $[***]^{1/2}$ in (3.29) is multiplied by $\hat{\xi}$.} Therefore the H_0, H_1, and H_2 terms in the expansion are the *same* as those given by (2.48) through (2.50). Consequently the design orbit and $\mathcal{R}$, the linear part of the transfer map about the design orbit, are the same as those found earlier. That is, the design orbit does *not* depend on the magnetic field, and the linear part of the transfer map depends *only* on the uniform part of the magnetic field, described by $A_\phi^{\text{min }1}$ or b. The design orbit and the linear part of the transfer map do *not* depend on field inhomogeneities described by the $\boldsymbol{A}^{\text{min }n}$ with $n \geq 2$. Field inhomogeneities play a role only in the calculation of the H_m with $m \geq 3$. Correspondingly, field inhomogeneities play a role in the transfer map only for the generators f_m with $m \geq 3$.

We close this subsection by computing, for example, the H_3 that occurs in the expansion of (3.29). We find the result

$$H_3 = . \tag{V.3.30}$$

See Exercise 3.1. Note that (2.67) and (3.30) agree when there are no field inhomogeneities.

Exercises

V.3.1. Verify that, in the computation of the H_3 term that occurs in the expansion of (3.29), the terms * are of too high an order to play a role, and therefore may be neglected.

Smoothing for Harmonic Functions

W.1 Introduction

W.2 The Line in Two Space

Consider in x, y space the line $y = 0$ and suppose a potential $\psi_0(x)$ is specified on this line. Define its Fourier transform $\tilde{\psi}_0(k_x)$ by the rule

$$\tilde{\psi}_0(k_x) = [1/\sqrt{(2\pi)}] \int dx \ \exp(-ik_x x)\psi_0(x). \tag{W.2.1}$$

Make the Ansatz

$$\psi(x, y) = [1/\sqrt{(2\pi)}] \int dk_x \exp(ik_x x) \exp(-ky)\tilde{\psi}_0(k_x) \tag{W.2.2}$$

where

$$k = \sqrt{k_x^2} = |k_x|. \tag{W.2.3}$$

Evidently this $\psi(x, y)$ is harmonic and vanishes as $y \rightarrow +\infty$. We also have the result

$$\psi(x, 0) = [1/\sqrt{(2\pi)}] \int dk_x \exp(ik_x x)\tilde{\psi}_0(k_x) = \psi_0(x). \tag{W.2.4}$$

It follows that we have found the solution to Laplace's equation in the upper half plane $y \geq 0$ associated with the $y = 0$ boundary value $\psi_0(x)$.

Note that the operation defined by (2.2) is smoothing for $y > 0$. High spatial frequencies are suppressed by the factor $\exp(-ky)$, and this *exponential* suppression/damping is ever more effective the larger the value of y. The higher the y observation line is above the $y = 0$ line, the smoother $\psi(x, y)$ on this observation line becomes as a function of x.

We also observe, in passing, two facts. First, suppose ψ_0, now to be called ψ_0^c, is a *constant* function,

$$\psi_0^c(x) = c. \tag{W.2.5}$$

Then, by (2.1),

$$\tilde{\psi}_0^c(k_x) = c\sqrt{2\pi}\delta(k_x). \tag{W.2.6}$$

It follows from (2.2) that there is the relation

$$\psi^c(x,y) = c. \tag{W.2.7}$$

As expected, if ψ is constant on the boundary $y = 0$, it will have the same constant value in the upper half plane $y \geq 0$. Second, for any solution, there is the relation

$$\begin{aligned} \int dx\ \psi(x,y) &= [1/\sqrt{(2\pi)}] \int dk_x \exp(-ky)\tilde{\psi}_0(k_x) \int dx\ \exp(ik_x x) \\ &= [1/\sqrt{(2\pi)}] \int dk_x \exp(-ky)\tilde{\psi}_0(k_x)(2\pi)\delta(k_x) \\ &= \sqrt{(2\pi)}\tilde{\psi}_0(0) = \int dx\ \psi_0(x). \end{aligned} \tag{W.2.8}$$

That is, the dx integral of $\psi(x,y)$ over any line of constant y is independent of y.

To further study smoothing in the case of a line, suppose ψ_0, now to be called ψ_0^δ, is a delta function centered on the origin,

$$\psi_0^\delta(x) = \delta(x). \tag{W.2.9}$$

Then, by (2.1),

$$\tilde{\psi}_0^\delta(k_x) = 1/\sqrt{(2\pi)}, \tag{W.2.10}$$

and (2.2) takes the form

$$\psi^\delta(x,y) = [1/(2\pi)] \int dk_x \exp(ik_x x)\exp(-ky). \tag{W.2.11}$$

This integral can be evaluated to give the result

$$\psi^\delta(x,y) = (1/\pi)[y/(x^2+y^2)]. \tag{W.2.12}$$

We next observe directly that, as expected, the function $\psi^\delta(x,y)$ given by (2.12) is harmonic. Define ρ by the rule

$$\rho = \sqrt{x^2+y^2}. \tag{W.2.13}$$

From 2-D potential theory we know that the function $\log(\rho)$ is harmonic. By the properties of the logarithm function there is the relation

$$\log(\rho^2) = 2\log(\rho), \tag{W.2.14}$$

and therefore the function $\log(\rho^2)$ is also harmonic. We next observe that the operators ∂_y and ∇^2 commute. It follows that the function $\partial_y \log(\rho^2)$ is also harmonic. Finally, there is the result

$$\partial_y \log(\rho^2) = \partial_y \log(x^2+y^2) = 2y/(x^2+y^2). \tag{W.2.15}$$

Upon comparing (2.12) and (2.15) we see that $\psi^\delta(x,y)$ is indeed harmonic.

Let us now, with the aid of (2.12), illustrate the general behavior of $\psi^\delta(x,y)$. Figure 2.1 displays $\psi^\delta(x,y)$ as a function of x for various values of y. Figure 2.2 displays $\psi^\delta(x,y)$ as a function of y for various values of x.

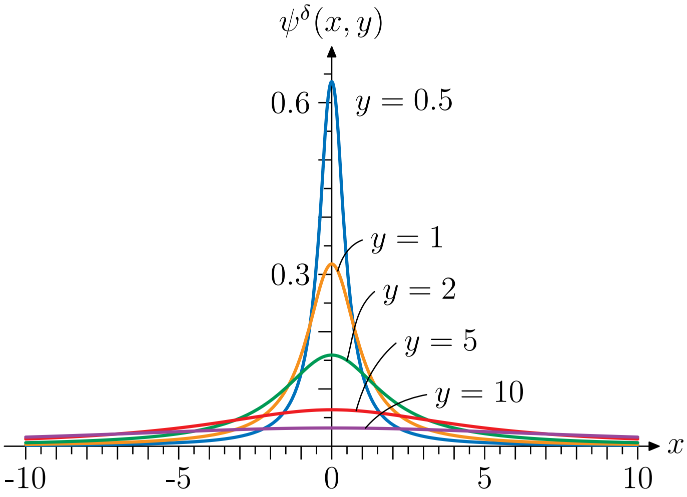

Figure W.2.1: The function $\psi^\delta(x,y)$ as a function of x for various values of y.

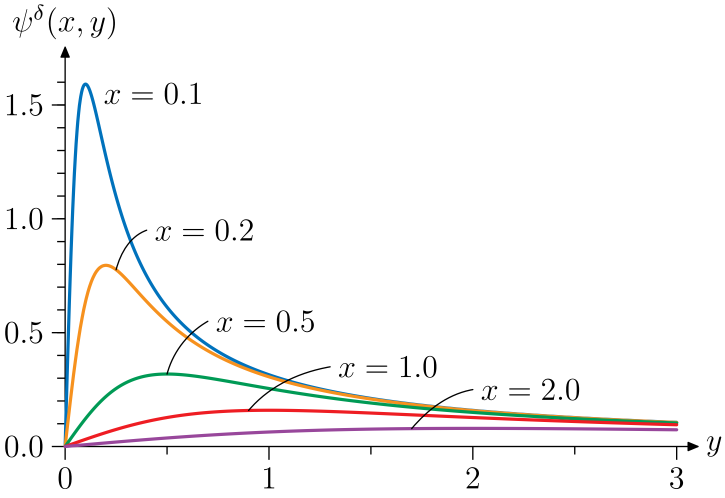

Figure W.2.2: The function $\psi^\delta(x,y)$ as a function of y for various values of x.

From Figure 2.1 we see that the delta function potential spike on the $y = 0$ line becomes an ever lower and broader bump on lines of increasing y. And we know from (2.8) that the weighted area under the bump remains the same for all y,

$$\int dx\ \psi^\delta(x,y) = \int dx\ \delta(x) = 1. \tag{W.2.16}$$

Thus the effect of a disturbance in the potential on the $y = 0$ line "decays" away as one moves to lines with successively larger values of y. Figure 2.2 illustrates this decay as a function of y for various values of x. Indeed, there are the expansions

$$\psi^\delta(x,y) = (1/\pi)(1/y)[1 - (x^2/y^2) + (x^2/y^2)^2 - \cdots] \text{ for } x < y, \tag{W.2.17}$$

$$\psi^\delta(x,y) = [1/(2\pi)](1/y) \text{ for } x = y, \tag{W.2.18}$$

$$\psi^\delta(x,y) = (1/\pi)(y/x^2)[1 - (y^2/x^2) + (y^2/x^2)^2 - \cdots] \text{ for } y < x. \tag{W.2.19}$$

Evidently, as expected, the sequence of functions $\psi^\delta(x,y)$ for varying y converges to the delta function,

$$\lim_{y\to 0^+} \psi^\delta(x,y) = \delta(x). \tag{W.2.20}$$

Finally, we see from (2.17) that $\psi^\delta(x,y)$ falls of as y^{-1} for fixed x and large y, and observe that the dimension of a line is 1. And, from (2.19), we see that $\psi^\delta(x,y)$ falls of as x^{-2} for fixed y and large x. For yet more insight, see Exercise 2.3.

What is the mechanism for this decay? In agreement with (2.8) and (2.16), this decay occurs entirely due to spreading. Indeed, the relations (2.5) and (2.7) illustrate that if the initial/boundary potential distribution is completely "spread out", i.e. constant, then no decay occurs.

We have seen an example of how the effects of a local disturbance in the potential diminish with distance from the disturbance.

From the response (2.12) to a delta function disturbance (2.9) we can derive the response to a general disturbance. With (2.12) in mind, define a kernel $G(x;x';y)$ by the rule

$$G(x;x';y) = (1/\pi)\{y/[y^2 + (x-x')^2]. \tag{W.2.21}$$

Observe that a general disturbance $\psi_0(x)$ has the integral representation

$$\psi_0(x) = \int dx'\psi_0(x')\delta(x-x'). \tag{W.2.22}$$

It follows that the response to $\psi_0(x)$ is given by the integral

$$\psi(x,y) = \int dx'\psi_0(x')G(x;x';y). \tag{W.2.23}$$

For what it's worth we remark that, according to the connection between Laplace and Monte Carlo, the quantity $G(x;x';y)$ is the probability that a random walk initiated at the point x, y will reach the point $x', 0$.

Exercises

W.2.1. Evaluate the integral (2.11) to verify the claim (2.12).

W.2.2. Evaluate directly the integral on the left side of (2.16) using (2.12). Verify (2.23) for the case (2.5).

W.2.3. The purpose of this exercise is to verify and employ an observation made by *Dan Abell.* Using (2.12), consider the *level curves* of ψ^δ having heights h by writing

$$\psi^\delta(x, y) = h. \tag{W.2.24}$$

Show that so doing yields the relation

$$x^2 + [y - 1/(2\pi h)]^2 = [1/(2\pi h)]^2. \tag{W.2.25}$$

Observe that the level curves (*equipotential lines*) are all circles, and that all the circles pass through the origin. Sketch them for yourself, and label them according to the values of h! Employ this result to explain the features of Figures 2.1 and 2.2.

W.3 The Plane in Three Space

Consider in x, y, z space the plane $z = 0$ and suppose a potential $\psi_0(x, y)$ is specified on this plane. Define its Fourier transform $\tilde{\psi}_0(k_x, k_y)$ by the rule

$$\tilde{\psi}_0(k_x, k_y) = [1/(2\pi)] \int dxdy\ \exp(-ik_x x)\exp(-ik_y y)\psi_0(x, y). \tag{W.3.1}$$

Make the Ansatz

$$\psi(x, y, z) = [1/(2\pi)] \int dk_x dk_y \exp(ik_x x)\exp(ik_y y)\exp(-kz)\tilde{\psi}_0(k_x, k_y) \tag{W.3.2}$$

where

$$k = \sqrt{k_x^2 + k_y^2}. \tag{W.3.3}$$

Evidently this $\psi(x, y, z)$ is harmonic and vanishes as $z \to +\infty$. We also have the result

$$\psi(x, y, 0) = [1/(2\pi)] \int dk_x dk_y \exp(ik_x x)\exp(ik_y y)\tilde{\psi}_0(k_x, k_y) = \psi_0(x, y). \tag{W.3.4}$$

It follows that we have found the solution to Laplace's equation in the upper half space $z \geq 0$ associated with the $z = 0$ boundary value $\psi_0(x, y)$.

Note that the operation defined by (3.2) is smoothing for $z > 0$. High spatial frequencies are suppressed by the factor $\exp(-kz)$, and this *exponential* suppression/damping is ever more effective the larger the value of z. The higher the z observation plane is above the $z = 0$ plane, the smoother $\psi(x, y, z)$ on this observation plane becomes as a function of x and y.

We also observe, in passing, two facts. First, suppose ψ_0, now to be called ψ_0^c, is a *constant* function,

$$\psi_0^c(x, y) = c. \tag{W.3.5}$$

Then, by (3.1),

$$\tilde{\psi}_0^c(k_x) = c(2\pi)\delta(k_x)\delta(k_y). \tag{W.3.6}$$

It follows from (3.2) that there is the relation

$$\psi^c(x, y, z) = c. \tag{W.3.7}$$

As expected, if ψ is constant on the boundary $z = 0$, it will have the same constant value in the upper half space $z \geq 0$. Second, for any solution, there is the relation

$$\begin{aligned}\int dxdy\ \psi(x, y, z) &= [1/(2\pi)] \int dk_x dk_y \exp(-kz)\tilde{\psi}_0(k_x, k_y) \int dxdy\ \exp(ik_x x)\exp(ik_y y)\\ &= [1/(2\pi)] \int dk_x dk_y \exp(-kz)\tilde{\psi}_0(k_x, k_y)(2\pi)^2\delta(k_x)\delta(k_y)\\ &= (2\pi)\tilde{\psi}_0(0, 0) = \int dxdy\ \psi_0(x, y). \end{aligned} \tag{W.3.8}$$

That is, the $dxdy$ integral of $\psi(x, y, z)$ over any plane of constant z is independent of z.

To further study smoothing in the case of a plane, suppose ψ_0, now to be called ψ_0^δ, is a delta function centered on the origin,

$$\psi_0^\delta(x, y) = \delta(x)\delta(y). \tag{W.3.9}$$

Then, by (3.1),

$$\tilde{\psi}_0^\delta(k_x, k_y) = 1/(2\pi), \tag{W.3.10}$$

and (3.2) takes the form

$$\psi^\delta(x, y, z) = [1/(2\pi)^2] \int dk_x dk_y \exp(ik_x x)\exp(ik_y y)\exp(-kz). \tag{W.3.11}$$

Let work to evaluate this double integral. Introduce polar variables by writing

$$\begin{aligned} x &= \rho\cos(\theta),\\ y &= \rho\sin(\theta); \end{aligned} \tag{W.3.12}$$

$$\begin{aligned} k_x &= k\cos(\phi),\\ k_y &= k\sin(\phi). \end{aligned} \tag{W.3.13}$$

Then we have the relations

$$k_x x + k_y y = k\rho[\cos(\phi)\cos(\theta) + \sin(\phi)\sin(\theta)] = k\rho\cos(\phi - \theta), \tag{W.3.14}$$

$$dk_x dk_y = kdkd\phi. \tag{W.3.15}$$

Correspondingly, (3.11) takes the form

$$\psi^\delta(x,y,z) = [1/(2\pi)^2]\int_0^\infty kdk\exp(-kz)\int_0^{2\pi} d\phi\ \exp[ik\rho\cos(\phi-\theta)]. \tag{W.3.16}$$

Next perform further manipulations. By periodicity we have the result

$$\int_0^{2\pi} d\phi\ \exp[ik\rho\cos(\phi-\theta)] = \int_0^{2\pi} d\phi\ \exp[ik\rho\cos(\phi)]. \tag{W.3.17}$$

Also there is the result

$$\exp[ik\rho\cos(\phi)] = \cos[k\rho\cos(\phi)] + i\sin[k\rho\cos(\phi)]. \tag{W.3.18}$$

Moreover, we recall the relations

$$\cos[k\rho\cos(\phi)] = J_0(k\rho) + 2\sum_{k=1}^\infty(-1)^k J_{2k}(k\rho)\cos(2k\phi), \tag{W.3.19}$$

$$\sin[k\rho\cos(\phi)] = 2\sum_{k=0}^\infty(-1)^k J_{2k+1}(k\rho)\cos[(2k+1)\phi]. \tag{W.3.20}$$

It follows that

$$\int_0^{2\pi} d\phi\ \cos[k\rho\cos(\phi)] = (2\pi)J_0(k\rho), \tag{W.3.21}$$

$$\int_0^{2\pi} d\phi\ \sin[k\rho\cos(\phi)] = 0, \tag{W.3.22}$$

and therefore

$$\int_0^{2\pi} d\phi\ \exp[ik\rho\cos(\phi)] = (2\pi)J_0(k\rho). \tag{W.3.23}$$

Upon combining the fruits of our labor we find the pleasant result

$$\psi^\delta(x,y,z) = [1/(2\pi)]\int_0^\infty kdkJ_0(k\rho)\exp(-kz). \tag{W.3.24}$$

Note that $\psi^\delta(x,y,z)$ depends on x and y only through the rotationally invariant quantity ρ, as expected by axial symmetry about the z axis.

Yet more can be accomplished. There is the general Bessel function relation

$$\int_0^\infty tdt\exp(-at)J_0(bt) = a/(a^2+b^2)^{3/2}. \tag{W.3.25}$$

Consequently, we have the final result

$$\psi^\delta(x,y,z) = [1/(2\pi)][z/(z^2+\rho^2)^{3/2}]. \tag{W.3.26}$$

We next observe directly that, as expected, the function $\psi^\delta(x,y,z)$ given by (3.26) is harmonic. Define r by the rule

$$r = \sqrt{x^2+y^2+z^2} = \sqrt{z^2+\rho^2}. \tag{W.3.27}$$

From 3-D potential theory we know that the function $1/r$ is harmonic. We next observe that the operators ∂_z and ∇^2 commute. It follows that the function $\partial_z(1/r)$ is also harmonic. Finally, there is the result

$$\partial_z(1/r) = \partial_z(1/\sqrt{z^2+\rho^2}) = z/(z^2+\rho^2)^{3/2}. \tag{W.3.28}$$

Upon comparing (3.26) and (3.28) we see that $\psi^\delta(x,y,z)$ is indeed harmonic.

Let us now, with the aid of (3.26), illustrate the general behavior of $\psi^\delta(x,y,z)$. Figure 3.1 displays $\psi^\delta(x,y,z)$ as a function of ρ for various values of z. Figure 3.2 displays $\psi^\delta(x,y,z)$ as a function of z for various values of ρ.

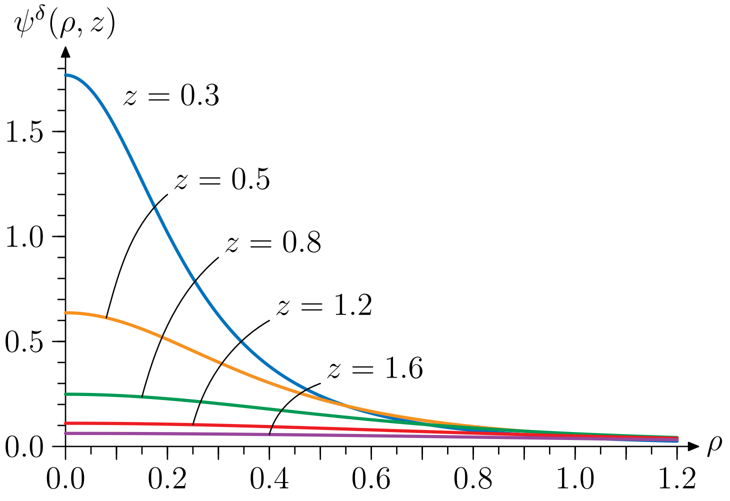

Figure W.3.1: The function $\psi^\delta(x,y,z) = \psi^\delta(\rho,z)$ as a function of ρ for various values of z.

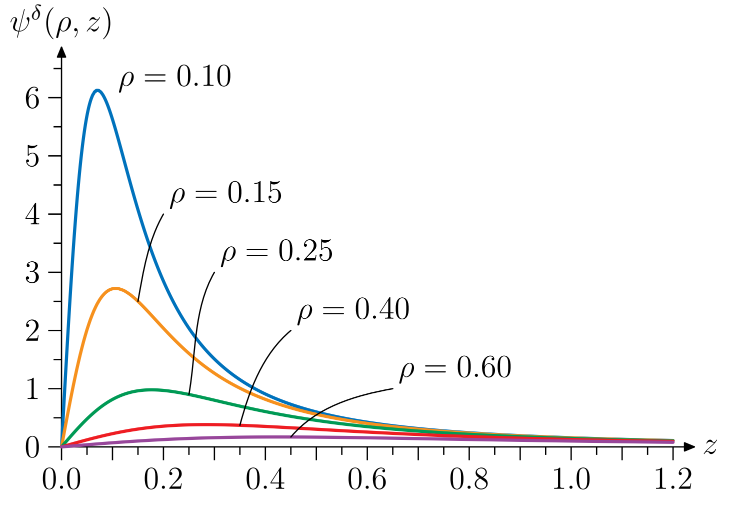

Figure W.3.2: The function $\psi^\delta(x,y,z) = \psi^\delta(\rho,z)$ as a function of z for various values of ρ.

From Figure 3.1 we see that the delta function potential spike in the $z = 0$ plane becomes an ever lower and broader bump in planes with increasing z. And we know from (3.8) that the weighted area under the bump remains the same for all z,

$$\int dxdy\ \psi^{\delta}(x,y,z) = \int dxdy\ \delta(x)\delta(y) = 1. \tag{W.3.29}$$

Thus the effect of a disturbance in the potential in the $z = 0$ plane "decays" away as one moves to planes with successively larger values of z. Figure 3.2 illustrates this decay as a function of z for various values of ρ. Indeed, there are the expansions

$$\psi^{\delta}(x,y,z) = [1/(2\pi)](1/z^2)[1-(3/2)(\rho^2/z^2)+(15/8)(\rho^2/z^2)^2-\cdots] \text{ for } \rho < z, \tag{W.3.30}$$

$$\psi^{\delta}(x,y,z) = [1/(2\pi)](1/2^{3/2})(1/z^2) \text{ for } \rho = z, \tag{W.3.31}$$

$$\psi^{\delta}(x,y,z) = [1/(2\pi)](z/\rho^3)[1-(3/2)(z^2/\rho^2)+(15/8)(z^2/\rho^2)^2-\cdots] \text{ for } z < \rho. \tag{W.3.32}$$

Evidently, as expected, the sequence of functions $\psi^{\delta}(x,y,z)$ for varying z converges to the delta function,

$$\lim_{z\to 0^+} \psi^{\delta}(x,y,z) = \delta(x)\delta(y). \tag{W.3.33}$$

Finally, we see from (3.30) that $\psi^{\delta}(x,y,z)$ falls of as z^{-2} for fixed ρ and large z, and observe that the dimension of a plane is 2. And, from (3.32), we see that $\psi^{\delta}(x,y,z)$ falls of as ρ^{-3} for fixed z and large ρ. What is the mechanism for this decay? In agreement with (3.8) and (3.29), this decay occurs entirely due to spreading. Indeed, the relations (3.5) and (3.7) illustrate that if the initial/boundary potential distribution is completely "spread out", i.e. constant, then no decay occurs.

We have again seen an example of how the effects of a local disturbance in the potential diminish with distance from the disturbance.

From the response (3.26) to a delta function disturbance (3.9) we can derive the response to a general disturbance. With (3.26) in mind, define a kernel $G(x,y;x',y';z)$ by the rule

$$G(x,y;x',y';z) = [1/(2\pi)]\{z/[z^2+(x-x')^2+(y-y')^2]^{3/2}\}. \tag{W.3.34}$$

Observe that a general disturbance $\psi_0(x,y)$ has the integral representation

$$\psi_0(x,y) = \int dx'dy'\ \psi_0(x',y')\delta(x-x')\delta(y-y'). \tag{W.3.35}$$

It follows that the response to $\psi_0(x,y)$ is given by the integral

$$\psi(x,y,z) = \int dx'dy'\ \psi_0(x',y')G(x,y;x',y';z). \tag{W.3.36}$$

For what it's worth we remark that, according to the connection between Laplace and Monte Carlo, the quantity $G(x,y;x',y';z)$ is the probability that a random walk initiated at the point x,y,z will reach the point $x',y',0$.

Exercises

W.3.1. Evaluate directly the integral on the left side of (3.29) using (3.26). Verify (3.36) for the case (3.5).

W.4 The Circle in Two Space

Consider in x, y space a circle of radius R centered on the origin, and suppose a potential ψ_R is specified on this circle. More specifically, employ the polar variables (3.9) so that

$$\psi(x, y) = \psi(\rho, \theta) \tag{W.4.1}$$

and

$$\psi(R, \theta) = \psi_R(\theta). \tag{W.4.2}$$

Define the angular Fourier transform of $\psi_R(\theta)$ by the rule

$$\tilde{\psi}_R(m) = ([1/(2\pi)] \int_0^{2\pi} d\theta \ \exp(-im\theta)\psi_R(\theta). \tag{W.4.3}$$

Make the Ansatz

$$\psi(\rho, \theta) = \sum_{m=-\infty}^{m=\infty} (\rho/R)^{|m|} \exp(im\theta)\tilde{\psi}_R(m). \tag{W.4.4}$$

Evidently this $\psi(\rho, \theta)$ is harmonic. We also have the result

$$\psi(R, \theta) = \sum_{m=-\infty}^{m=\infty} \exp(im\theta)\tilde{\psi}_R(m) = \psi_R(\theta). \tag{W.4.5}$$

It follows that we have found the solution to Laplace's equation in the disk of radius R with the boundary value $\psi_R(\theta)$.

Note that the operation defined by (4.4) is smoothing for $(\rho/R) < 1$. We see that high angular frequencies are suppressed by the factor

$$(\rho/R)^{|m|} = \exp[|m| \log(\rho/R)], \tag{W.4.6}$$

and observe that $\log(\rho/R) < 0$. This *exponential* suppression/damping is ever more effective the larger the value of R and/or the smaller the value of ρ. The larger the radius R of the boundary circle and/or the smaller the radius ρ of the observation circle, the smoother $\psi(\rho, \theta)$ becomes as a function of θ.

We also observe, in passing, three facts. First, suppose ψ_R, now to be called ψ_R^c, is a *constant* function,

$$\psi_R^c(\theta) = c. \tag{W.4.7}$$

Then, by (4.3),

$$\tilde{\psi}_R^c(m) = c\delta_{m,0}. \tag{W.4.8}$$

It follows from (4.4) that there is the relation

$$\psi^c(\rho, \theta) = c. \tag{W.4.9}$$

As expected, if ψ is constant on the boundary $\rho = R$, it will have the same constant value inside the circle. Second, for any solution, there is the relation

$$\int_0^{2\pi} d\theta \ \psi(\rho, \theta) = (2\pi) \sum_{m=-\infty}^{m=\infty} (\rho/R)^{|m|}\tilde{\psi}_R(m)\delta_{m,0} = (2\pi)\tilde{\psi}_R(0) = \int_0^{2\pi} d\theta \ \psi_R(\theta). \tag{W.4.10}$$

That is, the $d\theta$ integral of $\psi(\rho, \theta)$ over any circle of constant ρ is independent of ρ. Third, we also see from (4.4) that there is the relation

$$\psi(0, \theta) = \tilde{\psi}_R(0) = [1/(2\pi)] \int_0^{2\pi} d\theta \psi_R(\theta), \tag{W.4.11}$$

which shows that the average value of an harmonic function over a circle equals its value at the center of the circle, a result which in turn is a special case of the connection between Laplace and Monte Carlo.

To further study smoothing in the case of a circle in two space, suppose ψ_R, now to be called ψ_R^δ, is a delta function centered on $\theta = 0$,

$$\psi_R^\delta(\theta) = \delta(\theta). \tag{W.4.12}$$

Then, by (4.3),

$$\tilde{\psi}_R^\delta(m) = 1/(2\pi), \tag{W.4.13}$$

and (4.4) takes the form

$$\psi^\delta(\rho, \theta) = [1/(2\pi)] \sum_{m=-\infty}^{m=\infty} (\rho/R)^{|m|} \exp(im\theta). \tag{W.4.14}$$

Let us work to evaluate this sum. Introduce the simplifying notation

$$\lambda = \rho/R \tag{W.4.15}$$

with the understanding that, for our purposes,

$$\lambda \in [0, 1]. \tag{W.4.16}$$

Correspondingly, make the definition

$$\hat{\psi}^\delta(\lambda, \theta) = \psi^\delta(\rho, \theta) = [1/(2\pi)] \sum_{m=-\infty}^{m=\infty} \lambda^{|m|} \exp(im\theta). \tag{W.4.17}$$

Observe that there is the result

$$\sum_{m=-\infty}^{m=\infty} \lambda^{|m|} \exp(im\theta) = -1 + \sum_{m=0}^{m=\infty} \lambda^m \exp(im\theta) + \sum_{m=0}^{m=\infty} \lambda^m \exp(-im\theta). \tag{W.4.18}$$

Each of the series appearing on the right side of (4.18) is a geometric series, and can therefore be evaluated. We find the results

$$\sum_{m=0}^{m=\infty} \lambda^m \exp(im\theta) = 1/[1 - \lambda \exp(i\theta)], \tag{W.4.19}$$

$$\sum_{m=0}^{m=\infty} \lambda^m \exp(-im\theta) = 1/[1 - \lambda \exp(-i\theta)]. \tag{W.4.20}$$

Consequently,

$$\hat{\psi}^{\delta}(\lambda,\theta)=[1/(2\pi)]\{-1+1/[1-\lambda\exp(i\theta)]+1/[1-\lambda\exp(-i\theta)]\}. \tag{W.4.21}$$

The three terms on the right side of (4.21) can be put over a common denominator. Doing so, and recalling that

$$\cos(\theta)=(1/2)[\exp(i\theta)+\exp(-i\theta)], \tag{W.4.22}$$

give the final result

$$\hat{\psi}^{\delta}(\lambda,\theta)=[1/(2\pi)]\{[\lambda^{-1}-\lambda]/[\lambda^{-1}+\lambda-2\cos(\theta)]\}. \tag{W.4.23}$$

We know that, by construction, the function $\hat{\psi}^{\delta}(\lambda,\theta)$ is harmonic. See (4.14). We will next observe *directly* that the function $\hat{\psi}^{\delta}(\lambda,\theta)$, as given by (4.23), is harmonic. To do so we will exploit a fact about analytic functions. Suppose f is an *analytic* function of the complex variable $z=x+iy$. (Here z is *not* a Cartesian coordinate.) Define a function $u(x,y)$ by writing

$$u(x,y)=f(z)=f(x+iy). \tag{W.4.24}$$

Then, by the chain rule, it follows that

$$(\partial_x)^2u(x,y)=f''(z) \tag{W.4.25}$$

and

$$(\partial_y)^2u(x,y)=(i^2)f''(z)=-f''(z), \tag{W.4.26}$$

from which it follows that

$$[(\partial_x)^2+(\partial_y)^2]u(x,y)=0; \tag{W.4.27}$$

the function $u(x,y)$ defined by (4.24) is harmonic. Similarly the function $v(x,y)$ defined by

$$v(x,y)=f(\bar{z})=f(x-iy) \tag{W.4.28}$$

is also harmonic. Now look at the right sides of (4.19) and (4.20). They can be rewritten in the forms

$$1/[1-\lambda\exp(i\theta)]=1/[1-(1/R)(x+iy)]=1/[1-(1/R)z], \tag{W.4.29}$$

$$1/[1-\lambda\exp(-i\theta)]=1/[1-(1/R)(x-iy)]=1/[1-(1/R)\bar{z}]. \tag{W.4.30}$$

It follows that both these functions are harmonic. Finally, we see from (4.23) that $\hat{\psi}^{\delta}(\lambda,\theta)$ is the sum of a constant (which is a harmonic function) and multiples of the harmonic functions in (4.29) and (4.30). Therefore $\hat{\psi}^{\delta}(\lambda,\theta)$ is harmonic.

Let us now, with the aid of (4.23), illustrate the general behavior of $\hat{\psi}^{\delta}$. Figure 4.1 displays the function $\hat{\psi}^{\delta}(\lambda,\theta)$ as a function of $\theta\in(-\pi,\pi)$ for various values of $\lambda\in[0,1]$. Note that there are the relations

$$(\lambda^{-1}+\lambda)>2 \text{ for } \lambda\in(0,1) \tag{W.4.31}$$

and

$$(\lambda^{-1}+\lambda)=2 \text{ for } \lambda=1. \tag{W.4.32}$$

From the figure two facts are evident:

- For $\lambda \simeq 1$, $\hat{\psi}^{\delta}(\lambda,\theta)$ is highly peaked about $\theta = 0$ and is small for $\theta \neq 0$.
- For $\lambda \simeq 0$, $\hat{\psi}^{\delta}(\lambda,\theta)$ is nearly 1. Indeed, by (4.14), there is the small λ expansion

$$\hat{\psi}^{\delta}(\lambda,\theta) = [1/(2\pi)][1 + 2\lambda\cos(\theta) + 2\lambda^2\cos(2\theta) + \cdots]. \tag{W.4.33}$$

Also, again by (4.14), there is the integral relation

$$\int_{-\pi}^{\pi} d\theta\ \hat{\psi}^{\delta}(\lambda,\theta) = 1. \tag{W.4.34}$$

[Note that (4.34) is a special case of (4.10).] Putting all these facts together, we conclude that the sequence of functions $\hat{\psi}^{\delta}(\lambda,\theta)$ for varying λ converges to the delta function,

$$\lim_{\lambda\to 1^-} \hat{\psi}^{\delta}(\lambda,\theta) = \delta(\theta). \tag{W.4.35}$$

We see that the delta function spike about $\theta = 0$ on the circle $\rho = R$ (which corresponds to $\lambda = 1$) becomes an ever lower and broader bump with decreasing ρ. Thus the effect of a disturbance in the potential on the $\rho = R$ circle "decays" away as one moves to circles with successively smaller values of ρ. Finally we note that, in agreement with (4.10), the "decay" we have been observing is entirely due to spreading. Indeed, the relations (4.7) and (4.9) illustrate that if the initial/boundary potential distribution is completely "spread out", i.e. constant, then no decay occurs.

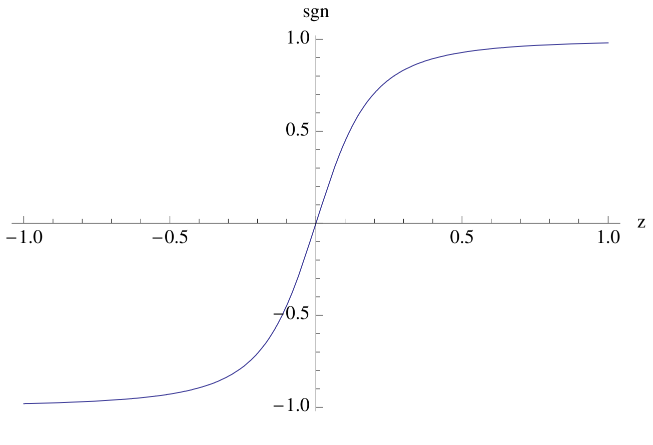

Figure W.4.1: (Place Holder) The function $\hat{\psi}^{\delta}(\lambda,\theta)$ as a function of θ for various values of λ.

We have again seen an example of how the effects of a local disturbance in the potential diminish with distance from the disturbance.

From the response (4.23) to a delta function disturbance (4.12) we can derive the response to a general disturbance. With (4.23) in mind, define a kernel $G(\theta;\theta';\lambda)$ by the rule

$$G(\theta;\theta';\lambda) = [1/(2\pi)]\{[\lambda^{-1} - \lambda]/[\lambda^{-1} + \lambda - 2\cos(\theta - \theta')]\}. \tag{W.4.36}$$

Observe that a general disturbance $\psi_R(\theta)$ has the integral representation

$$\psi_R(\theta) = \int_{-\pi}^{\pi} d\theta' \psi_R(\theta')\delta(\theta - \theta'). \tag{W.4.37}$$

It follows that the response to $\psi_R(\theta)$ is given by the integral

$$\psi(\rho,\theta) = \int_{-\pi}^{\pi} d\theta' \psi_R(\theta') G(\theta;\theta';\lambda). \tag{W.4.38}$$

For what it's worth we remark that, according to the connection between Laplace and Monte Carlo, the quantity $G(\theta;\theta';\lambda)$ is the probability that a random walk initiated at the point ρ, θ will reach the point R, θ'.

We close this section by making two calculations that will be of future use. First we will present a previous result in terms of the Cartesian coordinates x, y. From (4.33) we see that there is the result

$$\psi^\delta(x,y) = \psi^\delta(\rho,\theta) = [1/(2\pi)][1 + 2(\rho/R)\cos(\theta) + 2(\rho/R)^2\cos(2\theta) + \cdots]. \tag{W.4.39}$$

There are also the relations

$$\rho\cos(\theta) = x, \tag{W.4.40}$$

$$\rho^2\cos(2\theta) = \rho^2[\cos^2(\theta) - \sin^2(\theta)] = x^2 - y^2. \tag{W.4.41}$$

It follows that there is the result

$$\psi^\delta(x,y) = [1/(2\pi)][1 + 2(1/R)x + 2(1/R^2)(x^2 - y^2) + \cdots]. \tag{W.4.42}$$

As a second complementary case, suppose ψ_R, now to be called ψ_R^Δ, is a delta function centered on $\theta = \pi/2$,

$$\psi_R^\Delta(\theta) = \delta(\theta - \pi/2). \tag{W.4.43}$$

Then, by (4.3),

$$\tilde{\psi}_R^\Delta(m) = 1/(2\pi)\exp(-im\pi/2), \tag{W.4.44}$$

and (4.4) takes the form

$$\begin{aligned}\psi^\Delta(x,y) &= \psi^\Delta(\rho,\theta) = [1/(2\pi)] \sum_{m=-\infty}^{m=\infty} (\rho/R)^{|m|} \exp[im(\theta - \pi/2)] \\ &= [1/(2\pi)\{1 + 2(\rho/R)\cos(\theta - \pi/2) + 2(\rho/R)^2\cos[2(\theta - \pi/2)] + \cdots\} \\ &= [1/(2\pi)\{1 + 2(\rho/R)\sin(\theta) - 2(\rho/R)^2\cos(2\theta) + \cdots\} \\ &= [1/(2\pi)\{1 + 2(1/R)y - 2(1/R^2)(x^2 - y^2) + \cdots\}.\end{aligned} \tag{W.4.45}$$

Exercises

W.4.1. Verify the steps that led from (4.14) to (4.23).

W.4.2. Verify (4.29) and (4.30).

W.4.3. Verify (4.31).

W.4.4. Show that

$$\lim_{\lambda \to 1^-} \hat{\psi}^\delta(\lambda, \theta) = 0 \text{ for } \theta \neq 0. \tag{W.4.46}$$

Show that

$$\lim_{\lambda \to 1^-} \hat{\psi}^\delta(\lambda, 0) = +\infty. \tag{W.4.47}$$

W.4.5. Verify directly the relation (4.34) using (4.23). Verify (4.38) for the case (4.7).

W.5 The Circular Cylinder in Three Space

Consider in x, y, z space a circular cylinder of radius R centered on the z axis, and suppose a potential $\psi_R(\phi, z)$ is specified on this cylinder. [Here we have used the cylindrical coordinates ρ, ϕ, and z specified by the rules (15.2.12) through (15.2.16).] More specifically, write

$$\psi(x, y, z) = \psi(\rho, \phi, z) \tag{W.5.1}$$

and

$$\psi(R, \phi, z) = \psi_R(\phi, z). \tag{W.5.2}$$

Given the boundary potential $\psi_R(\phi, z)$, we wish to find the interior harmonic function (solution to Laplace's equation) $\psi(\rho, \phi, z)$ associated with this boundary potential.

From (15.3.7) we know that the most general ψ that is harmonic and finite within the cylinder is of the form

$$\psi(\rho, \phi, z) = \sum_{m=-\infty}^{\infty} \int_{-\infty}^{\infty} dk \, G_m(k) \exp(ikz) \exp(im\phi) I_m(k\rho). \tag{W.5.3}$$

Next define the *double* Fourier transform $\tilde{\tilde{\psi}}(R, m', k')$ of the boundary potential by the rule

$$\tilde{\tilde{\psi}}(R, m', k') = [1/(2\pi)]^2 \int_{-\infty}^{\infty} dz \; \exp(-ik'z) \int_0^{2\pi} d\phi \; \exp(-im'\phi) \psi_R(\phi, z). \tag{W.5.4}$$

See (17.2.2). Then we know from (17.2.5) that

$$G_m(k) = \tilde{\tilde{\psi}}(R, m, k)/I_m(kR). \tag{W.5.5}$$

Consequently, the desired ψ is given by the relation

$$\psi(\rho, \phi, z) = \sum_{m=-\infty}^{\infty} \exp(im\phi) \int_{-\infty}^{\infty} dk \; \exp(ikz) \tilde{\tilde{\psi}}(R, m, k)[I_m(k\rho)/I_m(kR)]. \tag{W.5.6}$$

Let us verify that our criteria have been met. By construction the ψ given by (5.6) is a superposition of the functions $\exp(ikz)\exp(im\phi)I_m(k\rho)$ and therefore is harmonic. Also it has the property

$$\psi(R, \phi, z) = \sum_{m=-\infty}^{\infty} \exp(im\phi) \int_{-\infty}^{\infty} dk \; \exp(ikz) \tilde{\tilde{\psi}}(R, m, k) = \psi_R(\phi, z). \tag{W.5.7}$$

We have found the solution to Laplace's equation in the circular cylinder in three space having boundary $\rho = R$ and the boundary value $\psi_R(\phi, z)$.

We also observe, in passing, two facts. First, suppose ψ_R, now to be called ψ_R^c, is a *constant* function,

$$\psi_R^c(\phi, z) = c. \tag{W.5.8}$$

Then, by (5.4),

$$\tilde{\tilde{\psi}}^c(R, m', k') = c\delta(k')\delta_{m',0}. \tag{W.5.9}$$

It follows from (5.6) that there is the relation

$$\psi^c(\rho, \phi, z) = c. \tag{W.5.10}$$

As expected, if ψ is constant on the cylinder boundary $\rho = R$, it will have the same constant value everywhere within the cylinder. Second, for any solution, there is the relation

$$\begin{aligned}\int_0^{2\pi} d\phi \int_{-\infty}^{\infty} dz\ \psi(\rho, \phi, z) &= (2\pi)^2 \sum_{m=-\infty}^{\infty} \delta_{m,0} \int_{-\infty}^{\infty} dk\ \delta(k) \tilde{\tilde{\psi}}(R, m, k)[I_m(k\rho)/I_m(kR)] \\ &= (2\pi)^2 \tilde{\tilde{\psi}}(R, 0, 0) = \int_0^{2\pi} d\phi \int_{-\infty}^{\infty} dz\ \psi_R(\phi, z). \end{aligned} \tag{W.5.11}$$

That is, the $d\phi dz$ integral of $\psi(\rho, \phi, z)$ over any cylinder of constant ρ is independent of ρ.

We are now prepared to address the general subject of smoothing. We will examine the asymptotic behavior of the kernel $K(m, k; \rho, R)$, defined by the rule

$$K(m, k; \rho, R) = [I_m(k\rho)/I_m(kR)], \tag{W.5.12}$$

that appears in (5.6). Note that, because

$$I_{-m}(w) = I_m(w) \tag{W.5.13}$$

and

$$I_m(-w) = (-1)^m I_m(w), \tag{W.5.14}$$

the kernel $K(m, k; \rho, R)$ is evidently an *even* function of both m and k. Therefore we only need consider the cases $m \geq 0$ and $k \geq 0$. Finally, by (15.3.11), we see that

$$K(m, 0; \rho, R) = (\rho/R)^{|m|}. \tag{W.5.15}$$

For fixed m and large w the Bessel functions $I_m(w)$ have the asymptotic property

$$|I_m(w)| \simeq (1/\sqrt{2\pi w}) \exp(w) \text{ as } w \to \infty. \tag{W.5.16}$$

Consequently, for fixed m, there is the asymptotic relation

$$K(m, k; \rho, R) \simeq (\sqrt{R/\rho}) \exp[k(\rho - R)] \text{ as } k \to \infty. \tag{W.5.17}$$

We see that, for each fixed m, there is smoothing/damping in the longitudinal variable z when $\rho < R$. Note that this smoothing is analogous to that for the line in two space and the plane in three space.

For fixed w and large m the Bessel functions $I_m(w)$ have the asymptotic property

$$\begin{aligned} |I_m(w)| &\simeq (1/\sqrt{2\pi m})[(e|w|)/(2m)]^m \\ &\simeq (1/2)^m[\sqrt{2\pi m}(m/e)^m]^{-1}|w|^m \\ &\simeq (1/2)^m(1/m!)|w|^m \text{ as } m \to \infty. \end{aligned} \tag{W.5.18}$$

Here we have used the Stirling large m approximation

$$m! \simeq \sqrt{2\pi m}(m/e)^m, \tag{W.5.19}$$

which is actually already quite accurate for $m \geq 2$.[1] Consequently, for fixed k, there is the asymptotic relation

$$K(m,k;\rho,R) \simeq (\rho/R)^m \text{ as } m \to \infty. \tag{W.5.20}$$

We see that, for each fixed k, there is smoothing/damping in the angular variable ϕ when $\rho < R$. Note that this smoothing is analogous to that for the circle in two space.

With regard to angular smoothing there is also the consideration that the angular Fourier transform filters out all angular Fourier modes save for the one of interest. Moreover, the disturbance in the angular Fourier mode of interest produced by an error in any given grid-point value is suppressed by $1/N$ where N is the number of sampling points used in the discrete angular Fourier transform.

What happens if k and m increase simultaneously? This is a more difficult question. We will explore the case were k and m are proportional,

$$k = \lambda m \tag{W.5.21}$$

where λ is some proportionality constant having the dimensions of inverse length.

If $w = \tau m$, where τ is some proportionality constant, there is the uniform doubly asymptotic relation

$$I_m(\tau m) \simeq (1/\sqrt{2\pi m})[1/(1+\tau^2)^{1/4}]\exp(m\eta) \text{ as } m \to \infty. \tag{W.5.22}$$

Here η is a function of τ given by the relation

$$\eta(\tau) = \sqrt{1+\tau^2} + \log[\tau/(1+\sqrt{1+\tau^2})]. \tag{W.5.23}$$

We will use the assumption (5.21) and the result (5.22) to estimate $I_m(\lambda m\rho)$ and $I_m(\lambda mR)$, the numerator and denominator appearing in (5.9).

For the numerator define a quantity $\hat{\tau}$ by the rule

$$\hat{\tau} = \lambda\rho, \tag{W.5.24}$$

and for the denominator define a quantity $\check{\tau}$ by the rule

$$\check{\tau} = \lambda R. \tag{W.5.25}$$

[1] Note that the final result in (5.18) also follows from retaining only the $\ell = 0$ term in (15.3.11).

(Note that both $\hat{\tau}$ and $\check{\tau}$ are dimensionless.) In terms of these definitions we have, as a consequence of (5.22), the large m results

$$I_m(\lambda m\rho) \simeq (1/\sqrt{2\pi m})[1/(1+\hat{\tau}^2)^{1/4}]\exp(m\hat{\eta}), \tag{W.5.26}$$

$$I_m(\lambda mR) \simeq (1/\sqrt{2\pi m})[1/(1+\check{\tau}^2)^{1/4}]\exp(m\check{\eta}). \tag{W.5.27}$$

Here we have used the notation

$$\hat{\eta} = \eta(\hat{\tau}), \tag{W.5.28}$$

$$\check{\eta} = \eta(\check{\tau}). \tag{W.5.29}$$

It follows that there is the large m result

$$K(m, \lambda m; \rho, R) \simeq [(1+\check{\tau}^2)^{1/4}/(1+\hat{\tau}^2)^{1/4}]\exp[m(\hat{\eta}-\check{\eta})] \text{ as } m \to \infty. \tag{W.5.30}$$

We see that there is *exponential* smoothing/damping if

$$\hat{\eta} < \check{\eta}. \tag{W.5.31}$$

When does the smoothing condition (5.31) hold? Let us examine the function $\eta(\tau)$ given by (5.23). Its behavior is displayed in Figure 5.1. Evidently, for $\tau \geq 0$, it appears to be *monotonically increasing*. This surmise is proved in Exercise 5.1. Consequently, (5.31) holds if $\hat{\tau} < \check{\tau}$ and hence $\rho < R$. We conclude, assuming $\rho < R$, that there is exponential smoothing/damping as one goes out in any direction from the origin in the m k plane; and the damping rate depends on the direction. For example, Figure 5.2 displays $K(m, k; \rho, R)$ as function of m and k for the case $\rho = 2$ cm and $R = 2.5$ cm.

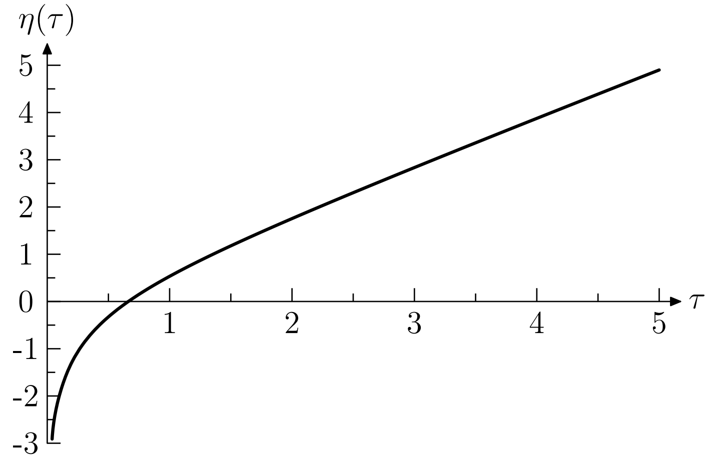

Figure W.5.1: The function $\eta(\tau)$. It appears to be monotonically increasing.

To further study smoothing in the case of a circular cylinder in three space, suppose ψ_R, now to be called ψ_R^δ, is a delta function centered on $(\phi, z) = (0, 0)$,

$$\psi_R^\delta(\phi, z) = \delta(\phi)\delta(z). \tag{W.5.32}$$

Then, by (5.4),

$$\tilde{\tilde{\psi}}^\delta(R, m', k') = [1/(2\pi)]^2, \tag{W.5.33}$$

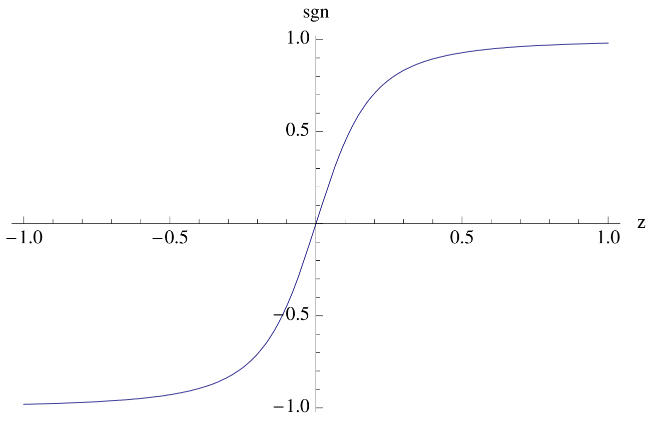

Figure W.5.2: (Place Holder) The kernel $K(m, k; \rho, R)$ as function of m and k for the case $\rho = 2$ cm and $R = 2.5$ cm. The quantity k has units of inverse centimeters.

and (5.6) takes the form

$$\psi^\delta(\rho, \phi, z) = [1/(2\pi)]^2 \sum_{m=-\infty}^{\infty} \exp(im\phi) \int_{-\infty}^{\infty} dk\ \exp(ikz)[I_m(k\rho)/I_m(kR)]. \tag{W.5.34}$$

Our task now is to study the properties of $\psi^\delta(\rho, \phi, z)$. We begin by observing that, as a consequence of (5.11), there is the integral relation

$$\int_0^{2\pi} d\phi \int_{-\infty}^{\infty} dz\ \psi^\delta(\rho, \phi, z) = (2\pi)^2 \tilde{\tilde{\psi}}^\delta(R, 0, 0) = 1. \tag{W.5.35}$$

To proceed further, and in analogy to what was done in previous sections for ψ^δ, it would be ideal if the representation (5.34) could be evaluated analytically in terms of known functions. However, this seems to be a difficult. What we can do is to evaluate (5.34) numerically for various values of ρ and R. Figure 5.3 shows $\psi^\delta(\rho, \phi, z)$ as a function of ϕ and z when $\rho = 2$ cm and $R = 2.5$ cm. And Figure 5.4 shows $\psi^\delta(\rho, \phi, z)$ as a function of ϕ and z when $\rho = 1$ cm and $R = 2.5$ cm. Evidently $\psi^\delta(\rho, \phi, z)$ falls off for large z. Moreover, it is smaller and less peaked about $(\phi, z) = (0, 0)$ for the smaller value of ρ. The effect of a disturbance in the potential at the point $(\phi, z) = (0, 0)$ "decays" away as one moves to cylinders with successively smaller values of ρ. Conversely, as ρ increases, the sequence of functions $\psi^\delta(\rho, \phi, z)$ for varying ρ converges to the delta function,

$$\lim_{\rho \to R^-} \psi^\delta(\rho, \phi, z) = \delta(\phi)\delta(z). \tag{W.5.36}$$

Finally we note that, in agreement with (5.11), the "decay" we have been observing is entirely due to spreading. Indeed, the relations (5.8) and (5.10) illustrate that if the initial/boundary potential distribution is completely "spread out", i.e. constant, then no decay occurs.

At this point we might wonder how fast the effect of a disturbance falls off as a function of z. Figure 5.5 shows $\psi^\delta(1, 0, z)$ as a function of z when $R = 2.5$ cm. We can also study the on-axis case $\rho = 0$ for which (5.34) takes the simpler form

$$\psi^\delta(0, \phi, z) = [1/(2\pi)]^2 \int_{-\infty}^{\infty} dk\ \exp(ikz)[1/I_0(kR)]. \tag{W.5.37}$$

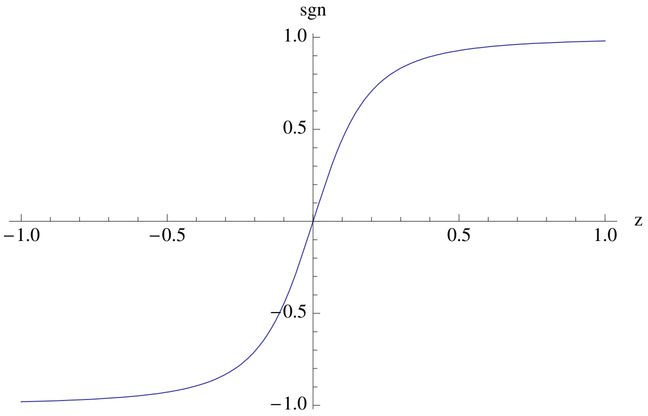

Figure W.5.3: (Place Holder) The function $\psi^{\delta}(\rho,\phi,z)$ as a function of ϕ and z when $\rho = 2$ cm and $R = 2.5$ cm.

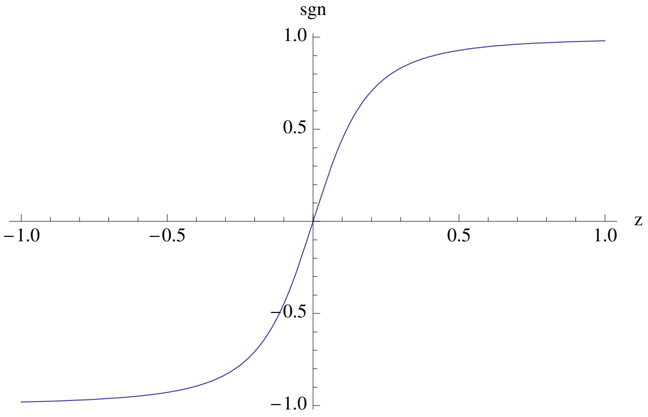

Figure W.5.4: (Place Holder) The function $\psi^{\delta}(\rho,\phi,z)$ as a function of ϕ and z when $\rho = 1$ cm and $R = 2.5$ cm.

Make the change of variables $\lambda = kR$. So doing brings (5.37) to the form

$$\psi^{\delta}(0, \phi, z) = [1/(2\pi)]^2 (1/R) \int_{-\infty}^{\infty} d\lambda \; \exp(i\lambda z/R)/I_0(\lambda). \tag{W.5.38}$$

We have already studied the integral appearing on the right side of (5.38). Reference to (21.1.37) shows that there is the result

$$\psi^{\delta}(0, \phi, z) = [1/(2\pi)](1/R) F(z/R, 0). \tag{W.5.39}$$

It follows from the work of Section 21.1.3, see Figure 21.1.2, that there is the asymptotic behavior

$$\psi^{\delta}(0, \phi, z) \propto \exp[-\pi |z|/(2R)] \text{ as } |z| \to \infty. \tag{W.5.40}$$

When viewed from on axis the effect of a disturbance falls off exponentially. Reference to Figure 5.5 shows that there is a similar rapid fall off with z in the off-axis case.

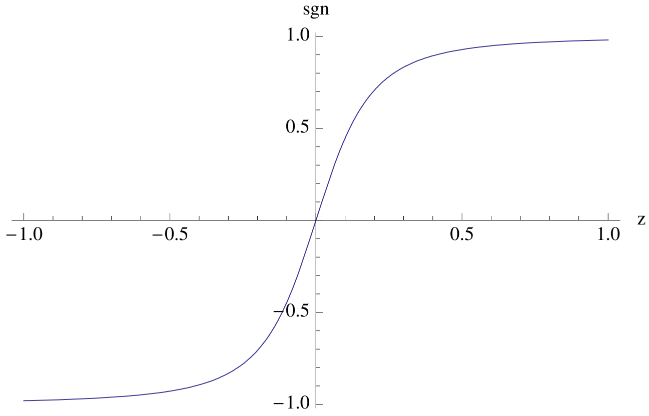

Figure W.5.5: (Place Holder) The function $\psi^{\delta}(1, 0, z)$ as a function of z when $R = 2.5$ cm.

We have again seen an example of how the effects of a local disturbance in the potential diminish with distance from the disturbance.

From the response (5.34) to a delta function disturbance (5.32) we can derive the response to a general disturbance. With (5.34) in mind, define a kernel $G(\phi, z; \phi', z'; \rho)$ by the rule

$$G(\phi, z; \phi', z'; \rho) = \psi^{\delta}(\rho, \phi - \phi', z - z'). \tag{W.5.41}$$

Observe that a general disturbance $\psi_R(\phi, z)$ has the integral representation

$$\psi_R(\phi, z) = \int_{-\pi}^{\pi} d\phi' \int_{-\infty}^{\infty} dz' \psi_R(\phi', z') \delta(\phi - \phi') \delta(z - z'). \tag{W.5.42}$$

It follows that the response to $\psi_R(\phi, z)$ is given by the integral

$$\psi(\rho, \phi, z) = \int_{-\pi}^{\pi} d\phi' \int_{-\infty}^{\infty} dz' \psi_R(\phi', z') G(\phi, z; \phi', z'; \rho). \tag{W.5.43}$$

For what it's worth we remark that, according to the connection between Laplace and Monte Carlo, the quantity $G(\phi, z; \phi', z'; \rho)$ is the probability that a random walk initiated at the point ρ, ϕ, z will reach the point R, ϕ', z'.

Exercises

W.5.1. The purpose of this exercise is to prove that $\eta(\tau)$ is a monotonically increasing function of τ. We begin by observing that the $\sqrt{1+\tau^2}$ term just to the right of the equal sign in (5.23) is a monotonically increasing function of τ, and we know that the log function is a monotonically increasing function of its argument. It remains to be shown that the function $f(\tau)$ defined by

$$f(\tau) = \tau/(1+\sqrt{1+\tau^2}), \tag{W.5.44}$$

the argument of the log function, is monotonically increasing. If this can be verified, then $\eta(\tau)$ is a monotonically increasing function of τ.

To complete the proof, show that

$$\begin{aligned} f'(\tau) &= 1/(1+\sqrt{1+\tau^2}) - (\tau^2/\sqrt{1+\tau^2})/(1+\sqrt{1+\tau^2})^2 \\ &= [1/(1+\sqrt{1+\tau^2})^2][(1+\sqrt{1+\tau^2}) - (\tau^2/\sqrt{1+\tau^2})] \\ &= [1/(1+\sqrt{1+\tau^2})^2](1/\sqrt{1+\tau^2})(\sqrt{1+\tau^2}+1+\tau^2-\tau^2) \\ &= [1/(1+\sqrt{1+\tau^2})^2](1/\sqrt{1+\tau^2})(\sqrt{1+\tau^2}+1) \\ &= [1/(1+\sqrt{1+\tau^2})](1/\sqrt{1+\tau^2}). \end{aligned} \tag{W.5.45}$$

Evidently all factors on the far right side of (5.45) are positive, and therefore $f(\tau)$ is monotonically increasing.

W.5.2. Verify (5.15) given (15.3.11).

W.5.3. Verify (5.17) given (5.16).

W.5.4. Verify (5.20) given (5.18).

W.5.5. Verify (5.30) given (5.22).

W.5.6. Verify (5.38) given (5.37).

W.5.7. Compare the fall off in the case of a plane in three space given by (3.32) with the fall off in the case of a circular cylinder in three space given (5.40). Explain why the fall off is so much more rapid in the case of a cylinder.

W.6 The Ellipse in Two Space

For the ellipse in two space let us employ the coordinates given by (17.4.1) and (17.4.2) and illustrated in Figure 17.4.2. Then, upon writing the relation

$$\psi(x, y) = \psi(u, v), \tag{W.6.1}$$

we find from (17.4.12) that

$$\nabla^2\psi = (1/f^2)[\cosh^2(u) - \cos^2(v)]^{-1}[(\partial_u)^2 + (\partial_v)^2]\psi. \tag{W.6.2}$$

Consequently, ψ will be harmonic provided it satisfies the relation

$$[(\partial_u)^2 + (\partial_v)^2]\psi = 0. \tag{W.6.3}$$

In analogy with (17.4.35) through (17.4.37) let us define functions $\mathrm{c}_n(v)$ and $\mathrm{s}_n(v)$ by the rules

$$\mathrm{c}_0(v) = 1/\sqrt{2}, \tag{W.6.4}$$

$$\mathrm{c}_n(v) = \cos(nv) \text{ for } n \geq 1, \tag{W.6.5}$$

$$\mathrm{s}_0(v) = 0, \tag{W.6.6}$$

$$\mathrm{s}_n(v) = \sin(nv) \text{ for } n \geq 1. \tag{W.6.7}$$

Evidently they form a complete orthogonal set and are normalized so that

$$\int_0^{2\pi} dv \; \mathrm{c}_m(v) \; \mathrm{c}_n(v) = \pi\delta_{mn}, \tag{W.6.8}$$

$$\int_0^{2\pi} dv \; \mathrm{s}_m(v) \; \mathrm{s}_n(v) = \pi\delta_{mn}, \tag{W.6.9}$$

$$\int_0^{2\pi} dv \; \mathrm{c}_m(v) \; \mathrm{s}_n(v) = 0. \tag{W.6.10}$$

Also, in analogy with (17.4.70) and (7.4.71), let us define functions $\mathrm{C}_n(u)$ and $\mathrm{S}_n(u)$ by the rules

$$\mathrm{C}_n(u) = \mathrm{c}_n(iu), \tag{W.6.11}$$

$$\mathrm{S}_n(u) = -i\mathrm{s}_n(iu). \tag{W.6.12}$$

In view of (6.4) through (6.7) we have the results

$$\mathrm{C}_0(u) = 1/\sqrt{2}, \tag{W.6.13}$$

$$\mathrm{C}_n(u) = \cosh(nu) \text{ for } n \geq 1, \tag{W.6.14}$$

$$\mathrm{S}_0(u) = 0, \tag{W.6.15}$$

$$\mathrm{S}_n(u) = \sinh(nu) \text{ for } n \geq 1. \tag{W.6.16}$$

Evidently the functions $\mathrm{C}_n(u)$ and $\mathrm{S}_n(u)$ are entire functions of u, and the functions $\mathrm{c}_n(v)$ and $\mathrm{s}_n(v)$ are entire functions of v. However, they are not entire functions of x and y because of the singularities described in Exercise 17.4.2.

It is easily verified that functions $\psi_n^c(u,v)$ and $\psi_n^s(u,v)$ of the form

$$\psi_n^c(u,v) \propto \mathrm{C}_n(u)\mathrm{c}_n(v), \tag{W.6.17}$$

$$\psi_n^s(u,v) \propto \mathrm{S}_n(u)\mathrm{s}_n(v) \tag{W.6.18}$$

satisfy (6.3) and are therefore harmonic functions. We claim that they are also polynomial, and therefore entire analytic, functions of x and y. For example, there are the relations

$$\mathrm{C}_0(u)\mathrm{c}_0(v) = 1/2, \tag{W.6.19}$$

$$\mathrm{S}_0(u)\mathrm{s}_0(v) = 0, \tag{W.6.20}$$

$$\mathrm{C}_1(u)\mathrm{c}_1(v) = \cosh(u)\cos(v) = x/f, \tag{W.6.21}$$

$$\mathrm{S}_1(u)\mathrm{s}_1(v) = \sinh(u)\sin(v) = y/f, \tag{W.6.22}$$

$$\begin{aligned}
\mathrm{C}_2(u)\mathrm{c}_2(v) &= \cosh(2u)\cos(2v) = (1/2)\cosh(2u)\cos(2v) + (1/2)\cosh(2u)\cos(2v) \\
&= (1/2)[2\cosh^2(u) - 1][2\cos^2(v) - 1] \\
&\quad -(1/2)[2\sinh^2(u) + 1][2\sin^2(v) - 1] \\
&= (1/2)\{4\cosh^2(u)\cos^2(v) - 2[\cosh^2(u) + \cos^2(v)] + 1\} \\
&\quad -(1/2)\{4\sinh^2(u)\sin^2(v) - 2[\sinh^2(u) - \sin^2(v)] - 1\} \\
&= 2\cosh^2(u)\cos^2(v) - 2\sinh^2(u)\sin^2(v) \\
&\quad - \cosh^2(u) + \sinh^2(u) - \cos^2(v) - \sin^2(v) + 1/2 + 1/2 \\
&= 2\cosh^2(u)\cos^2(v) - 2\sinh^2(u)\sin^2(v) - 1 \\
&= 2(x^2 - y^2)/f^2 - 1.
\end{aligned} \tag{W.6.23}$$

$$\begin{aligned}
\mathrm{S}_2(u)\mathrm{s}_2(v) &= \sinh(2u)\sin(2v) = 4\sinh(u)\cosh(u)\sin(v)\cos(v) \\
&= 4xy/f^2.
\end{aligned} \tag{W.6.24}$$

For a general proof for all n, see Exercise 6.3.

With the above background in mind, consider the ellipse $u = U$ and suppose a potential $\psi_U(v)$ is specified on this ellipse. Since the functions $\mathrm{c}_n(v)$ and $\mathrm{s}_n(v)$ form a complete set, we may make the expansion

$$\psi_U(v) = \sum_{n=0}^{\infty} \tilde{\psi}_U^c(n)\mathrm{c}_n(v) + \sum_{n=1}^{\infty} \tilde{\psi}_U^s(n)\mathrm{s}_n(v) \tag{W.6.25}$$

with

$$\tilde{\psi}_U^c(n) = (1/\pi)\int_0^{2\pi} dv\ \mathrm{c}_n(v)\psi_U(v), \tag{W.6.26}$$

$$\tilde{\psi}_U^s(n) = (1/\pi)\int_0^{2\pi} dv\ \mathrm{s}_n(v)\psi_U(v). \tag{W.6.27}$$

Now make the Ansatz

$$\psi(u,v) = \sum_{n=0}^{\infty} \tilde{\psi}_U^c(n)[\mathrm{C}_n(u)/\mathrm{C}_n(U)]\mathrm{c}_n(v) + \sum_{n=1}^{\infty} \tilde{\psi}_U^s(n)[\mathrm{S}_n(u)/\mathrm{S}_n(U)]\mathrm{s}_n(v). \tag{W.6.28}$$

By construction $\psi(u,v)$ is a harmonic function, and also has the property

$$\psi(U,v) = \psi_U(v). \tag{W.6.29}$$

We have found the solution to Laplace's equation in the ellipse having boundary $u = U$ and the boundary value $\psi_U(v)$.

Note that the operation (6.28) is smoothing for $u < U$. Indeed, according (6.14) and (6.16), there are the asymptotic results

$$\mathrm{C}_n(u) \propto \exp(nu) \text{ as } n \to \infty, \tag{W.6.30}$$

$$\mathrm{S}_n(u) \propto \exp(nu) \text{ as } n \to \infty. \tag{W.6.31}$$

It follows that there are the asymptotic results

$$[\mathrm{C}_n(u)/\mathrm{C}_n(U)] \propto \exp[-n(U-u)] \text{ as } n \to \infty, \tag{W.6.32}$$

$$[\mathrm{S}_n(u)/\mathrm{S}_n(U)] \propto \exp[-n(U-u)] \text{ as } n \to \infty. \tag{W.6.33}$$

Consequently, there is exponential smoothing provided $u < U$.

We also observe, in passing, two facts. First, suppose ψ_U, now to be called ψ_U^d, is a *constant* function with value d,

$$\psi_U^d(v) = d. \tag{W.6.34}$$

Then, by (6.26) and (6.27),

$$\tilde{\psi}_U^{dc}(n) = d\sqrt{2}\delta_{n,0}, \tag{W.6.35}$$

$$\tilde{\psi}_U^{ds}(n) = 0. \tag{W.6.36}$$

It follows from (6.28) that there is the relation

$$\psi^d(u,v) = d. \tag{W.6.37}$$

As expected, if ψ is constant on the boundary $u = U$, it will have the same constant value inside the ellipse. Second, for any solution, we find from (6.28) that there is the relation

$$\int_0^{2\pi} dv\ \psi(u,v) = (\pi\sqrt{2})\sum_{n=0}^{\infty}\tilde{\psi}_U^c(n)[\mathrm{C}_n(u)/\mathrm{C}_n(U)]\delta_{n,0} = (\pi\sqrt{2})\tilde{\psi}_U^c(0) = \int_0^{2\pi} dv\ \psi_U(v). \tag{W.6.38}$$

That is, the dv integral of $\psi(u,v)$ over any ellipse of constant u is independent of u.

To further study smoothing in the case of an ellipse in two space, suppose ψ_U, now to be called ψ_U^δ, is a delta function centered on $v = 0$,

$$\psi_U^\delta(v) = \delta(v). \tag{W.6.39}$$

Then, by (6.26) and (6.27),

$$\tilde{\psi}_U^{\delta c}(0) = 1/(\pi\sqrt{2}), \tag{W.6.40}$$

$$\tilde{\psi}_U^{\delta c}(n) = 1/\pi \text{ for } n \geq 1, \tag{W.6.41}$$

$$\tilde{\psi}_U^{\delta s}(n) = 0, \tag{W.6.42}$$

and (6.28) takes the form

$$\begin{aligned}
\psi^\delta(u,v) &= \sum_{n=0}^{\infty}\tilde{\psi}_U^{\delta c}(n)[1/\mathrm{C}_n(U)]\mathrm{C}_n(u)\mathrm{c}_n(v) \\
&= [1/(\pi\sqrt{2})][1/\mathrm{C}_0(U)]\mathrm{C}_0(u)\mathrm{c}_0(v) + (1/\pi)\sum_{n=1}^{\infty}[1/\mathrm{C}_n(U)]\mathrm{C}_n(u)\mathrm{c}_n(v). \\
&= [1/(2\pi)] + (1/\pi)\sum_{n=1}^{\infty}[1/\cosh(nU)]\cosh(nu)\cos(nv).
\end{aligned} \tag{W.6.43}$$

Figure 6.1 shows $\psi^{\delta}(u,v)$ as a function of v for various values of u. For this example $U = 0.5$. We see that the delta function spike about $v = 0$ on the ellipse $u = U$ becomes an ever lower and broader bump with decreasing u. Thus the effect of a disturbance in the potential on the $u = U$ ellipse "decays" away as one moves to ellipses with successively smaller values of u. Finally we note that, in agreement with (6.38), the "decay" we have been observing is entirely due to spreading. Indeed, the relations (6.34) and (6.37) illustrate that if the initial/boundary potential distribution is completely "spread out", i.e. constant, then no decay occurs.

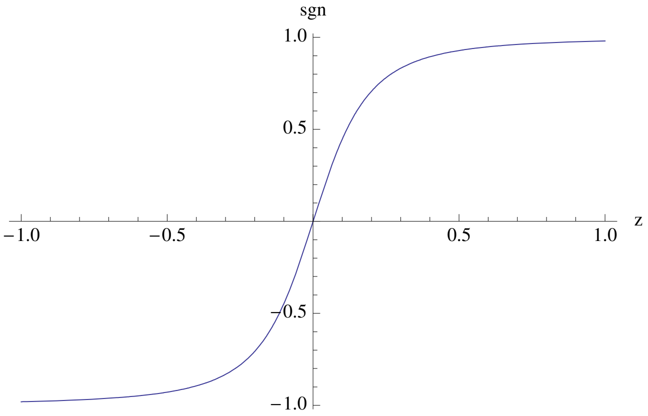

Figure W.6.1: (Place Holder) The function $\psi^{\delta}(u,v)$ as a function of v for various values of u when $U = 0.5$ and therefore $\tanh(U) = 0.46\cdots$.

For future use let us examine the behavior of $\psi^{\delta}(u,v)$ about the origin. Evidently there is the expansion

$$\begin{aligned}
\psi^{\delta}(u,v) &= \sum_{n=0}^{2} \tilde{\psi}_U^{\delta c}(n)[1/\mathrm{C}_n(U)]\mathrm{C}_n(u)\mathrm{c}_n(v) + \cdots \\
&= [1/(\pi\sqrt{2})][1/\mathrm{C}_0(U)]\mathrm{C}_0(u)\mathrm{c}_0(v) + (1/\pi)[1/\mathrm{C}_1(U)]\mathrm{C}_1(u)\mathrm{c}_1(v) \\
&\quad +(1/\pi)[1/\mathrm{C}_2(U)]\mathrm{C}_2(u)\mathrm{c}_2(v) + \cdots \\
&= [1/(\pi\sqrt{2})][1/\sqrt{2}] + (1/\pi)[1/\mathrm{C}_1(U)](x/f) \\
&\quad +(1/\pi)[1/\mathrm{C}_2(U)][2(x^2-y^2)/f^2 - 1] + \cdots . \\
&= 1/(2\pi) + (1/\pi)[1/\cosh(U)](x/f) \\
&\quad +(1/\pi)[1/\cosh(2U)][2(x^2-y^2)/f^2 - 1] + \cdots . \qquad \text{(W.6.44)}
\end{aligned}$$

Next, suppose ψ_U, now to be called ψ_U^{Δ}, is a delta function centered on $v = \pi/2$,

$$\psi_U^{\Delta}(v) = \delta(v - \pi/2). \qquad \text{(W.6.45)}$$

Then, by (6.26) and (6.27), the first few Fourier coefficients results are

$$\tilde{\psi}_U^{\Delta c}(0) = 1/(\pi\sqrt{2}), \qquad \text{(W.6.46)}$$

$$\tilde{\psi}_U^{\Delta c}(1) = 0, \qquad \text{(W.6.47)}$$

$$\tilde{\psi}_U^{\Delta c}(2) = -1/\pi; \tag{W.6.48}$$

$$\tilde{\psi}_U^{\Delta s}(0) = 0, \tag{W.6.49}$$

$$\tilde{\psi}_U^{\Delta s}(1) = 1/\pi, \tag{W.6.50}$$

$$\tilde{\psi}_U^{\Delta s}(2) = 0. \tag{W.6.51}$$

Correspondingly, (6.28) now takes the form

$$\begin{aligned}
\psi^{\Delta}(u,v) &= \sum_{n=0}^{2} \tilde{\psi}_U^{\Delta c}(n)[\mathrm{C}_n(u)/\mathrm{C}_n(U)]\mathrm{c}_n(v) + \cdots \\
&\quad + \sum_{n=1}^{2} \tilde{\psi}_U^{\Delta s}(n)[\mathrm{S}_n(u)/\mathrm{S}_n(U)]\mathrm{s}_n(v) + \cdots \\
&= [1/(\pi\sqrt{2})][1/\mathrm{C}_0(U)]\mathrm{C}_0(u)\mathrm{c}_0(v) - (1/\pi)[1/\mathrm{C}_2(U)]\mathrm{C}_2(u)\mathrm{c}_2(v) + \cdots \\
&\quad + (1/\pi)[1/\mathrm{S}_1(U)]\mathrm{S}_1(u)\mathrm{s}_1(v) + \cdots \\
&= 1/(2\pi) + (1/\pi)[1/\sinh(U)](y/f) \\
&\quad - (1/\pi)[1/\cosh(2U)][2(x^2-y^2)/f^2 - 1] + \cdots .
\end{aligned} \tag{W.6.52}$$

Let us compare the terms in ψ^{δ} given by (6.44) with the terms in ψ^{Δ} given by (6.52). In particular, let us begin by making the comparison

$$[1/\cosh(U)](x/f) \text{ versus } [1/\sinh(U)](y/f). \tag{W.6.53}$$

For ψ^{δ} the delta function disturbance in the boundary potential is made at the point $(x,y) = (x^{\delta},0)$ with

$$x^{\delta} = f\cosh(U). \tag{W.6.54}$$

See (17.4.1) and Figure 17.4.2. And for ψ^{Δ} the delta function disturbance in the boundary potential is made at the point $(x,y) = (0,y^{\Delta})$ with

$$y^{\Delta} = f\sinh(U). \tag{W.6.55}$$

See (17.4.2). With this observation in mind, we see that the comparison (6.53) can be rewritten in the form

$$x/x^{\delta} \text{ versus } y/y^{\Delta}. \tag{W.6.56}$$

Now suppose the bounding ellipse $u = U$ has been chosen so that

$$y^{\Delta} < x^{\delta}. \tag{W.6.57}$$

See Figure 17.4.3. Then, according to (6.56), near the origin the effect of a disturbance at $(x^{\delta},0)$ is diminished from the effect of a disturbance at $(0,y^{\Delta})$ by a factor of

$$y^{\Delta}/x^{\delta} = \tanh(U). \tag{W.6.58}$$

By contrast, comparison of (4.42) and (4.45) shows, as expected, there is no such effect in the case of a circular boundary. Our findings are in accord with the expectation described in Section 17.4.1 to the effect that, for wigglers or dipoles with small gaps and wide pole faces, use of a cylinder with elliptical cross section should give improved error insensitivity.

Let us also examine the next higher-order (and non constant) terms in ψ^{δ} and ψ^{Δ} which, according to (6.44) and (6.52), are

$$\pm (1/\pi)[1/\cosh(2U)][2(x^2-y^2)/f^2]. \tag{W.6.59}$$

Note that there is the relation

$$f^2\cosh(2U) = f^2[\cosh^2(U)+\sinh^2(U)] = (x^{\delta})^2 + (y^{\Delta})^2. \tag{W.6.60}$$

Thus, (6.59) can also be written in the form

$$\pm (1/\pi)(x^2-y^2)/\{(1/2)[(x^{\delta})^2+(y^{\Delta})^2]\}. \tag{W.6.61}$$

The comparable term for the circle in two-space case, that given in (4.42) or (4.49), is

$$\pm (1/\pi)(x^2-y^2)/R^2. \tag{W.6.62}$$

Thus, to contrast the use of a circle with the use of an ellipse, we should make the comparison

$$R^2 \text{ versus } \{(1/2)[(x^{\delta})^2+(y^{\Delta})^2]\}. \tag{W.6.63}$$

Moreover, when contrasting the use of a circle to the use of an ellipse, it is reasonable to presume that the ellipse just contains the circle so that

$$y^{\Delta} = R. \tag{W.6.64}$$

In this case (6.63) becomes

$$(1/2)(y^{\Delta})^2 \text{ versus } (1/2)(x^{\delta})^2. \tag{W.6.65}$$

In view of (6.57) the left term in the comparison (6.65) is smaller than the term on the right. Correspondingly, the denominator in (6.61) is larger than that in (6.62) thereby again illustrating that the use of a cylinder with elliptical cross section should give improved error insensitivity.

Exercises

W.6.1. Verify that the functions (6.17) and (6.18) are harmonic.

W.6.2. Since deriving the result (6.23) involved considerable algebra, it is useful to check a few specific cases. Consider the points $(x,y) = (0,0)$ and $(x,y) = (\pm f, 0)$ for which $(u,v) = (0, \pi/2 \text{ or } 3\pi/2)$ and $(u,v) = (0, 0 \text{ or } \pi)$. See Figure 17.4.3. Verify that (6.23) holds at these points.

W.6.3. The purpose of this exercise is to prove the claim that, for all n, functions ψ_n^c and ψ_n^s of the form (6.17) and (6.18) are polynomial functions of x and y. Recall (17.4.7). Show that from this relation it follows that

$$(x+iy)^n/f^n = [\cosh(w)]^n. \tag{W.6.66}$$

Next verify the expansion

$$\begin{aligned}[\cosh(w)]^n &= (1/2^n)\{\exp(w)+\exp(-w)\}^n \\ &= (1/2^n)\{\exp(nw)+n\exp[(n-2)w]+[n(n-1)/2!]\exp[(n-4)w] \\ &\quad +\cdots+[n(n-1)/2!]\exp[-(n-4)w]+n\exp[-(n-2)w]+\exp(-nw)\}.\end{aligned} \tag{W.6.67}$$

Show that the terms in this expansion can be combined to yield the result

$$[\cosh(w)]^n = (1/2^{n-1})\{\cosh(nw)+n\cosh[(n-2)w]+[n(n-1)/2!]\cosh[(n-4)w]+\cdots\}. \tag{W.6.68}$$

Verify that the last term on the right side of (6.68) is

$$(1/2)^n \begin{pmatrix} n \\ n/2 \end{pmatrix} \text{ if } n \text{ is even,} \tag{W.6.69}$$

and is

$$(1/2)^{n-1} \begin{pmatrix} n \\ (n-1)/2 \end{pmatrix} \cosh(w) \text{ if } n \text{ is odd.} \tag{W.6.70}$$

Next verify that

$$\begin{aligned}\cosh(mw) &= \cosh(mu+imv) = \cosh(mu)\cosh(imv)+\sinh(mu)\sinh(imv) \\ &= \cosh(mu)\cos(mv)+i\sinh(mu)\sin(mv),\end{aligned} \tag{W.6.71}$$

from which it follows that

$$\cosh(mu)\cos(mv) = \Re[\cosh(mw)], \tag{W.6.72}$$

$$\sinh(mu) sin(mv) = \Im[\cosh(mw)]. \tag{W.6.73}$$

Using the results found so far, take real and imaginary parts to rewrite (6.66) in the form

$$(1/2^{n-1})\cosh(nu)\cos(nv) = \Re[(x+iy)^n/f^n]-(1/2^{n-1})\Re\{n\cosh[(n-2)w]+\cdots\}, \tag{W.6.74}$$

$$(1/2^{n-1})\sinh(nu)\sin(nv) = \Im[(x+iy)^n/f^n]-(1/2^{n-1})\Im\{n\cosh[(n-2)w]+\cdots\}. \tag{W.6.75}$$

Conclude that $\cosh(nu)\cos(nv)$ is a polynomial in x and y provided the same is true of $\cosh(mu)\cos(mv)$ for $m = n-2, n-4, \cdots$. Make a similar conclusion for $\sinh(nu)\sin(nv)$. Finally prove by induction, starting with (6.19) through (6.22), the claim stated at the beginning of this exercise.

W.6.4. Use some of the machinery of Exercise 6.3 above to produce an easy derivation of the relations (6.23) and (6.24).

W.7 The Elliptical Cylinder in Three Space

W.8 The Rectangle in Two Space

W.9 The Rectangular Cylinder in Three Space

W.10 The Sphere in Three Space

Higher angular modes are suppressed by the exponential factor $(r/R)^\ell = \exp[\ell \log(r/R)]$. Note that $\log(r/R) < 0$.

Appendix X

Lie Algebraic Theory of Light Optics

Overview

Need text here.

X.1 Hamiltonian Formulation

Consider the optical system illustrated schematically in Figure 1.1. A ray originates at the general *initial* point P^i with spatial coordinate $\boldsymbol{r}^i$ and moves in an initial direction specified by the unit vector $\hat{\boldsymbol{s}}^i$. After passing through an optical device it arrives at the *final* point P^f with with spatial coordinate $\boldsymbol{r}^f$ and moves in a final direction specified by the unit vector $\hat{\boldsymbol{s}}^f$. Given the initial quantities $(\boldsymbol{r}^i, \hat{\boldsymbol{s}}^i)$, the fundamental problem of geometrical optics is to determine the final quantities $(\boldsymbol{r}^f, \hat{\boldsymbol{s}}^f)$ and to design an optical device in such a way that the relation between the initial and final ray quantities has various desired properties.

Suppose the z coordinates of the initial and final points P^i and $P^f$are held fixed. In some instances the planes $z = z^i$ and $z = z^f$ can be viewed as object and image planes, respectively. But in other cases they simply serve as convenient reference planes. Further, suppose the general light ray from P^i to P^f is parameterized using z as an *independent/time-like* variable. That is, the path of a general ray is described by specifying the two functions $x(z)$ and $y(z)$. Then the element of path length ds along a ray is given by the expression

$$ds = [(dz)^2 + (dx)^2 + (dy)^2]^{1/2} = [1 + (x')^2 + (y')^2]^{1/2} dz. \tag{X.1.1}$$

Here a prime denotes the differentiation d/dz. Consequently the optical path length along a ray from P^i to P^f is given by the integral

$$A = \int_{z^i}^{z^f} n(x, y, z)[1 + (x')^2 + (y')^2]^{1/2} dz. \tag{X.1.2}$$

Here the function $n(x, y, z) = n(\boldsymbol{r})$ specifies the index of refraction at each point before and after the optical device and in the device itself.

Fermat's principle requires that A be an extremum for the path of an actual ray. Therefore the ray path satisfies the Euler-Lagrange equations

$$d/dz(\partial L/\partial x') - \partial L/\partial x = 0, \tag{X.1.3}$$

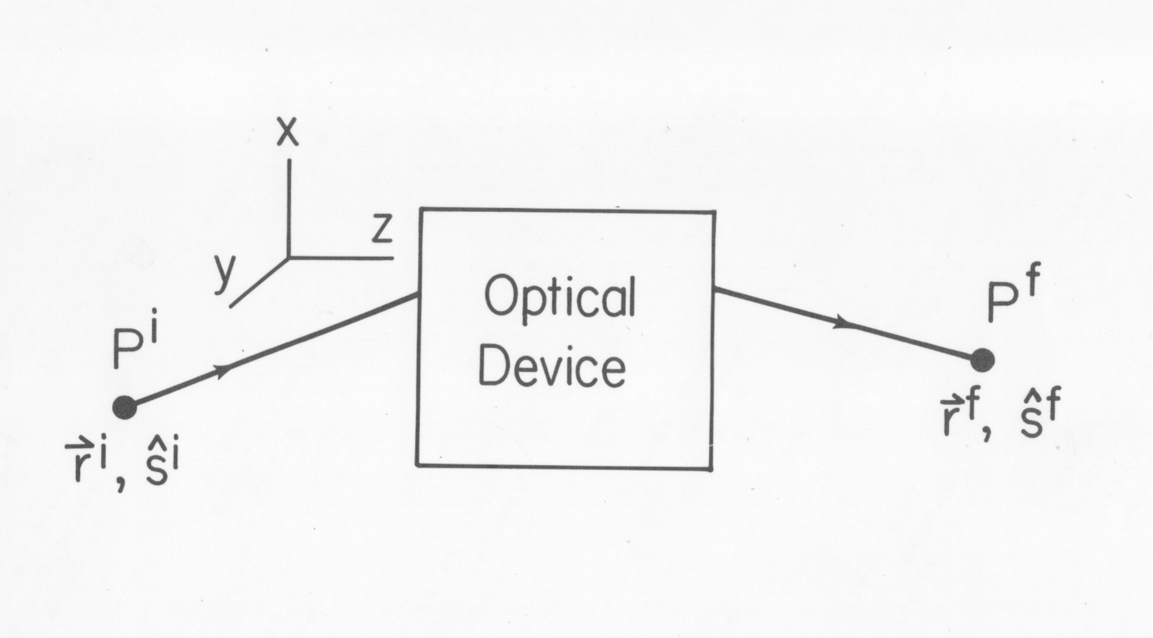

Figure X.1.1: Optical system consisting of an optical device preceded and followed by simple transit. A ray originates at P^i with *initial* location $\boldsymbol{r}^i$ and *initial* direction $\hat{\boldsymbol{s}}^i$, and terminates at P^f with *final* location $\boldsymbol{r}^f$ and *final* direction $\hat{\boldsymbol{s}}^f$

.

$$d/dz(\partial L/\partial y') - \partial L/\partial y = 0, \tag{X.1.4}$$

with a Lagrangian L given by the expression

$$L = n(x, y, z)[1 + (x')^2 + (y')^2]^{1/2}. \tag{X.1.5}$$

To proceed further, it is useful to pass from a Lagrangian formulation to a Hamiltonian formulation. Introduce two momenta p_x and p_y conjugate to the coordinates x and y by the rule

$$p_x = \partial L/\partial x', \tag{X.1.6}$$

$$p_y = \partial L/\partial y', \tag{X.1.7}$$

with the explicit results that

$$p_x = n(\boldsymbol{r})x'/[1 + (x')^2 + (y')^2]^{1/2}, \tag{X.1.8}$$

$$p_y = n(\boldsymbol{r})y'/[1 + (x')^2 + (y')^2]^{1/2}. \tag{X.1.9}$$

The Hamiltonian H is defined in terms of the Lagrangian L by the Legendre transformation

$$H(x, y, p_x, p_y; z) = p_x x' + p_y y' - L. \tag{X.1.10}$$

It follows from (1.5) through (1.10) that in our case H is given by the relation

$$H = -[n^2(\boldsymbol{r}) - p_x^2 - p_y^2]^{1/2}. \tag{X.1.11}$$

Let $\boldsymbol{q}$ be a two-component vector with entries $q_x = x$ and $q_y = y$, and let $\boldsymbol{p}$ be a two-component vector with entries p_x and p_y. Evidently, a ray leaving the initial point P^i is characterized by the quantities z^i, $\boldsymbol{q}^i$, and $\boldsymbol{p}^i$. The quantity $\boldsymbol{q}^i$ specifies the initial point of origin on the plane $z = z^i$ and, according to (1.8) and (1.9), $\boldsymbol{p}^i$ describes the initial direction of the ray. Similarly, $\boldsymbol{q}^f$ and $\boldsymbol{p}^f$ characterize the ray as it arrives at the final point P^f in the plane $z = z^f$. Finally, the relation between the initial conditions $\boldsymbol{q}^i$ and $\boldsymbol{p}^i$ and the final conditions $\boldsymbol{q}^f$ and $\boldsymbol{p}^f$ is given by following from $z = z^i$ to $z = z^f$ a trajectory $\boldsymbol{q}(z)$, $\boldsymbol{p}(z)$ governed by the Hamiltonian H.

At this point it is convenient to introduce a four-component vector $\boldsymbol{w}$ with entries $\boldsymbol{q}$, $\boldsymbol{p}$:

$$\boldsymbol{w} = (w_1, w_2, w_3, w_4) = (q_x, p_x, q_y, p_y). \tag{X.1.12}$$

Also, let $\boldsymbol{w}^i$ and $\boldsymbol{w}^f$ denote initial and final values of $\boldsymbol{w}$. The fact that initial conditions *determine* the final conditions can be expressed in terms of a functional relationship or *mapping* $\mathcal{M}$. This relationship can be defined formally by writing the expression

$$\boldsymbol{w}^f = \mathcal{M}\boldsymbol{w}^i. \tag{X.1.13}$$

Hamilton's equations of motion for the canonical variables $\boldsymbol{q}$ and $\boldsymbol{p}$ read

$$q'_\alpha = \partial H/\partial p_\alpha =: -H : q_\alpha, \tag{X.1.14}$$

$$p'_\alpha = -\partial H/\partial q_\alpha =: -H : p_\alpha. \tag{X.1.15}$$

Correspondingly, there is an equation of motion for $\mathcal{M}$ given by the relation

$$\mathcal{M}' = \mathcal{M} : -H : \tag{X.1.16}$$

with the initial condition

$$\mathcal{M}|_{z=z^i} = \mathcal{I} \tag{X.1.17}$$

where $\mathcal{I}$ is the identity map. Recall Subsection 10.1.1.

As has been seen, Fermat's principle is equivalent to the statement that the initial conditions $\boldsymbol{w}^i$ and the final conditions $\boldsymbol{w}^f$ are related by following a trajectory governed by a Hamiltonian, namely the Hamiltonian (1.11). From the work of Subsection 6.4.1 this statement is equivalent in turn to the statement that $\mathcal{M}$ is a *symplectic* map.

Let us recapitulate briefly for the light optics context some of what we have learned about symplectic maps. Let M be the Jacobian matrix associated with the mapping $\mathcal{M}$. It is defined by the relation

$$M_{\alpha\beta} = \partial w^f_\alpha/\partial w^i_\beta, \tag{X.1.18}$$

and describes how small changes in $\boldsymbol{w}^i$ produce small changes in $\boldsymbol{w}^f$. Also, let J be the four-by-four matrix defined by the equation

$$J = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix}. \tag{X.1.19}$$

Then from earlier work we know that M satisfies the matrix equation

$$M^T J M = J. \tag{X.1.20}$$

Equation (1.20) is the condition that M be a *symplectic* matrix (and in the context of optics is sometimes called the *lens equation*). Correspondingly, as described earlier, a map $\mathcal{M}$ whose Jacobian matrix M is symplectic is said to be a *symplectic map.* Note that, as indicated by the notation $M(\boldsymbol{w}^i; z^i, z^f)$, the matrix M depends in general on the variables $\boldsymbol{w}^i$, z^i, and z^f. Observe, however, that the right side of (1.20), namely the matrix J given by (1.19), does not depend on these variables and is in fact a constant matrix. The requirement that (1.20) holds for all values of $\boldsymbol{w}^i$, z^i, and z^f places strong restrictions on the nature of symplectic maps. These restrictions were first studied by Hamilton (in the context of light optics!) and led to the introduction/invention of *characteristic/generating* functions to describe and manage symplectic maps. In this appendix we will see, in the context of light optics, how Lie methods can also be used for this purpose.

Exercises

X.1.1. Verify that H as given by (1.11) is indeed the Hamiltonian associated with the Lagrangian L given by (1.5).

X.1.2. Recall Liouville's theorem. See Subsection 6.8.1. Google the word *etendue.* Work out the consequences of Liouville's theorem when applied to the case of light optics.

X.2 Assumption of Axial Symmetry and Lie-algebraic Consequences

Although framed in the context of light optics, the discussion so far is applicable to general Hamiltonian systems having a four-dimensional phase space. We are dealing with symplectic maps $\mathcal{M}$ whose linear parts M about any trajectory/ray are elements of $Sp(4, \mathbb{R})$. We now turn to the specific case of the optical Hamiltonian (1.11). Moreover, at this point we also assume that the optical device has *axial/rotational symmetry* about the z axis. Introduce the definitions

$$q^2 = (q_x)^2 + (q_y)^2 = \boldsymbol{q} \cdot \boldsymbol{q}, \tag{X.2.1}$$

$$p^2 = (p_x)^2 + (p_y)^2 = \boldsymbol{p} \cdot \boldsymbol{p}, \tag{X.2.2}$$

$$\boldsymbol{p} \cdot \boldsymbol{q} = p_x q_x + p_y q_y. \tag{X.2.3}$$

(Note that this notation can be misleading since, for example, q^2 is not the square of any Cartesian coordinate.) From (1.11) we see that the optical Hamiltonian depends on $\boldsymbol{p}$ only through the quantity p^2. To enforce axial symmetry, we assume that $n(\boldsymbol{r})$ is of the functional form

$$n(\boldsymbol{r}) = \hat{n}(q^2, z) \tag{X.2.4}$$

so that the index of refraction also has axial symmetry. Now imagine that H as given by (1.11) and the assumption (2.4) is expanded in a power series in the components of $\boldsymbol{q}$ and $\boldsymbol{p}$. By the assumption of axial symmetry, such an expansion must be of the form

$$H = H_0 + H_2 + H_4 + H_6 + \cdots \tag{X.2.5}$$

where the H_n are homogeneous polynomials of degree n in the components of $\boldsymbol{q}$ and $\boldsymbol{p}$. That is, only even powers can occur. Indeed, the H_n depend only on powers of q^2 and p^2 and products of these powers. Since only even powers of the components of $\boldsymbol{w}$ can occur in H, it follows that the z axis, $\boldsymbol{w}(z) = 0$, is a trajectory/ray for the equations of motion generated by H, and the phase-space origin is a fixed point of $\mathcal{M}$, $\mathcal{M}0 = 0$.

Let L_z denote the second degree homogeneous polynomial

$$L_z = (\boldsymbol{q} \times \boldsymbol{p}) \cdot \boldsymbol{e}_z = q_x p_y - q_y p_x \tag{X.2.6}$$

and let $\mathcal{L}_z$ be the associated Lie operator

$$\mathcal{L}_z =: L_z : . \tag{X.2.7}$$

Then, as a Lie-algebraic expression of the condition of axial symmetry for the quantities q^2, p^2, and $(\boldsymbol{p} \cdot \boldsymbol{q})$, we have the relations

$$\mathcal{L}_z q^2 = \mathcal{L}_z p^2 = \mathcal{L}_z(\boldsymbol{p} \cdot \boldsymbol{q}) = 0. \tag{X.2.8}$$

And, as a Lie-algebraic expression of the condition of axial symmetry for H, we have the relations

$$\mathcal{L}_z H_n = 0 \tag{X.2.9}$$

and

$$\mathcal{L}_z H = 0. \tag{X.2.10}$$

We conclude from (2.10) that L_z is an integral of motion,

$$\mathcal{L}_z H =: L_z : H = [L_z, H] = 0 \tag{X.2.11}$$

from which it follows that there is the relation

$$L_z^f = L_z^i \tag{X.2.12}$$

which takes the explicit form

$$q_x^f p_y^f - q_y^f p_x^f = q_x^i p_y^i - q_y^i p_x^i. \tag{X.2.13}$$

We note, for future use, that there is the relation

$$(L_z)^2 = (q_x p_y - q_y p_x)^2 = q_x^2 p_y^2 - 2 q_x p_x q_y p_y + p_x^2 q_y^2 = p^2 q^2 - (\boldsymbol{p} \cdot \boldsymbol{q})^2, \tag{X.2.14}$$

and the relation

$$\begin{aligned} (\mathcal{L}_z)^\dagger &= : L_z :^\dagger = (: q_x p_y - q_y p_x :)^\dagger =: q_x p_y :^\dagger - : q_y p_x :^\dagger \\ &= : q_y p_x : - : q_x p_y := -\mathcal{L}_z. \end{aligned} \tag{X.2.15}$$

For the steps made in obtaining the latter relation, recall (7.3.16) through (7.3.18).

We also pause to make the definitions

$$\mathcal{L}_+ =: -p^2/2 :, \tag{X.2.16}$$

$$\mathcal{L}_0 =: (\boldsymbol{p}\cdot\boldsymbol{q})/2 :, \tag{X.2.17}$$

$$\mathcal{L}_- =: q^2/2 : . \tag{X.2.18}$$

From (7.3.16) through (7.3.18) we see that

$$(\mathcal{L}_+)^\dagger =: -p_x^2/2 - p_y^2/2 :^\dagger =: q_x^2/2 + q_y^2/2 := \mathcal{L}_-, \tag{X.2.19}$$

$$(\mathcal{L}_0)^\dagger =: (\boldsymbol{p}\cdot\boldsymbol{q})/2 :^\dagger =: p_x q_x + p_y q_y :^\dagger =: p_x q_x + p_y q_y := \mathcal{L}_0, \tag{X.2.20}$$

$$(\mathcal{L}_-)^\dagger =: q_x^2/2 + q_y^2/2 :^\dagger =: -p_x^2/2 - p_y^2/2 := \mathcal{L}_+. \tag{X.2.21}$$

The Lie operators (2.16) through (2.18) obey the commutation rules

$$\{\mathcal{L}_+, \mathcal{L}_-\} = 2\mathcal{L}_0, \tag{X.2.22}$$

$$\{\mathcal{L}_0, \mathcal{L}_+\} = \mathcal{L}_+, \tag{X.2.23}$$

$$\{\mathcal{L}_0, \mathcal{L}_-\} = -\mathcal{L}_-. \tag{X.2.24}$$

According to Exercise 27.5.5 these commutation rules are a variant of the commutation rules for $sp(2,\mathbb{R})$. (Only some labeling and normalizations have been changed.) Therefore we will be able to work with a particular $Sp(2,\mathbb{R})$ subgroup of $Sp(4,\mathbb{R})$, thereby simplifying/organizing many computations and results.

The rules (2.22) through (2.24) are also the commutation rules for $su(2)$ in its raising and lowering operator form. [Recall that $su(2)$ and $sp(2,\mathbb{R})$ are equivalent over the complex field, and therefore a relation of this form between them should not be a surprise. See Subsection 3.7.6.] Finally note, as a consequence of (5.3.14) and (2.8), that $\mathcal{L}_z$ commutes with $\mathcal{L}_\pm$ and $\mathcal{L}_0$,

$$\{\mathcal{L}_z, \mathcal{L}_\pm\} = \{\mathcal{L}_z, \mathcal{L}_0\} = 0. \tag{X.2.25}$$

Next we invoke a Lie algebraic fact: It can be shown that the solution of (1.16) involves only the ingredients of H and quantities that can be formed by taking Poisson brackets of the ingredients of H. See Chapter 10. It follows that, under the assumption of axial symmetry, the solution to (1.16) must be of the form

$$\begin{aligned} \mathcal{M} &= \exp(: f_2^c :)\exp(: f_2^a :)\exp(: f_4 :)\exp(: f_6 :)\exp(: f_8 :)\cdots \\ &= \mathcal{R}\exp(: f_4 :)\exp(: f_6 :)\exp(: f_8 :)\cdots . \end{aligned} \tag{X.2.26}$$

That is, only the f_n with *even* n can occur in the factored product representation of $\mathcal{M}$. Moreover, all the f_n must satisfy the axial symmetry (rotational invariance) relation

$$\mathcal{L}_z f_n = 0. \tag{X.2.27}$$

Also, there is the Poisson bracket relation

$$[q^2, p^2] = 4\boldsymbol{q}\cdot\boldsymbol{p} = 4\boldsymbol{p}\cdot\boldsymbol{q}. \tag{X.2.28}$$

Therefore f_2^c and f_2^a, and hence $\mathcal{R}$, can depend only on the quantities q^2, $\boldsymbol{p}\cdot\boldsymbol{q}$, and p^2. (We note, as can be easily verified, that p^2-q^2 and $\boldsymbol{p}\cdot\boldsymbol{q}$ are f_2^a polynomials, and p^2+q^2 is an f_2^c polynomial.) Similarly, f_4 can depend only on the six quantities $(p^2)^2$, $p^2(\boldsymbol{p}\cdot\boldsymbol{q})$, $(\boldsymbol{p}\cdot\boldsymbol{q})^2$, p^2q^2, $(\boldsymbol{p}\cdot\boldsymbol{q})q^2$, and $(q^2)^2$. That is, under the assumption of axial symmetry, we may write

$$f_4 = A(p^2)^2 + Bp^2(\boldsymbol{p}\cdot\boldsymbol{q}) + C(\boldsymbol{p}\cdot\boldsymbol{q})^2 + Dp^2q^2 + E(\boldsymbol{p}\cdot\boldsymbol{q})q^2 + F(q^2)^2 \tag{X.2.29}$$

where the coefficients A through F are to be determined. Note that all these ingredients of f_4 are rotationally invariant [as required by (2.27)] and are powers and products of powers of the ingredients for f_2. Similarly, the ingredients of all the f_n for $n \geq 4$ are axially symmetric and are powers and products of powers of the ingredients for f_2. Finally we remark it can be demonstrated that (for an imaging system) the polynomials in (2.29), shown multiplied by the coefficients A through E, are related to the Seidel aberrations of spherical aberration, coma, astigmatism, curvature of field, and distortion, respectively:[1]

$$A(p^2)^2 \leftrightarrow \text{spherical aberration,} \tag{X.2.30}$$

$$Bp^2(\boldsymbol{p}\cdot\boldsymbol{q}) \leftrightarrow \text{coma,} \tag{X.2.31}$$

$$C(\boldsymbol{p}\cdot\boldsymbol{q})^2 \leftrightarrow \text{astigmatism,} \tag{X.2.32}$$

$$Dp^2q^2 \leftrightarrow \text{curvature of field,} \tag{X.2.33}$$

$$E(\boldsymbol{p}\cdot\boldsymbol{q})q^2 \leftrightarrow \text{distortion,} \tag{X.2.34}$$

$$F(q^2)^2 \leftrightarrow \text{nameless.} \tag{X.2.35}$$

The nameless aberration does not affect the ability of an imaging system to form images, but may be important for other systems.

Suppose we present a general/arbitrary f_4 in terms of monomials by writing

$$f_4 = \sum_{|k|=4} f(k_1,k_2,k_3,k_4)q_x^{k_1}p_x^{k_2}q_y^{k_3}p_y^{k_4} \tag{X.2.36}$$

where the coefficients $f(k_1,k_2,k_3,k_4)$ are arbitrary and we have used the notation

$$|k| = k_1+k_2+k_3+k_4. \tag{X.2.37}$$

Under the assumption of axial symmetry, as exemplified by (2.27), there will be relations among the various $f(k_1,k_2,k_3,k_4)$. For example, we see from (2.2) that there is the monomial expansion

$$(p^2)^2 = [(p_x)^2+(p_y)^2]^2 = (p_x)^4 + 2(p_x)^2(p_y)^2 + (p_y)^4. \tag{X.2.38}$$

Also, we see from (2.29) that only the $A(p^2)^2$ term in (2.29) contributes to monomials that are of degree four in the components of $\boldsymbol{p}$. Therefore comparison of (2.29) and (2.36) gives the relations

$$f(0,4,0,0)=A,\ \ f(0,2,0,2)=2A,\ \ f(0,0,0,4)=A. \tag{X.2.39}$$

[1] Philipp Ludwig von Seidel (1821-1896) classified and described the possible third-order geometric aberrations for axially symmetric optical systems.

In Exercise 2.2 you will have the pleasure of working out the further relations of this kind that are implied by (2.29). From these relations one can extract formulas for the coefficients A through F in terms of the $f(k_1, k_2, k_3, k_4)$ with $|k| = 4$, and vice versa. In particular, you will verify the relations

$$A = f(0, 4, 0, 0), \tag{X.2.40}$$

$$B = f(1, 3, 0, 0), \tag{X.2.41}$$

$$C = (1/2)f(1, 1, 1, 1), \tag{X.2.42}$$

$$D = f(0, 2, 2, 0), \tag{X.2.43}$$

$$E = f(3, 1, 0, 0), \tag{X.2.44}$$

$$F = f(4, 0, 0, 0). \tag{X.2.45}$$

Exercises

X.2.1. Verify (2.14).

X.2.2. Verify that (2.27) follows from (2.9) and the work of Chapter 10.

X.2.3. Consider the ingredients of (2.29). We have already found the monomial decomposition (2.38). Verify that all the ingredients of (2.29) have the monomial decompositions

$$(p^2)^2 = [(p_x)^2 + (p_y)^2]^2 = (p_x)^4 + 2(p_x)^2(p_y)^2 + (p_y)^4, \tag{X.2.46}$$

$$p^2(\boldsymbol{p} \cdot \boldsymbol{q}) = [(p_x)^2 + (p_y)^2](p_x q_x + p_y q_y) = q_x(p_x)^3 + (p_x)^2 q_y p_y + q_x p_x (p_y)^2 + q_y (p_y)^3, \tag{X.2.47}$$

$$(\boldsymbol{p} \cdot \boldsymbol{q})^2 = (p_x q_x + p_y q_y)^2 = (q_x)^2(p_x)^2 + 2q_x p_x q_y p_y + (q_y)^2(p_y)^2, \tag{X.2.48}$$

$$p^2 q^2 = [(p_x)^2+(p_y)^2][(q_x)^2+(q_y)^2] = (q_x)^2(p_x)^2+(p_x)^2(q_y)^2+(q_x)^2(p_y)^2+(q_y)^2(p_y)^2, \tag{X.2.49}$$

$$(\boldsymbol{p} \cdot \boldsymbol{q})q^2 = (p_x q_x + p_y q_y)[(q_x)^2 + (q_y)^2] = (q_x)^3 p_x + q_x p_x (q_y)^2 + q_x (q_y)^2 p_y + (q_y)^3 p_y, \tag{X.2.50}$$

$$(q^2)^2 = [(q_x)^2 + (q_y)^2]^2 = (q_x)^4 + 2(q_x)^2(q_y)^2 + (q_y)^4. \tag{X.2.51}$$

From (2.29), (2.36), and (2.40) we have already found the results

$$f(0, 4, 0, 0) = A,\ f(0, 2, 0, 2) = 2A,\ f(0, 0, 0, 4) = A. \tag{X.2.52}$$

Verify from (2.41) that there are the results

$$f(1, 3, 0, 0) = B,\ f(2, 0, 1, 1) = B,\ f(1, 1, 0, 2) = B,\ f(0, 0, 1, 3) = B. \tag{X.2.53}$$

Verify from (2.42) and (2.43) that there are the results

$$f(2, 2, 0, 0) = C + D,\ f(0, 0, 2, 2) = C + D, \tag{X.2.54}$$

$$f(1, 1, 1, 1) = 2C, \tag{X.2.55}$$

$$f(0, 2, 2, 0) = D,\ f(2, 0, 0, 2) = D. \tag{X.2.56}$$

Verify from (2.44) that there are the results

$$f(3, 1, 0, 0) = E,\ f(1, 1, 2, 0) = E,\ f(1, 0, 2, 1) = E,\ f(0, 0, 3, 1) = E. \tag{X.2.57}$$

Verify from (2.45) that there are the results

$$f(4, 0, 0, 0) = F,\ f(2, 0, 2, 0) = 2F,\ f(0, 0, 4, 0) = F. \tag{X.2.58}$$

Verify (2.40) through (2.45).

X.3 Lie-Algebraic Decomposition of Polynomials

X.3.1 Fourth Degree Homogeneous Polynomials

Define the *fourth* degree homogeneous polynomials ${}^4\chi_0^0(\boldsymbol{w})$ and ${}^4\chi_m^2(\boldsymbol{w})$ by the rules

$$ {}^4\chi_0^0 = (L_z)^2 = q_x^2 p_y^2 - 2q_x p_x q_y p_y + p_x^2 q_y^2 = p^2 q^2 - (\boldsymbol{p}\cdot\boldsymbol{q})^2; \tag{X.3.1}$$

$$ {}^4\chi_2^2 = (p^2)^2, \tag{X.3.2}$$

$$ {}^4\chi_1^2 = 2p^2(\boldsymbol{p}\cdot\boldsymbol{q}), \tag{X.3.3}$$

$$ {}^4\chi_0^2 = (2/3)^{1/2}[p^2q^2 + 2(\boldsymbol{p}\cdot\boldsymbol{q})^2], \tag{X.3.4}$$

$$ {}^4\chi_{-1}^2 = 2q^2(\boldsymbol{p}\cdot\boldsymbol{q}), \tag{X.3.5}$$

$$ {}^4\chi_{-2}^2 = (q^2)^2. \tag{X.3.6}$$

(Note that all these polynomials are axially symmetric.) Then it can be verified that there are the operator results

$$ \mathcal{L}_\pm {}^4\chi_0^0 = 0, \tag{X.3.7}$$

$$ \mathcal{L}_0 {}^4\chi_0^0 = 0; \tag{X.3.8}$$

$$ \mathcal{L}_+ {}^4\chi_m^2 = [(2-m)(3+m)]^{1/2}\, {}^4\chi_{m+1}^2, \tag{X.3.9}$$

$$ \mathcal{L}_- {}^4\chi_m^2 = [(2+m)(3-m)]^{1/2}\, {}^4\chi_{m-1}^2, \tag{X.3.10}$$

$$ \mathcal{L}_0\, {}^4\chi_m^2 = m\, {}^4\chi_m^2. \tag{X.3.11}$$

Note that, in a manner identical to that found in the subject of quantum-mechanical angular momentum [which amounts to a study of the representations of $su(2)$], the operator $\mathcal{L}_0$ extracts the m value, and the operators $\mathcal{L}_+$ and $\mathcal{L}_-$ raise and lower m values, respectively. In particular, the results (3.7) through (3.11) can be written in the form

$$ \mathcal{L}_+ {}^n\chi_m^j = [(j-m)(j+m+1)]^{1/2}\, {}^n\chi_{m+1}^j, \tag{X.3.12}$$

$$ \mathcal{L}_- {}^n\chi_m^j = [(j+m)(j-m+1)]^{1/2}\, {}^n\chi_{m-1}^j, \tag{X.3.13}$$

$$ \mathcal{L}_0\, {}^n\chi_m^j = m\, {}^n\chi_m^j. \tag{X.3.14}$$

with j, which (as will become evident subsequently) plays the role of “spin”, having the values $j = 0$ or $j = 2$.[2] Thus, under the action of $\mathcal{L}_\pm$ and $\mathcal{L}_0$, ${}^4\chi_0^0$ behaves as a singlet and the $5 = 2j + 1$ with $j = 2$ quantities ${}^4\chi_{m}^2.$ behave as a quintuplet. Lastly, n denotes the degree of the homogeneous polynomial, with $n = 4$ in this case. This similarity arises because the underlying Lie algebra/group theory is the same here and in the treatment of quantum-mechanical angular momentum.

[2] We have placed the word *spin* in quotation marks because here j does not arise in the context of physical rotations, but rather in this instance is an aspect of the symplectic Lie algebra $sp(2,\mathbb{R})$. Note also that, because of the $(j - m)$ term on the right side of (3.12), the raising operation terminates when $m = j$. Similarly, the lowering operation terminates when $m = -j$.

Finally we observe that, in the present context, f_4 decomposes into a singlet spanned by ${}^4\chi_0^0$ and a quintuplet spanned by the ${}^4\chi_m^2$. That is, we may write

$$f_4 = {}^4c_0^0\ {}^4\chi_0^0 + \sum_{m=-2}^{2} {}^4c_m^2\ {}^4\chi_m^2 \tag{X.3.15}$$

where ${}^4c_0^0$ and the ${}^4c_m^2$ are uniquely defined coefficients.[3]

Let us compare the presentations (2.29) and (3.15). Upon equating like powers we obtain the the relations

$$A(p^2)^2 = {}^4c_2^2\,{}^4\chi_2^2 \Leftrightarrow A = {}^4c_2^2 \Leftrightarrow {}^4c_2^2 = A, \tag{X.3.16}$$

$$Bp^2(\boldsymbol{p}\cdot\boldsymbol{q}) = {}^4c_1^2\,{}^4\chi_1^2 \Leftrightarrow B = 2\,{}^4c_1^2 \Leftrightarrow {}^4c_1^2 = B/2, \tag{X.3.17}$$

$$C(\boldsymbol{p}\cdot\boldsymbol{q})^2 + Dp^2q^2 = {}^4c_0^0\,{}^4\chi_0^0 + {}^4c_0^2\,{}^4\chi_0^2, \tag{X.3.18}$$

$$E(\boldsymbol{p}\cdot\boldsymbol{q})q^2 = {}^4c_{-1}^2\,{}^4\chi_{-1}^2 \Leftrightarrow E = 2\,{}^4c_{-1}^2 \Leftrightarrow {}^4c_{-1}^2 = E/2, \tag{X.3.19}$$

$$F(q^2)^2 = {}^4c_{-2}^2\,{}^4\chi_{-2}^2 \Leftrightarrow F = {}^4c_{-2}^2 \Leftrightarrow {}^4c_{-2}^2 = F. \tag{X.3.20}$$

Further equating of like terms in (3.18 yields the results

$$C = -{}^4c_0^0 + 2(2/3)^{1/2}\ {}^4c_0^2, \tag{X.3.21}$$

$$D = {}^4c_0^0 + (2/3)^{1/2}\ {}^4c_0^2. \tag{X.3.22}$$

See Exercise 3.4. Finally, the relations (3.21) and (3.22) can be inverted to yield the relations

$${}^4c_0^0 = (1/3)(-C + 2D), \tag{X.3.23}$$

$${}^4c_0^2 = (1/6)^{1/2}(C + D). \tag{X.3.24}$$

If we make use of (2.34) through (2.39), and the results of the previous paragraph, we can also express the c_m^j in terms of various $f(k_1, k_2, k_3, k_4)$. So doing gives the results

$$\begin{aligned} {}^4c_0^0 &= (1/3)(-C + 2D) = (1/3)[-(1/2)f(1,1,1,1) + 2f(0,2,2,0)] \\ &= (1/6)[-f(1,1,1,1) + 4f(0,2,2,0)]; \end{aligned} \tag{X.3.25}$$

$${}^4c_2^2 = A = f(0,4,0,0), \tag{X.3.26}$$

$${}^4c_1^2 = B/2 = (1/2)f(1,3,0,0), \tag{X.3.27}$$

$$\begin{aligned} {}^4c_0^2 &= (1/6)^{1/2}(C + D) = (1/6)^{1/2}[(1/2)f(1,1,1,1) + f(0,2,2,0)] \\ &= (1/2)(1/6)^{1/2}[f(1,1,1,1) + 2f(0,2,2,0)], \end{aligned} \tag{X.3.28}$$

$${}^4c_{-1}^2 = E/2 = (1/2)f(3,1,0,0), \tag{X.3.29}$$

$${}^4c_{-2}^2 = F = f(4,0,0,0). \tag{X.3.30}$$

[3] It is interesting to note that, while in the case of $su(2)$ the construction of representations involves the mathematical use of two-variable polynomials, these variables otherwise play no direct physical role. By contrast, in the construction/representation of symplectic maps, polynomials in the phase-space variables play a direct physical role and have specific physical interpretations.

There is another way of obtaining explicit formulas for the c_m^j in terms of f_4 that is both instructive and convenient. Let $\langle *, * \rangle$ denote the scalar product defined in Section 7.3. See (7.3.1) through (7.3.9). Upon employing this scalar product we find, as will be seen subsequently, the results

$$\langle {}^4\chi_0^0, {}^4\chi_0^0 \rangle = 12, \tag{X.3.31}$$

$$\langle {}^4\chi_m^2, {}^4\chi_{m'}^2 \rangle = 64\delta_{mm'}, \tag{X.3.32}$$

$$\langle {}^4\chi_m^2, {}^4\chi_0^0 \rangle = 0. \tag{X.3.33}$$

Consequently, there are the formulas

$${}^4c_0^0 = (1/12)\langle {}^4\chi_0^0, f_4 \rangle, \tag{X.3.34}$$

$${}^4c_m^2 = (1/64)\langle {}^4\chi_m^2, f_4 \rangle. \tag{X.3.35}$$

Finally, we remark that the quantity

$${}^4c_0^0\ {}^4\chi_0^0 = {}^4c_0^0\,(L_z)^2 = {}^4c_0^0\,[p^2q^2 - (\boldsymbol{p}\cdot\boldsymbol{q})^2] = {}^4c_0^0\,p^2q^2 - {}^4c_0^0\,(\boldsymbol{p}\cdot\boldsymbol{q})^2, \tag{X.3.36}$$

which evidently is a combination of astigmatism and curvature of field, is called the (Joseph Maximilian) Petzval (1807-1891) in honor of his early analytic work on geometric aberrations. From (3.23) we see that the Petzval vanishes when

$$-C + 2D = 0. \tag{X.3.37}$$

X.3.2 Second Degree Homogeneous Polynomials

Let us continue with the Lie-algebraic decomposition of polynomials. The polynomials q^2, p^2, and $\boldsymbol{p}\cdot\boldsymbol{q}$ that go into making up f_2 may be labelled according to a scheme that is analogous to that used in (3.2) through (3.6). Define the axially-symmetric *second* degree homogeneous polynomials ${}^2\chi_m^1(\boldsymbol{w})$ by the rules

$${}^2\chi_1^1 = p^2, \tag{X.3.38}$$

$${}^2\chi_0^1 = (2)^{1/2}(\boldsymbol{p}\cdot\boldsymbol{q}), \tag{X.3.39}$$

$${}^2\chi_{-1}^1 = q^2. \tag{X.3.40}$$

Then we find the operator results

$$\mathcal{L}_+ {}^2\chi_m^1 = [(1-m)(2+m)]^{1/2}\ {}^2\chi_{m+1}^1, \tag{X.3.41}$$

$$\mathcal{L}_- {}^2\chi_m^1 = [(1+m)(2-m)]^{1/2}\ {}^2\chi_{m-1}^1, \tag{X.3.42}$$

$$\mathcal{L}_0\ {}^2\chi_m^1 = m\ {}^2\chi_m^1. \tag{X.3.43}$$

Consequently the rules (3,12) through (3.14) continue to hold with, in this case, $j = 1$ and $n = 2$.

We may also define an axially-symmetric second degree homogeneous polynomial ${}^2\psi_0^0(\boldsymbol{w})$ by the rule

$${}^2\psi_0^0 = L_z. \tag{X.3.44}$$

It meets our requirement for axial symmetry because it satisfies

$$\mathcal{L}_z\,{}^2\psi^0_0 =: L_z : L_z = 0. \tag{X.3.45}$$

It also satisfies the relation

$$\mathcal{L}_0\,{}^2\psi^0_0 = (1/2) : (\boldsymbol{p}\cdot\boldsymbol{q}) : L_z = (1/2)[(\boldsymbol{p}\cdot\boldsymbol{q}), L_z] = -(1/2)\mathcal{L}_z(\boldsymbol{p}\cdot\boldsymbol{q}) = 0. \tag{X.3.46}$$

Similarly, there are the relations

$$\mathcal{L}_\pm\,{}^2\psi^0_0 = 0. \tag{X.3.47}$$

(The polynomial ${}^2\psi^0_0$ is therefore entitled to carry the index values $j = 0$ and $m = 0$.) According to our previous discussion, $L_z = {}^2\psi^0_0$ does not appear as an odd power in f_2 or any other f_n. Only the ${}^2\chi^1_m$ can appear in the f_n. That is why we have used the symbol ψ for it rather than χ.

However that is not the end of the matter. According to (2.14) L_z^2 depends on p^2, q^2, and $(\boldsymbol{p}\cdot\boldsymbol{q})$, which are allowed ingredients for the f_n. Therefore, although *odd* powers of L_z are not allowed to appear in the f_n, *even* powers are allowed as, for example, in ${}^4\chi^0_0$. See (3.1).[4]

At this point it may be observed that there are the relations

$${}^4\chi^0_0 = (4/3)^{1/2}[({}^2\chi^1_1)({}^2\chi^1_{-1}) - ({}^2\chi^1_0)^2]; \tag{X.3.48}$$

$${}^4\chi^2_2 = ({}^2\chi^1_1)^2, \tag{X.3.49}$$

$${}^4\chi^2_1 = (2)^{1/2}({}^2\chi^1_1)({}^2\chi^1_0), \tag{X.3.50}$$

$${}^4\chi^2_0 = (2/3)^{1/2}[({}^2\chi^1_1)({}^2\chi^1_{-1}) + ({}^2\chi^1_0)^2], \tag{X.3.51}$$

$${}^4\chi^2_{-1} = (2)^{1/2}({}^2\chi^1_{-1})({}^2\chi^1_0), \tag{X.3.52}$$

$${}^4\chi^2_{-2} = ({}^2\chi^1_{-1})^2. \tag{X.3.53}$$

These relations are examples of the Clebsch-Gordan series for $sp(2,\mathbb{R})$, and are identical to the relations in quantum mechanics for coupling spin 1 and spin 1 to achieve net spin 0 or net spin 2. Agreement between the Clebsch-Gordan series for $sp(2,\mathbb{R})$ and $su(2)$ is to be expected because the commutation rules (2.22) through (2.24) for $sp(2,\mathbb{R})$ are the same as those for $su(2)$ in raising and lowering operator form, and the state relations (3.12) through (3.14) are the same in both cases.

X.3.3 Sixth and Eighth Degree Homogeneous Polynomials

The homogeneous polynomials that go into making f_6, f_8, etc., may be classified in similar fashion. One finds, for example, that f_6 decomposes into a triplet and a septuplet given by the relations

$${}^6\chi^1_m = ({}^4\chi^0_0)({}^2\chi^1_m); \tag{X.3.54}$$

$${}^6\chi^3_3 = (p^2)^3, \tag{X.3.55}$$

[4] *Odd* (as well as even) powers of L_z are allowed in the f_n for the magnetic optics case of a solenoid, which also has axial symmetry. See Section 16.2.

$${}^6\chi^3_2 = (6)^{1/2}(p^2)^2(\boldsymbol{p}\cdot\boldsymbol{q}), \tag{X.3.56}$$

$${}^6\chi^3_1 = (3/5)^{1/2}[4p^2(\boldsymbol{p}\cdot\boldsymbol{q})^2 + (p^2)^2q^2], \tag{X.3.57}$$

$${}^6\chi^3_0 = (4/5)^{1/2}[2(\boldsymbol{p}\cdot\boldsymbol{q})^3 + 3(\boldsymbol{p}\cdot\boldsymbol{q})p^2q^2], \tag{X.3.58}$$

$${}^6\chi^3_{-1} = (3/5)^{1/2}[4q^2(\boldsymbol{p}\cdot\boldsymbol{q})^2 + (q^2)^2p^2], \tag{X.3.59}$$

$${}^6\chi^3_{-2} = (6)^{1/2}(q^2)^2(\boldsymbol{p}\cdot\boldsymbol{q}), \tag{X.3.60}$$

$${}^6\chi^3_{-3} = (q^2)^3. \tag{X.3.61}$$

Consequently we may present a general (axially symmetric) f_6 in the form

$$f_6 = \sum_{m=-1}^{1} {}^6c^1_m\ {}^6\chi^1_m + \sum_{m=-3}^{3} {}^6c^3_m\ {}^6\chi^3_m \tag{X.3.62}$$

where the ${}^6c^1_m$ and ${}^6c^3_m$ are uniquely defined coefficients.

Similarly, f_8 decomposes into a singlet, a quintuplet, and a 9-tuplet given by the relations

$${}^8\chi^0_0 = ({}^4\chi^0_0)^2; \tag{X.3.63}$$

$${}^8\chi^2_m = ({}^4\chi^0_0)({}^4\chi^2_m); \tag{X.3.64}$$

$${}^8\chi^4_4 = ({}^2\chi^1_1)^4 = (p^2)^4, \tag{X.3.65}$$

$${}^8\chi^4_3 = (8)^{1/2}(p^2)^3(\boldsymbol{p}\cdot\boldsymbol{q}), \tag{X.3.66}$$

$${}^8\chi^4_2 = (4/7)^{1/2}[(p^2)^3q^2 + 6(p^2)^2(\boldsymbol{p}\cdot\boldsymbol{q})^2], \tag{X.3.67}$$

$${}^8\chi^4_1 = (8/7)^{1/2}[3(p^2)^2(\boldsymbol{p}\cdot\boldsymbol{q})q^2 + 4(p^2)(\boldsymbol{p}\cdot\boldsymbol{q})^3], \tag{X.3.68}$$

$${}^8\chi^4_0 = (2/35)^{1/2}[24p^2q^2(\boldsymbol{p}\cdot\boldsymbol{q})^2 + 3(q^2)^2(p^2)^2 + 8(\boldsymbol{p}\cdot\boldsymbol{q})^4], \tag{X.3.69}$$

$${}^8\chi^4_{-1} = (8/7)^{1/2}[3(q^2)^2(\boldsymbol{p}\cdot\boldsymbol{q})p^2 + 4(q^2)(\boldsymbol{p}\cdot\boldsymbol{q})^3], \tag{X.3.70}$$

$${}^8\chi^4_{-2} = (4/7)^{1/2}[(q^2)^3p^2 + 6(q^2)^2(\boldsymbol{p}\cdot\boldsymbol{q})^2, \tag{X.3.71}$$

$${}^8\chi^4_{-3} = (8)^{1/2}(q^2)^3(\boldsymbol{p}\cdot\boldsymbol{q}), \tag{X.3.72}$$

$${}^8\chi^4_{-4} = ({}^2\chi^1_{-1})^4 = (q^2)^4. \tag{X.3.73}$$

Consequently we may present a general (axially symmetric) f_8 in the form

$$f_8 = {}^8c^0_0\ {}^8\chi^0_0 + \sum_{m=-2}^{2} {}^8c^2_m\ {}^8\chi^2_m + \sum_{m=-4}^{4} {}^8c^4_m\ {}^8\chi^4_m \tag{X.3.74}$$

where ${}^8c^0_0$ and the ${}^8c^2_m$ and the ${}^8c^4_m$ are uniquely defined coefficients.

It can be checked, as implied by the presentations (3.15), (3.62), and (3.74), that the decompositions given above are exhaustive. That is, the various ${}^n\chi^j_m$ span each (axially symmetric) f_n. Moreover, the ${}^n\chi^j_m$ have been defined in such a way that one has the general relations (3.12) through (3.14).

X.3.4 Proof of Orthogonality and Definition/Use of the Quadratic Casimir Operator

The aim of this subsection is to prove the scalar product relations

$$\langle {}^{n'}\chi^{j'}_{m'}\,,\,{}^{n}\chi^{j}_{m}\rangle = N(n,j)\delta_{n'n}\delta_{j'j}\delta_{m'm} \tag{X.3.75}$$

where the $N(n,j)$ are normalization constants *independent* of m. One of the tools for doing so will be the quadratic Casimir operator for our realization of $sp(2,\mathbb{R})$.

That (3.75) should contain the delta function $\delta_{n'n}$ is obvious because, by definition, $\langle *, *\rangle$ is zero for unlike monomial pairs, and hence vanishes for homogeneous polynomials of different degrees. See Subsection 7.3.1 and Exercise 7.3.25.

Let us next verify the $\delta_{m'm}$ factor. Consider the quantity $\langle {}^{n'}\chi^{j'}_{m'}\,,\,\mathcal{L}_0\,{}^{n}\chi^{j}_{m}\rangle$. With the aid of (3.14) we may write

$$\langle {}^{n'}\chi^{j'}_{m'}\,,\,\mathcal{L}_0\,{}^{n}\chi^{j}_{m}\rangle = m\langle {}^{n'}\chi^{j'}_{m'}\,,\,{}^{n}\chi^{j}_{m}\rangle. \tag{X.3.76}$$

But, with the aid of (2.20) and (3.14), we may also write

$$\langle {}^{n'}\chi^{j'}_{m'}\,,\,\mathcal{L}_0\,{}^{n}\chi^{j}_{m}\rangle = \langle (\mathcal{L}_0)^{\dagger}\,{}^{n'}\chi^{j'}_{m'}\,,\,{}^{n}\chi^{j}_{m}\rangle = \langle \mathcal{L}_0\,{}^{n'}\chi^{j'}_{m'}\,,\,{}^{n}\chi^{j}_{m}\rangle = m'\langle {}^{n'}\chi^{j'}_{m'}\,,\,{}^{n}\chi^{j}_{m}\rangle. \tag{X.3.77}$$

It follows that

$$(m'-m)\langle {}^{n'}\chi^{j'}_{m'}\,,\,{}^{n}\chi^{j}_{m}\rangle = 0 \tag{X.3.78}$$

from which we conclude that

$$\langle {}^{n'}\chi^{j'}_{m'}\,,\,{}^{n}\chi^{j}_{m}\rangle = 0 \text{ when } m' \neq m. \tag{X.3.79}$$

To see that $N(n,j)$ is (as the notation asserts) independent of m, consider the quantity $\langle \mathcal{L}_+\,{}^{n}\chi^{j}_{m}\,,\,\mathcal{L}_+\,{}^{n}\chi^{j}_{m}\rangle$. Making use of (3.12) gives the result

$$\langle \mathcal{L}_+\,{}^{n}\chi^{j}_{m}\,,\,\mathcal{L}_+\,{}^{n}\chi^{j}_{m}\rangle = [(j-m)(j+m+1)]^{1/2}[(j-m)(j+m+1)]^{1/2}\langle {}^{n}\chi^{j}_{m+1}\,,\,{}^{n}\chi^{j}_{m+1}\rangle. \tag{X.3.80}$$

From (2.19) we conclude that

$$\langle \mathcal{L}_+\,{}^{n}\chi^{j}_{m}\,,\,\mathcal{L}_+\,{}^{n}\chi^{j}_{m}\rangle = \langle {}^{n}\chi^{j}_{m}\,,\,(\mathcal{L}_+)^{\dagger}\mathcal{L}_+\,{}^{n}\chi^{j}_{m}\rangle = \langle {}^{n}\chi^{j}_{m}\,,\,\mathcal{L}_-\mathcal{L}_+\,{}^{n}\chi^{j}_{m}\rangle. \tag{X.3.81}$$

But from (3.12) and (3.13) we see that

$$\begin{aligned} \mathcal{L}_-\mathcal{L}_+\,{}^{n}\chi^{j}_{m} &= [(j-m)(j+m+1)]^{1/2}\mathcal{L}^{n}_{-}\chi^{j}_{m+1} \\ &= [(j-m)(j+m+1)]^{1/2}[(j+m+1)(j-m)]^{1/2}\,{}^{n}\chi^{j}_{m} \end{aligned} \tag{X.3.82}$$

so that

$$\langle \mathcal{L}_+\,{}^{n}\chi^{j}_{m}\,,\,\mathcal{L}_+\,{}^{n}\chi^{j}_{m}\rangle = [(j-m)(j+m+1)]^{1/2}[(j+m+1)(j-m)]^{1/2}\,\langle {}^{n}\chi^{j}_{m}\,,\,{}^{n}\chi^{j}_{m}\rangle. \tag{X.3.83}$$

Upon comparing (3.80) with (3.83) we see that there is the relation

$$\begin{aligned} &[(j-m)(j+m+1)]^{1/2}[(j-m)(j+m+1)]^{1/2}\langle {}^{n}\chi^{j}_{m+1}\,,\,{}^{n}\chi^{j}_{m+1}\rangle = \\ &[(j-m)(j+m+1)]^{1/2}[(j+m+1)(j-m)]^{1/2}\,\langle {}^{n}\chi^{j}_{m}\,,\,{}^{n}\chi^{j}_{m}\rangle. \end{aligned} \tag{X.3.84}$$

Therefore, as long as $[(j-m)(j+m+1)] \neq 0$ (which will be true if raising of m is possible), we have found the relation

$$\langle {}^n\chi^j_{m+1}\,,\,{}^n\chi^j_{m+1}\rangle = \langle {}^n\chi^j_m\,,\,{}^n\chi^j_m\rangle. \tag{X.3.85}$$

With this result we can repeatedly increase m starting from $m=-j$ to obtain the result

$$\langle {}^n\chi^j_m\,,\,{}^n\chi^j_m\rangle = \langle {}^n\chi^j_{-j}\,,\,{}^n\chi^j_{-j}\rangle \text{ for } m \in [-j,j], \tag{X.3.86}$$

which verifies that N does not depend on m.

The last step is to verify the $\delta_{j'j}$ factor in (3.75). This can be done with the aid of the quadratic Casimir operator $\mathcal{C}_2$ for our realization of $sp(2,\mathbb{R})$. For the purposes of this appendix, it is defined by the rule

$$\mathcal{C}_2 = (\mathcal{L}_+\mathcal{L}_- + \mathcal{L}_-\mathcal{L}_+ + 2\mathcal{L}_0^2)/2. \tag{X.3.87}$$

(For a discussion of Casimir operators, see Section 27.11.) It follows from (2.19) through (2.21) that $\mathcal{C}_2$ is Hermitian,

$$\mathcal{C}_2^\dagger = \mathcal{C}_2. \tag{X.3.88}$$

And it follows from (2.22) through (2.24) that $\mathcal{C}_2$ commutes with all the $sp(2,\mathbb{R})$ generators, $\mathcal{L}_\pm$ and $\mathcal{L}_0$,

$$\{\mathcal{C}_2, \mathcal{L}_\pm\} = \{\mathcal{C}_2, \mathcal{L}_0\} = 0, \tag{X.3.89}$$

as expected for a Casimir operator.

Let us compute $\mathcal{C}_2\,{}^n\chi^j_j$. Evidently,

$$\mathcal{C}_2\,{}^n\chi^j_j = (1/2)(\mathcal{L}_+\mathcal{L}_- + \mathcal{L}_-\mathcal{L}_+ + 2\mathcal{L}_0^2)\,{}^n\chi^j_j. \tag{X.3.90}$$

Evaluate each of the three terms appearing in (3.90). For $\mathcal{L}_0^2\,{}^n\chi^j_j$ there is the result

$$\mathcal{L}_0^2\,{}^n\chi^j_j = j^2\,{}^n\chi^j_j. \tag{X.3.91}$$

Recall (3.14). For $(1/2)\mathcal{L}_-\mathcal{L}_+\,{}^n\chi^j_j$ there is the result

$$(1/2)\mathcal{L}_-\mathcal{L}_+\,{}^n\chi^j_j = 0. \tag{X.3.92}$$

Recall (3.82) evaluated for $m=j$. Finally, for $(1/2)\mathcal{L}_+\mathcal{L}_-\,{}^n\chi^j_j$, there is the result

$$(1/2)\mathcal{L}_+\mathcal{L}_-\,{}^n\chi^j_j = (1/2)\mathcal{L}_+(2j)^{1/2}\,{}^n\chi^j_{j-1} = (1/2)(2j)^{1/2}(2j)^{1/2}\,{}^n\chi^j_j = j\,{}^n\chi^j_j. \tag{X.3.93}$$

Recall (3.12) and (3.13). Consequently, as in the analogous quantum-mechanical calculation, there is the net result

$$\mathcal{C}_2\,{}^n\chi^j_j = (j+j^2)\,{}^n\chi^j_j = [j(j+1)]\,{}^n\chi^j_j. \tag{X.3.94}$$

To continue our exploration, multiply both sides of (3.94) by $\mathcal{L}_-^\ell$ where $\ell = j-m$. So doing gives the result

$$[j(j+1)]\mathcal{L}_-^\ell\,{}^n\chi^j_j = \mathcal{L}_-^\ell\mathcal{C}_2\,{}^n\chi^j_j = \mathcal{C}_2\mathcal{L}_-^\ell\,{}^n\chi^j_j \tag{X.3.95}$$

where (3.89) has been used. But from (repeated, if necessary) use of (3.13) it follows that there is a relation of the form

$$\mathcal{L}_-^\ell \, {}^n\chi_j^j = \lambda(j,\ell) \, {}^n\chi_m^j \tag{X.3.96}$$

where $\lambda(j,\ell)$ is a non-vanishing proportionality constant. Combining (3.95) and (3.96) gives the final result

$$\mathcal{C}_2 \, {}^n\chi_m^j = [j(j+1)] \, {}^n\chi_m^j. \tag{X.3.97}$$

We are now prepared to verify the $\delta_{j'j}$ factor in (3.75). Using (3.97) gives the relation

$$\langle {}^n\chi_m^{j'}, \mathcal{C}_2 \, {}^n\chi_m^j \rangle = [j(j+1)] \langle {}^n\chi_m^{j'}, {}^n\chi_m^j \rangle = [(j+1/2)^2 - 1/4] \langle {}^n\chi_m^{j'}, {}^n\chi_m^j \rangle. \tag{X.3.98}$$

But, from (3.88), we also have the relation

$$\langle {}^n\chi_m^{j'}, \mathcal{C}_2 \, {}^n\chi_m^j \rangle = \langle \mathcal{C}_2 \, {}^n\chi_m^{j'}, {}^n\chi_m^j \rangle = [(j'+1/2)^2 - 1/4] \langle {}^n\chi_m^{j'}, {}^n\chi_m^j \rangle. \tag{X.3.99}$$

Upon combining (3.98) and (3.99) we see that

$$[(j'+1/2)^2 - (j+1/2)^2] \langle {}^n\chi_m^{j'}, {}^n\chi_m^j \rangle = 0. \tag{X.3.100}$$

It is easily verified that

$$[(j'+1/2)^2 - (j+1/2)^2] = 0 \Leftrightarrow j' = j \text{ or } j' + j = -1. \tag{X.3.101}$$

The second possibility on the right side of (3.101) cannot occur since we are only working with nonnegative values of j and j'. We conclude that for our purposes the factor

$$[(j'+1/2)^2 - (j+1/2)^2] \neq 0 \text{ for } j' \neq j, \tag{X.3.102}$$

and therefore (3.100) requires that

$$\langle {}^n\chi_m^{j'}, {}^n\chi_m^j \rangle = 0 \text{ for } j' \neq j. \tag{X.3.103}$$

What remains is to evaluate/specify the $N(n,j)$. Presumably there is a relatively simple formula that does so. But for our purposes the Table below suffices for values of n and j of present interest.

Table X.3.1: Some Values of $N(n, j)$.

n	$N(n,0)$	$N(n,1)$	$N(n,2)$	$N(n,3)$	$N(n,4)$
2	*	4	*	*	*
4	12	*	64	*	*
6	*	160	*	2304	*
8	?	*	?	*	?

Exercises

X.3.1. Verify (3.7) through (3.11) and (3.41) through (3.43).

X.3.2. Verify (3.25) through (3.30).

X.3.3. Review Exercise 2.3. Equation (3.1) provides the monomial decomposition for ${}^4\chi^0_0$. Verify that the relations below provide the monomial decompositions for the ${}^4\chi^2_m$:

$$ {}^4\chi^2_2 = (p^2)^2 = (p_x)^4 + 2(p_x)^2(p_y)^2 + (p_y)^4, \tag{X.3.104}$$

$$ {}^4\chi^2_1 = 2p^2(\boldsymbol{p}\cdot\boldsymbol{q}) = 2q_x(p_x)^3 + 2(p_x)^2 q_y p_y + 2q_x p_x (p_y)^2 + 2q_y(p_y)^3, \tag{X.3.105}$$

$$\begin{aligned} {}^4\chi^2_0 &= (2/3)^{1/2}[p^2q^2 + 2(\boldsymbol{p}\cdot\boldsymbol{q})^2] \\ &= (2/3)^{1/2}\{[(p_x)^2+(p_y)^2][(q_x)^2+(q_y)^2] + 2(q_xp_x+q_yp_y)^2\} \\ &= (2/3)^{1/2}[(q_x)^2(p_x)^2 + (p_x)^2(q_y)^2 + (q_x)^2(p_y)^2 + (q_y)^2(p_y)^2 \\ &\quad +2(q_x)^2(p_x)^2 + 4q_xp_xq_yp_y + 2(q_y)^2(p_y)^2] \\ &= (2/3)^{1/2}[3(q_x)^2(p_x)^2 + (p_x)^2(q_y)^2 + (q_x)^2(p_y)^2 + 3(q_y)^2(p_y)^2 + 4q_xp_xq_yp_y], \end{aligned} \tag{X.3.106}$$

$$ {}^4\chi^2_{-1} = 2(\boldsymbol{p}\cdot\boldsymbol{q})q^2 = 2(q_x)^3p_x + 2q_xp_x(q_y)^2 + 2(q_x)^2q_yp_y + 2(q_y)^3p_y, \tag{X.3.107}$$

$$ {}^4\chi^2_{-2} = (q^2)^2 = (q_x)^4 + 2(q_x)^2(q_y)^2 + (q_y)^4. \tag{X.3.108}$$

X.3.4. The aim of this exercise is to verify the relations (3.21) through (3.24). Review the results (2.46) through (2.51), (3.1), and (3.104) through (3.108). Verify that

$$\begin{aligned} C(\boldsymbol{p}\cdot\boldsymbol{q})^2 + Dp^2q^2 &= C[(q_x)^2(p_x)^2 + 2q_xp_xq_yp_y + (q_y)^2(p_y)^2] \\ &+ D[(q_x)^2(p_x)^2 + (p_x)^2(q_y)^2 + (q_x)^2(p_y)^2 + (q_y)^2(p_y)^2] \\ &= (C+D)[(q_x)^2(p_x)^2 + (q_y)^2(p_y)^2] \\ &+ 2Cq_xp_xq_yp_y + D[(p_x)^2(q_y)^2 + (q_x)^2(p_y)^2]. \end{aligned} \tag{X.3.109}$$

Verify that

$$\begin{aligned}
&{}^4c_0^0\,{}^4\chi_0^0 + {}^4c_0^2\,{}^4\chi_0^2 = {}^4c_0^0\,[q_x^2p_y^2 - 2q_xp_xq_yp_y + p_x^2q_y^2]\\
&+{}^4c_0^2(2/3)^{1/2}[3(q_x)^2(p_x)^2 + (p_x)^2(q_y)^2 + (q_x)^2(p_y)^2 + 3(q_y)^2(p_y)^2 + 4q_xp_xq_yp_y]\\
&= (6)^{1/2}\,{}^4c_0^2[(q_x)^2(p_x)^2 + (q_y)^2(p_y)^2] + [-2\,{}^4c_0^0 + 4(2/3)^{1/2}\,{}^4c_0^2]q_xp_xq_yp_y\\
&+[{}^4c_0^0 + (2/3)^{1/2}\,{}^4c_0^2][(p_x)^2(q_y)^2 + (q_x)^2(p_y)^2]. \qquad \text{(X.3.110)}
\end{aligned}$$

Since the monomials appearing on the right sides of (3.109) and (3.110) are linearly independent, we may equate the coefficients of like terms. In particular, we may equate the coefficients of the polynomials

$$[(q_x)^2(p_x)^2 + (q_y)^2(p_y)^2],\ q_xp_xq_yp_y,\ \text{and}\ [(p_x)^2(q_y)^2 + (q_x)^2(p_y)^2]. \qquad \text{(X.3.111)}$$

Conclude that (3.18), when combined with (3.109) and (3.110), implies the relations

$${}^4c_0^2 = 6^{-1/2}(C+D) \Leftrightarrow C + D = (6)^{1/2}\,{}^4c_0^2, \qquad \text{(X.3.112)}$$

$$2C = [-2\,{}^4c_0^0 + 4(2/3)^{1/2}\,{}^4c_0^2] \Leftrightarrow C = [-\,{}^4c_0^0 + 2(2/3)^{1/2}\,{}^4c_0^2], \qquad \text{(X.3.113)}$$

$$D = [{}^4c_0^0 + (2/3)^{1/2}\,{}^4c_0^2], \qquad \text{(X.3.114)}$$

from which it follows that

$${}^4c_0^0 = (1/3)(-C+2D) \Leftrightarrow (-C+2D) = 3\,{}^4c_0^0. \qquad \text{(X.3.115)}$$

Observe that (3.113) and (3.114) agree with the claims (3.21) and (3.22). Also, observe that taking the sum of (3.21) and (3.22) produces (3.24), which agrees with (3.112). Finally, verify that (3.23) follows from (3.21) and (3.22).

X.3.5. Observe that the operators $\mathcal{L}_\pm$ and $\mathcal{L}_0$ are derivations. Work out their effects on ${}^4\chi_0^0$ and the ${}^4\chi_m^2$ using (3.1) and (3.48) through (3.53) and (3.41) through (3.43). Verify that your results agree with (3.7) through (3.11).

X.3.6. Review the derivation of the result (3.85) obtained with the use of the operator $\mathcal{L}_+$. Using the operator $\mathcal{L}_-$ in a similar way, derive the relation

$$\langle {}^n\chi_{m-1}^j\,,\,{}^n\chi_{m-1}^j\rangle = \langle {}^n\chi_m^j\,,\,{}^n\chi_m^j\rangle. \qquad \text{(X.3.116)}$$

X.3.7. Verify that the ${}^n\chi_m^j$ given by (3.1) through (3.6), (3.38) through (3.40), (3.54) through (3.61), and (3.63) through (3.73) all obey the rules (3.12) through (3.14).

X.3.8. Verify the relations

$$\mathcal{L}_+ =: -p^2/2 := -(1/2) : {}^2\chi_1^1 :, \qquad \text{(X.3.117)}$$

$$\mathcal{L}_0 =: (\boldsymbol{p}\cdot\boldsymbol{q})/2 := (1/8)^{1/2} : {}^2\chi_0^1 :, \qquad \text{(X.3.118)}$$

$$\mathcal{L}_- =: q^2/2 := (1/2) : {}^2\chi_{-1}^1 : . \qquad \text{(X.3.119)}$$

X.3.9. Verify the correctness of the entries in Table 3.1.

X.4 Application of Multiplet Decomposition

It has been shown that the various f_n can be decomposed into multiplets with members ${}^n\chi^j_m$. What is this decomposition good for? Suppose an optical system is composed of N elements, and let $\mathcal{M}_i$ be the optical transfer map for the i'th element. Then the net optical transfer map $\mathcal{M}$ for the entire system can be written as the product

$$\mathcal{M}_{\rm net} = \mathcal{M}_1\mathcal{M}_2\cdots\mathcal{M}_N. \tag{X.4.1}$$

Next observe that each of the $\mathcal{M}_i$ has a factorization of the form (2.26). Suppose further that the various f's for the various $\mathcal{M}_i$ are all known. Then the only problem involved in computing $\mathcal{M}_{\rm net}$ is that of combining a collection of known maps and writing the result in factorized form.

The general problem of combining/concatenating maps has been treated in Section 8.4. Let us briefly summarize the consequences of this treatment for the present discussion. Suppose $\mathcal{M}_f$ and $\mathcal{M}_g$ are two optical transfer maps written in factored product form,

$$\mathcal{M}_f = \mathcal{R}_f \exp(:f_4:)\exp(:f_6:)\exp(:f_8:)\cdots\,, \tag{X.4.2}$$

$$\mathcal{M}_g = \mathcal{R}_g \exp(:g_4:)\exp(:g_6:)\exp(:g_8:)\cdots\,. \tag{X.4.3}$$

Let $\mathcal{M}_h$ be their product,

$$\mathcal{M}_h = \mathcal{M}_f\mathcal{M}_g, \tag{X.4.4}$$

and write $\mathcal{M}_h$ in the factorized form

$$\mathcal{M}_h = \mathcal{R}_h \exp(:h_4:)\exp(:h_6:)\exp(:h_8:)\cdots\,. \tag{X.4.5}$$

Employ (4.2) and (4.3) in (4.4), and judiciously insert factors of $\mathcal{I} = \mathcal{R}_g\mathcal{R}_g^{-1}$, to write

$$\begin{aligned}\mathcal{M}_h &= \mathcal{R}_f \exp(:f_4:)\exp(:f_6:)\exp(:f_8:)\cdots\times\mathcal{R}_g \exp(:g_4:)\exp(:g_6:)\exp(:g_8:)\cdots\\ &= \mathcal{R}_f\mathcal{R}_g\mathcal{R}_g^{-1}\exp(:f_4:)\mathcal{R}_g\mathcal{R}_g^{-1}\exp(:f_6:)\mathcal{R}_g\mathcal{R}_g^{-1}\exp(:f_8:)\mathcal{R}_g\cdots\\ &\quad\times\exp(:g_4:)\exp(:g_6:)\exp(:g_8:)\cdots\,.\end{aligned} \tag{X.4.6}$$

Next manipulate and make the definition

$$\mathcal{R}_g^{-1}\exp(:f_n:)\mathcal{R}_g = \exp[\mathcal{R}_g^{-1}:f_n:\mathcal{R}_g] = \exp(:\mathcal{R}_g^{-1}f_n:) = \exp(:f_n^{\rm tr}:). \tag{X.4.7}$$

Here the *transformed* polynomials $f_n^{\rm tr}$ are defined in terms of the original f_n by the relations

$$f_n^{\rm tr} = \mathcal{R}_g^{-1}f_n, \tag{X.4.8}$$

from which it follows that

$$f_n^{\rm tr}(\boldsymbol{w}) = f_n[(R^g)^{-1}\boldsymbol{w}] \tag{X.4.9}$$

where R^g is the matrix associated with $\mathcal{R}_g$. [See (8.2.26).] Upon combining the results of our manipulation and definition we conclude that

$$\mathcal{M}_h = \mathcal{R}_f\mathcal{R}_g \exp(:f_4^{\rm tr}:)\exp(:f_6^{\rm tr}:)\exp(:f_8^{\rm tr}:)\cdots\times\exp(:g_4:)\exp(:g_6:)\exp(:g_8:)\cdots\,. \tag{X.4.10}$$

Now compare (4.5) and (4.10) to conclude that

$$\mathcal{R}_h = \mathcal{R}_f \mathcal{R}_g, \tag{X.4.11}$$

and

$$\begin{aligned}&\exp(:h_4:)\exp(:h_6:)\exp(:h_8:)\cdots = \\ &\exp(:f_4^{\mathrm{tr}}:)\exp(:f_6^{\mathrm{tr}}:)\exp(:f_8^{\mathrm{tr}}:)\cdots \times \exp(:g_4:)\exp(:g_6:)\exp(:g_8:)\cdots .\end{aligned} \tag{X.4.12}$$

It follows from (4.11) that the associated matrices obey the relation

$$R^h = R^g R^f. \tag{X.4.13}$$

And, from the work of Section 8.4, we know that (4.12) yields the aberration generator relations

$$h_4 = f_4^{\mathrm{tr}} + g_4, \tag{X.4.14}$$

$$h_6 = f_6^{\mathrm{tr}} + g_6 + [f_4^{\mathrm{tr}}, g_4]/2, \tag{X.4.15}$$

$$h_8 = f_8^{\mathrm{tr}} + g_8 + [f_6^{\mathrm{tr}}, g_4] - [f_4^{\mathrm{tr}}, [f_4^{\mathrm{tr}}, g_4]]/6 + [g_4, [g_4, f_4^{\mathrm{tr}}]]/3, \text{ etc.} \tag{X.4.16}$$

Inspection of (4.14) through (4.16) shows that the determination of the aberration generators involves carrying out the transformations (4.9) and the evaluation of certain Poisson brackets. It is these two tasks that may, in some cases, be simplified by multiplet decomposition.

Observe that any $\mathcal{R}_g^{-1}$ is generated by $\mathcal{L}_\pm$ and $\mathcal{L}_0$. It follows from (3.12) through (3.14) that any $\mathcal{R}_g^{-1}$ acting on any element of a given multiplet must give a result in the *same* multiplet. Specifically, one must have results of the form

$$\mathcal{R}_g^{-1}\ {}^n\chi_m^j = \sum_{m'=-j}^{j} D_{m'm}^j[(R^g)^{-1}]\ {}^n\chi_{m'}^j. \tag{X.4.17}$$

Here the $D_{m'm}^j[(R^g)^{-1}]$ are the transformation functions associated with the symplectic matrices $(R^g)^{-1}$ and are the analytic continuation from $SU(2)$ to $Sp(2,\mathbb{R})$ of the $SU(2)$ Wigner functions (which are entire so that unique analytic continuation is always well defined). Special cases of the relations (4.17) are the results

$$\mathcal{R}_g^{-1}\ {}^n\chi_0^0 \ = \ {}^n\chi_0^0 \text{ for } n = 4, 8, \tag{X.4.18}$$

which are immediately evident consequences of (3.7) and (3.8), and analogous relations for ${}^8\chi_0^0$.

The relations (4.17) in analytic form may or may not be computationally useful.[5] However, they do show what contributes to what. Suppose, for example, that f_4 is given by (3.15), and similarly g_4 is given by

$$g_4 = {}^4d_0^0\ {}^4\chi_0^0 + \sum_{m=-2}^{2} {}^4d_m^2\ {}^4\chi_m^2. \tag{X.4.19}$$

[5] What is essentially involved here is the operation (4.9). It can be realized numerically utilizing the efficient and fast algorithm described in Section 39.9. The operation (4.9) is of direct/immediate use if one wishes to compute the f_n^{tr}. It is of intermediate use if one wishes to compute the $D_{m'm}^j$ using (4.52).

Then, from the definition (4.8) and using (4.17) and (4.18), we find that

$$\begin{aligned} f_4^{\rm tr} &= \mathcal{R}_g^{-1} f_4 = \mathcal{R}_g^{-1}[{}^4c_0^0\ {}^4\chi_0^0 + \sum_{m=-2}^{2} {}^4c_m^2\ {}^4\chi_m^2] = \\ &= {}^4c_0^0\ {}^4\chi_0^0 + \sum_{m'=-2}^{2}\{\sum_{m=-2}^{2} D^2_{m'm}[(R^g)^{-1}]\ {}^4c_m^2\ \}\ {}^4\chi_{m'}^2 \\ &= {}^4c_0^0\ {}^4\chi_0^0 + \sum_{m=-2}^{2}\{\sum_{m'=-2}^{2} D^2_{mm'}[(R^g)^{-1}]\ {}^4c_{m'}^2\ \}\ {}^4\chi_m^2 \\ &= {}^4c_0^0\ {}^4\chi_0^0 + \sum_{m=-2}^{2} {}^4e_m^2\ {}^4\chi_m^2 \end{aligned} \tag{X.4.20}$$

where the coefficients ${}^4e_m^2$ are given by the relation

$${}^4e_m^2 = \sum_{m'=-2}^{2} D^2_{mm'}[(R^g)^{-1}]\ {}^4c_{m'}^2. \tag{X.4.21}$$

All the ingredients are now available for insertion into (4.14) to yield the result

$$h_4 = f_4^{\rm tr} + g_4 = ({}^4c_0^0 + {}^4d_0^0)\ {}^4\chi_0^0\ + \sum_{m=-2}^{2}({}^4e_m^2 + {}^4d_m^2)\ {}^4\chi_m^2. \tag{X.4.22}$$

We see that the singlet contributions (the Petzval contributions) to h_4 are *purely additive*, and depend *only* on the singlet content of f_4 and g_4, Similarly, the quintuplet content of h_4 depends *only* on the quintuplet content of f_4 and g_4, although in a somewhat more complicated way: The quintuplet content of f_4 first has to be transformed by $\mathcal{R}_g^{-1}$ before its addition to the quintuplet content of g_4 to yield the net quintuplet content for h_4.

The discussion so far has dealt with the combining of third-order aberrations as described by (4.14). Now look at (4.15) which describes how fifth-order aberrations combine/arise. Evidently, by an argument similar to that made for third-order aberrations, the triplet and septuplet components of f_6 and g_6 contribute separately and independently to the triplet and septuplet components, respectively, of h_6. Moreover, according to (4.15), there is a contribution arising from third-order aberrations due to the Poisson bracket term. We will discuss Poisson bracket terms shortly,

We end this part of the discussion with the observation that there are some similarities in the computation of h_8 and the computation of h_4. From (3.63) and (3.74) we see that eight-order polynomials of the form f_8 may also have a singlet content ${}^8\chi_0^0$, which may be viewed as a higher-order Petzval. And these singlet contributions to h_8 will also be purely additive. Moreover, there are quintuplet, and 9-tuple components of f_8 and g_8 that contribute separately and independently to the quintuplet, and 9-tuple components, respectively, of h_8

What remains is to study the Poisson bracket terms in the expressions (4.15), (4.16) etc. for h_6, h_8, etc. These terms describe how lower-order aberrations combine (feed up) to produce higher-order aberrations. We will begin with the Poisson bracket term $[f_4^{\rm tr}, g_4]$ in

(4.15). Before going into specifics, there are two general observations. First, the ordinary product and the Lie product (the Poisson bracket) of any two axially symmetric polynomials must also be axially symmetric. See Exercise 4.3. Second, there is the rule (7.6.14) relating the degree of a Poisson bracket to the degrees of its ingredients. From these observations it follows, for example, that $[f_4^{\rm tr}, g_4]$ must be some linear combination of the ${}^6\chi_m^1$ and the ${}^6\chi_m^3$.

Let us now be more specific. From (4.19) and (4.20) we see that $[f_4^{\rm tr}, g_4]$ is some linear combination of the Poisson brackets

$$[{}^4\chi_0^0, {}^4\chi_0^0], \tag{X.4.23}$$

$$[{}^4\chi_0^0, {}^4\chi_m^2], \tag{X.4.24}$$

$$[{}^4\chi_m^2, {}^4\chi_{m'}^2]. \tag{X.4.25}$$

Evidently the Poisson bracket term (4.23) vanishes due to antisymmetry. We will soon see that the Poisson bracket terms (4.24) vanish due to axial symmetry. All that remains are the Poisson brackets (4.25). It follows that the only feed-up terms contributing to h_6 arise from quintuplet terms in f_4 interacting with quintuplet terms in g_4. There are no feed up terms arising from a singlet term interacting with a singlet term, nor from the interaction of singlet and quintuplet terms.

To see that (4.24) vanishes, observe that

$$[{}^4\chi_0^0, {}^4\chi_m^2] = [(L_z)^2, {}^4\chi_m^2] = 2L_z[L_z, {}^4\chi_m^2] = 0. \tag{X.4.26}$$

Here we have used (3.1), the derivation property (1.7.7), and the axial symmetry of the ${}^4\chi_m^2$.

We now study the remaining quantities (4.25). Define polynomials $\theta_{m,m'}^{22}$ by the rule

$$\theta_{m,m'}^{22} = [{}^4\chi_m^2, {}^4\chi_{m'}^2]. \tag{X.4.27}$$

Then, since $\mathcal{L}_0$ and $\mathcal{L}_\pm$ are derivations with respect to the Poisson bracket Lie product, recall (5.3.9), we find the results

$$\mathcal{L}_0\theta_{m,m'}^{22} = [\mathcal{L}_0\ {}^4\chi_m^2, {}^4\chi_{m'}^2] + [{}^4\chi_m^2, \mathcal{L}_0\ {}^4\chi_{m'}^2] = (m+m')\theta_{m,m'}^{22}, \tag{X.4.28}$$

$$\begin{aligned}
\mathcal{L}_+\theta_{m,m'}^{22} &= [\mathcal{L}_+\ {}^4\chi_m^2, {}^4\chi_{m'}^2] + [{}^4\chi_m^2, \mathcal{L}_+\ {}^4\chi_{m'}^2] \\
&= [(2-m)(2+m+1)]^{1/2}[{}^4\chi_{m+1}^2, {}^4\chi_{m'}^2] + [(2-m')(2+m'+1)]^{1/2}[{}^4\chi_m^2, {}^4\chi_{m'+1}^2] \\
&= [(2-m)(2+m+1)]^{1/2}\theta_{m+1,m'}^{22} + [(2-m')(2+m'+1)]^{1/2}\theta_{m,m'+1}^{22},
\end{aligned} \tag{X.4.29}$$

$$\begin{aligned}
\mathcal{L}_-\theta_{m,m'}^{22} &= [\mathcal{L}_-\ {}^4\chi_m^2, {}^4\chi_{m'}^2] + [{}^4\chi_m^2, \mathcal{L}_-\ {}^4\chi_{m'}^2] \\
&= [(2+m)(2-m+1)]^{1/2}[{}^4\chi_{m-1}^2, {}^4\chi_{m'}^2] + [(2+m')(2-m'+1)]^{1/2}[{}^4\chi_m^2, {}^4\chi_{m'-1}^2] \\
&= [(2+m)(2-m+1)]^{1/2}\theta_{m-1,m'}^{22} + [(2+m')(2-m'+1)]^{1/2}\theta_{m,m'-1}^{22}.
\end{aligned} \tag{X.4.30}$$

Inspection of the relations (4.28) through (4.30) shows that they are analogous to the behavior of the (tensor) product of two $j = 2$ entities. Therefore all the standard Clebsch-Gordan and Wigner-Eckart $su(2)$ machinery is available. Also, following earlier reasoning, all the entries in (4.25) must be some linear combination of the ${}^6\chi^1_m$ and the ${}^6\chi^3_m$. Consequently there must be relations of the form

$$\sum_{m_1 m_2} C(22j; m_1, m_2, m)\ [{}^4\chi^2_{m_1}, {}^4\chi^2_{m_2}] = \sum_{m_1 m_2} C(22j; m_1, m_2, m)\theta^{22}_{m_1 m_2}$$
$$= \delta_{j1}\alpha(221)\ {}^6\chi^1_m + \delta_{j3}\alpha(223)\ {}^6\chi^3_m, \tag{X.4.31}$$

where the coefficients C are $su(2)$ Clebsch-Gordan coefficients and the coefficients $\alpha(221)$ and $\alpha(223)$ are to be determined. See Exercise 4.5. The relations (4.31) can be inverted using the completeness properties of the Clebsch-Gordan coefficients to yield the final result

$$\begin{aligned}[{}^4\chi^2_m, {}^4\chi^2_{m'}] &= \alpha(221)\ C(221; m, m', m+m')\ {}^6\chi^1_{m+m'} \\ &+ \alpha(223)\ C(223; m, m', m+m')\ {}^6\chi^3_{m+m'},\end{aligned} \tag{X.4.32}$$

where the coefficients α are seen to play the role of the reduced matrix elements that occur in applications of the Wigner-Eckart theorem. Again see Exercise 4.5. The needed Clebsch-Gordan coefficients are listed in Tables 4.1 and 4.2 below.

Table X.4.1: Some values of $C(221; m, m', m+m')$ and $C(223; m, m', m+m')$

.

m	m'	$m+m'$	$C(221; ***)$	$C(223; ***)$
2	2	4	0	0
2	1	3	0	$\sqrt{1/2}$
2	0	2	0	$\sqrt{1/2}$
2	-1	1	$\sqrt{1/5}$	$\sqrt{3/10}$
2	-2	0	$\sqrt{2/5}$	$\sqrt{1/10}$
1	2	3	0	$-\sqrt{1/2}$
1	1	2	0	0
1	0	1	$-\sqrt{3/10}$	$\sqrt{1/5}$
1	-1	0	$-\sqrt{1/10}$	$\sqrt{2/5}$
1	-2	-1	$\sqrt{1/5}$	$\sqrt{3/10}$
0	2	2	0	$-\sqrt{1/2}$
0	1	1	$\sqrt{3/10}$	$-\sqrt{1/5}$
0	0	0	0	0

Table X.4.2: Remaining values of $C(221;m,m',m+m')$ and $C(223;m,m',m+m')$

.

m	m'	$m+m'$	$C(221;***)$	$C(223;***)$
0	-1	-1	$-\sqrt{3/10}$	$\sqrt{1/5}$
0	-2	-2	0	$\sqrt{1/2}$
-1	2	1	$-\sqrt{1/5}$	$-\sqrt{3/10}$
-1	1	0	$\sqrt{1/10}$	$-\sqrt{2/5}$
-1	0	-1	$\sqrt{3/10}$	$-\sqrt{1/5}$
-1	-1	-2	0	0
-1	-2	-3	0	$\sqrt{1/2}$
-2	2	0	$-\sqrt{2/5}$	$-\sqrt{1/10}$
-2	1	-1	$-\sqrt{1/5}$	$-\sqrt{3/10}$
-2	0	-2	0	$-\sqrt{1/2}$
-2	-1	-3	0	$-\sqrt{1/2}$
-2	-2	-4	0	0

What remains is to find $\alpha(221)$ and $\alpha(223)$. An easy computation gives the result

$$[{}^4\chi^2_2, {}^4\chi^2_{-2}] = -(384/25)^{1/2}\ {}^6\chi^1_0 - (64/5)^{1/2}\ {}^6\chi^3_0. \tag{X.4.33}$$

For the same j and m values use of (4.32) gives the result

$$\begin{aligned}[{}^4\chi^2_2, {}^4\chi^2_{-2}] &= \alpha(221)\ C(221; 2, -2, 0)\ {}^6\chi^1_0 \\ &+ \alpha(223)\ C(223; 2, -2, 0)\ {}^6\chi^3_0,\end{aligned} \tag{X.4.34}$$

Upon comparing (4.33) and (4.34) and with the knowledge that ${}^6\chi^1_0$ and ${}^6\chi^3_0$ are linearly independent, see (3.75), we conclude that

$$\alpha(221)\ C(221; 2, -2, 0) = -(384/25)^{1/2}, \tag{X.4.35}$$

$$\alpha(221)\ C(223; 2, -2, 0) = -(64/5)^{1/2}. \tag{X.4.36}$$

According to Table 4.1 the Clebsch-Gordan coefficients associated with (4.35) and (4.36) are given by the relations

$$C(221; 2, -2, 0) = \sqrt{2/5}, \tag{X.4.37}$$

$$C(223; 2, -2, 0) = \sqrt{1/10}. \tag{X.4.38}$$

It follows from (4.35) through (4.38) that the constants $\alpha(221)$ and $\alpha(223)$ have the values

$$\alpha(221) = -(384/25)^{1/2}/(2/5)^{1/2} = -(192/5)^{1/2}, \tag{X.4.39}$$

$$\alpha(223) = -(64/5)^{1/2}/(1/10)^{1/2} = -(128)^{1/2}. \tag{X.4.40}$$

Correspondingly, (4.32) takes the final form

$$\begin{aligned}[{}^4\chi^2_m, {}^4\chi^2_{m'}] &= -(192/5)^{1/2}\ C(221; m, m', m+m')\ {}^6\chi^1_{m+m'} \\ &\quad -(128)^{1/2}\ C(223; m, m', m+m')\ {}^6\chi^3_{m+m'}.\end{aligned} \tag{X.4.41}$$

Upon reflection, we see that what has been illustrated is that the evaluation of Poisson brackets can be carried out in general in terms of $su(2)$ Clebsch-Gordan coefficients and a few simply computed numbers analogous to reduced matrix elements.

The discussion of the combining of fifth-order aberrations, and the feed-up effect of lower-order aberrations to contribute to fifth-order aberrations, is now complete. Moreover, it is clear from (4.16) and Poisson bracket relations analogous to (4.41) that the the combining of seventh and still higher-order aberrations, and the feed-up effect of lower-order aberrations to contribute to these higher-order aberrations, follow a similar pattern. All that is needed is the computation of the $f^{\rm tr}_n$ and various single and multiple Poisson brackets. Finally we remark that, although the existence and knowledge of explicit formulas, such as (4.41), for Poisson brackets may be illuminating, they are not required for actual numerical computation. Their rapid numerical evaluation may be performed using the methods described in Section 39.8.

Exercises

X.4.1. Show that (4.14) through (4.16) are special cases of (8.4.32), (8.4.34), and (8.4.36).

X.4.2. Show, using (3.75) and (4.17), that there is the relation

$$D^j_{m'm}[(R^g)^{-1}] = [1/N(n,j)]\langle {}^n\chi^j_{m'} \, , \mathcal{R}_g^{-1} \, {}^n\chi^j_m\rangle. \tag{X.4.42}$$

X.4.3. Recall (1.7.7), review Exercise 5.2.3, and recall the axial symmetry relation/condition (2.27). Show that if two functions f and g have axial symmetry, then so does their ordinary product fg and their Lie product (Poisson bracket) $[f,g]$.

X.4.4. Verify (4.33).

X.4.5. The purpose of this exercise is to establish (4.31) and its inverse (4.32). We have seen from (4.28) through (4.30) that the behavior of the $\theta^{22}_{m_1m_2}$ is analogous to the behavior of the product of two $j = 2$ entities. From the Quantum Theory of angular momentum, we know that two entities of spin 2 can be combined/coupled to produce entities of spins $0, 1, 2, 3,$ and 4. That is what the left side of (4.31) seeks to do for the values $j = 0, 1, 2, 3, 4$. The right side of (4.31) states the expected results for these same j values. The expected results seem sensible for the cases $j = 1$ and $j = 3$. But what about the cases $j = 0, 2, 4$? Do we expect the left side of (4.31) to actually *vanish* in these cases as the right side states? We do. It can be shown that the $su(2)$ Clebsch-Gordan coefficients have the symmetry property

$$C(j_1j_2j;m_1,m_2,m_1+m_2) = (-1)^{j_1+j_2-j}C(j_2j_1j;m_2,m_1,m_1+m_2). \tag{X.4.43}$$

A special case of (4.43) is the relation

$$C(22j;m_1,m_2,m_1+m_2) = (-1)^{-j}C(22j;m_2,m_1,m_1+m_2). \tag{X.4.44}$$

That is, these C values are *even* under the interchange of m_1 and m_2 for even values of j, and *odd* under the interchange for odd values of j. But from the antisymmetry property of the Poisson bracket we know that

$$\theta^{22}_{m_1m_2} = -\theta^{22}_{m_2m_1}. \tag{X.4.45}$$

Verify, therefore, that there must be the result

$$\sum_{m_1m_2} C(22j;m_1,m_2,m)\theta^{22}_{m_1m_2} = 0 \text{ for } j = 0,2,4. \tag{X.4.46}$$

And this desired result follows simply from symmetry considerations alone without any additional information.

It can be shown that the $su(2)$ Clebsch-Gordan coefficients satisfy the *completeness relation*

$$\sum_j C(j_1j_2j;m_1,m_2,m_1+m_2)C(j_1j_2j;m_1',m_2',m_1'+m_2') = \delta_{m_1m_1'}\delta_{m_2m_2'}. \tag{X.4.47}$$

Use this result to derive (4.32) from (4.31).

Finally note that, because of the described symmetry properties of the Clebsch-Gordan coefficients and Poisson brackets, both sides of (4.32) are antisymmetric under the interchange of m and m', as desired, and the Clebsch-Gordan coefficients involved in (4.32) vanish when $m = m'$. Scan the entries of Tables 4.1 and 4.2 to verify that the listed C values do indeed have these advertised symmetry properties.

X.4.6. Using (3.75) and (4.32) show that there is the relation

$$\begin{aligned}\langle {}^6\chi^j_{m+m'}, [{}^4\chi^2_m, {}^4\chi^2_{m'}]\rangle &= -(192/5)^{1/2}\, C(221; m, m', m+m')N(6,1)\delta_{j1} \\ &\quad -(128)^{1/2}\, C(223; m, m', m+m')N(6,3)\delta_{j3}. \qquad \text{(X.4.48)}\end{aligned}$$

X.5 Maps/Lie Generators for Continuous Systems

X.6 Maps/Lie Generators for Discontinuous Systems

X.7 Two Sample Designs

X.7.1 Aberration Corrected Doublet

In this subsection we will illustrate how some of out earlier results can be used to design an imaging doublet system that is free of all third-order aberrations and four fifth-order aberrations. This system is illustrated schematically in Figure 7.1 below.

The system consists of four surfaces separated by drift spaces either in air or two possibly different refractive media. Between the object plane and *Surface* S^1 there is a *left-side* drift space (in air) of on-axis length D_L. Surfaces S^1 and S^2, with an on-axis separation of thickness t_L, constitute a first lens made of a medium with refractive index n_L. Surfaces S^3 and S^4, with an on-axis separation of thickness t_R, constitute a second lens made of a medium with refractive index n_R. Between surfaces S^2 and S^3 there is a drift space (in air) of on-axis length D. Finally, between S^4 and the image plane there is a *right-side* drift space (in air) of on-axis length D_R. The surfaces S^1 and S^2 will be chosen so that (in paraxial approximation) the first lens is converging, and the surfaces S^3 and S^4 will be chosen so that (in paraxial approximation) the second lens is diverging.

Elimination of Petzval

We begin our design with the requirement that the net (third-order) Petzval aberration vanish. From our earlier work we know that only the maps associated with the surfaces S^1 through S^4 contribute to the Petzval, and their contributions are additive. According to *, passage through a surface S from a medium with refraction index n^- to a medium with refraction index n^+ makes a contribution to the Petzval coefficient given by the relation

$$\text{contribution } = \beta_2[(1/n^+) - (1/n^-)]. \qquad \text{(X.7.1)}$$

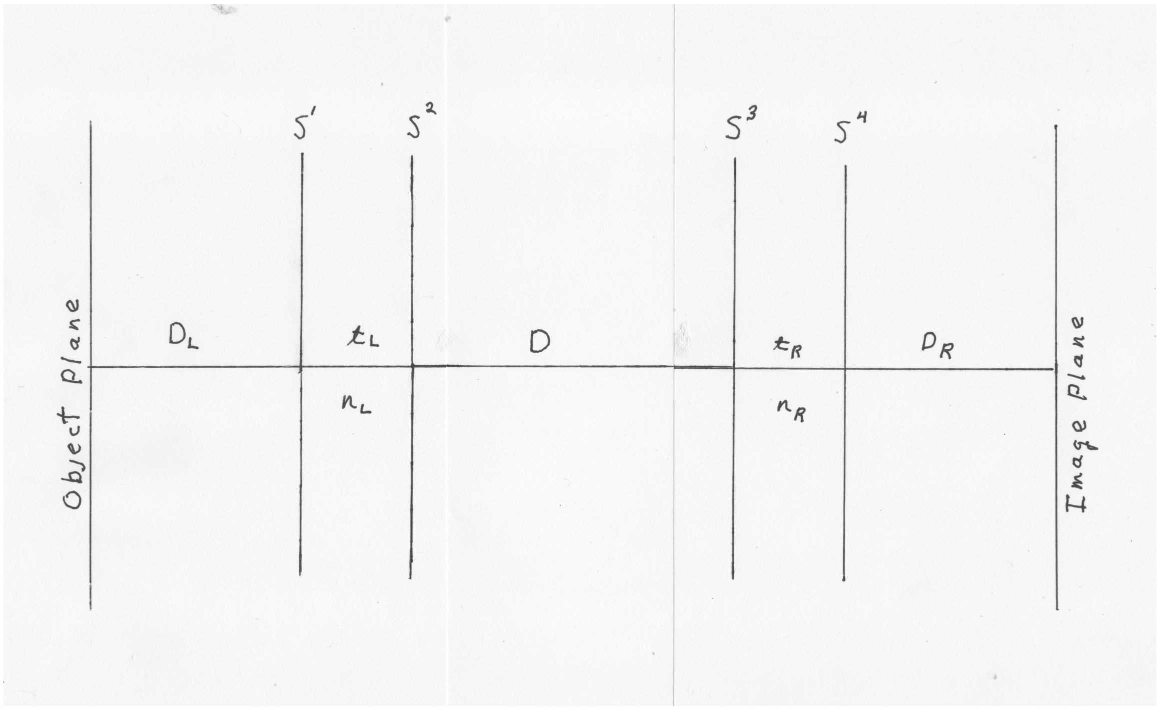

Figure X.7.1: Schematic layout of imaging doublet system that is free of all third-order aberrations and four fifth-order aberrations. The object plane is on the left and the image plane is on the right.

Here β_2 is the quadratic parameter of the surface.[6] Consequently, for the four surfaces, we find the Petzval coefficient contributions to be as follows:

$$\text{For } S^1,\ n^- = 1 \text{ and } n^+ = n_L \Rightarrow \text{contribution } = \beta_2^1[(1/n_L) - 1], \tag{X.7.2}$$

$$\text{For } S^2,\ n^- = n_L \text{ and } n^+ = 1 \Rightarrow \text{contribution } = \beta_2^2[1 - (1/n_L)], \tag{X.7.3}$$

$$\text{For } S^3,\ n^- = 1 \text{ and } n^+ = n_R \Rightarrow \text{contribution } = \beta_2^3[(1/n_R) - 1], \tag{X.7.4}$$

$$\text{For } S^4,\ n^- = n_R \text{ and } n^+ = 1 \Rightarrow \text{contribution } = \beta_2^4[1 - (1/n_R)]. \tag{X.7.5}$$

Here the quantity β_2^j is the quadratic parameter for the j^{th} surface. The net Petzval coefficient is the sum of these terms, and we require that it vanish,

$$\text{Net Petzval coefficient} = (\beta_2^1 - \beta_2^2)[(1/n_L) - 1] + (\beta_2^3 - \beta_2^4)[(1/n_R) - 1] = 0. \tag{X.7.6}$$

There are several ways to satisfy (7.6). For simplicity, we specify that

$$n_L = n_R = n. \tag{X.7.7}$$

[6] Unlike the third-order aberrations associated with the ${}^4\chi_m^2$, the Petzval aberration (associated with ${}^4\chi_0^0$) is independent of the quartic parameter β_4 of surfaces. We may view parameters that govern paraxial behavior as being "paraxial" parameters. Consequently, the β_2 parameters, as well as indices of refraction and lengths, are paraxial parameters. By contrast, the β_4, β_6, etc. have no effect on paraxial behavior and therefore are not paraxial parameters. The Petzval is different from other third-order aberrations in that is governed by paraxial parameters, and is independent of the β_4 parameters.

Also we specify that

$$\beta_2^1 > 0 \text{ and } \beta_2^2 = -\beta_2^1 \tag{X.7.8}$$

so that the first lens is (symmetrically) biconvex and converging. And we specify that

$$\beta_2^3 < 0 \text{ and } \beta_2^4 = -\beta_2^3 \tag{X.7.9}$$

so that the second lens is (symmetrically) biconcave and diverging. (Our intuition, which can be checked, is that minimizing the curvatures of all lens surfaces by making lenses symmetrical, which essentially amounts to sharing power equally between leading and trailing lens surfaces save for finite lens thickness effects, should on average help minimize aberrations.) With these specifications the requirement (7.6) takes the simpler form

$$\text{Net Petzval coefficient} = 2\beta_2^1[(1/n) - 1] + 2\beta_2^3[(1/n) - 1] = 0, \tag{X.7.10}$$

and we see that (7.10) is satisfied providing

$$\beta_2^3 = -\beta_2^1. \tag{X.7.11}$$

See Figure 7.2 where these specifications and the requirements (7.7) through (7.9) and (7.11) are depicted graphically. We conclude that, in order to be Petzval aberration free, a system must have both focusing and defocusing elements.

Paraxial Properties

The next design step is to examine, in the paraxial approximation, the optical transfer map associated with the drifts and lenses depicted in Figure 7.2. These maps can all be written as products of maps of the form exp(: f_2 :). Listed below are the f_2 polynomials for the various items depicted in Figure 7.2.

$$\text{Drift space of length } d \text{ in air: } f_2 = -(d/2)p^2. \tag{X.7.12}$$

Here d takes the values

$$d = D_L, \ d = D, \text{ and } d = D_R. \tag{X.7.13}$$

$$\text{Drift space of length } d \text{ in medium with index } n\text{: } f_2 = -[d/(2n)]p^2. \tag{X.7.14}$$

Here we assume that both lenses in the doublet have on-axis thickness t so that

$$d = t. \tag{X.7.15}$$

According to (*) the f_2 associated with passage through a surface S from a medium with refraction index n^- to a medium with refraction index n^+ is given by the relation

$$f_2 = \beta_2(n^- - n^+)q^2. \tag{X.7.16}$$

Here again β_2 is the quadratic parameter for the surface. Therefore, for the surfaces S^1 through S^4, there are the following general results:

$$\text{For } S^1, \ n^- = 1 \text{ and } n^+ = n_L \Rightarrow f_2 = \beta_2^1(1 - n_L)q^2, \tag{X.7.17}$$

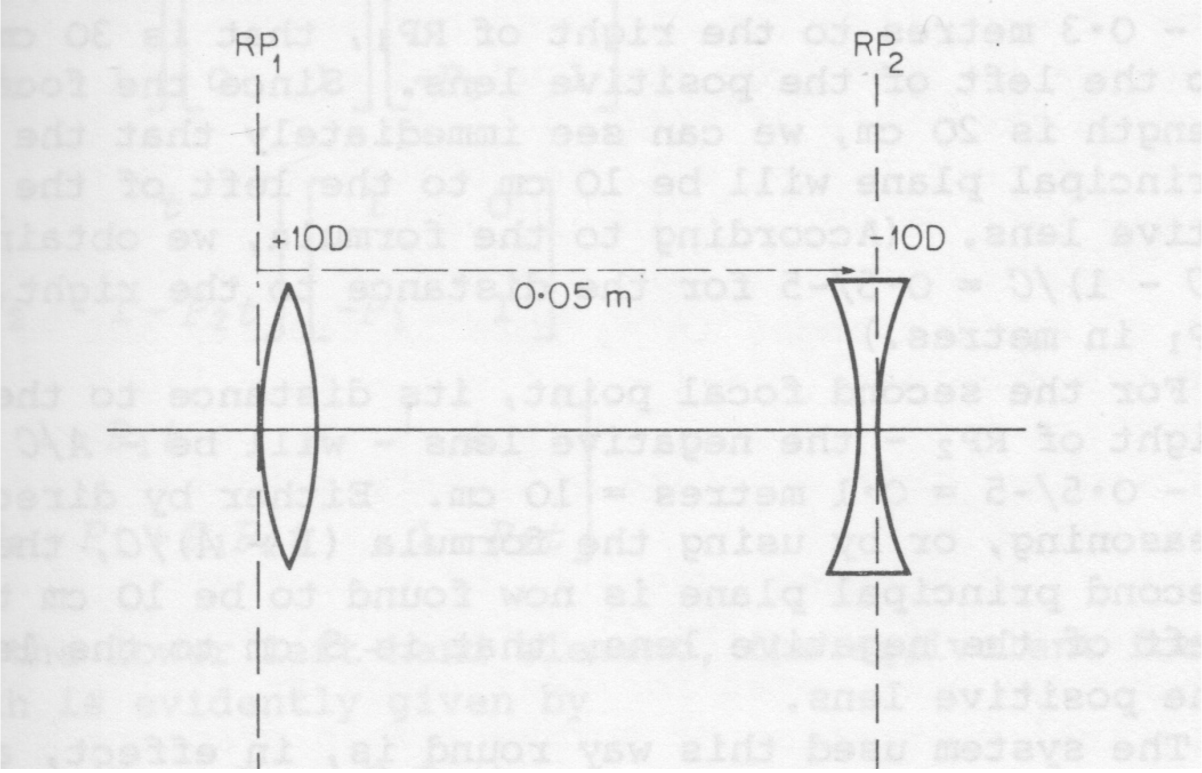

Figure X.7.2: Less schematic layout of imaging doublet system that is free of all third-order aberrations and four fifth-order aberrations. The object plane is on the far left and the image plane is on the far right (so that both are not visible), and only the shapes of the various lens surfaces and the lens thicknesses and spacings are illustrated.

$$\text{For } S^2,\ n^- = n_L \text{ and } n^+ = 1 \Rightarrow f_2 = \beta_2^2(n_L - 1)]q^2, \tag{X.7.18}$$

$$\text{For } S^3,\ n^- = 1 \text{ and } n^+ = n_R \Rightarrow\ f_2 = \beta_2^3(1 - n_R)q^2, \tag{X.7.19}$$

$$\text{For } S^4,\ n^- = n_R \text{ and } n^+ = 1 \Rightarrow f_2 = \beta_2^4(n_R - 1)q^2. \tag{X.7.20}$$

We will use these general results for the specific cases described by (7.7) through (7.9), (7.11), (7.13), and (7.15).

We are now prepared to compute $\mathcal{R}$, the linear part of the transfer map for the optical system illustrated in Figure 7.2. Based on the results summarized in *, it is given by the product

$$\begin{aligned}&\mathcal{R} = \exp[-(D_L/2) : p^2 :] \exp[\beta_2^1(1-n) : q^2 :] \exp\{-[t/(2n)] : p^2 :\} \exp[\beta_2^1(1-n) : q^2 :] \times \\ &\exp[-(D/2) : p^2 :] \exp[-\beta_2^1(1-n) : q^2 :] \exp\{-[t/(2n)] : p^2 :\} \exp[-\beta_2^1(1-n) : q^2 :] \times \\ &\exp[-(D_R/2) : p^2 :].\end{aligned} \tag{X.7.21}$$

Let R be the matrix associated with $\mathcal{R}$. Since only the Lie operators $: p^2 :$ and $: q^2 :$ appear in $\mathcal{R}$, and since these operators map the pairs q_x, p_x and q_y, p_y into themselves and in the same way, it follows that R must be of the block form

$$R = \begin{pmatrix} G & O \\ O & G \end{pmatrix} \tag{X.7.22}$$

where each block is 2×2, the block G is symplectic, and the block O is the zero matrix. Therefore, for the computation of R, there is the simplification of only needing to work with various 2×2 matrices corresponding to the various $\exp(: f_2 :)$. Let us list these matrices, call them K: For f_2 of the form (7.12) there is the correspondence

$$f_2 = -(d/2)p^2 \leftrightarrow K = \begin{pmatrix} 1 & d \\ 0 & 1 \end{pmatrix}. \tag{X.7.23}$$

For f_2 of the form (7.14) there is the correspondence

$$f_2 = -[(d/(2n)p^2] \leftrightarrow K = \begin{pmatrix} 1 & d/n \\ 0 & 1 \end{pmatrix}. \tag{X.7.24}$$

For f_2 of the form (7.16) there is the correspondence

$$f_2 = \beta_2(n^- - n^+)q^2 \leftrightarrow K = \begin{pmatrix} 1 & 0 \\ 2\beta_2(n^- - n^+) & 1 \end{pmatrix}. \tag{X.7.25}$$

Since (7.21) has nine factors, it follows that the G associated with $\mathcal{R}$ is the product of nine 2×2 matrices of the form (7.23) through (7.25). We will eventually compute this G numerically. But we will first make some preliminary observations/calculations.

Map $\mathcal{R}$ for the System and Map $\mathcal{R}'$ for the Device

In practical applications, we may imagine that most of the parameter values in (7.21) are fixed save for D_L and D_R, which could be fairly readily adjusted to achieve imaging and the desired magnification. This circumstance suggests that we should understand the nature of the map that these leading and trailing drifts surround. That is, we are interested in the map $\mathcal{R}'$ defined by the product

$$\mathcal{R}' = \exp[\beta_2^1(1-n) : q^2 :] \exp\{-[t/(2n)] : p^2 :\} \exp[\beta_2^1(1-n) : q^2 :] \times \\ \exp[-(D/2) : p^2 :] \exp[-\beta_2^1(1-n) : q^2 :] \exp\{-[t/(2n)] : p^2 :\} \exp[-\beta_2^1(1-n) : q^2 :]. \tag{X.7.26}$$

Compare (7.21) and (7.26). That is, we have the relation

$$\mathcal{R} = \exp[-(D_L/2) : p^2 :]\mathcal{R}' \exp[-(D_R/2) : p^2 :]. \tag{X.7.27}$$

Put another way, we may view $\mathcal{R}'$ as being the linear part of the map for the *optical device* and $\mathcal{R}$ as being the linear part of the map for the complete *optical system.*

Normal Form

What would we like to know about $\mathcal{R}'$ or, equivalently, the matrices R' and G'? We will see that it is possible to associate with $\mathcal{R}'$ a kind of *normal form.* Suppose, as a mathematical trick, we consider the map $\mathcal{R}''$ defined by relation

$$\mathcal{R}'' = \exp[(d_L/2) : p^2 :]\mathcal{R}' \exp[(d_R/2) : p^2 :]. \tag{X.7.28}$$

We have "sandwiched" $\mathcal{R}'$ between two *negative* length drift maps where d_L and d_R are to be determined. Let us compute the matrix G'' associated with $\mathcal{R}''$. With the aid of (7.23) we see that it is given by the relation

$$\begin{aligned} G'' &= \begin{pmatrix} 1 & -d_R \\ 0 & 1 \end{pmatrix} G' \begin{pmatrix} 1 & -d_L \\ 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 1 & -d_R \\ 0 & 1 \end{pmatrix} \begin{pmatrix} G'_{11} & G'_{12} \\ G'_{21} & G'_{22} \end{pmatrix} \begin{pmatrix} 1 & -d_L \\ 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 1 & -d_R \\ 0 & 1 \end{pmatrix} \begin{pmatrix} G'_{11} & -G'_{11}d_L + G'_{12} \\ G'_{21} & -G'_{21}d_L + G'_{22} \end{pmatrix} \\ &= \begin{pmatrix} G'_{11} - d_R G'_{21} & -G'_{11}d_L + G'_{12} - d_R(-G'_{21}d_L + G'_{22}) \\ G'_{21} & -G'_{21}d_L + G'_{22} \end{pmatrix} \\ &= \begin{pmatrix} G''_{11} & G''_{12} \\ G''_{21} & G''_{22} \end{pmatrix}. \end{aligned} \tag{X.7.29}$$

Upon comparing the last two lines in (7.29) we see that

$$G''_{21} = G'_{21}. \tag{X.7.30}$$

Next we seek values of d_L and d_R such that

$$1 = G''_{11} = G'_{11} - d_R G'_{21} \Rightarrow d_R = (G'_{11} - 1)/G'_{21}, \tag{X.7.31}$$

$$1 = G''_{22} = -G'_{21} d_L + G'_{22} \Rightarrow d_L = (G'_{22} - 1)/G'_{21}. \tag{X.7.32}$$

We see that the goals $G''_{11} = 1$ and $G''_{22} = 1$ can be achieved provided

$$G'_{21} \neq 0. \tag{X.7.33}$$

For the values of d_R and d_L given by (7.31) and (7.32) we find that

$$\begin{aligned} G''_{12} &= -G'_{11} d_L + G'_{12} - d_R(-G'_{21} d_L + G'_{22}) \\ &= -G'_{11}(G'_{22} - 1)/G'_{21} + G'_{12} - [(G'_{11} - 1)/G'_{21}]\{-G'_{21}[(G'_{22} - 1)/G'_{21}] + G'_{22}\} \\ &= -G'_{11}(G'_{22} - 1)/G'_{21} + G'_{12} - [(G'_{11} - 1)/G'_{21}] \\ &= [-G'_{11}(G'_{22} - 1) + G'_{12}G'_{21} - (G'_{11} - 1)]/G'_{21} \\ &= [-G'_{11}G'_{22} + G'_{12}G'_{21} + 1]/G'_{21} \\ &= [-\det(G') + 1]/G'_{21} \\ &= 0. \end{aligned} \tag{X.7.34}$$

Here we have used the fact that G' is symplectic.[7] We have verified the remarkable result that there is a (unique) choice for the pair d_L, d_R such that G'' takes the simple/normal form

$$G'' = \begin{pmatrix} 1 & 0 \\ G'_{21} & 1 \end{pmatrix}. \tag{X.7.35}$$

Upon solving (7.29) for G', we find the result

$$G' = \begin{pmatrix} 1 & d_R \\ 0 & 1 \end{pmatrix} G'' \begin{pmatrix} 1 & d_L \\ 0 & 1 \end{pmatrix}. \tag{X.7.36}$$

We conclude that, in paraxial approximation, the device acts like a thin lens preceded by a drift of length d_L and followed by a drift of length d_R. And the thin lens has a focal length f given by

$$1/f = -G'_{21} \Leftrightarrow f = -1/(G'_{21}). \tag{X.7.37}$$

That is, (7.35) can be rewritten in the form

$$G'' = \begin{pmatrix} 1 & 0 \\ -1/f & 1 \end{pmatrix} \tag{X.7.38}$$

with f given by (7.37). For the problem at hand we will eventually find that

$$f > 0. \tag{X.7.39}$$

From (7.35) we see that $\mathcal{R}''$ has the Lie form

$$\mathcal{R}'' = \exp[(G'_{21}/2) : q^2 :]. \tag{X.7.40}$$

Correspondingly, from (7.28) and (7.40), we see that $\mathcal{R}'$ has the factorization

$$\mathcal{R}' = \exp[-(d_L/2) : p^2 :] \exp[(G'_{21}/2) : q^2 :] \exp[-(d_R/2) : p^2 :].$$

Note that this result is consistent with (7.35) and (7.36).

[7] As rewarding as the messy calculation (7.34) ultimately proved to be, it is/was actually not necessary. Once (7.31) through (7.33) are established, the relation $G''_{12} = 0$ must hold in order for G'' to be symplectic, which we already know to be the case.

Imaging Condition and Computation of Magnification

Let us use the normal form for $\mathcal{R}'$ and the associated matrix G' to discuss the possible imaging and magnification properties of $\mathcal{R}$. We will do this by working with the associated matrix G. According to (7.27), it is given by the product

$$\begin{aligned} G &= \begin{pmatrix} 1 & D_R \\ 0 & 1 \end{pmatrix} G' \begin{pmatrix} 1 & D_L \\ 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 1 & D_R \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & d_R \\ 0 & 1 \end{pmatrix} G'' \begin{pmatrix} 1 & d_L \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & D_L \\ 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 1 & D_R + d_R \\ 0 & 1 \end{pmatrix} G'' \begin{pmatrix} 1 & D_L + d_L \\ 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 1 & D_R + d_R \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -1/f & 1 \end{pmatrix} \begin{pmatrix} 1 & D_L + d_L \\ 0 & 1 \end{pmatrix}. \end{aligned} \tag{X.7.41}$$

At this point, to simplify continuation of this calculation, it is convenient to define *effective* drift lengths D_L^e and D_R^e by the rules

$$D_L^e = D_L + d_L, \tag{X.7.42}$$

$$D_R^e = D_R + d_R, \tag{X.7.43}$$

With these definitions we can move the calculation (7.41) forward to find the result

$$\begin{aligned} G &= \begin{pmatrix} 1 & D_R + d_R \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -1/f & 1 \end{pmatrix} \begin{pmatrix} 1 & D_L + d_L \\ 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 1 & D_R^e \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -1/f & 1 \end{pmatrix} \begin{pmatrix} 1 & D_L^e \\ 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} 1 & D_R^e \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & D_L^e \\ -1/f & -D_L^e/f + 1 \end{pmatrix} \\ &= \begin{pmatrix} 1 - D_R^e/f & D_L^e - D_R^e D_L^e/f + D_R^e \\ -1/f & -D_L^e/f + 1 \end{pmatrix}. \end{aligned} \tag{X.7.44}$$

Suppose further we attempt to select D_L^e and D_R^e in such a way that

$$G_{12} = 0 \tag{X.7.45}$$

so that R is imaging. Enforcing the relation (7.45) produces the chain of relations

$$\begin{aligned} &0 = D_L^e - D_R^e D_L^e/f + D_R^e \Leftrightarrow \\ &0 = 1/D_R^e - 1/f + 1/D_L^e \Leftrightarrow \\ &1/D_L^e + 1/D_R^e = 1/f. \end{aligned} \tag{X.7.46}$$

Note that the last line of (7.46) is the familiar elementary imaging condition except that it involves effective quantities.

When (7.45) is enforced, (7.44) takes the form

$$G = \begin{pmatrix} 1 - D_R^e/f & 0 \\ -1/f & -D_L^e/f + 1 \end{pmatrix}. \tag{X.7.47}$$

As a sanity check, let us verify that this G is symplectic. We find that for this G

$$\begin{aligned} G_{11}G_{22} &= (1 - D_R^e/f)(1 - D_L^e/f) = 1 - (D_R^e/f + D_L^e/f) + (D_R^e/f)(D_L^e/f) \\ &= 1 - (D_L^e d_R^e/f)(1/D_L^e + 1/D_R^e) + (D_R^e D_L^e/f)(1/f) \\ &= 1 - (D_L^e d_R^e/f)(1/D_L^e + 1/D_R^e - 1/f^e) = 1 \end{aligned} \tag{X.7.48}$$

as expected. [Here we have used the last line of (7.46).] It follows that (7.47) can be rewritten in the form

$$G = \begin{pmatrix} m & 0 \\ -1/f & 1/m \end{pmatrix} \tag{X.7.49}$$

where m is the magnification given by the upper left entry in (7.47),

$$\begin{aligned} m &= -(D_R^e/f - 1) \\ &= -(D_R/f + d_R/f - 1). \end{aligned} \tag{X.7.50}$$

From (7.50) it is evident that, for sufficiently large values of D_R, m is negative (the image is inverted as expected) and can become large in magnitude as $D_R \to \infty$ providing physically possible values of D_L can be found such that (7.46 is satisfied. Expressing the imaging condition (7.46) in terms of D_L and D_R yields the result

$$1/(D_L + d_L) + 1/(D_R + d_R) = 1/f. \tag{X.7.51}$$

In the limit $D_R \to \infty$ we find from (7.51) that

$$D_L \to f - d_L. \tag{X.7.52}$$

The right side of (7.52) is a physically possible value for D_L provided

$$f - d_L \geq 0 \Leftrightarrow f \geq d_L. \tag{X.7.53}$$

We conclude that

$$m \to +\infty \text{ as } D_R \to \infty \tag{X.7.54}$$

provided (7.53) holds. In this case the magnification can be made arbitrarily large in magnitude.

How small can the magnification be? Can it be made vanishingly small for physical values of D_L and D_R? From the second line of (7.50) we see that

$$m = 0 \Leftrightarrow D_R = f - d_R \tag{X.7.55}$$

so that D_R is non-negative (physically possible) provided

$$f - d_R \geq 0 \Leftrightarrow f \geq d_R. \tag{X.7.56}$$

But does the D_R given by (7.55) lead to a physical value of D_L when employed in (7.51)? Inserting the right side of (7.55) into (7.51) yields the relation

$$1/(D_L + d_L) + 1/f = 1/f \Rightarrow 1/(D_L + d_L) = 0 \Rightarrow D_L = +\infty. \tag{X.7.57}$$

We conclude that $D_R \to (f - d_R)$ and $D_L \to +\infty$ is consistent with imaging and results in vanishing magnification. This conclusion is valid provided (7.56) holds.

Thin-Lens Approximation

Eventually we will want to compute to compute G' and hence R'. According to (7.26) this computation involves the product of 7 matrices, and is therefore best done numerically. But before doing so it would be useful to have an approximate result to get some feeling for the expected nature of the exact result. This can be done by treating the two lenses in the thin-lens approximation. That is, we will set $t = 0$ in (7.26). When this is done, what remains is to compute the map $\bar{\mathcal{R}}'$ defined by the product

$$\bar{\mathcal{R}}' = \exp[2\beta_2^1(1-n) : q^2 :] \exp[-(D/2) : p^2 :] \exp[-2\beta_2^1(1-n) : q^2 :]. \tag{X.7.58}$$

Since the Lie transformation $\exp[2\beta_2^1(1-n) : q^2 :]$ is that for a thin lens, let us make the correspondence

$$\exp[2\beta_2^1(1-n) : q^2 :] \leftrightarrow \begin{pmatrix} 1 & 0 \\ -1/F & 1 \end{pmatrix} \tag{X.7.59}$$

where F is the focal length of the first lens in the thin-lens approximation. So doing yields the relation

$$-1/F = 4\beta_2^1(1-n). \tag{X.7.60}$$

Note, according to our prescription that the first lens in the doublet be focusing, recall (7.8), it follows that

$$F > 0. \tag{X.7.61}$$

Now, to compute the matrix $\bar{G}'$ associated with $\bar{\mathcal{R}}'$, we only need to compute the matrix product

$$\begin{aligned} \bar{G}' &= \begin{pmatrix} 1 & 0 \\ 1/F & 1 \end{pmatrix} \begin{pmatrix} 1 & D \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -1/F & 1 \end{pmatrix} \\ &= \begin{pmatrix} 1 & 0 \\ 1/F & 1 \end{pmatrix} \begin{pmatrix} 1-D/F & D \\ -1/F & 1 \end{pmatrix} \\ &= \begin{pmatrix} 1-D/F & D \\ -D/F^2 & 1+D/F \end{pmatrix}. \end{aligned} \tag{X.7.62}$$

What can we conclude in the thin-lens approximation? Let us apply the normal-form procedure to $\bar{G}'$. First, in analogy to (7.35) and from (7.62), we see that

$$\bar{G}'' = \begin{pmatrix} 1 & 0 \\ \bar{G}'_{21} & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ -D/F^2 & 1 \end{pmatrix}. \tag{X.7.63}$$

Also we know that $D > 0$ and therefore

$$\bar{G}'_{21} = -D/F^2 < 0. \tag{X.7.64}$$

That is, in the thin-lens approximation, the net effect of the doublet is *focusing*.[8] In analogy to (7.37) we make the definition

$$1/\bar{f} = -\bar{G}'_{21} \Leftrightarrow \bar{f} = -1/(\bar{G}'_{21}) = F^2/D. \tag{X.7.65}$$

[8] Note that this conclusion holds no matter the sign F. This observation is the essence of *strong focussing* in Accelerator Physics applications. Although only obtained here in the thin-lens approximation, there are analogous results for thick lenses and thick magnetic elements.

That is, (7.63) can be rewritten in the form

$$G'' = \begin{pmatrix} 1 & 0 \\ -1/\bar{f} & 1 \end{pmatrix} \tag{X.7.66}$$

with $\bar{f}$ given by (7.65). Moreover, from (7.31) and (7.32) we find that

$$\bar{d}_L = (\bar{G}'_{22} - 1)/\bar{G}'_{21} = (D/F)/(-D/F^2) = -F \tag{X.7.67}$$

$$\bar{d}_R = (\bar{G}'_{11} - 1)/\bar{G}'_{21} = -(D/F)/(-D/F^2) = F. \tag{X.7.68}$$

Let us use these thin-lens results to examine what magnifications can be achieved in the thin-lens approximation. According to (7.54) the magnification can be made arbitrarily large in magnitude providing (7.53) holds. But, in the thin-lens approximation, we find that

$$\bar{f} - \bar{d}_L = \bar{f} + F > 0 \tag{X.7.69}$$

because both $\bar{f}$ and F are positive. Thus, if the thin-lens approximation is to be believed, the magnification can be made arbitrarily large in magnitude. What about making the magnification arbitrarily small? According to (7.55) the magnification can be made to vanish providing (7.56) holds. But, in the thin-lens approximation we find

$$\bar{f} - \bar{d}_R = F^2/D - F. \tag{X.7.70}$$

Therefore

$$\bar{f} - \bar{d}_R \geq 0 \Leftrightarrow F^2/D - F \geq 0 \Leftrightarrow F/D - 1 \geq 0 \Leftrightarrow F \geq D \Leftrightarrow D \leq F. \tag{X.7.71}$$

The inequality on the far right side of (7.71) provides a design criterion: D must not be too large. And if this criterion is met and the thin-lens approximation is to be believed, then arbitrarily small magnification can also be achieved.

Case for which Both Lenses Have Finite Thickness

We have verified that a doublet can be designed to have satisfactory paraxial performance in the thin-lens approximation. The next step is to verify that a doublet system can be found that has satisfactory paraxial performance when the two lenses have finite thickness. As an example, we suppose the doublet has the parameter values

$$\beta_2^1 = \text{to be determined by fitting}, \tag{X.7.72}$$

$$n = 1.5, \tag{X.7.73}$$

$$t = 0.75, \tag{X.7.74}$$

$$D = 4.75, \tag{X.7.75}$$

and that the remaining β_2^j are given by (7.8), (7.9), and (7.11).

Fitting the Focal Length

We now compute G' while varying β_2^1 to achieve some desired value for the focal length as given by (7.37). For example, suppose we wish/aim to have

$$f = 20 \Leftrightarrow G'_{21} = -.05. \tag{X.7.76}$$

For the aim ($G'_{21} = -.05$) we find for the doublet that

$$G' = \begin{pmatrix} 4.69171E-01 & 5.74703E+00 \\ -5.00000E-02 & 1.51895E+00 \end{pmatrix} \tag{X.7.77}$$

and

$$\beta_2^1 = 5.0003711901875095E-02. \tag{X.7.78}$$

Verification that Any Magnification can be Achieved

From (7.77) we see that

$$-1/f = G'_{21} = -5.00000E-02 \Leftrightarrow f = 20 \text{ as desired,} \tag{X.7.79}$$

$$d_L = (G'_{22} - 1)/G'_{21} = (1.51895 - 1.0)/(-.05) = -10.3790424, \tag{X.7.80}$$

$$d_R = (G'_{11} - 1)/G'_{21} = (0.469171 - 1.0)/(-.05) = 10.6165777. \tag{X.7.81}$$

Consequently,

$$f - d_L = 20 + 10.3790424 = 30.3790424 > 0 \tag{X.7.82}$$

and

$$f - d_R = 20 - 10.6165777 = 9.3834224 > 0. \tag{X.7.83}$$

We conclude that for this doublet there are physical/positive values of D_L and D_R for which any desired (negative) value of m can be achieved for the full system.

Selection of Magnification m and Determination of Lengths D_L and D_R

From (7.47) and (7.49) we see that

$$-D_L^e/f + 1 = 1/m \tag{X.7.84}$$

from which it follows that

$$D_L = f[1 - (1/m)] - d_L. \tag{X.7.85}$$

And from (7.50) we see that

$$D_R = f(1 - m) - d_R. \tag{X.7.86}$$

Let us now select some value for m. For example, suppose we select the value

$$m = -0.5 = -1/2. \tag{X.7.87}$$

Then D_L and D_R have the values

$$D_L = 20[1 + 2] + 10.3790424 = 70.3790424 \tag{X.7.88}$$

and

$$D_R = 20(3/2) - 10.6165777 = 19.3834223. \tag{X.7.89}$$

And, for the full system consisting of the device plus leading and trailing drifts, we find that the matrix R associated with the full linear map $\mathcal{R}$ has the related matrix G given by

$$G = \begin{pmatrix} -5.00000E-01 & 0.00000E+00 \\ -5.00000E-02 & -2.00000E+00 \end{pmatrix}. \tag{X.7.90}$$

Evidently, the full map $\mathcal{M}$ is imaging in paraxial approximation because $G_{12} = 0$, and the magnification is

$$m = G_{11} = -0.50, \tag{X.7.91}$$

as desired.

Vanishing of Petzval

What can be said about the third-order aberrations of this system consisting of the doublet plus leading and trailing drifts ? The f_4 entries for $\mathcal{M}$ are listed below.

```

Calculation shows that for this f_4

$$\langle {}^4\chi_0^0\,,\, f_4\rangle = 0, \tag{X.7.92}$$

thereby indicating that the Petzval aberration indeed vanishes as desired. Alternatively, using (2.42), (2.43), and (3.23), we expect that

$$0 = (2C - 4D) = f(1,1,1,1) - 4f(0,2,2,0) = 0 \Leftrightarrow f(111) - 4f(145) = 0. \tag{X.7.93}$$

Examination of the values for $f(111)$ and $f(145)$ in the list of f_4 values above shows that the relation on the right side of (7.87) is indeed satisfied.

Evidently many of the f_4 entries listed above are nonzero. Calculation shows that there are the results

$$\langle {}^4\chi_2^2\,,\, f_4\rangle = *, \tag{X.7.94}$$

$$\langle {}^4\chi_1^2\,,\, f_4\rangle = *, \tag{X.7.95}$$

$$\langle {}^4\chi_0^2\,,\, f_4\rangle = *, \tag{X.7.96}$$

$$\langle {}^4\chi_{-1}^2\,,\, f_4\rangle = *, \tag{X.7.97}$$

$$\langle {}^4\chi_{-2}^2\,,\, f_4\rangle = *. \tag{X.7.98}$$

In view of (3.15) the scalar product results (7.92) and (7.94) through (7.98) specify f_4 completely because of the assumption/imposition of axial symmetry.

We have examined a particular system which is specified by the parameter values given by (7.73) through (7.75), (7.8), (7.9), (7.11) and the requirements (7.76) [which led to (7.78)] and (7.91). For this system we have verified that the third-order Petzval aberration vanishes, as desired. But upon reflection we see that, no matter what parameter values and requirements are imposed, the third-order Petzval aberration will vanish as long as (7.6) is satisfied.

Elimination of Remaining Third-Order Aberrations

Ideally we would like to have vanishing values for *all* the coefficients A through E appearing in (2.30) through (2.34). There are five such coefficients, but we have already caused the Petzval combination $(C-2D)$ to vanish thereby leaving four more goals to be met. We also observe that there are four surfaces S^1 through S^4 for which values β_4^1 through β_4^4 can be assigned. Can they be set in such a way that all the f_4 save for the F terms vanish? We will find that the answer is *yes*, but the matter is subtle.

For a spherical surface of radius r there are the relations

$$\beta_2 = 1/(2r) \tag{X.7.99}$$

and

$$\beta_4 = 1/(8r^3) \tag{X.7.100}$$

so that

$$\beta_4 = (\beta_2)^3. \tag{X.7.101}$$

For the calculation that produced the f_4 in Exhibit *, the β_4^j values were set in such a way that the relation (7.100) was satisfied for all four surfaces. Equivalently, the surfaces were assumed to be spherical.

But what happens if the β_4^j values are instead set to zero? In this case, because all surfaces are now parabolas of revolution through fourth order, one might hope that third-order aberrations would be reduced. Below are the relevant scalar products for the f_4 found in this case:

$$\langle {}^4\chi_0^0\,,\ f_4\rangle = 0, \tag{X.7.102}$$

$$\langle {}^4\chi_2^2\,,\ f_4\rangle = *, \tag{X.7.103}$$

$$\langle {}^4\chi_1^2\,,\ f_4\rangle = *, \tag{X.7.104}$$

$$\langle {}^4\chi_0^2\,,\ f_4\rangle = *, \tag{X.7.105}$$

$$\langle {}^4\chi_{-1}^2\,,\ f_4\rangle = *, \tag{X.7.106}$$

$$\langle {}^4\chi_{-2}^2\,,\ f_4\rangle = *. \tag{X.7.107}$$

Looking at (7.102), we see that the Petzval still vanishes as before. But this is not surprising since we know that the Petzval is independent of β_4, and the condition (7.6) is still met because the paraxial parameters have not been changed. What about the remaining entries? Comparison of the entries in (7.94) through (7.98) with those in (7.103) through (7.107) shows that the latter are still sizable despite all surfaces being parabolic. Why is this? First of all, surface maps are not the only source of aberrations. As we see from *, transfer maps for drifts involve ${}^4\chi_2^2$, ${}^6\chi_3^3\cdots$ generators. And these generators can turn into ${}^4\chi_m^2$, ${}^6\chi_m^3\cdots$ generators under the action of $\exp(:f_2:)$ maps that occur/act in the course of concatenation. Second, inspection of * for example, shows that for a surface map f_4 generator there is the expansion

$$f_4 = *{}^4\chi_0^0 + *{}^4\chi_0^2 + *{}^4\chi_{-1}^2 + *{}^4\chi_{-2}^2, \tag{X.7.108}$$

and only the ${}^4\chi_{-2}^2$ term depends on β_4 but does not vanish when $\beta_4 = 0$. See Exercise *. Evidently there are non-vanishing ${}^4\chi_m^2$ terms even when $\beta_4 = 0$.

What to do now that a simple strategy has been explored and found wanting? Since there are four goals to be achieved and four β_4^j parameters to be set, we might try varying the β_4^j to meet the goals

$$\langle {}^4\chi_m^2\,,\ f_4\rangle = 0 \text{ for } m = 2,1,0,-1. \tag{X.7.109}$$

Experience shows that this strategy succeeds. Below are values for the f_4 when the β_4^j are optimally set. Evidently all entries vanish save for the coefficients of q_x^4, $q_x^2q_y^2$, and q_y^4. All third-order aberrations that affect image formation have been caused to vanish. This was accomplished by selecting the values

$$\beta_4^1 =, \tag{X.7.110}$$

$$\beta_4^2 =, \tag{X.7.111}$$

$$\beta_4^3 =, \tag{X.7.112}$$

$$\beta_4^4 = . \tag{X.7.113}$$

It can be shown that the calculation leading to the satisfaction of (7.109), after the Petzval has already been eliminated, amounts to a linear fitting operation, and consequently the values (7.110) through (7.113) are unique.

Entries in f_4 when the β_4^j are given the values (7.110) through (7.113).

Elimination of First Four Leading Fifth-Order Aberrations

The values of the β_6^j are also available to be set thereby attempting to cause four fifth-order aberrations to vanish. On the assumption that it is the sixth-order monomials with the highest powers of p_x and p_y that are the most damaging for image formation, we may attempt to cause the coefficients of ${}^6\chi_3^3$, ${}^6\chi_2^3$, ${}^6\chi_1^3$, and ${}^6\chi_0^3$ in f_6 to vanish by a suitable choice of the β_6^j. This goal can also be achieved. Below are the entries in f_6 for two cases. In the first case the β_6^j are set to zero [and the β_4^j are set to the values (7.88) through (7.91)]. In the second case the β_6^j are set to cause the coefficients of ${}^6\chi_3^3$ through ${}^6\chi_0^3$ in f_6 to vanish. These β_6^j have the values

$$\beta_6^1 =, \tag{X.7.114}$$

$$\beta_6^2 =, \tag{X.7.115}$$

$$\beta_6^3 =, \tag{X.7.116}$$

$$\beta_6^4 = . \tag{X.7.117}$$

Entries in f_6 when the β_6^j =0.
Entries in f_6 when the β_6^j have the values (7.114) through (7.117).

Corrector Strengths Depend on Magnification

Ray Traces

X.7.2 Aberration Corrected Hubble Telescope

Exercises

X.8 Inclusion of Chromatic Effects

X.9 Possibly Complementary Approaches

X.9.1 The Constant Index Case

Suppose the lenses of an optical system are all made of constant (not graded) index materials. In that case computers can numerically trace a large number of rays through the system in a very short time simply by invoking Snell's law at each interface.

In that case fairly rapid ray traces can also be performed using Lie methods. The interface maps $\mathcal{S}$ described in the Technical Report *Foundations of a Lie* $\cdots$ can be computed in milliseconds using equations (7.46a) through (7.46d) of that paper and combined in further milliseconds with surrounding transit maps (6.10) to yield the f_m displayed in the first line of equation (2.44) below:

$$\begin{aligned} w_\alpha^f &= \mathcal{M} w_\alpha^i = \{\exp(:f_2:)\exp(:f_4:)\exp(:f_6:)\exp(:f_8:)\cdots\} w_\alpha^i \\ &= g_1^\alpha(\boldsymbol{w}^i) + g_3^\alpha(\boldsymbol{w}i) + g_5^\alpha(\boldsymbol{w}^i) + g_7^\alpha(\boldsymbol{w}^i)\cdots . \end{aligned} \tag{X.9.1}$$

Then the homogeneous polynomials g_m^α displayed in the second line of (2.44) can be found in a few milliseconds more. The terms $g_1^\alpha(\boldsymbol{w}^i)$ describe the paraxial behavior of the optical system, and the terms $g_3^\alpha(\boldsymbol{w}^i)$, $g_5^\alpha(\boldsymbol{w}^i)$, $\cdots$ describe ever higher degree departures from paraxial behavior. [Note that the g_m^α are *not* independent because of the symplectic condition (1.16). Therefore they are ill suited for use in optimization/fitting procedures. By contrast, the f_m are independent, and any choice for them is consistent with the symplectic condition.] Finally, these polynomials $g_m^\alpha(\boldsymbol{w}^i)$ can be evaluated rapidly for any collection of initial conditions $\boldsymbol{w}^i$ to find the associated finial conditions $\boldsymbol{w}^f$. And if ray coordinates are desired at intermediate positions, they may be found by performing ray traces at intermediate positions as the full end-to-end map $\mathcal{M}$ is being built up.

Of course, this use of Lie methods presumes that the series in the second line of (2.44) is convergent and that to good approximation terms beyond some degree can be neglected. But this can be checked using the Snell's law ray trace. For example, let $w_\alpha^{fs\ell\mathrm{rt}}$ denote the result of a Snell's law ray trace for some initial condition $\boldsymbol{w}^i$ and let $w_\alpha^{f[7]}$ be the associated through seventh order result

$$w_\alpha^{f[7]} = g_1^\alpha(\boldsymbol{w}^i) + g_3^\alpha(\boldsymbol{w}^i) + g_5^\alpha(\boldsymbol{w}^i) + g_7^\alpha(\boldsymbol{w}^i). \tag{X.9.2}$$

Then we expect the result

$$w_\alpha^{f[7]} = w_\alpha^{fs\ell\mathrm{rt}} + O(|\boldsymbol{w}^i|^9). \tag{X.9.3}$$

The validity of (2.46) can be verified by comparing $w_\alpha^{f[7]}$ and $w_\alpha^{fs\ell\mathrm{rt}}$ for a variety of initial conditions $\boldsymbol{w}^i$ as $\boldsymbol{w}^i \to 0$.

Assuming that the series in the second line of (2.44) is convergent and that to good approximation terms beyond some degree can be neglected, it might be illuminating/interesting to monitor the Lie generators f_m during the course of a ray-trace-driven design/optimization process to observe, from a Lie perspective, what is being accomplished during the process. If it is observed, for example, that some particular f_m or set of f_m is being driven to zero, then one might experiment with including their values as part of a merit function.

In some settings, at least in the context of magnetic optics, it is useful to replace an optimization process by a *fitting* process is which several parameters are varied to drive several or all "offensive" Lie generators to zero. (To verify that some set of f_m is offensive, one can perform Lie algebraic ray traces with some of the f_m set to zero to see what effect that has on the $\boldsymbol{w}^f$ so computed. Note that so doing does not violate the symplectic condition.) For example, it is possible to design a complete third-order achromat in which the strengths of three quadrupoles, three sextuples, and eight octupoles are varied to set/remove various f_m in a particular basis, and all remaining f_m are cancelled by repetitive symmetry. (In magnetic optics parlance, an achromat bends a charged-particle beam, but otherwise acts as the identity map.) In so doing, 203 conditions are met. (Magnetic optical systems generally do not have axial symmetry and, therefore, there are many more aberrations to be corrected.) It is unlikely that this goal could have been achieved with an optimization program.

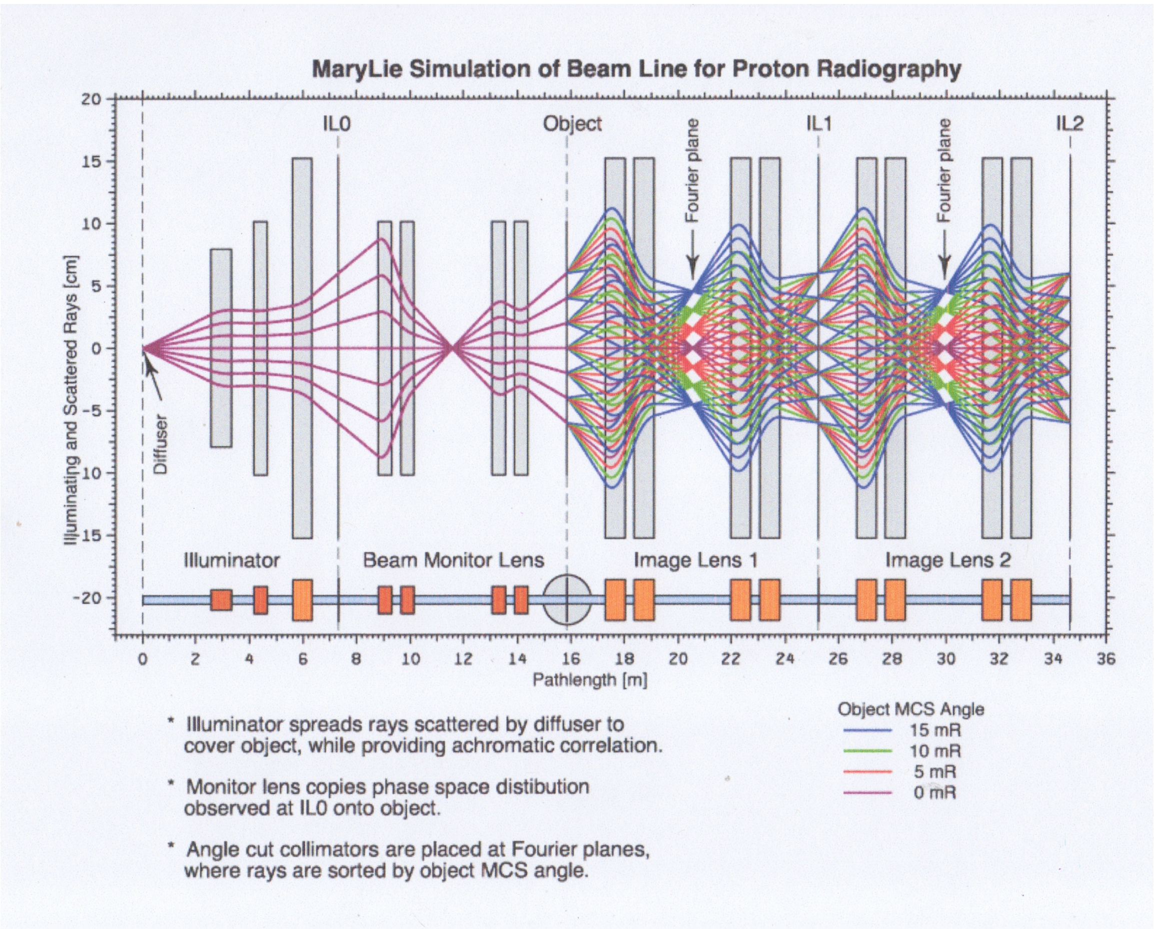
It is also possible to carry out procedures in which fitting loops are inside an optimization loop. This was done in connection with some octupole-corrected Los Alamos charged-particle beam projects.

X.9.2 The Graded Index Case

Suppose one wishes to employ lenses made of graded index material. (Something analogous is always the case in magnetic optics since magnetic fields are position dependent.) In that case one ray-tracing possibility is to employ direct numerical integration of the equations of motion (1.34) and (1.35) associated with H, perhaps with the aid of symplectic integrators to ensure maintenance of the symplectic condition. But this process is slow if many rays are to be traced with high accuracy. Moreover, extraction of aberration data from ray data, if desired, is subject to the numerical errors associated with high-order numerical differentiation.

A second option is to employ Lie methods. Suppose all the graded-index lenses have *flat faces*. In that case there are equations of motion for the Lie generators f_m that can be integrated to yield a Lie representation for the end-to-end $\mathcal{M}$. (See Chapter 10 of *Lie Methods for Nonlinear* $\cdots$.) And, once $\mathcal{M}$ is found in Lie form, numerous ray traces can be carried out rapidly. (And fitting/optimization can be carried out using both the values of the Lie generators and ray-trace results.) Figures 2 and 3 illustrate ray traces for two charged-particle beam devices carried out in this fashion.

The treatment of graded-index lenses with curved faces is more complicated, but some progress has also been made in handling this problem. And again, once $\mathcal{M}$ is found in Lie form, numerous ray traces can be carried out rapidly. And fitting/optimization can again be carried out using both the values of the Lie generators and ray-trace results.



* Illuminator spreads rays scattered by diffuser to cover object, while providing achromatic correlation.

* Monitor lens copies phase space distibution observed at IL0 onto object.

* Angle cut collimators are placed at Fourier planes, where rays are sorted by object MCS angle.

Appendix Y

Relation between the Classical Poisson Bracket Lie Algebra and the Quantum Commutator-Based Lie Algebra

Overview

This appendix explores the relation between the classical Poisson bracket Lie algebra and the quantum commutator-based Lie algebra. Lie methods are used to construct bases for each. It is found that the basis in the quantum case coincides with the Weyl basis. Next a natural correspondence is set up between the classical and quantum bases. Finally, these bases are used to determine the structure constants for the classical and quantum Lie algebras. It is found that many, *but not all*, of the structure constants for the two Lie algebras are the same. In particular, it is found that the classical Lie algebra is a contraction of the quantum Lie algebra. Conversely, the quantum Lie algebra is a deformation of the classical Lie algebra.

Y.1 Classical Polynomial Basis

For introductory simplicity, work with a two-dimensional phase space with variables q and p. (Higher-dimensional cases can be treated in a similar manner.) Let f and g be any functions of the phase-space variables. Introduce a *classical mechanical* Lie product $[*,*]_{\rm cm}$ among such functions by use of the Poisson bracket,

$$[f,g]_{\rm cm} = (\partial f/\partial q)(\partial g/\partial p) - (\partial f/\partial p)(\partial g/\partial q). \tag{Y.1.1}$$

Given any phase-space function f, define an associated *Lie operator*, denoted by $:f:$, by the rule

$$:f:g = [f,g]_{\rm cm}. \tag{Y.1.2}$$

In view of (1.1) and (1.2), this is the usual definition of $:f:$, but presented with a slightly different notation.

Introduce basis monomials $a_{r-s,s}$ by the rule

$$a_{r-s,s}(q,p) = [(r-s)!/r!] : -p^2/2 :^s q^r. \tag{Y.1.3}$$

So doing yields, for the first few monomials, the results

$$a_{00} = 1; \tag{Y.1.4}$$

$$a_{10} = q, \tag{Y.1.5}$$

$$a_{01} = p; \tag{Y.1.6}$$

$$a_{20} = q^2, \tag{Y.1.7}$$

$$a_{11} = qp, \tag{Y.1.8}$$

$$a_{02} = p^2; \tag{Y.1.9}$$

$$a_{30} = q^3, \tag{Y.1.10}$$

$$a_{21} = q^2p, \tag{Y.1.11}$$

$$a_{12} = qp^2, \tag{Y.1.12}$$

$$a_{03} = p^3; \tag{Y.1.13}$$

$$a_{40} = q^4, \tag{Y.1.14}$$

$$a_{31} = q^3p, \tag{Y.1.15}$$

$$a_{22} = q^2p^2, \tag{Y.1.16}$$

$$a_{13} = qp^3, \tag{Y.1.17}$$

$$a_{04} = p^4. \tag{Y.1.18}$$

The degree of a monomial a_{rs} is given by the sum $(r+s)$, and we refer to the monomials of a fixed degree as a forming a *ladder*. Within a ladder and up to multiplicative factors, $: -p^2/2 :$ acts on a_{rs} as an operator that lowers r and raises s. Indeed, there is the recursion relation

$$: -p^2/2 : a_{r,s} = r a_{r-1,s+1}. \tag{Y.1.19}$$

Similarly, within a ladder and up to multiplicative factors, $: q^2/2 :$ acts as an operator that raises r and lowers s.

Y.2 Quantum Polynomial Basis

Let Q and P be the quantum-mechanical counterparts of q and p. They obey the commutation rule

$$\{Q,P\} = QP - PQ = i\hbar I \tag{Y.2.1}$$

where $\hbar$ is the reduced Planck's constant $h/(2\pi)$, and which we will eventually view as an adjustable parameter in Section 4. Suppose $F(Q,P)$ and $G(Q,P)$ are any polynomial functions of Q and P with some ordering rule for products of Q's and P's. Given these functions, define a *quantum mechanical* Lie product $[*,*]_{\rm qm}$ by the rule

$$[F,G]_{\rm qm} = (i\hbar)^{-1}\{F,G\}. \tag{Y.2.2}$$

Here we note two facts: First, $[*,*]_{\rm qm}$ is a Lie product because the commutator is a Lie product. Second, if F and G are Hermitian, $[F,G]_{\rm qm}$ will also be Hermitian. Indeed, from the definition (2.2) there is the relation

$$[F,G]^\dagger_{\rm qm} = -(i\hbar)^{-1}\{F,G\}^\dagger. \tag{Y.2.3}$$

But, there is also the relation

$$\{F,G\}^\dagger = (FG-GF)^\dagger = (FG)^\dagger - (GF)^\dagger = G^\dagger F^\dagger - F^\dagger G^\dagger = GF - FG = -\{F,G\}. \tag{Y.2.4}$$

Consequently, there is the advertised result

$$[F,G]^\dagger_{\rm qm} = [F,G]_{\rm qm}. \tag{Y.2.5}$$

Within the quantum mechanical context, define an operator $: -P^2/2 :$ by the rule

$$: -P^2/2 : G = [-P^2/2, G]_{\rm qm}. \tag{Y.2.6}$$

Powers of $: -P^2/2 :$ are defined by the rules

$$: -P^2/2 :^0 G = G, \tag{Y.2.7}$$

$$: -P^2/2 :^2 G = [-P^2/2, [-P^2/2, G]_{\rm qm}]_{\rm qm},\ \text{etc.} \tag{Y.2.8}$$

Next, in analogy to the construction (1.3), use $: -P^2/2 :$ to define polynomials $A_{r-s,s}$ by the rule

$$A_{r-s,s}(Q,P) = [(r-s)!/r!] : -P^2/2 :^s Q^r. \tag{Y.2.9}$$

Here use is to be made of the relation (2.1) to evaluate the commutators that occur, and we presume that

$$Q^0 = I. \tag{Y.2.10}$$

Doing so gives, for the first few values of r and s, the results

$$A_{00} = I; \tag{Y.2.11}$$

$$A_{10} = Q, \tag{Y.2.12}$$

$$A_{01} = P; \tag{Y.2.13}$$

$$A_{20} = Q^2, \tag{Y.2.14}$$

$$A_{11} = (QP + PQ)/2, \tag{Y.2.15}$$

$$A_{02} = P^2; \tag{Y.2.16}$$

$$A_{30} = Q^3, \tag{Y.2.17}$$

$$A_{21} = (Q^2P + PQ^2)/2, \tag{Y.2.18}$$

$$A_{12} = (QP^2 + P^2Q)/2, \tag{Y.2.19}$$

$$A_{03} = P^3; \tag{Y.2.20}$$

$$A_{40} = Q^4, \tag{Y.2.21}$$

$$A_{31} = (Q^3P + PQ^3)/2, \tag{Y.2.22}$$

$$A_{22} = (QP + PQ)^2/6 + (Q^2P^2 + P^2Q^2)/6, \tag{Y.2.23}$$

$$A_{13} = (QP^3 + P^3Q/)2, \tag{Y.2.24}$$

$$A_{04} = P^4. \tag{Y.2.25}$$

Note that the A_{rs} are Hermitian, as expected. Also, the A_{rs} are polynomials in the *Weyl* basis. That is, products of Q's and P's are Weyl ordered. Moreover, this ordering of constituents has not been achieved by demanding/imposing permutation symmetry, but instead arises *naturally* from a Lie algebraic procedure.

The degree of a polynomial A_{rs} is again given by the sum $(r+s)$, and we again refer to the polynomials of a fixed degree as a forming a ladder. Within a ladder and up to multiplicative factors, $: -P^2/2 :$ acts on A_{rs} as an operator that lowers r and raises s. Indeed, there is the recursion relation

$$: -P^2/2 : A_{r,s} = rA_{r-1,s+1}. \tag{Y.2.26}$$

Similarly, within a ladder and up to multiplicative factors, $: Q^2/2 :$ acts as an operator that raises r and lowers s.

Y.3 A Natural Correspondence between Classical and Quantum Bases

How can we set up a natural correspondence between the classical and quantum bases? In so doing, by linearity, we will also set up a natural correspondence between the classical Lie algebra of phase-space functions with Lie product $[*,*]_{\rm cm}$ and the quantum Lie algebra of polynomials in Q and P with Lie product $[*,*]_{\rm qm}$. We will call these Lie algebras $\mathcal{L}_{\rm cm}$ and $\mathcal{L}_{\rm qm}$.

First, it is natural to set up the correspondences

$$1 \leftrightarrow I, \tag{Y.3.1}$$

$$q^n \leftrightarrow Q^n, \tag{Y.3.2}$$

$$p^n \leftrightarrow P^n. \tag{Y.3.3}$$

But then, because of the Lie algebraic similarity of the definitions (1.3) and (2.9), it is also natural to set up the correspondences

$$a_{rs}(q,p) \leftrightarrow A_{rs}(Q,P), \tag{Y.3.4}$$

for which (3.1) through (3.3) are special cases.

Y.4 Relation between the Lie Algebras $\mathcal{L}_{\rm cm}$ and $\mathcal{L}_{\rm qm}$

The Lie algebra $\mathcal{L}_{\rm cm}$ has structure constants $c^{tu}_{jk;rs}$ defined by the relation

$$[a_{jk}, a_{rs}]_{\rm cm} = \sum_{tu} c^{tu}_{jk;rs}\, a_{tu}. \tag{Y.4.1}$$

Similarly, the Lie algebra $\mathcal{L}_{\rm qm}$ has structure constants $C^{tu}_{jk;rs}$ defined by the relation

$$[A_{jk}, A_{rs}]_{\rm qm} = \sum_{tu} C^{tu}_{jk;rs}\, A_{tu}. \tag{Y.4.2}$$

How do the structure constants $c^{tu}_{jk;rs}$ and $C^{tu}_{jk;rs}$ compare? They are not all the same, and therefore the two Lie algebras $\mathcal{L}_{\rm cm}$ and $\mathcal{L}_{\rm qm}$ are not manifestly the same.[1] However, *many* of the structure constants are the same. In particular, there are the equalities

$$C^{tu}_{jk;rs} = c^{tu}_{jk;rs} \text{ for } j+k \le 2. \tag{Y.4.3}$$

One consequence of (4.3) is that the subalgebras generated by classical and quantum polynomials of degree ≤ 2 are identical, and are in fact the Lie algebra $isp(2,\mathbb{R})$, the Lie algebra of the *inhomogeneous* symplectic group in two dimensions over the real field.[2]

Another consequence is the special role played by the a_{jk} and the A_{jk} with $j+k=2$. Both generate the Lie algebra for $sp(2,\mathbb{R})$. We have already seen that p^2 and q^2, and their quantum counterparts, act as raising and lowering operators within ladders. Recall (1.19)

[1] In the very early editions of Dirac's classic text *The Principles of Quantum Mechanics* he proceeded as if these two Lie algebras were the same. This misconception was removed by more careful wording in later editions.

[2] In light wave optics the quantity $\lambda/(2\pi)$, where λ is the wavelength, plays the role of $\hbar$. Consequently, Fourier optics results can be read off from paraxial ray optics results. We also remark that although the subalgebras are identical, the underling groups are not identical. In the classical case the group is the inhomogeneous symplectic group in two dimensions over the real field. In the quantum case the group is the inhomogeneous metaplectic group in two dimensions over the real field, which is a two-fold cover of the inhomogeneous symplectic group in two dimensions over the real field.

and (2.26). What can be said about the action of a_{11} and its quantum counterpart A_{11}? Simple calculation gives the result

$$: a_{11} : a_{rs} = [qp, q^r p^s]_{\text{cm}} = (s-r)a_{rs}. \tag{Y.4.4}$$

Thus the a_{rs} are eigenfunctions of the operator $: a_{11} :$ with eigenvalues $(s-r)$. It follows from (4.3) that there are the analogous quantum results

$$: A_{11} : A_{rs} = (s-r)A_{rs}. \tag{Y.4.5}$$

The A_{rs} are eigenfunctions of the operator $: A_{11} :$ with eigenvalues $(s-r)$.

The first differences between $\mathcal{L}_{\text{cm}}$ and $\mathcal{L}_{\text{qm}}$ results occur at degree 4. There are the classical relations

$$[a_{03}, a_{30}]_{\text{cm}} = -9a_{22} \tag{Y.4.6}$$

and

$$[a_{12}, a_{21}]_{\text{cm}} = -3a_{22}. \tag{Y.4.7}$$

By contrast, there are the quantum relations

$$[A_{03}, A_{30}]_{\text{qm}} = -9A_{22} + (3/2)\hbar^2 A_{00}, \tag{Y.4.8}$$

and

$$[A_{12}, A_{21}]_{\text{qm}} = -3A_{22} - (1/2)\hbar^2 A_{00}. \tag{Y.4.9}$$

The Lie products of all other degree 3 polynomials yield degree 4 results that are identical in the classical and quantum cases.

It can be verified that there are the relations

$$\lim_{\hbar \to 0} C^{tu}_{jk;rs} = c^{tu}_{jk;rs}, \tag{Y.4.10}$$

and consequently there is the limiting correspondence

$$[a_{jk}, a_{rs}]_{\text{cm}} \leftrightarrow \lim_{\hbar \to 0} [A_{jk}, A_{rs}]_{\text{qm}}. \tag{Y.4.11}$$

Thus, $\mathcal{L}_{\text{cm}}$ is a *contraction* of $\mathcal{L}_{\text{qm}}$ and, conversely, $\mathcal{L}_{\text{qm}}$ is a *deformation* of $\mathcal{L}_{\text{cm}}$.

It is notable that the differences between the classical and quantum cases actually involve $\hbar^2$ and not $\hbar$ itself.[3] Thus, the relation (4.10) may be replaced by the stronger result

$$C^{tu}_{jk;rs} = c^{tu}_{jk;rs} + O(\hbar^2). \tag{Y.4.12}$$

Moreover note, as inspection of (4.8) and (4.9) illustrates, that the $O(\hbar^2)$ terms involve only lower-degree polynomials than those that occur classically.

We also observe that the nature of the terms that can occur in a Lie product can be inferred from the Clebsch-Gordan series for the symplectic group. We have already seen that in the case of a two-dimensional phase space the basis elements A_{jk} have well-defined

[3] It follows that wave-optics aberration results, up to corrections of order $[\lambda/(2\pi)]^2$, can be read off from ray-optics aberration results.

transformation properties under the action of the symplectic group Lie algebra $sp(2, \mathbb{R})$. Consequently, their Lie products must also have well-defined transformation properties under the action of $sp(2, \mathbb{R})$. For example, the A_{jk} with $j + k = d$ belong to an irreducible representation of $sp(2, \mathbb{R})$ that behaves like "spin" $d/2$.[4] In the cases of (4.8) and (4.9), the ingredients of the Lie products on the left sides carry the representation $3/2$. According to Clebsch and Gordan, two spin $3/2$ objects can combine to produce objects of spins $3, 2, 1$, and 0. Since the Lie product is antisymmetric under the interchange of its ingredients, the spins 3 and 1 are ruled out by symmetry considerations. What possibly remain are spins 2 and 0. The two terms that occur on the right sides of (4.8) and (4.9), namely A_{22} and A_{00}, have spins 2 and 0, respectively.

Exercises

Y.4.1. Verify the results (1.4) through (1.19) and the results (2.11) through (2.26).

Y.4.2. Verify the results (4.3) through (4.11).

Y.4.3. Determine the effect of $: q^2/2 :$ on a_{rs} and the effect of $: Q^2/2 :$ on A_{rs}.

[4] Here we use the fact that the Lie algebras $sp(2, \mathbb{R})$ and $su(2)$ are equivalent over the complex field, and therefore their Clebsch-Gordan series are essentially the same. In the case of phase spaces of dimension $2n$, one must know the Clebsch-Gordan series for $sp(2n, \mathbb{R})$.
